Although ontologies are community-wide contracts about representations of specific domain knowledge, the existing ontologies mainly address the technical dimension of service semantics, in turn ignoring business and development dimensions in service engineering. Most of the ontologies discussed are specific to Web/Internet-based services (e.g., e-commerce), in which services provided by devices are little addressed. Therefore, the future research effort should be directed towards enhancing ontology engineering by a stakeholder-centric modeling approach and providing support for i) developing industry strength business ontologies, ii) generic ontologies for QoS metrics and QoS execution management, iii) application specific domain ontologies, and iv) integrated orchestration of the developed ontologies in service engineering practices. In the software architecture field, the use of viewpoints is a community-wide accepted approach to cluster stakeholder-related concerns into a single view. This principle can be lent to service semantics engineering. The use of multiple views is a necessity; the interests of stakeholders differ, application domains differ, and service functionality and quality differ according to the usage/execution contexts. Moreover, different application domains, for example, e-business and pervasive computing applications, require modeling languages that take into account the characteristics of a domain by providing a notation that can be enhanced and adapted by domain specific extensions. The approach used in software family engineering, namely the separation of commonality and variability, would be a viable approach that solves the problems in separation of common and domain specific semantics, and the integrated use of defined service ontologies. Last, but not least, developer tools are required to provide specific support for software engineers and system administrators through the development and management process including the engineering of semantic services, their deployment, and subsequent management.

CONCLUSION

The present study provided an overview of the existing service description ontologies and thereby, improves the understanding of the benefits and drawbacks of service ontologies in defining the functionality, quality, and contexts of services by the available tools.

From a technical point of view, service description ontologies are to provide knowledge for describing the required and provided properties of a service, ability and rights of achieving a service, and the quality guaranteed for a service. XML, RDF, and OWL schema provide a basis for service description languages and ontologies, such as OWL-S, WSMO, and IRS, which in turn provide building blocks for service semantics. However, existing service ontologies focus mainly on Web services, and none of them provides complete support for service descriptions as required in modern service centric systems. Furthermore, QoS description ontologies also have a specific focus, for example, one or few quality attribute(s) in defining, managing, or matching OoS. To guarantee QoS requires comprehensive support for defining and managing all the relevant quality attributes of services, at the design time and run-time. Context ontologies assist in adapting services to the execution environment and to the observed changes in environmental or usage contexts. SOUPA, as the only standardized context ontology, provides the most promising approach to which QoS ontologies and domain ontologies can be integrated as extension ontologies.

Building ontologies consumes resources, in which these resources are justified only if the effort needed to establish and keep alive consensual representations of domains is outweighed by business gain, either in terms of cost, added value, or strategic dimensions. Therefore, future research activities should address the business and process agility dimensions by enhancing ontology engineering by a stakeholder centric modeling and separation of commonality and variability in service semantics. These topics are studied in the software architecture field. Therefore, the fusion of the design principles and techniques applied to the quality and

model driven architecture design is the most promising approach to enhance the existing service ontologies in order to better fit the service engineering and service semantics that are required in service centric computing systems.

KEY TERMS

Ontology: Ontology is a shared knowledge standard or a knowledge model defining the primitive concepts, relations, rules, and their instances comprising a relevant knowledge topic. Ontology is used for capturing, structuring, and enlarging explicit and tacit topic knowledge across people, organizations, systems, and software services.

QoS (Quality of Service): Refers to the nonfunctional properties of services at different levels. QoS is the degree to which a service meets its quality requirements and end user needs. QoS quantifies the service fitness based the collective behavior of composite services.

Service: A stateless piece of software with the predefined functional and quality properties that is used for achieving a particular action.

Service Composite: A cluster of services that are combined together from a bottom-up fashion in order to achieve an enhanced behavior, which no service by itself can provide. Service composites are made proactively (design-time) or reactively (run-time).

Service Description: A definition of what a service provides and how it is accessed and used. A service description includes descriptions of the functional and nonfunctional properties of the service, service interfaces, and the legal and technical constraints or rules for its usage.

Service Modeling: Service modeling produces a service description by exploiting generic graphical modeling languages, such as unified modeling language (UML), and/or textual notations such as Web services description language (WSDL) and Web ontology language for services (OWL-S).

Stakeholder: An individual, team, or organization (or classes thereof) with interests in, or concerns relative to, service development, service deployment, or service operation.

SLA (Service Level Agreement): A contract between a service provider and a service consumer that is related to the quality of service guaranteed by the service provider.

Vocabulary: Vocabularies express equivalent or the semantically closest concepts or concept expressions related to the domain of interest.

Shortest Path Routing Algorithms in Multihop Networks

Sudip Misra
Cornell University, USA

INTRODUCTION

The topic of *shortest path algorithms* is very fundamental and important in information science and technology. Shortest path algorithms have evolved over many years and have found applications in different domains such as telecommunication networks, military, and transportation. There has been a lot of work undertaken on this topic in this area in the past. A lot of research is still being conducted. The topic is still poorly understood. This article should be helpful to readers, because it reviews some of the important works conducted in the area, out of the plenty of works available on this topic. The problem is so fundamental that whatever the interest areas of the readers may be, they will find the article useful.

The popular traditional shortest path algorithms date back to 1958/1959 and were proposed by Dijkstra (1959), and Bellman (1958). Their algorithms found wide applications in the abovementioned domains for many years. However, they were static. Thereafter, many other algorithms were proposed in the last few decades, all of which can be classified to be either dynamic or semi-dynamic.

BACKGROUND

Multihop networks, such as the Internet and *mobile ad hoc networks* (MANETs) contain several routers and mobile hosts. The Internet typically employs routing protocols such as the open shortest path protocol (OSPF) and the intermediate system—intermediate system protocol (IS-IS), and the MANETs employ protocols such as the fisheye state routing (FSR), the optimized link state routing (OLSR), and the ad hoc on-demand distance vector routing (AODV).

In many of these protocols, each router (or a routing device) computes and stores a shortest path tree (SPT) from one router to all other routers and hosts in a routing domain (Moy, 1997; Peterson & Davie, 2000; Schwartz & Stern, 1980). Such networks, which can be modeled as graphs (Misra & Oommen, 2005b; Ramalingam & Reps, 1996), typically contain several routers/switches (nodes) connected by links (edges) with constantly changing costs (weights), link-ups (edge-insertions), and link-downs (edge-deletions).

SINGLE-SOURCE SHORTEST PATH ROUTING: DYNAMIC VERSUS STATIC

The problem of computing and maintaining information about the shortest paths information in a graph (with a single source)—where the edges are inserted/deleted and edge-weights constantly increase/decrease—is referred to as the *dynamic single source shortest path problem* (DSSSP). Although this problem is important, it has received little attention in the literature. The importance of the problem lies in the fact that it is representative of many practical situations in daily life, where most environments are dynamically changing. In such environments, one needs to devise efficient solutions to maintain the shortest path even though there are updates on the structure of the graph by virtue of edge-insertion/deletion, or edge-weight increase/decrease, and hopefully this can be achieved without recomputing everything "from scratch" following each topology update. An example of a single-source shortest path graph, after the insertion of an edge is shown in Figure 1. The new edge C→F appears in the list of shortest paths, and the existing edge B→F, which was earlier in the list of shortest paths, ceases to be so.

Out of the four possible edge operations (insertion/deletion and increase/decrease), it has been shown that edge-insertion is equivalent to edge-weight decrease, and edge-deletion is equivalent to edge-weight increase. Increasing or decreasing an edge-weight can be performed by inserting a new edge (with the new weight) parallel to the edge under consideration, and then deleting the old edge (Ramalingam & Reps, 1996). If all edge operations are allowed, the problem is referred to as the *fully dynamic problem*. If only edge-insertion/weight-decrease (or edge-deletion/weight-increase) is allowed, the problem is referred to as the *semi-dynamic problem* (Frigioni, Marchetti-Spaccamela, & Nanni, 1996).

Typically, with many present-day routing protocols,[1] with a unit change in network topology (e.g., link-ups, link-downs, and link-cost changes), each router in the routing domain is intimated of the change. This change typically triggers recomputation of each router's SPT.

There are well-known *static solutions* to the traditional combinatorial *single source shortest path problem* (Bellman, 1958; Dijkstra, 1959) which are unacceptably inefficient in

such dynamic practical scenarios because using them would involve recomputing the shortest path tree from scratch each time a topology change occurs in the graph. Static algorithms are unarguably more effective in fixed-infrastructure networks because of their polynomial time complexity. But they are extremely inefficient for time-critical, rapidly changing infrastructures. For instance, if such an algorithm is used in a real-time, large network routing scenario, where there are fast link-state changes, such recomputations will delay the execution of important routing functions considerably.

Two of the earliest known works on the dynamic shortest path problem date back to the papers by Spira and Pan (1975) and McQuillan, Richer, and Rosen (1980). While the former is theoretically proven to be inefficient, the latter has neither been proven theoretically nor through simulations.

The most recent and well-known solutions to the DSSSP problem on general graphs with positive real-valued edge-weights were proposed by Ramalingam and Reps (1996), Franciosa, Frigioni, and Giaccio (1997), and Frigioni, Marchetti-Spaccamela, and Nanni (2000). However, the solution by Franciosa et al. (2000) is limited to the semi-dynamic problem only. Although these recent works are theoretical in nature, Ramalingam and Reps (1996)'s and Frigioni et al. (2000)'s results were recently experimentally evaluated through simulations (Demetrescu, Frigioni, Marchetti-Spaccamela, & Nanni, 2001; Frigioni, Ioffreda, & Nanni, 1998). While the former was found to be superior when it concerns running time, the latter was shown to be better suited when the worst-case time was the main concern, or when the number of edges to be updated had to be minimized.

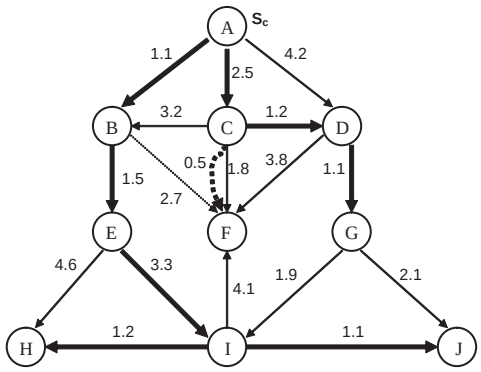
The well-known, fully dynamic algorithms (mentioned previously) are constrained by the following limitations:

1. The existing fully dynamic algorithms process unit changes to topology (i.e., edge-insertion/deletion or weight-increase/decrease) one change at a time, that is, sequentially. When there are several such operations occurring in the environment simultaneously, the algorithms are quite inefficient.
2. In environments where the edge-weights change stochastically and continuously, the existing algorithms (mentioned previously) would fail to converge to the actual underlying "average" solution.

The problems are worse in large topologies which have a large number of nodes and edges, and where a large number of topology changes can occur continuously at all times. In such cases the existing algorithms would fail to determine the shortest path information in a time-critical manner.

Since such scenarios are representative of the actual environments in which the dynamic shortest path algorithms are likely to operate, the existing solutions would be limitedly useful. Misra and Oommen (2005b) proposed a learning solution by taking the aforementioned aspects into consideration. To the best of my knowledge, other than their solution, there is no known solution to finding the shortest path in a real-weighted graph where multiple edges are changing stochastically at once, and at the same time, which is more efficient than calculating everything from scratch for every change. The work reported by them was inspired by the need for formulating an algorithm for finding the shortest path in such realistically occurring stochastic environments. Indeed, they sought to find the shortest path in the "average" graph (dictated by an "Oracle," also called the *environment*). Since, on query, the edge-weights supplied by the environment are assumed to follow an underlying unknown distribution, there exists a mean solution to the problem to which the algorithm would converge to after a sufficiently long time. Their intention was to find the "statistical" shortest path in the average graph that will be stable—regardless of the (possibly) continuously changing weights provided by the environment. Their solution generates superior results (when compared to the previous solutions). However, unfortunately, their scheme does not consider the insertion/deletion of edges. Thus, the problem they have considered assumes that there is one fixed structure graph with randomly changing edge weights, and that the distribution of these random variables is unknown.

Figure 1. Graph after the insertion of the edge C→F with weight 0.5



ALL-PAIRS SHORTEST PATH ROUTING: DYNAMIC VERSUS STATIC

Contrary to the previous discussions, in which the idea was of computing the shortest paths from one node to all the other nodes in a network, the problem of computing and maintaining all-pairs shortest paths information in a graph where the edges are inserted/deleted and edge-weights constantly increase/decrease is referred to as the *Dynamic*

all-pairs shortest paths problem (DAPSP) (Demetrescu & Italiano, 2003; Ramalingam & Reps, 1996). The DAPSP problem has found equal importance as the DSSSP problem, among researchers and practitioners alike. Both the problems aim to efficiently maintain shortest path solutions in environments that are representative of most practical situations in daily life, since most real-life environments are dynamically changing.

Similar to what was discussed for the DSSSP problem and for the DAPSP problem as well, it can be shown that edge-weight updates can be treated as edge-deletions and edge-insertions by setting the weights of edges to an infinitely large value (Demetrescu & Italiano, 2003). Likewise, an edge-update algorithm for the all-pairs shortest path problem is referred to as being fully dynamic if both weight-increase and weight-decrease operations are supported on the edges of the graph. A semi-dynamic algorithm handles only weight-increases or weight-decreases, but not both at the same time (Demetrescu & Italiano, 2003).

Like the static solutions of the single source shortest path problem, the well-known static solutions for the all-pairs shortest path problem, for example, the Floyd-Warshall's algorithm (Floyd, 1962), the all-pairs adaptations of Bellman-Ford's algorithm (Bellman, 1958), or the Dijkstra's algorithm (Dijkstra, 1959), which recompute the shortest paths from scratch each time a topology change occurs in the graph, are certainly inefficient in such dynamic practical scenarios.

Over the last few decades, there has been a lot of research done to solve the DAPSP problem. The earliest papers were written by Loubal (1967), Murchland (1967), and Rodinov (1968). Many other dynamic algorithms were proposed in the literature (e.g., Even & Gazit, 1985; Ramalingam & Reps, 1996; Rohnert, 1985); however, their worst-case running times were no better than recomputing the all-pairs shortest paths from scratch. Thereafter, a few solutions (Ausiello, Italiano, Marchetti-Spaccamela, & Nanni, 1991; Fakcharoemphol & Rao, 2001; Henzinger, Klein, Rao, & Subramanian, 1997; King, 1999) were proposed whose running times are better than a total recomputation. However, these solutions only work for integer weights. The algorithm proposed by Ausiello et al. (1991) is only applicable for the semi-dynamic case (decrease-only), and requires positive integer weights less than a constant "C." Their algorithm's amortized running time per insertion operation is O(Cnlogn) (Ausiello et al., 1991). Although Henzinger et al. (1997) provide a fully dynamic solution to the all-pairs shortest paths problem, their solution is only for planar graphs with integral values of edge-weights. The running time of their algorithm is $O(n^{4/3}\log(nC))$ per update operation. The first fully dynamic solution on general graphs was proposed by King (1999). Her solution too only works with positive integer weights less than C, and the running time of the algorithm is $O(n^{2.5}(C\log n)^{1/2})$. Later, Demetrescu and Italiano (2001) published a paper containing a fully dynamic algorithm that would perform edge-update operations on general graphs with real-valued edge-weights. If S represents the number of different real values, the amortized running time per update operation for their algorithm is $O(n^{2.5}(S\log^3 n))$. Finally, in 2003, Demetrescu and Italiano (2003) proposed a remarkable algorithm that solved the same problem for general digraphs with edge-weights that can assume positive real values but with a substantially improved running time per edge-update operation.

Misra and Oommen (2005a) proposed a learning algorithm that finds all-pairs shortest paths for the statistical average network topology, and the solution converges irrespective of whether there are new changes in edge-weights or not. They showed that their solution has better performance than the Demetrescu and Italiano (2003)'s solution. In their solution, not all the edges in a stochastic network topology are probed, and even if they are, they are not all probed equally often. Indeed, their algorithm attempts to almost always probe only those edges that will be included in the final list involving all pairs of nodes in the graph, while probing the other edges minimally. This increases the performance of the proposed algorithm. Their second contribution is the designing of a data structure, the elements of which represents the probability that a particular edge in the graph lies in the shortest path between a pair of nodes in the graph. Misra and Oommen (2005a)'s work is considered to represent the state of the art in this area.

APPLICATIONS

First of all, the application of shortest path algorithms in telecommunication is straightforward. They commonly find their use in routing equipments. In vast rapidly changing telecommunications wired or wireless networks, where links go up and down continuously and rapidly, and where there are simultaneous random updates in link costs, the existing algorithms are inefficient. Shortest paths need to be computed within a very short time (in the order of microseconds) with minimal number of nodes to be processed and edges to be scanned. Furthermore, in the *transportation domain*, there are complex road networks in urban areas. The costs of routing shipments from a warehouse to (all) other retail outlets constantly change. Changes occur because of a range of reasons such as road construction, accidents, traffic jams, office hours, and the presence of emergency vehicles. There are often several alternative routes that can be taken by a vehicle, whenever the predetermined route is unsuitable to deliver the shipments in time. Shipment vehicles may be equipped with suitable technology (like the global positioning system [GPS]) to guide them through alternative routes. The proposed learning algorithms can then be used to achieve such a vehicle routing. The same arguments

would be true if airplanes have to be redirected adaptively to take care of changes.

In the military, the proposed learning algorithms also have several potential applications. For example, in complex military networks, ground forces may have to be rapidly rerouted based on sudden changes in enemy information and strategies along existing routes, and self-guided missiles may need to change their trajectories (within microseconds) to account for changes in the path along which it travels.

FUTURE TRENDS

Interested researchers or practitioners could perform the following works to advance the state of the art in this area:

- Most of the aforementioned solutions (especially the recent ones) were reported on simulated networks of relatively small number of nodes. They have not been tested on massive sized networks. Testing the previous algorithms on large (on topologies with 10,000 to 100,000 nodes) simulated networks is required to understand their performance characteristics well.
- It is also required to test the performance of the algorithms in real-life networks, as most of the solutions mentioned previously have not been tried on such networks.
- Similarly, assessing the suitability of the aforementioned generic solutions in different application domains.

CONCLUSION

In this article we reviewed different shortest path solutions that have been proposed since 1958/1959 when Bellman and Ford, and Dijkstra proposed their solutions for a static network. Of all the algorithms, the solutions proposed by Misra and Oommen (2005a) and Misra and Oommen (2005a) represent the state of the art. The experimental evaluation of their algorithms shows the superiority of their proposed algorithms. The characteristic of their algorithm is that once their algorithms have converged, the average number of processed nodes, scanned links, and the time per update operation is superior to the previously proposed algorithms by a few orders of magnitude. The advantage of their solution is that in stochastic network environments, it possesses a statistical shortest paths list that should be actual shortest paths irrespective of whether there are new changes in link costs taking place continuously. In such cases, their solution converges to a shortest paths list, while the existing algorithms would recalculate affected shortest paths after every change in link cost.

KEY TERMS

Algorithm: An algorithm is a set of clear steps that is used to define how a task or a set of tasks can be accomplished.

Dynamic Shortest Path Algorithm: An algorithm that is capable of finding a path that has the least distance (among all possible paths) between a pair of source and destination nodes in a network, when the status of nodes and links change with time.

Fully Dynamic All-Pairs Shortest Path Algorithm: If in a dynamic shortest-path algorithm, all edge operations (edge-insertion, weight-decrease, edge-deletion, weight-increase) are allowed, the algorithm is referred to as the fully dynamic algorithm.

Routing: The mechanism by which a path or a set of paths is selected to send information or commodities.

Semi-Dynamic Shortest Path Algorithm: If in a dynamic shortest-path algorithm, only edge-insertion/weight-decrease, or edge-deletion/weight-increase is allowed, the algorithm is referred to as the semi-dynamic algorithm.

Shortest Path Algorithm: An algorithm that is capable of finding a path that has the least distance (among all possible paths) between a pair of source and destination nodes in a network.

Static Shortest Path Algorithm: An algorithm that is capable of finding a path that has the least distance (among all possible paths) between a pair of source and destination nodes in a network, when all the nodes and links remain stationary.

ENDNOTE

[1] It should, however, be noted that some routing protocols in MANETs are based on the knowledge of a partial topology and provide the shortest path to any destination in the network. The advertised topology is a subset of the whole topology. Hence, ideally, only link-ups and link-downs concerning the advertised topology must be accounted for in the whole network.

Signal Processing Techniques for Audio and Speech Applications

Hector Perez-Meana
National Polytechnic Institute, Mexico

Mariko Nakano-Miyatake
National Polytechnic Institute, Mexico

INTRODUCTION

Since the apparition of the first standalone digital signal processor (DSP) in 1980, the development of very-large-scale integration (VLSI) technology has allowed an impressive improvement on the performance of signal processing devices. This fact has made it possible to implement more efficient systems for storage, transmission, enhancement, protection, and reproduction of speech and audio signals. Some of these successful applications, shown in Table 1, have contributed to improving the performance of communications, storage, and medical systems, as well as security and copyright protection.

BACKGROUND

Since the apparition of electronics technology, several devices have been introduced to improve received, produced, and recorded audio and speech signal quality—such as that of low pass and band pass analog filters, amplifiers, and so forth—that allowed suppression of some kinds of interfering signals. Next, with the development of solid state technology in the late of 1960s and the apparition of the op-amp, several analog signal processes were developed; although there were limitations, these allowed import improvements in audio and speech systems. The limitations of analog technology encouraged the development of digital technology. As a result in 1980 the Nippon Electric Corporation (NEC) and American Telegraph and Telephone (AT&T) released the first standalone complete digital signal processors, the PD7220 and the DSP1. Since then, digital signal processing technology has experienced impressive growth, allowing performance improvement of already available systems, as well as development of many other successful systems in several other fields, some described in this article.

REVIEW OF MAIN SIGNAL PROCESSING APPLICATIONS IN SPEECH AND AUDIO FIELDS

As mentioned before, the signal processing applications in speech and audio fields have increased, contributing to the solution of many important problems, constituting an important part of many practical systems. To understand the importance of this technology and how it has contributed in the development of audio and speech fields, this section provides a review of some successful signal processing systems.

Echo Cancellation for Long-Distance Transmission

A very successful speech signal processing application is the adaptive echo cancellation used to reduce a common but undesirable phenomenon in most telecommunications systems, called echo. Here when mismatch impedance is present in any telecommunications system, a portion of the transmitted signal is reflected to the transmitter as an echo, which represents an impairment that degrades the system quality (Hansler & Schmidt, 2006; Manolakis, Ingle, & Kogon, 2005). In most telecommunications systems, such as a telephone circuit, the echo is generated when the long-distance portion consisting of two one-directional channels (four wires) is connected with a bidirectional channel (two wires) by means of a hybrid transformer. If the hybrid impedance is perfectly balanced, the two one-directional channels are uncoupled and no signal is returned to the transmitter side (Hansler & Schmidt, 2006; Manolakis et al., 2005). However in general the bridge is not perfectly balanced because the

required impedance to properly balance the hybrid depends on the overall impedance network. In this situation, part of the signal is reflected, producing an echo. To avoid this problem an adaptive filter is used to generate an echo replica, which is then subtracted from the signal to be transmitted. Subsequently, the adaptive filter coefficients are updated to minimize, usually, the mean square value of the residual echo (Madisetti & Williams, 1998; Perez-Meana, 2007). To obtain an appropriate operation, the echo canceller impulse response must be larger than the longer echo path to be estimated. Thus assuming a sampling frequency of 8kHz and an echo delay of about 60ms, an echo canceller with 256 or more taps is required (Manolakis et al., 2005; Perez-Meana, 2007). Besides the echo path estimation, another important problem is how to handle the double talk—that is, the simultaneous presence of the echo and the near speech signal (Hansler & Schmidt, 2006; Manolakis et al., 2005).

Acoustic Echo Cancellation

A critical problem affecting speech communication in a teleconferencing system is the acoustic echo. When a bi-directional line links two rooms, the acoustic coupling between the loudspeaker and microphones in each room causes an acoustic echo perceivable to the users in the other room. The best way to handle it appears to be the adaptive echo cancellation. An acoustic echo canceller generates an echo replica and subtracts it from the signal picked up by the microphones. The residual echo is then used to update the filter coefficients such that the mean square value of approximation error is kept to a minimum (Perez Meana, Nakano-Miyatake, & Nino-de-Rivera, 2002.; Huang & Banesty, 2005).

Adaptive Noise Cancellation

The adaptive noise canceller is a generalization of the echo canceller in which a signal corrupted with additive noise must be restored or enhanced. When a reference signal correlated with the noise signal but uncorrelated with the desired one is available, the noise cancellation can be achieved by using an adaptive filter to minimize the total power of the output of the difference between the corrupted signal and the estimated noise, such that the resulting signal becomes the best estimate, in the mean square sense, of the desired signal. This system works fairly well when the reference and the desired signal are uncorrelated among them. However, appropriate reference signals are not always available. To solve this problem several noise canceling algorithms have been proposed which are resistant to crosstalk situations. A different approach, developed by Dolby Laboratories, is used in the Dolby noise reduction systems in which the dynamic range of the sound is reduced during recording and expanded during the playback (Davis, 2002; Hansler & Schmidt, 2006). Several types of Dolby noise reduction systems have been developed including the A, B, C, and HXpro. Most widely used is the Dolby B, which allows acceptable playback even on devices without noise reduction. The Dolby B noise reduction system uses a pre-emphasis that allows masking the background hiss of a tape with a stronger audio signal, especially at higher frequencies. This effect is called psychoacoustic masking (Davis, 2002; Perez-Meana, 2007).

A related problem to noise cancellation is the active noise cancellation that intends to reduce the noise produced in closed places by several electrical and mechanical pieces of equipment such as home appliances, industrial equipment, air conditioning units, airplanes turbines, motors, and so forth. Active noise is achieved by introducing a canceling

Table 2. Digital speech coding standards

Rate Kb/s	Application	Type of Coder	Year
64	Public Switched Telephone Network	Pulse Code Modulation (PCM)	1972
2.4	U.S. Government Federal Standard	Linear Predictive Coding	1977
32	Public Switched Telephone Network	Adaptive Differential PCM	1984
9.6	Skyphone	Multi-Pulse Linear Predictive Coding (MPLPC)	1990
13	Pan-European Digital Mobile Radio (DMR) Cellular System (GSM)	Regular Pulse Excitation Linear Prediction Coding (RPE-LPC)	1991
4.8	U.S. Government Federal Standard	Codebook Excited Linear Prediction Coding (CELP)	1991
16	Public Switched Telephone Network	Low Delay CELP (LD-CELP)	1992
6.7	Japanese Digital Mobile Radio (DMR)	Vector Sum Excited Linear Prediction Coding (VSELP)	1977

anti-noise wave through an appropriate array of secondary sources, which are interconnected through an electronic system using adaptive systems with a particular cancellation configuration. Here, the adaptive filter generates an anti-noise that is acoustically subtracted from the incoming noise wave. The resulting wave is captured by an error microphone and used to update the noise canceller parameters, such that the total error power is minimized. This technology has been successfully applied in earphones, electronic mufflers, noise reduction systems in airplane cabins, and so forth (Davis, 2002; Kuo & Morgan, 1996).

Speech and Audio Coding

Besides interference cancellation, speech and audio signal coding are other very important signal processing applications. This is because low bit rate coding is required to minimize the transmission costs or provide cost-efficient storage. Here we can distinguish two different groups: the narrowband speech coders used in telephone and some video telephone systems in which the quality of telephone-bandwidth speech is acceptable, and the wideband coders used in audio applications that require a bandwidth of at least 20kHz for high fidelity (Madisetti & Williams, 1998; Spanias, Painter, & Atti, 2007; Huang & Benesty, 2005).

Narrowband Speech Coding

The most efficient speech coding systems for narrowband applications use an analysis-synthesis-based method in which the speech signal is analyzed during the coding process to estimate the main parameters of speech that allow its synthesis during the decoding process. Two sets of speech parameters are usually estimated: (1) the linear filter system parameters that model the vocal track, estimating use of the linear prediction method, and (2) the excitation sequence. Most speech coders estimate the linear filter in a similar way, although several methods have been proposed to estimate the excitation sequence that determines the synthesized speech quality and compression rates. Among these speech coding systems, we have the multi-pulse and regular pulse linear predictive coding and the codebook exited linear predictive coding (CELP), which achieve bit rates among 9.6 Kb/s and 2.4 kb/s, with reasonable good speech quality (Madisetti & Williams, 1998; Huang & Benesty, 2005; Spanias et al., 2007). Table 2 shows the main characteristics of some of the most successful speech coders.

Wideband Audio and Speech Coding

Bandwidths higher than that of telephone bandwidth result in major subjective improvements. Thus a bandwidth of 50 to 20 kHz not only improves the intelligibility and naturalness of audio and speech, but also adds a feeling of transparent communication and eases speaker recognition. However, this will result in the necessity to store and transmit a much larger amount of data, unless efficient wideband coding schemes are used. Wideband speech and audio coding intend to minimize the storage and transmission costs, while providing an audio and speech signal with not audible differences between the compressed and the actual signals with 20kHz or higher bandwidth and a dynamic range equal to or above 90 dB. Four key technology aspects play a very important role in achieving this goal: perceptual coding, frequency domain coding, window switching, and dynamic bit allocation. Using these features, the speech signal is divided into a set of non-uniform subbands to encode with more precision the components perceptually more significant and with fewer bits the perceptually less significant frequency components. The subband approach also allows the use of the masking effect in which the frequency components close to those with larger amplitude are masked and then they can be discharged without audible degradation. These features, together with a dynamic bit allocation, allow significant reduction of the total bits required for encoding the audio signal without perceptible degradation of the audio signal quality. Some of the most representative coders of this type are listed in Table 3 (Kondoz, 1994; Madisetti & Williams, 1998; Spanias et al., 2007; Huang & Benesty, 2005).

Medical Applications

Signal processing has been successfully used to improve the life quality of persons with hearing and speaking problems (Davis, 2002; Hansler & Schmidt, 2006). Among them we have the development of hearing aid devices, which attempt selectively to amplify the frequencies if the sound is not properly perceived. The enhancement of alaryngeal speech is another successful application in which signal processing and pattern recognition methods are used to improve the intelligibility and speech quality of persons whose larynx and vocal cords have been extracted by a surgical operation. Signal processing algorithms have also been developed to

Table 3. Some of the most used wideband speech and audio coders

Coder Bitrate Application
• CCITT G.722 64 kbits/s, 56 kbits/s, 48 kbits/s Speech
• Low Delay CELP 32 kbits/s Speech

• OGG Vorbis 96 kbits/s Audio
• WAV 10 MB/min Audio

modify the time scale of speech signal to improve the hearing capabilities of elderly people.

Watermarking

Digital watermarking is a technique used to embed a collection of bits into a signal in such way that it will be kept imperceptible to users and the resulting watermarked signal remains with almost the same quality as the original one. Watermarks can be embedded into audio, images, videos, and other formats of digital data in either the temporal or spectral domains (Cox, Miller, & Bloom, 2001; Perez-Meana, 2007; Spanias et al., 2007). Here the temporal watermarking algorithms embed watermarks into audio signals in their temporal domain, while the spectral watermarking algorithms embed watermarks in certain transform domains, such as the Fourier transform domain, wavelet domain, or cepstrum domain. Depending on their particular application, the watermarking algorithms can be classified as robust or fragile watermarks. Here the robust watermarking algorithms, which cannot be removed by common signal processing operations, are used for copyright protection, distribution monitoring, copy control, and so forth, while the fragile watermark, which will be changed if the host audio is modified, is used to verify the authenticity of an audio or speech signal.

FUTURE TRENDS

Audio and speech processing have achieved an important development during the last three decades, however several problems still remain that must be solved, such as how to develop more efficient echo canceller structures with improved double talk control systems. In adaptive noise canceling a very important issue that remains unsolved is the crosstalk problem. To get efficient active noise cancellation systems, it is necessary to cancel the anti-noise wave inside the reference microphone which distorts the reference signal to reduce the computational complexity of ANC systems and develop a more accurate secondary path estimation. Other important issues are to develop low distortion speech coders for bit rates below 4.8 kBits and increase the convergence speed of adaptive equalizers, to allow the tracking of fast time varying communication channels. The speech and audio processing systems will also contribute to improve the performance of medical equipment such as hearing aids and alaryngeal speech enhancement systems, as well as to security through the development of efficient and accurate speaker recognition and verification systems. Finally, in recent years digital watermarking algorithms have grown rapidly, however several issues remain such as developing an efficient algorithm taking into account the human auditory system (HAS), solving synchronization problems using multi-bit watermarks, and developing efficient watermarking algorithms for copy control.

Table 4. Other successful audio and speech applications

• Signal processing for hearing aids
• Virtual musical instruments synthesis
• Alaryngeal speech enhancement
• Cross-language voice conversion
• Speech and speaker recognition
• Adaptive equalization

CONCLUSION

Audio and speech signal processing have been fields of intensive research during the last three decades, becoming an essential component for interference cancellation and speech compression and enhancement in telephone and data communication systems, high-fidelity broadband coding in audio and digital TV systems, speech enhancement for speech and speaker recognition systems, and so forth. However despite the development that speech and audio systems have achieved, the research in those fields is increasing in order to: provide new and more efficient solutions in the above-mentioned fields and several others, such as the acoustic noise reduction to improve the environmental conditions of people working in airports, factories, and the like; improve the security of restricted places through speaker verification systems; and improve the speech quality of alaryngeal people through more efficient speech enhancement methods. Thus it can be predicted that speech and audio processing will contribute to more comfortable living conditions in future years.

KEY TERMS

Adaptive Filter: Linear system that modifies its parameters minimizing some given criterion of the difference between its output and a given reference signal. Widely used in echo and noise canceling, equalization of communication channels, antenna arrays, and so forth.

Adaptive Algorithm: Method used to modify the filter coefficients, online, in order to minimize the power of an adaptive filter output error.

Alaryngeal Speech: Speech produced by persons whose larynx and vocal cords have been extracted by a surgical operation.

Anti-Noise: Estimated replica of acoustic noise generated by an active noise canceller system, which is used to cancel an environmental noise.

Crosstalk: Interference present in a signal propagating through a communication produced by another signal present at an adjacent channel.

Digital Watermarking: A technique used to embed a collection of bits into a host signal in such a way that the watermark remains imperceptible to the users.

Double Talk: An interference produced when the speakers in both ends of a telephone line simultaneously speak. This phenomenon greatly disturbs the echo canceller performance.

Hybrid Transformer: Device used to connect two one-directional channels with a bi-directional channel, keeping uncoupled among them the two one-directional channels.

Narrowband Speech Signal: Speech signal with a frequency band equal to that of the telephone channel — that is, with a bandwidth of 300 to 3,300 kHz.

Signal Compression: Signal coding that allows a reduction of the total number of bits required to represent a given signal without distortion or with negligible distortion.

Speech Enhancement: Signal processing performed in a given speech signal to improve its intelligibility and signal-to-noise-ratio.

Speaker Verification: Signal processing required for verifying the speaker identity by using his or her speech features.

Wideband Signal: Signal with a bandwidth wider than that of the telephone channel, usually between 50 Hz and 20 kHz.. This fact results in major subjective improvements.

Simulation for Supporting Business Engineering of Service Networks

Marijn Janssen
Delft University of Technology, The Netherlands

INTRODUCTION

Today, the services industry provides the majority of all jobs in Western countries, and services tend to be delivered more and more using the Internet. The service economy is becoming increasingly dominant in developed economies, with knowledge assets playing a great role relative to physical and financial assets. (Rouse & Baba, 2006)

Services are often characterized as intangible, perishable, experience-based, difficult-to-standardize products needing many interactions between customers and services providers. Grönroos (2001) identified three basic characteristics of services:

1. Services are processed consisting of activities or a series of activities rather than things.
2. Services are at least to some extent produced and consumed simultaneously.
3. The customer participates in the service delivery process.

All kinds of information and communication technology (ICT) are applied to support the creation of service networks. *Service networks* are constellations of independent organizations that work together in various configurations in order to deliver services. The provisioning of services can be viewed as a series of activities leading to some observable behavior between service providers (or service brokers) and service requesters. They are delivered using the Internet, accessible from any place at any time and often involve no direct human involvement of the service provider. The term *e-services* is typically used to describe a variety of electronic interactions ranging from basic services, such as the delivery of news and taking out an insurance policy, to more complex services, such as the delivery of context-aware, personalized services.

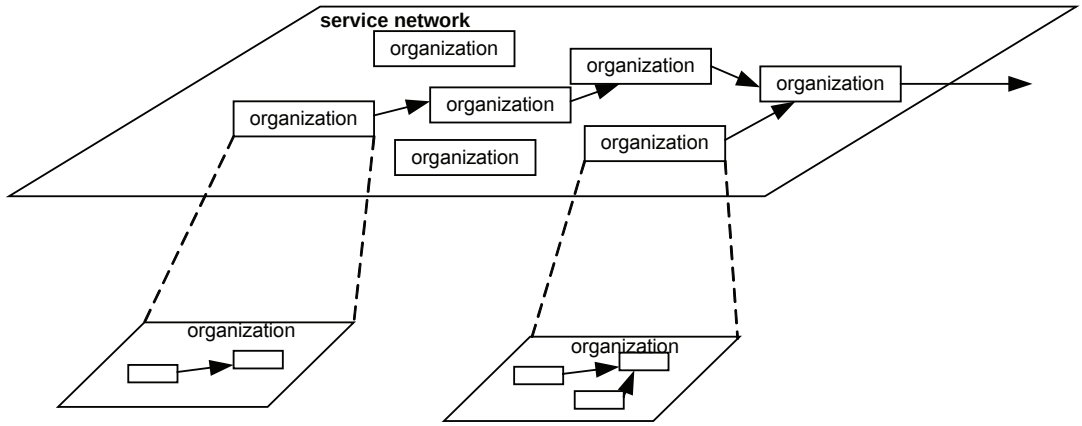
To understand a service network, both the network and the decision makers involved need to be understood. Stakeholder theory states that those who can effect change or be affected by it should be accounted for in the transformation process (Pfeffer, 1981). The diversity of key stakeholders and their interests makes evaluating the design and the efficiency and effectiveness of service networks very complex. Often stakeholders are characterized by opposing interests, having heterogeneous systems and being part of multiple service networks. The effective management of such services network is key to success, which requires understanding each other's interests, business processes, and information systems. Often organization network managers, a particular type of electronic intermediary (e-intermediary), specialize in coordinating such networks (Janssen & Verbraeck, 2005b). Design decisions are critical, as they determine the efficiency and effectiveness of the service networks. The development and growth of service networks requires the developer to carefully identify, evaluate, and understand the possible impact of the various design alternatives. A business engineering methodology can be of help in designing and developing service networks by providing insight into current network structure and potential structure, and by evaluating the implications of potential arrangements. Simulation can be used to compare the performance of the current and possible situations in a business engineering methodology. Simulation of service networks is much more difficult than physical networks, as the products often concerns intangibles. The *objective* of this article is to discuss research issues concerning the simulation of service networks to support business engineering.

BACKGROUND

Service networks can use a large variety of coordination mechanisms and structures to coordinate the activities of participants. Service networks consist of organizations cooperating together, and the management of the networks has a large impact on the total performance. Figure 1 shows a service network schematically.

The dynamic nature of service networks—that is, the changing number and/or types of partners, and the involvement in several networks—increases the difficulty and complexity to understand the dependencies in the network. The creation of flexible, temporary service networks results in the creation of business processes that are no longer self-contained within a single organization. The effectiveness of service networks depends more and more on the performance of external partners that are often unknown and viewed as black boxes (Tewoldeberhan & Janssen, 2007). Therefore,

Figure 1. Example of a service network



some organizations can be considered as white boxes and others as black boxes in the networks, as schematically depicted in Figure 1. Not all organizations must be involved in each service provisioning process. Organizations might be selected and dynamically assembled based on the services needed by the customers. A service network consists of multiple businesses having varying types of relationships.

The core of a service network is the *coordination* of the various interdependent activities performed by autonomous organizations. There are two opposing views on coordination. In a *coordination of tasks* approach, the design of processes is dependent on the coordination mechanisms that manage the dependencies between tasks (Malone & Crowston, 1994). The *coordination of commitments* approach emphasizes networks of commitments that organizations establish through intentional acts of speech (Winograd & Flores, 1987). This coordination approach emphasizes the fulfillment of human commitments and describes activities in terms of contracts and promises. A traditional approach to supply chains is the coordination of tasks view. In a service network, both views apply, as the activities performed by the independent organization needs to be coordinated in order to agree on and fulfill commitments.

The requirements of an organization are not easily elicited and can demand innovative mechanisms or deliberate trade-offs. The timely sharing of information among organizations is often a major issue (Christopher, 2003). Information sharing is necessary for efficient coordination of the service network and to optimize performance. The organizations making up the network often want to avoid that information is provided to other network members. Information might be used to negotiate lower prices or undermine competitive advantage, as competitors might learn from it. Another typical issue in the business engineering of service networks is the selection of coordination mechanisms, as members can have different and even opposing requirements. For

Table 1. A list of business engineering issues

• Which information architectures and structures are most beneficial in which situations?
• Aligning mechanism with service and markets characteristics?
• Integration of the information systems of network members?
• How to manage the service network?
• Should intermediaries be used to coordinate the service network?
• Level of coarse and fine-grained services
• Evaluation of implications of changes
• Pooling and sharing of services
• Conflicting interests of network members
• Incomplete information, ensuring information privacy
• Ensuring quality of product to buyer and payment to sellers
• Tracking and tracing
• Reducing transaction risk and increasing trust
• Use of software agents as assistance in search and evaluation
• Intelligent product and vendor matching mechanisms
• Product distribution/delivery
• Creating and disseminating product information
• Information processing and aggregation
• Open and closed networks
• Spot sourcing for dynamic networks vs. systematic sourcing for sustainable networks
• Type of management information and dissemination of management information

example one organization strategy might be to minimize trading time, while another might want to minimize costs. The most conspicuous opposing requirement is that buyers want to have the lowest price at the best possible trading conditions while sellers want to have the highest possible price to maximize revenue.

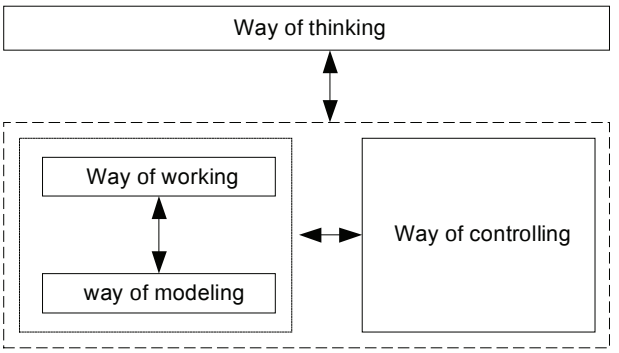
In short, a large number of other trade-offs and decisions need to be made before an efficient and effective service network can be established. A list of business engineering issues is shown in Table 1. Some limitations are coming from the state of the art of the technology and from market and/or service characteristics; others are coming from the opposing requirements and needs of the parties involved. Simulation for business engineering of service networks can help decision makers gain insight into these issues. This should support them in making deliberate choices without having to experiment in real life, which could be costly and even result in a loss of customers.

SIMULATION-SUPPORTING BUSINESS ENGINEERING

Service networks are by nature complex, and analytic methods can only be applied in a limited way. Although these approaches contribute to insight into and design of service networks, they do not help decision makers evaluate the impact and support their decision making in practice. Ideally, the implications of changes should be evaluated prior to implementation on criteria such as costs, utilization, trading time, delivery time, number of bids, matching chance, and so on. Analytical approaches also do not grasp the time-dependent dynamics resulting from the interplay between actors executing business processes.

A business engineering methodology can be seen as a continuum of approaches to process change (Kettinger, Teng, & Guha, 1997). Such a methodology is often seen as a way to tackle issues from an engineering perspective, as well as from a social perspective. The analytical framework of Sol (1990) provides a suitable way to describe business engineering methodologies. This framework classifies design methodologies by ways of thinking, working, modeling, and controlling. The *way of thinking* describes the philosophy on which the design methodology is based. It provides the basic assumptions of the business engineering approach and should contain, for example, whether it is aimed at radically changing the service network or at step-wise improvement, and will outside experts be used to analyze the situation or will the business engineering approach be based on stakeholders' participation? The *way of working* provides the subsequent steps that should be carried out to arrive at a new situation. An approach supporting relatively small steps and letting stakeholders participate so that they can gain the necessary knowledge to formulate their own incremental

Figure 2. Analytical framework for business engineering methodologies (based on Sol, 1990)



improvements or a radical approach can be taken. The *way of modeling* refers to the concepts that are used to abstract reality into models of the problem domain. Often models are used to support communication and evaluate the impact of changes. The *way of controlling* or management approach provides the components needed for the management of a design project. Often a project management approach is taken using milestones to guide the process.

The way of modeling provides the necessarily support for a business engineering approach. Simulation of business processes constitutes one of the most widely used applications of operational research, as it allows us to understand the essence of business systems, to identify opportunities for change, and to evaluate the effect of proposed changes on key performance indicators (Law & Kelton, 1991). The philosophy behind a business engineering approach is to develop a simulation model of the service network, experiment with this model, and experiment with alternative situations (Sol, 1982). An analysis of service networks needs to begin with an understanding of current processes and should investigate how conventional transaction methods are changed as a result of ICT adoption. One of the advantages of simulation is that what-if analysis can be carried out without changing reality at lower costs. These analyses often compare situations using time- and cost-based performance indicators such as delivery time, utilization of resources, cost of activities, and waiting time.

Animation is often a standard feature of simulation. An *animation* model is a graphical representation of a problem situation and includes visualization of the time-ordered dynamics of objects, a static background, an overview of performance indicators, and a user-interface (de Vreede & Verbraeck, 1996). The purposes of animation are to facilitate decision makers to acquire insight into the dynamic interactions of the modeled system, the performance of the 'as is' and 'to be' situation, and to facilitate communication between parties involved in a dynamic modeling study. Effecting enterprise-wide technology and business process change in the service networks is a massive and complex

undertaking, and animation might help to create a shared vision and understanding among participants.

FUTURE TRENDS

Business engineering methodology provides context to the simulation technique (Greasley, 2003). Business engineering approaches proposed by Streng (1994) and Giaglis, Paul, and Doukidis (1999) tackle the analysis of the added value of technology-enabled changes by making use of discrete-event simulation. Nikolaidou and Anagnostopoulos (2003) use a simulation approach for modeling distributed systems.

Dependent on the characteristics of the service network under study, certain issues shown in Table 1 dominate and should be simulated. A business engineering methodology should ensure the incorporation of the relevant business engineering issues, and simulation can be used to aid conscious decision making. A business engineering approach should help to focus on those issues most relevant to the particular situation and help to find solutions to those issues. A fruitful research direction seems to be which issues should be included in the business engineering for which types of situations.

The ability to create flexible alliances with partners to form supply chains or business networks becomes more and more important for businesses. Almost all of the current attention seems to be geared toward how static service networks can be configured, almost completely neglecting the dynamism of the environment in which a service network operates. Little attention is given to how these service networks evolve and emerge over time, or how environmental changes that require the service network to adapt can be dealt with. Various types of changes and their possible impact on the complete network and also on the individual organizations should be captured by further research.

In the early stages of service networks, management resembled like traditional business relationships, and the network participants where often modeled using black-box approaches. Most studies assume that all data was available, however in many service networks this might not be a valid premise. Many organizations will be reluctant to share data about their mission-critical business processes with others. Thus, the efficiency of service networks will be hampered by the fact that organizations often demand that their data and inner business processes remain hidden from the other organizations in the supply chain. Future research should also include the modeling of service networks for situations where the supply chain is not completely known and limited data is available.

Web services technologies are more and more used to support the creation of service networks and especially the use of Web service orchestration technology to coordinate the interactions between network participants. Fast adoption is often hampered by the need for experimentation to make efficient use of this technology (Tewoldeberhan & Janssen, 2007). As such, more insight in business engineering, simulation, and the effect of Web service technology is a research direction. Especially to evaluate the implications of new technologies, simulation of a service network should on *emulation*, which means that actual software is used and embedded in the simulation experiment. This combines a simulation and prototyping approach into one modeling approach.

A large number of independent organizations with their own strategies and sometimes even opposing aims carry out business with each other. The relations between organizations can change during the trading process, as organizations can enter or leave the playing field. The most powerful abstractions are the ones that minimize the semantic gap between the units of analysis that are intuitively used to conceptualize the problem and the constructs present in the modeling approach. Ideally, an organization should be simulated as distributed systems, where each system is represented by an autonomous entity. Software agents are autonomous entities that can be used for simulating organizations. The so-called agents are autonomous entities with their own interests and goals so they can decide to enter or leave a trading situation. *Agent-based simulation* has appeared for modeling organizations within electronic markets (Ramat & Preux, 2003; Janssen & Verbraeck, 2005a). Janssen and Verbraeck (2005a) developed an agent-based simulation technique for electronic markets. Agent-based simulation approaches view systems in terms of autonomous agents that engage in interactions to coordinate their activities. The coordination problem in a system consisting of a number of agents is analogous to the coordination problem of independent organizations trading with each other. This approach might also be suitable for a service network and seems to be a feasible research direction.

Communication over the Internet using a *Web-based* simulation is preferable for supporting communication between the researcher and persons involved in the design process. Another research issue is to use *distributed* simulation so multiple participants could interact with a simulation environment at the same time. In this way the participants can gain experiences with a hypothetical service network. This might lead to an increase in insight into the problem situation by participants and might help designers to make better decisions.

CONCLUSION

Organizations cooperate and compete more with each other in service networks, and the efficient and effective management of such networks determines success. Business engineering is aimed at creating change by simultaneously considering

organizational and technical aspects, and simulation can make change possible by supporting the business engineering approach. During the business engineering of service networks, numerous trade-offs and decisions must be made, influencing the performance and possible adoption. Business engineering using simulation should help decision makers focus on the most relevant issues and make appropriate decisions and trade-offs without having to experiment in real-life situations. It is still unclear what the most relevant issues are to focus on when engineering service networks.

Ideally, service networks should be modeled representing reality as close as possible. All types of electronic intermediaries can support the coordination of the dependencies among organizations in the service network. A fruitful direction seems to be the use of a distributed, agent-based simulation, making use of emulated mechanisms. In this way emergent behavior and changes can be modeled and their impact evaluated. Ideally, decision makers of various organizations should be able to view the animation of the simulation over the Internet, manipulate parameters, and view the consequences of their actions. The accomplishment of this ideal needs ample research attention in the domain of business engineering methodologies, distributed simulation, agent-based simulation, Web-based animation, and emulation of mechanism.

KEY TERMS

Agent-Based Simulation: Simulates organizations as interacting autonomous entities with their own interests and goals.

Animation Model: A graphical representation of a problem situation which can consist of a visualization of the time-ordered dynamics of objects, a static background, an overview of performance indicators, and a user interface.

Business Engineering: The integral design of both organizational structures and information systems.

Coordination of Commitments: The actions by humans leading to the completion of work. Coordination is described in terms of contracts and promises consisting of recurring loops of requesting, making, and fulfilling commitments.

Coordination of Tasks: The management of dependencies between tasks.

Discrete-Event Simulation: Models a system by changing the systems state at discrete points in time.

Emulation: Actual software is written to execute something, instead of simulating it.

Service Network: Constellations of independent organizations that work together in various configurations in order to deliver services.

INTRODUCTION

The job shop scheduling problem (JSSP) is generally defined as decision-making problems with the aim of optimizing one or more scheduling criteria. Many different approaches, such as simulated annealing (Wu et al., 2005), tabu search (Pezzella & Merelli, 2000), genetic algorithm (Watanabe, Ida, & Gen, 2005), ant colony optimization (Huang & Liao, 2007), neural networks (Wang, Qiao, &Wang, 2001), evolutionary algorithm (Tanev, Uozumi, & Morotome, 2004) and other heuristic approach (Chen & Luh, 2003; Huang & Yin, 2004; Jansen, Mastrolilli, & Solis-Oba, 2005; Tarantilis & Kiranoudis, 2002), have been successfully applied to JSSP.

Flexible job shop scheduling problem (FJSSP) is an extension of the classical JSSP which allows an operation to be processed by any machine from a given set. It is more complex than JSSP because of the addition need to determine the assignment of operations to machines. Bruker and Schlie (1990) were among the first to address this problem. The flexible job shop scheduling problem may be formulated as follows.

1. There is a set of n jobs that plan to process on m machines;
2. The set machine is noted M, $M = \{M_1, M_2, ..., M_m\}$;
3. Each job j consists of a sequence of n_j operations $O_{j1}, O_{j2}, ..., O_{jn_j}$;
4. The execution of each operation i of a job j (noted O_{ji}) requires one machine out of a set of given machines called $M_{ji} \subseteq M$.

The problem is thus to both determine an assignment and a sequence of the operations on all machines that minimize following criteria.

1. Maximal completion time of machines;
2. Total workload of the machines;
3. Critical machine workload.

The weighted sum of the above three objective values is taken as the objective function.

$$F(c) = 0.5*F_1(c) + 0.2*F_2(c) + 0.3*F_3(c) \quad (1)$$

Where $F(c)$ denotes the total evaluation value of the schedule c; $F_1(c)$ denotes the maximal completion time of machines (makespan) of the schedule c; $F_2(c)$ denotes the total workload of the machines of the schedule c; $F_3(c)$denotes the critical machine workload of the schedule c.

BACKGROUND

For solving the realistic case with more than two jobs, two types of approaches have been used: hierarchical approaches and integrated approaches (Xia & Wu, 2005).

In hierarchical approaches, assignment of operations to machines and the sequencing of operations on the machines are treated separately. Kacem, Hammadi, and Borne (2002a; 2002b) proposed a genetic algorithm controlled by the assigned model for the FJSSP. Xia and Wu (2005) present an effective hybrid optimization approach, which makes use of particle swarm optimization to assign operations on machines and simulated annealing algorithm to schedule operations, for the multi-objective FJSSP.

Integrated approaches were used by considering assignment and scheduling at the same time. The integrated approach which had been presented by Dauzere-Peres and Paulli (1997) was defined a neighborhood structure for the FJSSP where there is no distinction between reassigning and resequencing an operation, and the tabu search procedure is proposed based on the neighborhood structure. Mastrolilli and Gambardella (2002) improved Dauzere-Peres' tabu search techniques and presented two neighborhood functions. Most researchers were interested in applying tabu search techniques and genetic algorithms to FJSSP in the past (Xia & Wu, 2005).

SIMULATION MODEL OF ANT COLONY OPTIMIZATION

Framework of the Simulation Model

The framework of our proposed simulation model is displayed as Figure 1.

Input Subsystem

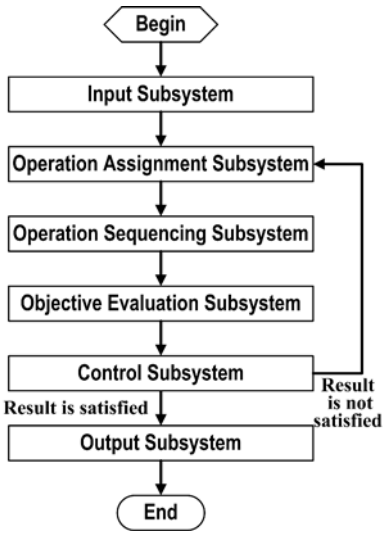
The leading function of input subsystem is inputting all necessary data for solving FJSSP. In our work, we apply file mode to implement the data inputting. Please note, it should have a verify function after data reading, for example, each input data should be a positive integer etc.

Operation Assignment Subsystem

The primary mission of operation assignment subsystem is achieving an excellent assignment of operations to machines. In this part, each assignment was evaluated by formula (2).

$$Fitness(\alpha) = 0.2*F_2(\alpha) + 0.8*F_3(\alpha) \quad (2)$$

Figure 1. The framework of our proposed simulation model



Also, the operation assignment machine knowledge (OAMK) is defined for operation assignment. OAMK is the accumulative knowledge of assigning the giving operation to a more appropriate machine. It was achieved from the near-optimal solution of FJSSP of each iterative. A knowledge matrix *OAMK* with size |*Oper*| × |*Mach*| is defined for the OAMK, where |*Mach*| denotes the number of machines, and |*Oper*| denotes the total account of all operations. For an arbitrary element *OAMK* [*i*][*j*], it means the probability of assigning the giving operation *i* to the current machine *j*.

For enhancing the assignment performance, we try to assign each operation to the machines which process the giving operation with a minimal processing time or the second minimal processing time. The implementing flow of operation assignment is listed as follows.

Step 1. Select an operation (i.e., O_{ij}) among all operations which need to be assigned.
Step 2. Search all machines (e.g., M_{ij}) which process the giving operation with a minimal processing time or the second minimal processing time.
Step 3. Choice a machine (i.e., M_{ijk}, $M_{ijk} \in M_{ij}$) among the achieved machine set M_{ij} randomly with a probability distribution, which was indicated by the OAMK, and assign operationO_{ij} to the selected machine M_{ijk}.
Step 4. Repeat *Step 1* to *Step 3* until all operations were assigned to the appropriate machines.

When obtaining the global optimal solution (the most excellent solution from the beginning of the trial), the OAMK will be updated by applying the rule of (3) according to the global optimal solution.

$$OAMK(i,m) = OAMK(i,m) + Q_G \quad (3)$$

Where *m* denotes each giving machine, *i* denotes each operation processed in machine *m*, Q_G denotes the incremental level in the knowledge updating phase.

Operation Sequencing Subsystem

In order to enhance the sequencing performance, we try to arrange each operation to the giving machine using ant colony optimization (ACO) algorithm. The computational flow of ACO algorithm is displayed as Figure 2.

1. Schedule knowledge initialization. In this part, operation assignment position knowledge (OAPK) is defined according to the traditional pheromone definition. OAPK is the accumulative knowledge of the more appropriate operation processing sequence at a giving machine. It is achieved from the near-optimal solution of FJSSP of each iterative.

In this work, a knowledge matrix *OAPK* with size |*Mach*| × |*Oper*| × |*Oper*| is defined for the OAPK, where |*Mach*| denotes the number of machines, and |*Oper*| denotes the total account of all operations. For an arbitrary element *OAPK*[*i*][*j*][*k*], it means the probability of processing sequence (from operation *j* to operation *k*) at machine *i*.

2. Schedule construction. In this phase, the ACO algorithm schedules operations on each machine and obtains the optimal sequencing of operations on the machines.
   a. Schedule construction mechanism. Based on the simulation advance mechanism, a new schedule construction mechanism was proposed and summarized as follows. If there are several idle machines, then the next operation will be selected according to the state transition rule (see next part) for these machines; if all the machines are busy, then the simulation process will be advanced until one or several machines are idle. The aforementioned process was executed till all the operations were finished.
   b. State transition rule. In the schedule construction phase, each artificial ant will choose the next operation from an allowed set for these idle machines. Let *allow*(*m*,*t*)denotes the allowed set (set of the allowed processing operation) for the machine *m* at the time *t*, and then it can be defined as follows (figure 3).

To the machine *m*, the following probability distribution (Formula 4) will be applied to select the next operation O_j when it finished the previous operation O_i. (See Box 1)

3. Local search algorithm. In ACO, the generated schedules by artificial ants may be so coarse that they should be improved by some complementary local search method. In this chapter, a proposed local search algorithm was applied to refine the feasible solution achieved by ACO. That is, the ACO algorithm, which has excellent exploration and information learning abilities, was applied to provide some appropriate initial schedules, and then these appropriate feasible solutions were refined by the proposed local search

Figure 2. The framework of the ant colony optimization algorithm

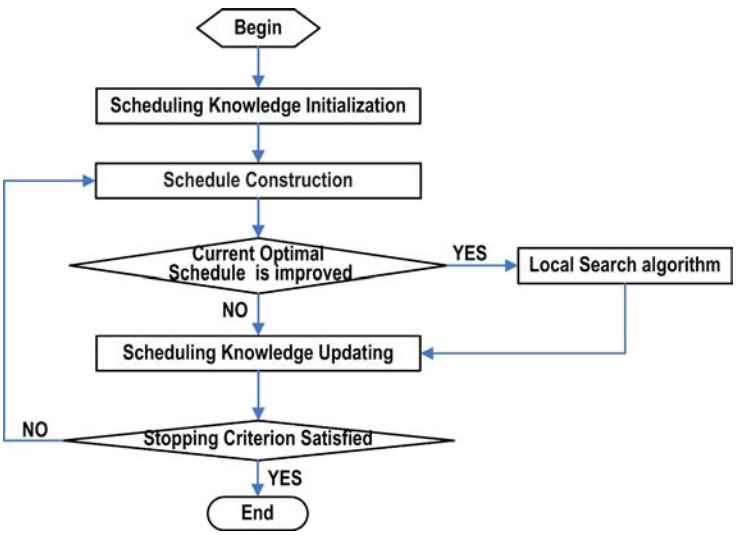


Figure 3. The definition for allowed processing operation set

```
for i = 1: OperNum    % OperNum denotes the account of the assigned operation to machine m;
    Oper = the i^th operation among the assigned operation to machine m;
    if (Oper is the first operation in its job)
        Oper ∈ allow(m,t);
    elseif (the predecessor of Oper was finished at the time t)
        Oper ∈ allow(m,t);
    end
end
```

algorithm. The essential points of this proposed local search algorithm is listed as follows.

a. Try to adjust each operation to the machine with the minimal processing time;
b. Try to adjust each operation to the machine with the second minimal processing time;
c Try to adjust each operation to the machine with the minimal total processing time.

4. Scheduling knowledge updating.
   a. **Local update rule:** The best ant, which constructed the best schedule at the current iterative, is allowed to deposit knowledge to its corresponding solution according to the local updating rule.

$$OAPK(m, i, j) = OAPK(m, i, j) + Q_L \quad (5)$$

Where, m denotes each giving machines; i and j denote two different operations processed at machine m respectively, and operation i was processed before operation j; Q_L denotes the incremental level in the local updating phase.

   b. **Global update rule:** The globally best ant, which constructed the most excellent solution from the beginning of the trial, is allowed to deposit knowledge to its corresponding solution according to the global updating rule.

$$OAPK(m, i, j) = OAPK(m, i, j) + Q_G \quad (6)$$

Where, Q_G denotes the incremental level in the global updating phase.

   c. **Knowledge evaporating rule:** The knowledge evaporating rule is performed after each iterative. In our applied ACO algorithm, knowledge trails on each solution component is limited to an interval $[\tau_{min}, \tau_{max}]$ to avoid stagnation state of possibility. (See Box 2)

5. In our work, the stopping criterion of ACO is defined through the iterative times. That is, the ACO algorithm is terminated when the maximal preset search iterative is exhausted.

Objective Evaluation Subsystem

The main function of objective evaluation subsystem is evaluating the objective value of these achieved schedules. In this part, the makespan, the total workload of the machines and the critical machine workload of the giving schedule were computed firstly, and the weighted sum of these above three objective values was computed as the objective function of the giving schedule according to the formula (1).

Control Subsystem

The elementary function of control subsystem is computation flow control, feasibility validation and other extensible function (module). Computation flow control includes whole flow design, termination condition setting, and so on. Feasibility validation is validating the feasibility of

Box 1.

$$\Pr(O_i, O_j, m, t) = \begin{cases} \dfrac{\left[\tau(m,i,j)\right]^a \times \left[\lambda(m,j)\right]^b}{\sum_{O_k \in allow(m,t)} \left(\left[\tau(m,i,k)\right]^a \times \left[\lambda(m,k)\right]^b\right)} & O_j \in allow(m,t) \\ 0 & O_j \notin allow(m,t) \end{cases} \quad (4)$$

Where, $\Pr(O_i, O_j, m, t)$ denotes the probability of selecting the next operation O_j when it finished the previous operation O_i on machine m at time t; $\tau(m, i, j)$ denotes the heuristic value achieved by OAPK, $\tau(m, i, j) = OAPK(m, i, j)$; $\lambda(m, j)$ denotes the heuristic value achieved by operation processing time, $\lambda(m, j) = 1/t(j, m)$; $t(j, m)$ denotes the time of processing operation j at machine m; a,b denote the weight of these two different heuristic information respectively. In our work, the pseudo-random-proportional rule (Dorigo & Stutzle, 2004) was used as state transition rule.

Box 2.

$$OAPK(m, i, j) = \max\{\tau_{min}, \min\{\tau_{max}, (1 - \rho)OAPK(m, i, j)\}\} \quad (7)$$

Where ρ is the knowledge evaporating parameter ($0 < \rho < 1$).

these interim solutions. If there has some errors, the control subsystem should respond these errors to the user.

Output Subsystem

The leading function of output subsystem is outputting some essential optimization result for the user. Data output modes and figure output modes were applied to the output subsystem.

SIMULATION EXPERIMENTS

To illustrate the effectiveness and performance of our proposed algorithm in this chapter, one representative instances based on practical data have been selected to compute. This instance has 15 jobs with 56 operations that plan to be processed on 10 machines with total flexibility. Larger scale instance is chosen to display the optimizing ability of our proposed approach. We have applied the proposed simulation system to them with following parameters (Table 1). The proposed approach was implemented on a Pentium IV 2.4 GHz personal computer with a single processor and 512M RAM. In order to eliminate the random fluctuation of the optimization process, each instance was run 20 times.

We present the comparison with the algorithms of Kacem et al. (2002a; 2002b) and Xia & Wu (2005) in Table 2. The column labeled 'AL+CGA' is one algorithm by Kacem et al. (2002a). The column labeled 'Hybridization of EA and FL' refers to Kacem et al. (2002b). 'PSO+SA' is proposed by Xia and Wu (2005). The experimental results of Table 2 suggest that our approach makes us reduce the makespan

Table 1. The parameter setting of this proposed algorithm

	Phase Name	Symbol	Value Setting	Material Signification
1	**Schedule Knowledge Initialization**	τ_0	5	The initialization of knowledge matrix $OAPK$;
2		η_0	$1/t(i,m)$	The initialization of knowledge matrix $OAMK$;
3		$t(i,m)$	---	the time of processing operation i in the machine m ;
4	**Operation Assignment**	Max_Iter1	10	The maximal iterative times in the implementation process of operation assignment subsystem;
5		Max_Iter2	5	The maximal iterative times in the local search phase;
6	**Operation Sequencing**	$AntSize$	50	The account of ant;
7		a	2	The weight of heuristic information of knowledge $OAPK$;
8		b	5	The weight of heuristic information of processing time;
9		Max_Iter3	3	The maximal iterative times in the local search phase;
10	**Scheduling Knowledge Updating**	τ_{max}	50	The maximal value of knowledge matrix $OAPK$ ($OAMK$);
11		τ_{min}	0.01	The minimal value of knowledge matrix $OAPK$;
12		ρ	0.02	The knowledge evaporating parameter;
13		Q_L	0.2	The incremental level in the local update knowledge phase;
14		Q_G	5	The incremental level in the global update knowledge phase;
15	**Stopping Criterion**	Max_Gen1	5	The maximal generation of ant colony optimization;
16		Max_Gen2	10-50 ①	The maximal generation of whole simulation system;

① It is preset as 10 when solving instance 1; it is preset as 20 when solving instance 2-4; it is preset as 50 when solving instance 5.

Table 2. Comparison of results on problem 15×10 *with 56 operations*

	AL+CGA		Hybridization of EA and FL			PSO+SA	Our Proposed Approach			
$F_1(c)$	23	24	23	23	24	12	12	11	11	11
$F_2(c)$	95	91	91	95	91	91	92	92	93	91
$F_3(c)$	11	11	10	11	11	11	11	11	10	11
$F(c)$	33.8	33.5	32.7	33.8	33.5	27.5	27.7	27.2	27.1	27.0

(12 instead of 11) and get the decline in terms of objective function value.

FUTURE TRENDS

About future research direction, we should pay more attention to the following two points. The first one is optimizing these parameters of our proposed approach for its quick constringency. The second one is reducing the sensitivity to the initial solution of our proposed approach.

CONCLUSION

The contribution of this chapter is summarized as follows. It presented a simulation model to work out flexible job shop scheduling problems with the multi-objective of minimizing makespan, the total workload of machines and the workload of the critical machine. The results obtained from the computational study have shown that the proposed approach is a feasible and effective approach for the multi-objective flexible job shop scheduling problem.

KEY TERMS

Ant Colony Optimization: ACO studies artificial systems that take inspiration from the behavior of real ant colonies and which are used to solve discrete optimization problems. ACO is a population-based approach to the solution of combinatorial optimization problems. The basic ACO idea is that a large number of simple artificial agents are able to build good solutions to hard combinatorial optimization problems via low-level based communications.

Combinatorial Optimization Problems: One can argue that combinatorial optimization and Integer programming are synonymous terms. This is because the majority (if not all) of the combinatorial optimization problems are integer programming problems, usually involving binary variables.

Job Shop Scheduling Problem: An instance of the job-shop scheduling problem consists of a set of *n* jobs and *m* machines. Each job consists of a sequence of *n* activities so there are *nm* activities in total. Each activity has a duration and requires a single machine for its entire duration. The activities within a single job all require a different machine. An activity must be scheduled before every activity following it in its job. Two activities cannot be scheduled at the same time if they both require the same machine. The objective is to find a schedule that minimizes the overall completion time of all the activities.

Flexible Job Shop Scheduling Problem: It is an extension of the classical job shop scheduling problem which allows an operation to be processed by any machine from a given set. The problem is to assign each operation to a machine and to order the operations on the machines, such that the maximal completion time (makespan) of all operations is minimized.

Multi-Objective Optimization: In the world around us it is rare for any problem to concern only a single value or objective. Generally, multiple objectives or parameters have to be met or optimized before any 'master' or 'holistic' solution is considered adequate. Most realistic optimization problems, particularly those in design, require the simultaneous optimization of more than one objective function.

Operation Assignment Machine Knowledge (OAMK): It is the accumulative knowledge of assigning the giving operation to a more appropriate machine. It was achieved from the near-optimal solution of FJSSP of each iterative.

Operation Assignment Position Knowledge (OAPK): It is the accumulative knowledge of the more appropriate operation processing sequence at a giving machine. It is achieved from the near-optimal solution of FJSSP of each iterative.

Simulation, Games, and Virtual Environments in IT Education

Norman Pendegraft
University of Idaho, USA

INTRODUCTION

The rapid change in information technology presents several problems to IS educators and trainers. In particular, the number of concepts that must be mastered is constantly increasing while the time available is not. This makes it essential to use class time efficiently as well as effectively. Simulations and games provide interesting and useful tools to help in this effort.

BACKGROUND

The idea that students learn better by doing goes back at least to Dewey (1938). The key idea underscoring this approach is that people learn better from experience than from reading or listening (Corbeil, Laveault, and Saint-Germain, 1989). This sort of experience can be gained in a simulation or game. By compressing time, the simulation allows the students to experience the consequences of their own actions or to see how a system operates.

Simulation, case studies, role playing, and gaming are related teaching methods based on experiential learning. They permit experience or experimentation with a situation modeling the real world (Senge, 1990). On a deeper level, simulation is claimed by some to be a fundamentally new way of studying the world (Pagels, 1998). Narayanasamy, Wong, Fung, and Rai (2006) distinguish between games, simulation games, and training simulators. Simulators are models used for systems analysis or policy formation. Simulators may use mathematical models and Monte Carlo or discrete event methodologies. They argue that training simulators offer real-world environments and challenges are focused on skill development rather than entertainment, and are not goal oriented. Klassen and Willoughby (2003) discuss the importance of assessment and present data supporting the notion that games help students learn more quickly than do lectures.

Case studies are a time honored approach of instruction in strategy courses (see, for example, Burgelman, Maidique, and Wheelwright, 2001). Barker (2002) suggests that they can also be very valuable for teaching technical skills such as software development. In some sense, a case study is a role play with the student acting the part of an analyst examining the case situation.

Role playing and simulation gaming are similar approaches in that they use simulated worlds, but instead of creating, or observing or analyzing that world, students are immersed in it. Role playing is a method in which students are presented a scenario simulating some real situation, and assigned roles in that scenario. The scenario can be based on real or simulated situations (Barker, 2003). Participants then assume the roles of relevant persons in the scenario and act out the situation to see what happens. Role playing is a commonly and successfully used tool in IS education (for example, Christozov, 2003).

According to Greenblat (1988), simulation gaming includes role playing as an element. Whereas role playing allows participants to play the roles as they please, simulation gaming emphasizes the interactions of the roles and constraints of various types on the players. In some sense, a simulation game strives to teach about a specific situation while a role play or game may have a more general lesson.

Greitzer, Kuchar and Huston. (2007) describe cognitive principles for learning and a process for designing and improving game based education. In particular, they argue that experience should be presented in realistic contexts. They identify features of games that attract extended play including levels, adaptability, clear goals, interactions, and shared experience with others. They describe the use of these principles in a security training game.

The use of modern information technology in developing these games and simulations, stimulated, no doubt, by the vibrant computer game industry, has led several authors to create "virtual" environments for training. This seems a good umbrella term to include all simulation and gaming approaches to training, as they do indeed create virtual realities in which the students operate. Summerfield (2004) suggests that role playing is superior for learning soft skills (like dealing with people) while technically based simulations are useful for learning hard skills.

Simulation and gaming have been used to enhance training in a variety of non IS areas including incident management (Jain and McLean, 2003), mass casualty medicine (Müller, Martens, Willen, and Müller, 2000), military technology

(Meeds, 2001), military tactics (Chatham, 2007), and immunology (Kelly, Howell, Glinert, Holding, Swain, Burrowbridge, and Roper, 2007). Mayo (2007) argues that video games can be used to teach science and engineering better than lectures.

After many years of using such exercises at all levels (undergraduate, graduate, and executive), it is the author's opinion that they are very useful and that major benefit accrues to the instructor in preparing the simulation as well as to the students when they play the game. Simulation and gaming are student centered learning, that is, the student is actively involved in the learning rather than passively observing the instructor (Greenblat, 1998). The student does the work, makes decisions and sees the impact of the decisions. Role playing and simulation gaming attempt to take advantage of this by creating a situation in which a student may "play a game" in which time is compressed and attention can be focused on a few key ideas. Finally, these kinds of exercises are fun. The class gets to move around, talk, and frequently laugh. Simulations and games epitomize the idea that learning should be fun.

SIMULATION AND GAMING IN IT

Simulation as a teaching tool suggests several approaches. Perhaps most obvious in an information systems curriculum is computer simulation. Using this technique, a computer program is written which exhibits behavior that models the behavior of the system under study. Butterfield and Pendegraft (1998) described a spread sheet simulation of a Fourier Series, adding sine wave to construct a square wave for a class demonstration of the impact of bandwidth limits on data rates. Campbell (1996) created a simulation of a computer and had his students write assembly language programs to execute on the simulation. Zant (2001) used a computer simulation of a CPU for in class demonstrations and for homework problems. Englander (2003) used Little Man Computer, a simple paper simulation of a CPU, as an example to explain basic CPU architecture, CPU operation, and machine language. In an extension of those ideas, Pendegraft and Stone (2003) had their students develop a Visual Basic simulation of a Little Man central processing unit on which they ran programs mandated by the instructor. In addition to having to execute simple programs written in Little Man's machine language, their simulation had to deal with other architectural issues like input and output.

Several authors have used simulations or games to teach networking. Voderhobli and Pattison (2005) developed a simulation system for network managers. Guo, Xiang and Wang (2007) developed a simulation network laboratory emphasizing the dynamics of network protocols rather than configuration. Leitner and Cane (2005) designed a virtual networking laboratory intended to address the need for a hands on experience in a distance education environment. Dennis (2002) and Pendegraft (2002, 2003) developed in class games to teach TCP/IP. These two games will be described in more detail in the next section. Leitner and Cane (2005) describe a virtual laboratory for distance education in IS. They argue that simulations do not provide direct experience. They distinguish virtual laboratories from simulations in that the former "is a true laboratory in which experiments are carried out under the control of remote users" (p.284).

There are many interesting efforts to improve the teaching of programming through the use of games. Several researchers have looked at the use of Robocode which uses a game to teach Java. Long (2007) evaluated Robocode as a vehicle for instruction and found that participants had fun and enjoyed the exercise. They mentioned that the exercise was intrinsically interesting because they learned something, but also that they had fun doing so. Bierre, Ventura, Phelps, and Egert (2006) had their students create simulated battle tanks. The assignment ended with a tournament in which the tanks fought against each other. They report that teams who used this environment learned more than those in traditional or Robocode environments. Alice is a visual environment for teaching programming by allowing them to easily create games or simulations (Alice.org). Students learn to think in terms of objects and their behaviors. Kelleher and Pausch (2007) used Alice to inspire middle school girls' interest in learning to program computers. Baker, Navarro, and van der Hoek (2003) describe a card game that they developed to teach software engineering. This approach is not limited on the software side to programming. Lawrence (2004) used a game to teach data structures.

Others have developed games to help students learn about IS management. For example, Jain and Boehm (2006) developed SimVBSE, a game to improve understanding of value-based software engineering. Students act as project managers to learn the fundamentals of software engineering. Sheng, Magnien, Kumaraguru, Acquisti, Cranor, Hong, and Nunge (2007) and Irvine, Thompson and Allen (2005) describe games used to teach about IS security. Curtin, Carpenter and Ritzo (2006) report on games developed to train help desk staff. They also offer a process for creating effective games.

EXAMPLE: USING A GAME TO TEACH TCP / IP

An example may help to clarify the mechanics of gaming and illustrate its utility. Consider two similar games, one designed by Dennis (2002) and one by Pendegraft (2002, 2003), to help teach how TCP/IP works. Both are published elsewhere and so will not be described in detail here. Both

games are designed to be run in one class session in a course on telecommunications and could be adapted to class sizes ranging from a dozen to more than 40. The games have similar structure. The class is divided into teams, each team representing a host. Each player represents one layer on that host.

In the play of the simulation, an application layer player writes a message to another application layer player on a paper form. The form is then handed to the TCP player of the sending host. The TCP player adds the TCP header and hands the packet to the IP player. The IP player adds the IP header and hands the packet to the DLL player. The message is then passed to another host where each player strips off the header for that layer and hands the message upward, or in the case of IP forwards it as necessary.

The games offer different points of view. Dennis' game allows many messages on the network at one time, while Pendegraft's game only one message is sent at a time and the entire class follows it along the way, discussing immediately problems that may occur such as a player incorrectly addressing a packet. In Dennis' game that sort of error is handled in discussion between the affected players.

Both games simplify TCP/IP ignoring some issues like handshaking or error detection. This is not to say that these issues are unimportant, but that these games focus attention on a limited set of issues of paramount importance.

FUTURE TRENDS

There is a trend in IT toward increased system complexity paralleled with efforts to hide that complexity from the user. Examples include third generation cell phone services, distributed databases, and web based applications in general. These systems raise questions about how to prepare students to deal with a world of increasing complexity. It may be that simulations and games offer a way to help students more quickly understand complex systems.

Holt (2000) identified several trends in modern training, especially as it related to IT. Among them are emphasis on individualized, self paced training that is realistic. Virtual environments seem ideal ways to meet these needs. The recent explosion of interest in computer based games and simulation for training has drawn from the entertainment industry for inspiration and techniques. As Malykhina (2005) and Narayansamy, Wong, Fung, and Rai (2006) note, simulation games and simulators are converging. As IS becomes more closely connected with other disciplines like the arts and entertainment, education needs will evolve. Hence, there is every reason to believe that this trend will continue and accelerate. It is interesting that most of the effort noted here has been directed at training as opposed to education.

CONCLUSION

Gaming and simulation have proven to be excellent ways to approach training in a variety of fields. In IS they have been used to teach about computer and network architecture, programming, and IS management. Increasingly these games are conducted as computer games making use of the very technology being studied. This use of simulation is consistent with the more conventional use of simulation as a vehicle for evaluating policies or designs prior to implementation. Those more traditional uses are in some sense about educating managers about the implications of their choices. More direct use in training seems a natural extension.

Understanding IT basics will remain an essential part of the education of IT professionals. As technology evolves it will continue to be a challenge to help students understand the basics and prepare themselves to keep learning. Simulation and gaming offer effective and fun tools to help students learn about new technology. They do so in a way that reinforces the need to learn how to learn and to continue learning.

There is an "ancient debate" over the difference between training and education (Fein, 1959). Education is understood to be theoretical or basic while training is practical and has immediate application. Both approaches address legitimate needs, and there is always tension between them. Most of the examples noted here seem to lean to training. In "Profession," one of the all time classic science fiction short stories, Asimov (1957) imagined a world in which young people were trained by being directly connected to a computer. In that world only a few were selected for education using books. One wonders if we a seeing a first step in that direction.

KEY TERMS

Case Study: An instruction tool containing a detailed description of a real world situation

Computer Simulation: A simulation built using a computer language

Experiential Learning: Learning based on experiences rather than listening or reading.

Game: A simulation in which people are part of the model and their decisions partially determine the outcome.

Role Playing: An element in gaming in which players assume the roles of other people.

Serious Games: Games used for serious training or analysis as opposed to entertainment.

Simulation: A model of a system focusing on selected behaviors or aspects of that system.

Simulator: A simulation model of a system used for systems analysis. May involve mathematical models, Monte Carlo or discrete event methods.

NOTE

Smart Assets Through Digital Capabilities

Jayantha P. Liyanage
University of Stavanger, Norway

Thore Langeland
Norwegian Oil Industry Association (OLF), Norway

INTRODUCTION

The history of oil and gas (O&G) production on the Norwegian Continental Shelf (NCS) dates back to the early 70s and began with the discovery and subsequent development of the great *Ekofisk asset* in 1969. Ever since, North Sea has been an attractive region, and Norway in particular has been a major supplier of O&G to the world energy market. The remaining production prospect on the Shelf is also said to be substantial and the more recent estimates indicate that it is equivalent to twice the already produced amount. However, a major part of the Norwegian O&G production portfolio will approach maturity by 2007/2008. Both *declining production* and *marginal discoveries* have given a clear indication that the Norwegian O&G industry will undergo a series of significant challenges during the next few years. These critical issues, in conjunction with volatile business environment, have brought a major turning point demanding immediate steps to enhance operational efficiency and to reduce operating risk in offshore exploration and production (E&P) activities on NCS.

BACKGROUND

Norwegian Oil Industry Association (OLF) constantly raised its concerns since the mid 90s about this emerging situation owing to its substantial commercial impact. By 2000-2002, major challenges for E&P activities on NCS became more visible and obvious. These included:

- declining investments and activity level on NCS and its immediate impact on the production profile and sustained growth;
- the need to enhance recovery efficiency to keep supply levels and to add more value;
- rising lifting costs and its direct impact on the cost of operatorship; and
- the volatile oil price and its direct implications on profit performance of offshore E&P activities.

Subsequently it appeared that the Norwegian O&G industry requires, a dedicated plan to re-engineer conventional practices in order to reduce commercial risk and to enhance value creation (see discussions by Lindgren & Bandhold, 2003). Thus, the O&G production scenario on the NCS stepped into its so-called *3rd efficiency leap* with the effect from 2003 (see Norwegian Oil Industry Association, 2003). This macro-scale national program is expected to induce a step change particularly related to smart use of advance information and communication technologies (ICT) and new data management techniques, and is completely dedicated to adapt to a fully integrated operational setting to smartly manage offshore-onshore activities by the year 2010. Issues related to this new development scenario were envisioned in the government white paper; *Storting white paper 38:2003–2004: On the petroleum activities* in 2003.

SMART ASSETS THROUGH *INTEGRATED E-OPERATIONS*

In more general terms, *smart assets* and *integrated e-operations* largely dedicate the Norwegian O&G industry toward:

- joint exploitation of advanced technologies, digital ICT capabilities, and real-time operational and technical data to optimize decisions, and
- tighter integration of work processes, decision loops with effective and efficient division of work to optimize activities.

This aims at enhancing connectivity and interactivity between offshore O&G assets and their onshore support systems (for further highlights see Barabasi, 2003). Advancement in information sciences and technologies, and long-term commercial benefits of their successful usage, have contributed much to the ongoing change process. Partner industries, particularly those related to electronic and communication technologies in general, play pivotal roles to establish the necessary stable and reliable *digital environment* around offshore assets and activities (see further discussions by

During, Oakey et al., 2002). The key enabling technologies that are already under implementation include:

- fiber-optic-based ICT-net laid on the sea-bed of the North Sea, and wireless communication capability ;
- smart sensors, intelligent transducers, and equipment with advanced functionalities;
- real-time visualization, 3D visualization, and simulation tools;
- online diagnostic and prognostic engineering capability;
- process automation and real-time data acquisition techniques; and
- online video monitoring and conferencing facilities.

Such a technological leap not only systematically builds strategic *digital capabilities*, but also provides necessary *digital environment* for active *knowledge and intelligent data* management. The onshore support system, with the support of such application technologies, systematically advances toward a highly connective and interactive *extended digital enterprise* through active strategic collaboration breaking the conventional inter-organizational gaps (see also Dyer, 2000; Faulkner & Rond, 2001; Lipnack & Stamps, 1997; Spekman, 2003; Tidd, 2001; Tonchia & Tramontano, 2004). This new organizational setting is capable of:

- joint online monitoring of offshore E&P activities at dispersed *onshore support centres*;
- real-time data acquisition, joint data analysis and data interpretation; and
- 24/7 network-based connectivity for collaborative decision making and work planning.

A diagramatic model of the new operating environment is illustrated in Figure 1.

The network-based and collaborative environment requires a highly robust ICT infrastructure to support decisions, core tasks, and activities (see also Barabasi, 2003; During, Oakey et al., 2002; Hosni & Khalil, 2004). *SOIL* (Secure Oil Information Link), introduced in 1998 to the NCS, is the result of the current industry demand to acquire necessary *digital infrastructure* using a large-scale information and communication network through a common data-hub, a large-scale network, and centralized information system, which is highly *reliable* (stable and dependable), *secure* (control of access and routing), and possesses a large *bandwidth* (high traffic capacity).

Today, SOIL is extended into the UK and functions as a collaboration arena, a secure interconnection point, and an industry network. This digital network between offshore facilities, major producers, and third-party organizations facilitates the connectivity through the use of fiber-optic cables, radio links, and satellite communications. A unique feature of SOIL application today is that it has moved the information sharing and communication capabilities from conventional setting to a *one-to-many* collaborative setting. SOIL allows consolidation of a traditional information and communication network into one single hub building 24/7 online and real-time information sharing and communication capabilities between O&G producers and their business partners. This is one of the most important application

Figure 1. New operational environment establishes an extended enterprise on the basis of advanced technological capability, digital infrastructure, and active collaboration

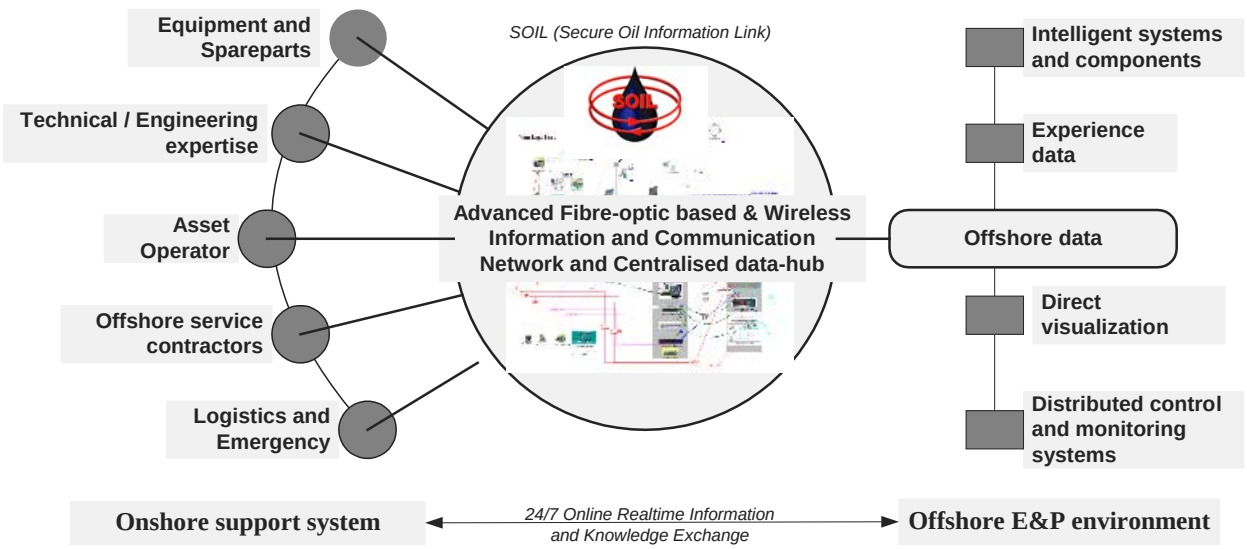

Figure 2. Digital infrastructure through SOIL is established using fibre-optic network and wireless communication capabilities enabling 24/7 online real-time communication between offshore assets and onshore support system

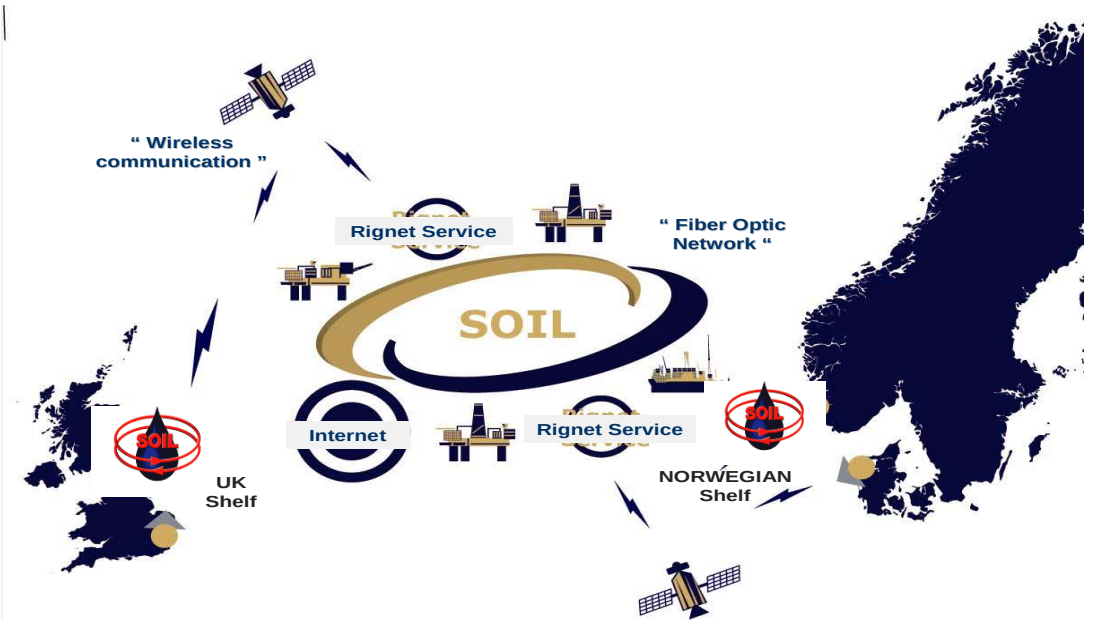

settings for onshore-based remote integrated operations or simply '*e-fields'* (Figure 2).

SOIL provides some key application services such as:

- *SOIL meeting* (that provides a virtual communication platform between member companies);
- *E2E monitoring* (that automatically monitor real-time network performance between operations on offshore rigs and onshore operation centers); and
- *Proex* (that is a Web-based solution to structure, define, execute, and follow-up tasks and activities in projects and/or work processes on a continuing basis).

The membership status of *SOIL* has grown from a total of 20 in 1998 to approximately 170 by 2005 with the recent extension to the UK sector.

The interactive nodes of the complex information and knowledge network are the *onshore online support centers*. Such centers are available at the premises of O&G producers (e.g., ConocoPhillips, BP, Hydro, Statoil) as well as service-support-supply organizations (e.g., BakerHughes INTEQ, RC-DEI). Technological capabilities built into these onshore centers, together with the licensed access via *SOIL*, allow real-time integration between offshore assets and onshore support system. For instance, the *Onshore Drilling Center (ODC)* of *ConocoPhillips of Norway (COPNO)* has the capability to actively integrate 3 functional arenas, namely:

- **Operational:** Where online monitoring of offshore drilling activities and equipment performance are enabled. This is equipped with table-top workstations and back-projected large VDUs.
- **Collaboration:** Where online communication between offshore facility and onshore support system takes place. This is equipped with video-conferencing facilities, CCTV, and other advanced technological capabilities and electronic gadgets (e.g. VisiWear, Smart boards) for joint decision-making.
- **Visualization:** Where complex data from reservoir and production/injection wells are processed to enhance visualization. This is equipped with advance technology to produce 3D images and to run simulations.

In general, *smart assets* and *intergated e-operations* exemplify a radical change in the offshore asset management practice in *North Sea* based on advances in information sciences and technologies.

OLF proclaims that the new step can directly contribute to, make offshore production on NCS more commercially attractive, improve recovery or production regularity, give more positive health, safety, and environmental results, and improve economical performance. The economical speculations, as of today, are in fact 10% increment in oil production from the continental shelf and, at the same time 30% reduction in overall operating costs.

FUTURE TRENDS

A unique feature of ongoing developments is that it induces a major transition in the industry infrastructure bridging the conventional gaps to jointly manage offshore E&P activities. It implies that new developments bring the O&G producers, service contractors, support and supply organizations, and expert services, closer together opening up greater opportunities through strategic partnerships (see further discussions in Dyer, 2000; Faulkner & Rond, 2001; Lipnack & Stamps, 1997; Spekman, 2003; Tonchia & Tramontano, 2004). The integration efforts across the industry will continue targeting full-scale integration by 2010. This will have to go through three major phases, namely:

- integration across different technical disciplines (e.g., data engineers, operation geologists, drilling engineers, reservoir engineers, safety risk analysts, etc.);
- integration across organizations, that is, O&G producers and external business partners (e.g., third party service-support-supply organizations); and
- integration across geographically diversified operational regions (with further expansions to the existing corporate network to other operating regions).

In general, the entire O&G industry remains optimistic about the future and the positive commercial impact of recent initiatives. However, ongoing developments and information technology implementation efforts have already brought a unique set of challenges that includes:

- data integration across disciplines and common standards for active data sharing;
- reliability of digital infrastructure and data security;
- standardisation of ICT platforms across different actors;
- information quality and data filtering techniques;
- work processes integration across disciplines and actors; and
- rapid integration of knowledge based industry.

While information technologies have brought their own challenges (Clarke, Coakes et al., 2003; Gunasekaran, Khalil et al., 2003; Hosni & Khalil, 2004), a major need is also to resolve some critical issues at human and organizational interface levels. A general concern both at socio-political and industrial levels is that ill-defined interfaces and increasing complexities of systems and data solutions can lead to unforeseen consequences, greater vulnerability, and greater risk (see for instance Duffey & Saull, 2003). This mainly demands further attention to a great extent on the critical interfaces between human, organizational, technical, and work process related aspects to realize full-scale benefits of reengineering efforts. For more information see Liyanage (2004a, 2004b, 2005a, 2005b) and Liyanage, Herbert, and Harestad (2006).

CONCLUSION

New asset management practice on NCS aims at reducing the risk exposure, enhancing the commercial value of O&G production assets on the continental shelf. The current setting and ongoing developments have given rise to an interesting *integrated e-operations* setting around offshore assets based on wireless & fiber-optic-based ICT system (i.e., SOIL) that allows 24/7 connectivity and online real-time interactivity among the partners leading the way towards *Smart assets*. Through the *digital capability* it brings together offshore assets, O&G producers, engineering, contractors, drilling companies, component and equipment producers, suppliers, consultants, service providers, and so forth, to a common 24/7 platform to share information, knowledge, and experience to optimize decisions and actions. The Norwegian industry has already experienced a number of success stories of the new environment. ConocoPhillips alone has claimed for substantial cost savings just over a period of nine months. The new environment created by the *smart assets* and *integrated e-operations* has resulted in major changes in human, technological, organizational, and operational aspects, and in particular within electronic information and knowledge sharing practice, organizational forms, work processes, decision loops, and knowledge industry integration. It has also resulted in a mass flow of R&D funds to stimulate innovative solutions to solve some unique challenges. These ongoing developments in general indicate a rapid reengineering process on North Sea assets and a completely new asset management practice based on digital capabilities.

KEY TERMS

Digital Capability: Abilities and strengths acquired through active integration of advanced application technologies (e.g., smart sensors, intelligent transducers, electronic gadgets, equipment with advanced functionalities, etc.) and digital infrastructure to optimize decisions and work processes through 24/7 online real-time connectivity.

Digital Infrastructure: Joint fiber-optic and wireless-based advanced information and communication technology platform with embedded multi-functional application services that facilitate 24/7 online real-time connectivity between nodes in the operational network to allow remote management of production assets.

E2E Monitoring: End-to-end monitoring of status of the operational network performed by the administrator of the digital infrastructure.

Extended Digital Enterprise: The organizational form resulted by the growth of conventional organizations into a virtual organizational setting where a number of organizations can simultaneously interact with each other, breaking the boundaries of traditional organizations, through digital infrastructure and digital capability for a common purpose.

Hybrid Techno-Organization: Highly technology dependent and team-based interactive organizational form that functions through a high-level synergy between human and technology.

Integrated Operations: The operational setting where both production assets and a technical support environment are tightly integrated across technical disciplines and organizations creating an active collaborative environment around production assets based on enhanced digital capabilities.

Integrated Work Processes: Work processes integrated across technical disciplines using large-scale information systems to streamline decisions and activities.

Intelligent Data: Data that are automatically acquired through advanced application technologies (smart sensors, intelligent transducers, electronic gadgets, equipment with advanced functionalities, etc.), systematically processed, and are presented in a meaningful form for active sharing, further assessments, and following interpretations.

One-to-Many Connectivity: The ability to connect from one active node to many active nodes in the digital infrastructure on top of the existing network infrastructures allowing consolidation of such conventional ICT networks into one-single common data-hub establishing 24/7 online real-time operational network.

Smart Assets: Those production assets that actively exploit digital capabilities and digital infrastructure smartly and strategically in conjunction with the extended data-knowledge-experience sharing enterprise setting, creating a highly interactive hybrid techno-organizational environment.

INTRODUCTION

An increasing number of educators are calling for high standards and challenging learning activities for students. Learning blended with technology can especially provide all possible sources of education. The technologies are not only going to act as technical add-ons to the system but also they can try their best to improve the quality of education.

New technologies can provide meaningful learning experiences for all learners, especially those who are in the developing countries. Educational centers that capitalize on the technological and educational reforms will help students to develop higher order skills and to function effectively in the world beyond the classroom. Achieving such fundamental change, however, requires a transformation of not only the underlying pedagogy but also the kinds of technology applications typically used in classrooms serving at-risk students.

The vision of classrooms structured around student involvement in challenging, long-term projects and focused on meaningful, engaged learning is important for all students. Yet such a change in practice would be especially dramatic for those students who have been characterized as *economically disadvantaged* or *at risk*. Traditionally, schools have had lower expectations for such students. Teachers have emphasized the acquisition of basic skills for at-risk students, often in special pullout programs or in lower level tracks.

BACKGROUND

The impact of technology is seen everywhere—at work, at home, and, indeed, at educational institutions. Educators, policy makers, businesses, and other community groups are looking to technology as a tool for reshaping and improving education.

The educational sectors, whether academic or training divisions, have enjoyed the benefits of technologies in various ways. The technologies used for education range from the storage device technologies to the recent e-learning technologies. Earlier computers were used for storing the contents as well for better information presentation only. With the advent of e-learning, new dimensions are realized by learners, educators, and administrators.

The e-learning environment, where the use of electronic tools like computers and the Internet deliver content, has emerged as the fastest growing segment in the field of education/training and development. The "e" in e-learning focuses on the technology-enabling feature of the learning. The e-learning environment came to forefront for taking the traditional classroom training model and applying technology advancements to create new ways for teaching and learning (Thorpe, 2004).

According to the report produced by the National Committee of Enquiry into Higher Education (2001), the rapid growth in e-learning, has overcome many of the barriers of higher education, thereby providing universities and educational sectors with an opportunity to meet the changing demand for education. The advent of e-learning is inevitably linked to a number of challenges. The real challenge of e-learning centers most on the usage pattern. The biggest myth surrounding e-learning is, "Build it and they will use it."

Recently, e-learning is evolving from the initial technology-driven approach towards a more measured, sophisticated evaluation of its strengths and weaknesses. Recently, the "e" has shifted the focus of learning and training onto the choices in design and delivery of education. But soon, the focus of learning and education will be back where it should be—on learning; the act, process, or experience of gaining knowledge or skill.

The modern-day learners demand knowledge and content that are more sophisticated, dynamic, interactive, and more relevant. Both the learners as well the organizations that depend on them need to learn new skills quickly, and they should have the ability to apply them at the right time. The problem of how to get inside an expert's head and transfer the wealth of knowledge that resides there is being aided by e-learning. While this remains a real challenge, we are beginning to develop tools and approaches for better capturing of that knowledge and delivering it directly into the hands of those who need the same knowledge.

In cases where e-learning is appropriately deployed, educators can generally anticipate student academic performance that is at least equivalent to traditional classroom instruction (Cavanaugh, 2001).

MAIN FOCUS—MERGING PERVASIVE COMPUTING AND E-LEARNING

Generations of Computing

In this history of computing, we have seen several various generations of computing. Initially, the mainframe computing was introduced to enable several people to share one large computer. The problem was that individuals have to personally be present in the proximity of such systems—then came the personal computing era. Personal computers are general purpose devices, designed to do any task. Though it is advantageous, PCs can not be flexibly used for any individual task, that is, not human centric. Another problem related to them is that they are not highly secured. While focusing on stability, security, or transparency aspects of the system, the user's flexibility may be limited.

Network computing is the next big thing that happened. As distinct from stand-alone computing, this term first appeared informally in the late 1970s to denote computers working together over a network. It later came to have a specific technical meaning, denoting a graphical form of remote computing. This led to the introduction of Internet computing.

The growth of the Internet today has exploded into the latest craze. It is the newest wave of communication through e-mail, file transfer, telnet access, transaction applications, and more. This in turn with the invention of World Wide Web has revolutionized computing to a greater extent.

In the history of computing the move towards the next generation of computing—the fourth generation—has happened (see Table 1). Over time, the cost and size of computers has reduced significantly to allow more people to participate in the world of computing (Amor, 2001).

Pervasive Computing

Pervasive computing is the integration of computing power into almost anything, including household equipment, toys, housing, furniture, or even a coffee pot. The name pervasive computing tells only part of the story; a parallel revolution also exists in network-enabling these pervasive computing devices by providing transparent, ubiquitous access to e-business services (Satyanarayanan, 2001). Pervasive solutions enable anytime, anywhere information exchange and access to applications. Davis (2002) points out the analysis of the implications and consequences of pervasive solutions as "anytime/anyplace computing" (p. 3) for future knowledge work.

It is done by natural interaction and control of the ambient environment by people and by artifacts. Interfaces used in pervasive computing support natural communication such as speech and gestures taking into account the user's preferences, personality, and context of use, and enabling multisensory interaction.

Pervasive computing is about making technology and computers disappear. In fact, the more technology becomes transparent, the more business will prosper. The move is towards linking devices like mobile phones, hand-held digital devices, automobiles, refrigerators, and several other easy-to-use devices to the Internet, thereby allowing people to connect anytime, anywhere. It will be pervasive—global—and it will change forever the way we think about the Internet.

Pervasive Approach to e-Learning

Pervasive computing, sometimes called ubiquitous or nomadic computing, describes not only a class of computing device that does not fit the form factor of the traditional personal computer, but also a set of new business models supporting these devices. Ubiquitous computing, prior to pervasive computing, defines a world where computers and associated technologies become invisible and thus makes

Table 1. Generations of computing

Type	Features
Mainframe computing	Many people sharing one large computer
Personal computing	A person works with one computer
Internet computing	One person using several services through global network
Pervasive computing	Many devices serve several people in a personalized way on a global network

them indistinguishable from every day life (Weiser, 1991). With the maturity of computing technologies like wireless LANs, portable and wearable computers, and embedded sensors, a new area emerged from ubiquitous approach called pervasive computing (Satyanarayanan, 2001). Where a desktop computer uses a familiar keyboard, monitor, and mouse interaction model, pervasive computing devices interact in a variety of different ways.

They may use handwriting recognition, voice processing, or imagery. They are often portable and may or may not have a persistent network connection. A pervasive computing device is meant to integrate our lifestyle with the global network of computing, freeing the users from desk-bound application interaction. With the ability to take corporate and personal processes and information with us, no matter our destination, opportunities are plenty for improving and enhancing our personal and professional life. In general, pervasive computing is characterized by certain key areas like smart spaces, invisibility, localized scalability, and uneven conditioning (Satyanarayanan, 2001).

In this context, an approach towards using pervasive computing for e-learning is thought of. Especially a system where embedded devices can help the learners to inform the status and the way in which the teaching aids and laboratory equipment are handled.

Normally, learning about any teaching aid in the curriculum or handling any laboratory equipment in the practical classes needs specialized instructions to be followed by the learners. It is very difficult for all the learners to follow these instructions in the beginning. In the same way, the understanding of these instructions and handling patterns will vary from person to person. Whenever the instrument or equipment is handled abnormally or in the wrong way, instead of the instructor going to the individual student and informing him or her about the improper handling of the equipment, we suggest the ways in which the device itself can be self-acting as a warning or guiding tool. That is the pervasiveness embedded in the device or the context should help the learner to perform things in a better way. By this, the learner and the teacher can use the device *on-the-go*. They do not have to spend more time on reading instruction manuals or searching the *How-To* notes for getting the guidelines. The equipment itself will instruct the user with the help of indicators, that is, lights and sounds. All the user has to know is the meaning of the sounds and the lights. In such a scenario even the normal light context can be used—such as a red light for danger, green light if everything is fine, or a siren sound for an action done by the user if he or she uses the equipment in an improper way.

Case Study: The E-Pipette

The importance of pervasiveness in the e-learning context is highlighted based on a case study in the science laboratory.

We are illustrating the possibility of using pervasive computing in e-learning by adding computing capabilities to a normal conventional pipette used in the chemistry laboratory. The pipette is a laboratory instrument used to transport a measured quantity of liquid. These devices are neither accurate nor precise and cannot be calibrated. Since normal pipettes are made of glass, they are fragile and susceptible to damage. There is a mark on the neck of the pipette which shows the *limit*, and if the user is not watching it, the liquid will enter the mouth.

By adding a circuit board to the pipette, the pipette is made into an intelligent device. The circuit board contains a number of sensors and audiovisual indicators, which helps the user to use the apparatus with comfort and avoids going through any instruction manual. The e-pipette design is shown in Figure 1.

Hardware Design

The heart of the system consists of an ultra low power microcontroller from Texas Instruments powered up by CR2032 Button Cell battery. There is an ADXL202 Accelerometer to sense the tilt and vibrations occurring to the pipette. The liquid level sensor that is present in the system can warn the user if the liquid in the pipette is going above the marked region. The patterns of sounds and the different indicators on the board of the pipette warn the user about the different

Figure 1. E-pipette

conditions the pipette can be used for. The small IR transceiver associated with the system transmits the information regarding the usage patterns to a nearby computer. The details regarding the pattern of handling the device or the laboratory equipment are stored in a database. This database enables the course administrators to analyze the usage pattern and helps them to assess the learners. The block diagram of the e-pipette board is given in Figure 2.

Software Design

The microcontroller in the system has algorithms, which can condition the signals received from the different sensors onboard. The communication protocol enables the connectivity between the computer and the e-pipette. A program running in the personal computer interfaces it with the e-pipette and sends the data over the network. This data helps the invigilator or instructor to provide individual attention to the learners. The entire system block diagram is shown in Figure 3.

Observations from the Screen Shots

When the learner uses the equipment, the sensors capture the usage pattern and store these details in a database. Two graphs are produced for every learner, one depicting the usage pattern defined for a particular instance of time and the other, the real-time plotting for a particular subinterval. The variations in the graph plotting, as shown in Figure 4, are used by the device to inform the learners as well the instructors about the user's characteristics. The remarks provided by the context-aware device define a smart environment thereby providing the learners individual attention during their learning process. The observations from the graph can be used by the instructors to take appropriate actions as and when needed.

FUTURE TRENDS

This idea of linking a pipette with devices to enable better and smart learning can be extended to other learning scenarios also. Pervasive computing provides ample opportunities to define smartness in the academic environment, linking devices with the global network. Further improvements in the learning scenario could be to encourage not only individual learning but also collaborative learning. Through collaborative activities, learners as well as instructors are more closely associated with the system thereby improving the pedagogical aspects of the learning domain. With the promising features of pervasive computing, it becomes possible for both the academic and industrial sectors to devise innovative models for incorporating training related to any concept, at anytime, from any place, and through any device.

Figure 2. Hardware block diagram

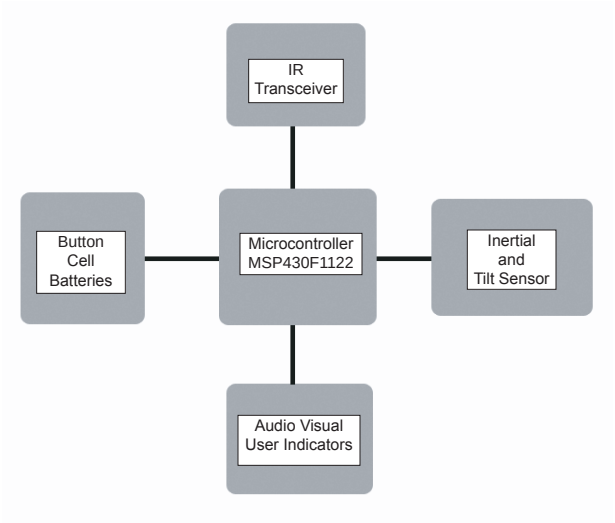

Figure 3. System block diagram

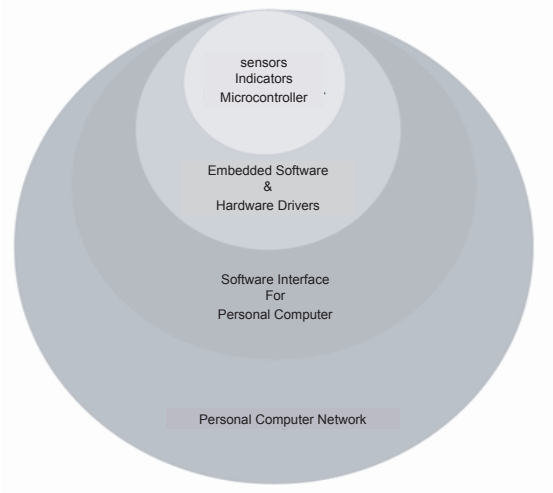

Figure 4. Sensor data analysis

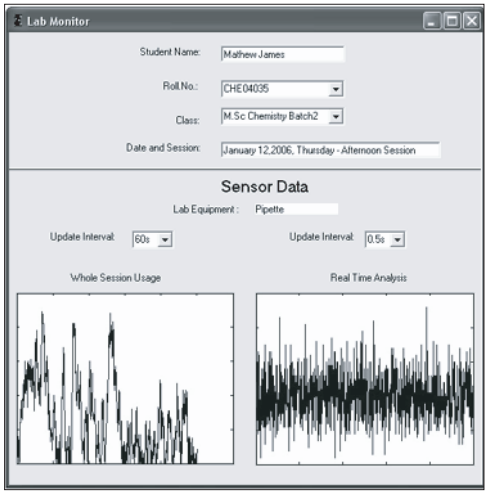

CONCLUSION

The ever-growing nature of educational systems, say academic- or organizational-level projects, poses several challenges to learners and instructors. Due to advancements in technology, the e-learning scenario has brought potential benefits and features to the learning and teaching process. Even then, some of the technical- and context-level hurdles make e-learning to be less effective. Especially, a domain-like laboratory where individual attention is needed for the learners of varying size, or where learners have to be taught how to use the equipment/apparatus as per the rules; e-learning has to be made still more effective. In this context, the use of pervasive computing for the use of pipettes in the chemistry laboratory is discussed. Here, the e-pipette provides enough assistance as well as individual attention to the learners thereby promoting the academic skills to a greater extent. The opportunity and, more importantly, the technology for taking e-learning to the next level are available at our fingertips. The industry has yet to reach its full potential, but it will definitely start to emerge as a profitable business for companies.

KEY TERMS

Accelerometer: An instrument that measures acceleration.

ADXL202E Accelerometer: A low cost, low power, complete 2-axis accelerometer with a measurement range of ±2 *g*. The ADXL202 can measure both dynamic acceleration (e.g., vibration) and static acceleration (e.g., gravity).

E-Learning: Learning that is facilitated and supported through the use of information and communication technology, e-learning can cover a spectrum of activities from supported learning, to blended learning (the combination of traditional and e-learning practices), to learning that is entirely online.

IR Transceiver: IR transceiver deals with infrared communications.

Microcontroller: A computer on a chip used to control electronic devices. It is a type of microprocessor emphasizing self-sufficiency and cost effectiveness, in contrast to a general purpose microprocessor, the kind used in a PC.

Pervasive Computing: Pervasive computing consists of inexpensive microprocessors embedded in everyday objects and environments. Characterized by being numerous, casually accessible, often invisible computing devices, frequently mobile or imbedded in the environment and connected to an increasingly ubiquitous network structure.

Transceiver: Communications device capable of both transmitting and receiving.

SMEs Amidst Global Technological Changes

Nabeel A. Y. Al-Qirim
United Arab Emirates University, UAE

BACKGROUND AND IMPLICATIONS

In small countries such as New Zealand, small to medium-sized enterprises (SMEs) are defined as enterprises employing 19 or fewer employees. Small enterprises are defined as those employing zero to five full-time employees (FTEs) (often called microbusinesses), and medium-sized enterprises as those employing six to nineteen FTEs. Other countries, such as the United States and European countries, define their SMEs as having a much larger number of employees (200–500 or fewer).

SMEs contribute significantly to the economies and to the employment levels of different countries in the world. For example, SMEs constitute around 95 percent of enterprises and account for 60–70 percent of employment within the countries of the Organisation for Economic Cooperation and Development (OECD, 1997) and other countries across the globe, including the United States. Not to forget that SMEs are usually the source of most of the profound inventions and innovations (Iacovou, Benbasat, & Dexter, 1995).

Historically, SMEs have been accused of being uncritical about the strategic importance of IT and its use in their businesses. This laggardness in adopting or using IT in business was attributed to various organisational, technological, and environmental deficiencies in SMEs. The recent emergence of the Internet, in general, and the Web, in particular, revolutionises business activities (Abell & Lim, 1996) and promises to provide unprecedented opportunities to SMEs to expand in scope and in market reach.

However, despite the apparent media hype (Premkumar & Roberts, 1999) and the enthusiasm among academicians (Adam & Deans, 2000; Abell & Lim, 1996; *Infotech Weekly*, 1997; Poon & Swatman, 1999a) and professionals (Deloitte, 2000; IDC, 1998; PWHC, 1999) about electronic commerce (EC), the published EC research portrayed a gloomy picture about EC uptake and use by SMEs. Thus, investigating reasons behind such laggardness in adopting and in using EC effectively is essential. This research attempts to highlight some of the important issues that could assist in bridging the existing divide between SMEs and EC. These issues could be of interest to SMEs and to other stakeholders interested in SMEs and EC.

ELECTRONIC COMMERCE SUCCESS IN SMES

In the SMEs scenario, different research emphasised the different EC advantages to SMEs (Abell & Black, 1997; Abell & Lim, 1996; Adam & Deans, 2000; Deloitte, 2000; Poon & Swatman, 1997, 1998, 1999a,b; PWHC, 1999):

1. The Internet is an efficient communication medium and a vast resource for information. The SMEs could use e-mail technology to communicate efficiently with their buyers and suppliers, reducing communication costs, including the buying of expensive equipment (e.g., fax/telex).
2. The Internet provides added-value services to customers/partners/suppliers by providing different primary/supplementary information about the organisation's industry, products, and services on their Web sites. This could result in increasing the loyalty and the stickiness of their customers (customer resource management; CRM). The preceding tangible and intangible tactics are of strategic importance in retaining and increasing customer bases by increasing switching costs.
3. The Internet would provide new opportunities to SMEs, otherwise not possible before the introduction of the Internet, such as the ability to reach global markets and the ability to mass-customise products and services to appeal to the different tastes of global consumers.
4. SMEs would adopt EC for image-enhancement purposes. Having an Internet account (URL, dot-com, Web page) and printing an e-mail address on business cards and letterhead were reported as major drivers as well. Whether the SMEs were able to elevate from such initial depiction to a more strategic posture in adopting more strategic EC initiatives, such as selling and buying online, is worth further investigation from the perspective of the different countries.

On the other hand, the EC research highlighted the following impediments:

1. Technological impediments: e.g., security (privacy concerns, viruses, e-payments), legalities (enforceability of contracts, confirmations of receipt, prosecutions), policies (lack of global or unified standards),

telecommunication services [bandwidth, convergence, reliability and quality of services (QoS)]
2. Organisational impediments: cost, busy nature, small size and limited resources, lack of knowledge/expertise about EC
3. Environmental impediments: Relating to the lack of regulatory frameworks pertinent to the above technological impediments highlighted in (1), above, either at the one-country level or even at the global level.

In the light of the above advantages and impediments, most of the existing EC research found most of the SMEs not witnessing real benefits (direct sales and tangible profits) in the short term due to difficulties in selling products over the Internet (Adam & Deans, 2000; Poon & Swatman, 1998, 1999a). Face-to-face interactions with customers and buyers proved to be more dominating than electronic interfaces (Ba et al., 1999; Poon & Swatman, 1997). They found the key motives for SMEs to adopt EC are the long-term indirect benefits, e.g., ongoing business transformation and new business initiatives (new opportunities), which could resemble a preparatory stage (infrastructure) for the long-run direct benefits stage (secure returning customers and form long-term business partnerships) (Poon & Swatman, 1998, 1999a). However, the biggest challenge for the SMEs here is to succeed in moving from such simple and preparatory EC initiatives (driven mostly by hype from the media, professionals, and researchers) to more sophisticated and strategic initiatives (e.g., efficiency à effectiveness à strategic advantage).

On the one hand, having EC requires an apparent investment in different areas: technological infrastructure upgrades or replacement, EC integration with existing IT systems, EC consultants, investments in bandwidth and applications (Web site, intranet, extranet, etc.). However, this considerable investment in the EC infrastructure is necessary to make it possible to process information efficiently, handle heavy traffic, and deliver satisfactory performance. SMEs would perceive this to be an expensive endeavour and, hence, represent a barrier to EC adoption (MOED, 2000; PWHC, 1999). It is worth mentioning here that unlike the investment in information science/information technology (IS/IT), which requires high initial investment and smaller ongoing maintenance and support costs, EC would require considerable continued investments in upgrading, overhauling, and replacing the whole EC system with an innovation or new designs, etc. Most probably, the investment in EC would materialise in the long term only as highlighted earlier (Poon & Swatman, 1998, 1999). However, this depends on different factors, such as the ability to develop economies of scale (Ba et al., 1999; Poon, 2000), e.g., having a well-established online customer base and ongoing business that enables the firm to sell massively and cheaply at the same time.

With the introduction of new EC technology like the intranet, Internet electronic data interchange (EDI), extranet, Web site, etc., there would be some fundamental changes in work processes and current practices (Alexander, 1999; Behrendorff & Rahman, 1999). EC is not only a new way of selling and marketing, but also a new way of thinking, which requires a change of mindset. Teo, Tan, and Buk (1998) pointed to the fact that organisations attempting to adopt the Internet should expect a possible change in communication and culture patterns. EC is changing the way business is conducted, even with individual customers. Firms that are able to streamline their products or processes or delivery agents on the Internet will be able to shift entirely to the pure EC arena (Choi et al., 1997). The success stories of small businesses using the Internet are apparent and are publicised and reported by the media. However, most of the businesses existing on the Internet are not necessarily transacting information-based products only, but rather complementing the sale and the delivery of a physical product with such things as publishing information about the usability of a physical product (e.g., user manuals), tracking the shipment, etc. (Teo et al., 1998).

Most of the IS literature on SMEs (Blili & Raymond, 1993; Cragg & King, 1992, 1993; Harrison et al., 1997; Jarvenpaa & Ives, 1991; Thong, 1999; Thong & Yap, 1995, 1996) and EC in SMEs (Poon & Swatman, 1998, 1997, 1999a, 1999b) emphasises the role and the characteristics of the manager (usually the owner) as a product champion. Poon and Swatman (1998, 1999a) pointed to the manager's role in their EC study, where they found direct management involvement was the norm in the different cases. Although the managers of small business lack formal IT qualifications and training, they were champions in adopting EC, specifically in microbusinesses, where the sole decision maker was the director of the business.

Due to the recent nature of EC, it is expected that the adoption decision for EC would include some sort of high-risk elements. Hence, the adoption decision for EC would require a risk-taking manager. Poon and Swatman (1997, 1998, 1999a) found that the entrepreneurial perspective differed between the different firms in their study. Managers/owners embraced EC technology and attempted to exploit it to the maximum. The managers who championed Internet adoption in their organisations demonstrated an innovative and risk-taking attitude toward EC, despite lacking formal IT training.

Adam and Deans (2000) and Poon and Swatman (1998) pointed to the market scope of small business, where SMEs transacting with international markets would perceive many advantages from the Internet, such as cost savings and market communication in comparison with other SMEs operating in local markets. In this scenario, EC is perceived to increase global competition and provide different opportunities to SMEs. Poon and Swatman (1999a) asserted that

if a small business retained a high percentage of customers and competitors online, this would increase the chances of adopting EC.

The field of EC is relatively new, and the actual functioning and utilisation of EC technologies are still unknown to most organisations (Teo et al., 1998), including SMEs. Therefore, it is expected that SMEs planning to adopt EC would seek assistance from consultants and vendors in the industry in different areas, such as planning and strategy, training, development, and implementation (Deloitte, 2000). Determining how efficient the technology vendors are in providing feasible and well-integrated EC products and services to SMEs is worth investigating in different countries.

CONCLUSION

SMEs contribute significantly to the national economies and to the employment levels of different countries and represent a viable source for inventions and innovations. The emergence of EC in the early 1990s could provide different opportunities to the small business sector to overcome its inadequacies. However, in review of the electronic commerce/business (EC) literature in organisations, in general, and in SMEs, specifically, it was observed that the available research portrayed a gloomy picture about EC uptake and use by SMEs. Therefore, this research attempted, by reviewing recent EC research, to depict an agenda for EC success in SMEs. By following the suggested guidelines in this research, SMEs could be in a better position to assess the viability of the new EC phenomenon to their survivability in the long term. Specifically, these points are addressed to the managers/owners of the SMEs in identifying the different perspectives surrounding the new innovations. These factors are of high importance to researchers, SMEs, professionals (including educational institutions), and policy makers in driving SMEs and EC forward.

KEY TERMS

Economical Importance of SMEs: SMEs contribute significantly to the economies and to the employment level of different countries in the world. For example, SMEs constitute around 95% of enterprises and account for 60% to 70% of employment within the countries of the OECD (OECD, 1997) and other countries across the global including the U.S. Not to forget the SMEs are usually the source for most of the profound inventions and innovations (Iacovou, Benbasat, & Dexter, 1995).

IT/E-Commerce Adoption and Use in SMEs: Historically, SMEs have always been accused of being uncritical about the strategic importance of IT and its use in their businesses. This laggardness in adopting or using IT in business was attributed to various organizational, managerial, technological and environmental deficiencies in SMEs. The recent emergence of the Internet in general and the Web in particular revolutionizes business activities (Abell & Lim, 1996) and promises to provide unprecedented opportunities to SMEs to expand in scope and in market reach.

Small Business Internet Commerce: the use of Internet technology and applications to support business activities of a small firm (Poon, 1999).

Small- to Medium-Sized Enterprises (SMEs): In small countries such as New Zealand, SMEs are defined as enterprises employing 19 or fewer employees. Small enterprises are defined as those employing zero to five full-time employees (FTEs) (often called microbusinesses) and medium-sized enterprises as those employing six to nineteen FTEs. Other countries, such as the United States and European countries, define their SMEs as having a much larger number of employees (200–500 or fewer).

Social and Legal Dimensions of Online Pornography

Yasmin Ibrahim
University of Brighton, UK

INTRODUCTION

The dialectics between private pleasures and public needs raise various dilemmas, especially in the domain of the erotic and aesthetics. These are relative and abstract terms that can vary from individual to individual. However, in the public spaces of the Internet, the need for community standards of decency, acceptability, and taste often drag many of the debates about the Internet into a legal space, despite its description as a virtual sphere and the libertarian endeavours to keep it free from government and organizational control. While the Internet is a global resource it is often ruled through the laws of its physical embeddedness, and the global nature of the Internet also means that it is consumed and assessed through the differing cultural practices and norms that prevail in various parts of the world. The Internet as a communication and information platform is then subject to varying codes of ethical and moral conduct by different communities whether online or off-line. While the realm of the erotic is often equated with individual pleasure and psyche, the proliferation of pornography on a public platform raises social, moral, and legal concerns for communities, states, and governments. One significant element in the development of the Internet as a market place has been the availability of explicit sexual material, and these electronic networks continue to feed the pornography boom and facilitate new methods for consumers to interact with sexual content as "porn" (Spencer, 1999). These networks highlight the "privatising" potential of technology, especially in relation to sexual matters, while illuminating new forms of formal and informal exchanges (Jacobs, 2004, p.72; Spencer, 1999). The Internet, from being a rather unregulated enterprise a few years ago, has recently become the focus of multiple ethical concerns and debates and in some cases, it has amounted to moral panic (Bkardjieva & Feenerg, 2000; Cavanagh, 1999).

BACKGROUND

The emergence of gaming culture and the simulation of reality through the design of gaming technology raises the age-old issues about image and representation; the effects it can have on our cognitive senses, and how these can, as a result, affect or mediate our ability to reason and engage with interactive technology. These questions become ever more salient with regard to online pornography or sexually explicit material. The distinctive element about online porn is its use of multimedia, its ubiquity, and consumer access to it. Due to the anonymity of the Internet and the difficulties in regulating this transnational and anonymous medium, transgressive forms of entertainment, including pornography, have flourished online. According to Spencer (1999), the Internet is structured at one level around the economics and politics of consumption, at another level around the politics of individuality, and at another around communitarian concerns (p. 242).

Online pornography has been acknowledged as a relatively new form of pornography. Authors Stack, Wasserman, and Kern (2004) point out that there were about 900 pornography sites on the Web in 1997 and just a year later, the figure had burgeoned to between 20,000 to 30,000 sites, with revenues reaching US$700 million by the late 1990s. Its growth has been attributed to the "triple a-engine" of accessibility, affordability, and anonymity (Cooper & Griffin-Shelly, 2002, p. 11). Fisher and Barak (2001) agree that "spectacular growth in availability of sexually explicit material on the Internet has created an unprecedented opportunity for individuals to have anonymous, cost-free, and unfettered access to an essentially unlimited range of sexually explicit texts, moving images and audio materials" (p. 312). This increased accessibility and convenience, as well as the exploiting of e-commerce by pornographers, means that the Internet makes it easier for individuals to come into contact with porn. Some suggest that this has enabled the normalization of practices that may have otherwise been stigmatized in traditional markets, leading to a mainstreaming of cyberporn through its visibility and presence (See Cronin & Davenport, 2001, p.35; O'Toole, 1998). In the last few years, undoubtedly, there has been increasing heterogeneity and decentralization on the Internet as a wider variety of producers and consumers participate in the making of globalized markets, and a contemporary notion of pornography should capture such networked sexual agency and politics (Jacobs, 2004).

MAIN FOCUS

Diane Russell (1998) defines sexually explicit material as that which "combines sex and/or the exposure of genitals with abuse or degradation in a manner that appears to endorse,

condone or encourage such behaviour" (p. 3). James Check (1985), on the other hand, terms pornography as "sexually explicit material" without further qualifying it. The Internet poses new questions about the reality, regulation, definition, and availability of pornography, as it has dramatically increased the accessibility of pornography, and of violent pornographic images in particular (Gosset & Byrne, 2002). The danger of pornography to adults is much more disputed, and often the arguments for pornography include freedom of speech and the expression of civil liberties, the right to choose, and the right to privacy (Kuipers, 2006).

Nevertheless, what constitutes pornography is often contested in societies. While in terms of ethics adult pornography is a contested terrain, child pornography, on the other, is almost universally prohibited. But in the online environment, a digital image can be manipulated and altered and consequentially it may be difficult to clearly define the distinction between adult and child images. Jenkins (2001) posits that child pornography can be accessed in various ways in the online environment, where it can be distributed via credit-card access Web sites, bulletin boards, and encrypted e-mails, as well as through peer-to-peer file sharing. These are constitutive of not only the new configurations between producers and users, but also of new forms of abuse (Oswell, 1999, 2006, p. 253).

A report by the Washington-based research and policy group, Third Way, highlights how this accessibility and presence can present new problems for Internet users, particularly children (cf. Whitehead, 2005). According to the report, only 3% of more than 450 million individual porn Web sites ask for proof of age. Additionally, a majority of these Web sites do not carry any warning of adult content, and nearly three-quarters display free teasers of pornography images on their homepages; it is therefore likely that children may accidentally come across a porn site while doing homework or surfing the Web. While child pornography is almost universally illegal, adult pornography is prevalent and easy to access on the Web. Whitehead (2005, p. 18) contends that unlike off-line pornography, which can be curbed through measures imposed by the community such as zoning laws and curfews, the politics of online pornography is very different, as online porn, through its technology, can be seen to be "everywhere and nowhere." This has meant the loss of power for parents to control what their children come into contact with.

The status of a photograph as a verifiable fact continues to linger with the Internet despite the radical impact of digital technology on photographic practice. This has been problematic as digital technology can manipulate and distort images, thus further compounding the relationship between reality and representation. David Oswell (2006) describes this as the ethics of virtual observation, where the referentiality of the image in representing the scene of abuse that is real, and our ethical response to it, is predicated by our perceptions of reality (p. 258).

In discussing the ethics of the virtual, Oswell (1999, 2006) observes that there are often epistemological inconsistencies and disjuncture between knowledge, law, and sociological perspectives. In the context of the US and UK, there is often an implicit understanding that child pornography is the record of actual child sexual abuse, and this has become widely used in legal discourses and public discourses of law enforcement charities and child protection agencies (Williams, 1991, p. 88).

According to Tate (1990), while child pornography has been a problem for decades, until relatively recently it has been a hidden crime (p. 1). In the UK, the principal legislation that addresses the indecent images of children is the Protection of Children Act 1978 (PoCA), which differentiates between different mediums representing the abuse. Photographic images are the subject of this specific legislation that focuses on child pornography, whereas all other mediums are treated as obscene articles and are subject to general obscenity legislation (Gillespie, 2005).

The ontological status of visual depiction has legal ramifications both in the context of the UK and the US. In the US, the Child Pornography Prevention Act (CPPA) of 1996 addresses the legal implications of visual depiction. In 2002, a ruling by the US Court of Appeals for the Ninth Circuit found that the CPPA ruled solely on the image without considering the set of contextual factors catered for in an earlier ruling in 1973, and in view of this, the CPPA's emphasis on the image was "overbroad" and "unconstitutional" (Oswell, 2006). It also reiterated that the proximity or distance of a photograph from the scene of the actual event is an important criterion in the legality of child pornographic images. The court also overruled the argument in the CPPA that virtual child pornography is "intrinsically related" to the sexual abuse of children as the link between the two is contingent and indirect. Harm here does not necessarily accrue from the image but is dependent on the potential for subsequent criminal abuse. The ruling showed the court's unease with the assumption that the image takes up the position of the "modest witness" whose account of the scene is "unadorned, factual and compelling" (Haraway, 1997, p. 26).

Virtual child pornography may have no link to crime or sexual abuse that has actually been committed, and in the same vein, the virtual image has no necessary link to future cases of abuse. As with child pornography, virtual child pornography cannot be prohibited on the basis of its possible harm to some children or the possibility some children may be exposed to it. In this sense, the CPPA defies the "principle that speech within the rights of adults to hear may not be silenced completely in an attempt to shield children from it" (Oswell, 2006, p. 251). In April 2002, the US Supreme Court found the Child Pornography Prevention Act (CPPA) unconstitutional. Though it remains illegal to make, show, or possess sexually explicit material of children, the court

found that there were not compelling reasons to prohibit the manufacture or exhibition of pictures that merely appear to be children. As a consequence, two categories of pornography that were prohibited under the act are now permitted in the US. These include sexually explicit pictures of actual models who appear to be younger than they are and computer-generated sexually explicit pictures of children (Gillespie 2005; Levy, 2002; Oswell, 2006).

In contrast, the UK treats indecent pseudo-photographs of children "as indecent photographs of children." In the UK, the term pseudo-photography was introduced by the Criminal Justice and Public Order Act of 1994. This act defines a "pseudo-photograph" as "an image, whether made by computer graphics or otherwise, which appears to be a photograph" (cf. Gillespie 2005, p. 435). With the police finding images on computers that could not be readily verified as those of a child or an adult, the 1994 amendment became the rationale for addressing this problem (Hansard, 1994, cf. Gillespie, 2005, p. 435).

In UK legislation, while the indecent photograph and the indecent pseudo-photograph are not identical, they are treated as identical. This means that the act of downloading child pornography constitutes a crime, regardless of whether these images are records or not of actual abuse. This legal response to pornography intrinsically associates an image and a crime and provides a legal platform for the authorities to act. In contrast, the actual images are illegal in the US but not the virtual. Oswell (2006, p. 252) points out that such an equivalence creates challenges in a court of law as reservations can be raised as to the evidential status of the image, i.e. as to whether the image is an image of the incident of sexual abuse at all. Oswell contends that the photograph becomes the measure of the real and its observation, and hence, the implicit prioritization in UK law of virtual child pornography means the crime of possession, making, or distribution of child pornography (whether virtual or real) is a crime not only against a particular child but against all children, invoking it as a universal crime against childhood. The debates on adult pornography often delineate between the vague boundaries of erotics and aesthetics but these distinctions can be subjective and may influenced by the context of the immediate society, making them arbitrary criteria.

Prior to the Internet, the debate about pornography in the US centred on the First Amendment, and the need to regulate pornography was stressed on the grounds that pornography violates community standards. Under the US Constitution, it is legal for adults to own and distribute most types of pornography. However, since the 2002 Supreme Court Ruling over COPA (Child Online Protection Act), the US government has made serious efforts to monitor and impose restrictions on Internet pornography traffic by arguing that juveniles or minors (18 years or less) are automatically exposed to and harmed by pornographic images (Jacobs, 2004). As Taylor and Quayle (2003, pp. 159-163) point out, one of the principal elements of Internet-facilitated child pornography is an exponential growth in the size of the individual collection. Here the imaging and archiving features of Internet technology cannot be overlooked. In the UK, for example, legislation does not distinguish between accessing images for personal use (including downloading) and the creation and distribution of images (Gillespie, 2005).

Often censorship and obscenity laws have provided the basis to tackle pornography on the Internet, and this has been the case in the US, Australia, the UK, and France. In Australia, the Western Australia Censorship Act (1996) is designed to protect the local and state territory from the influx of pornographic material over the Internet (Jacobs, 2004:, p.71). On the other hand, South Australia's Censorship Act criminalizes any content that is deemed "unsuitable for children online," even if the content is intended for adults. This leaves content open to police interpretation, as authorities can evaluate and arrest users who post information that is deemed offensive to children.

Akedeniz (2002) stresses that there is a difference between illegal and harmful content, as the former is criminalized by national law while the latter is merely deemed offensive or disgusting by some sections of society. In tandem with this, Jacob (2004) queries whether community standards of decency can be transmitted from one place to another. With the Internet being perceived as a global resource, the issue of community standards creates different cultural and legal approaches to solving the issues at hand.

While there is often a societal acknowledgement of child pornography as a heinous and universal crime, there is, nevertheless, a difficulty in defining what constitutes child pornography as different jurisdictions can define it differently, and equally, the issue of obscenity can also be culturally mediated in different environments. The consensus in terms of what constitutes child pornography can emerge within the context of supra-national agencies such as the Council of Europe, which defines child pornography as "any audiovisual material which uses children in a sexual context" (Oswell, 2006, p. 246).

Akdeniz (2001) points out that the legal regulation of this sort of Internet content may differ from country to country, and this is certainly the case within the European Union, where member countries have taken different approaches to sexually explicit material. Akdeniz streses that in terms of Internet content and young users, harm remains a criterion, and this is accepted within the jurisprudence of the European Court of Human Rights. Harm in societies again is culturally defined. In terms of illegal or harmful content, the UK adopts a multilayered approach with the involvement of both national and international levels. The government also favours a coregulatory approach in which there is a role to be played by the industry's own self-regulation.

Before the Internet, the US already had some antipornography legislation that has since been applied to the Internet.

In the US, pornographic sites are legally obliged to refuse access to minors (Kuipers, 2006). Until recently, further attempts to penalize or regulate Internet pornography failed due to the fact they conflicted with the First Amendment. Beyond legal restraints, countries can also encourage the use of technology to filter undesirable content deemed harmful to children. In June 2003, the Child Internet Protection Act (CIPA) was approved by the US Supreme Court to force libraries and schools to block pornographic sites. The CIPA requires public libraries to filter their computers if they want to retain federal funding, but such software is not completely reliable. Judith Levine (2002) has argued that it is important to promote media literacy and moral intelligence rather than to deal with the Internet through technology. This means that governments and societies should also invest in public awareness and education campaigns instead of phasing out controversial sexuality debates that can polarise the public.

FUTURE TRENDS

Online pornography in many countries has been regulated through existing censorship and decency laws. However, due to the complexity of the Internet environment and the availability of different technologies on one platform, there has been a need to enact and revisit what a photograph or "psuedo-photograph" can constitute in the digital environment and the consequences of admitting it as evidence in courts. The legal trajectories in the US and UK highlight the complexities of the digital image and its treatment in different legal contexts. In the future, new forms of technologies and the convergence of these on the Internet will pose more challenges for the legal domain. Societies would then have to enact new legislation to cope with legal systems that predate modern technologies and the challenges they present. It illuminates the sort of legal and moral dilemmas that have emerged from the Internet environment.

The criminalization of child pornography and the ubiquity of pornography on the Web raise legal issues for users as their private actions in their personal domain can have legal consequences. On an international level, in the domain of child pornography there has been cooperation at a global level between governments to share databases of perpetrators involved in child trafficking and pornography. The future as such alludes to both centralization and surveillance to curb criminal behaviour on the Web as well as to the rise of fragmented and diverse forms of pleasure-seeking on the Internet.

CONCLUSION

The issues of online pornography are entangled with private pleasures, community standards, increasing commercialisation of the Internet, and a proliferation of sites and images offering sexually explicit content. It raises the need to address numerous concerns and issues with regard to online pornography. Concepts of privacy, harm, offence, taste, decency, legality, and protection of children as a universal ideal as well as the evidential status of the digital image on the Internet compound the problems of online pornography. Online digital images, and their referential authenticity to the actual event or person, capture the complexities of the Internet as a medium where convergence of technologies and amalgamation of sound and images, as well as editing technologies, enable simulated realities and new forms of gaze and pleasures. These will continue to pose new moral panics and debates in societies and communities, particularly in terms of protecting the vulnerable and the young while catering to a well-established market that has capitalised on e-commerce and new forms of voyeurism.

KEY TERMS

Cyber Porn: Sexually explicit material that is available on the Internet

Digital Image: A visual content constructed through pixels which can be altered or manipulated through technology.

Ethics: The code of conduct in a society or community that may be tacit or explicitly expounded

Pornography: Sexually explicit material that may be available in any medium

Regulations: Formal rules and legislation that are enacted to address a particular issue.

Social Learning Aspects of Knowledge Management

Irena Ali
Department of Defence, Australia

Leoni Warne
Department of Defence, Australia

Celina Pascoe
Department of Defence, Australia

INTRODUCTION

There are probably as many variations of knowledge management definitions as there are practitioners and researchers in the discipline. Complete consensus in such a group would be a surprising finding. This is because the two words are loaded with pre-existing meanings that do not always sit comfortably in juxtaposition, so what it means to "manage knowledge" is difficult to ascertain, and hence comes to mean different things to different people.

We do know however, that knowledge exists in the minds of individuals and is generated and shaped through interaction with others. In an organizational setting, knowledge management must, *at the very least*, be about how knowledge is acquired, constructed, transferred, and otherwise shared with other members of the organization, in a way that seeks to achieve the organization's objectives. Put another way, knowledge management seeks to harness the power of individuals by supporting them with information technologies and other tools, with the broad aim of enhancing the *learning capability* of individuals, groups, and in turn, organizations (Ali, Warne, Bopping, Hart, & Pascoe, 2004). Social learning, in this context, is defined as learning occurring in or by a cultural cluster or organizational group or team and includes procedures for transmitting knowledge and practices across different work situations, settings, and time. However, the application of technology must be guided by the needs of the organization and its workers. As Davenport (2005, p.162) states, "While I don't question the importance of technology in organizations today, it's only one source of knowledge and learning for knowledge workers."

BACKGROUND

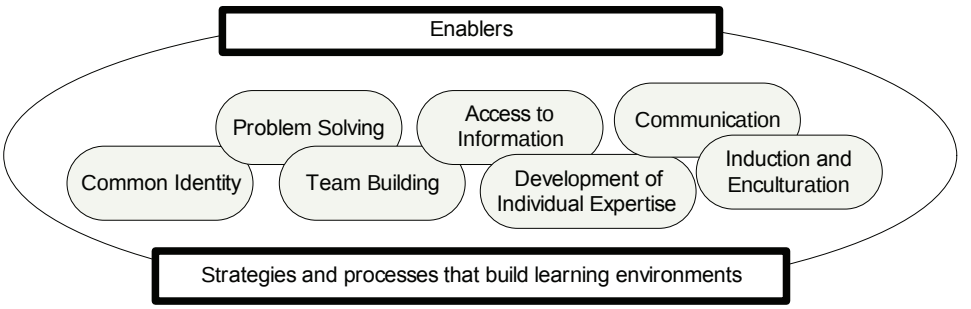
In this article, we examine both theoretical and practical socio-cultural aspects of knowledge management based on years of research by the authors in a large and diverse organization. The study involved numerous functional settings of the organization and the researchers used qualitative and quantitative methodology to gather data. Elements required to build an organizational culture that supports knowledge management are discussed. Unless otherwise specified, words in double quotes in the text are direct quotes from personnel in research settings.

ENABLERS OF SOCIAL LEARNING

The research team identified seven basic categories that constitute enabling processes and strategies to facilitate social learning: common identity, problem solving, team building, access to information, development of individual expertise, communication, and induction and enculturation (see Figure 1).

- **Common identity:** A common ground/understanding to which many people/groups can subscribe, and requires a shift from seeing oneself as separate to seeing oneself as connected to and part of an organization unit. Based on our research, motivators impacting on *common identity* are: goal alignment, cultural identity, gendered identity, language, morale, and workplace design (spatial and physical design).
  - Doney et al. (1998) discuss the relationship between goal alignment and group cohesiveness, claiming that the extent of group cohesiveness relies on the extent to which a team's goals are clear and accepted and also on the degree to which all members adopt team behaviors.
  - The term cultural identity refers to member's sense of self in relation to the specific "tribe" and "tradition" to which they belong and how this distinctiveness applies in their workplace. Cultural identity is another important motivator for social learning because, like common identity, it impacts on the extent to which staff feel that they are part of the system or alienated from it.

Figure 1. Constructs enabling social learning



- Gendered identity relates specifically to one's sense of self, which is imbued with the social, cultural and historical constructions surrounding femininity and masculinity. Gender identity, because of its relationship with common identity, was also seen to impact on social learning (Agostino, 1998).
- Language is another important factor fundamental to the overall social learning processes. By reflecting the social and political relationship between various members, language can impact on common identity. Language is also important in terms of creating a shared understanding among workers and their relationship to the wider organization. "Words are bullets. Never, never use imprecise language." Thus learning the specific work related language is of central importance to broader social learning development, and is an important outcome of the enculturation process.
- Morale has been a significant focus in the overall study because the research team found evidence of low morale being coupled with higher levels of alienation towards senior management. Such alienation has obvious implications for the broader understanding of a common identity and thus for social learning.
- Workplace design and proximity also threatens common identity when staff are not working in the same location. "[Building X] and us. We don't see them. There is not any spirit that we are belonging to one branch. I have more to do with [a specific area] than anything else and I've made some good contacts in there... who I sit around with."

- **Problem solving:** A core activity. It fosters social learning, because each problem represents an opportunity to generate knowledge. Motivators associated with this enabler are: networking, perceptions of the organization, systemic understanding, and time for inquiry and reflection.
  - An individual's personal and social networks are an important means of acquiring, propagating, and sharing knowledge. As Davenport and Prusack (1998) claim, when those who are in a position of "know-how" share their expertise, they contribute to problem solving. Personal networks were seen to function as channels supporting both "information pull" and "information push." Atkinson and Moffat (2005) state that sharing of information is based on trust developed through social interaction, shared values, and beliefs. A human is a node in such interactions and a link is a bond that people develop which is based on mutual trust. Therefore, a significant component of a person's information environment consists of the relationships he or she can tap into for various informational needs.
  - Individual and shared perceptions of the organization, and how they operate, provide an essential backdrop to problem solving within an organizational context. These perceptions may consist of deeply ingrained assumptions, generalizations, or even pictures or images that influence how people understand their organizational world and how they should act within it (Senge, 1992). The importance of these perceptions cannot be stressed enough, because they directly influence the construction of individuals' knowledge and understandings that they draw upon in their day-to-day-activities.
  - Effective problem solving often requires a systemic understanding of organizational and inter-organizational issues. Systemic understanding requires a holistic view of an organization and its inter-relationships, an understanding of the fabric of relationships and the likely effect of interrelated actions (Davenport, 2005; Senge, 1992).

- Inquiry and reflection together are a powerful means of enhancing social learning and knowledge creation. Inquiries, or questions, are triggered by problems that require solutions or explanation. Reflection allows time for examination, contemplation and, often, resolution of the inquiries. To use a common metaphor, it is perhaps the best means for distinguishing between the forests and the trees of everyday working life.

- **Team building:** Working together and understanding what each member is trying to do. Team building was seen to be essential for effective social learning and problem solving. As team-members got to know each other they become aware of each other's strengths and weaknesses, what they could or could not do, their expertise and experience. Motivators associated are: leadership, team-based morale, performance management, public recognition and reward systems, use of humour, and workplace design (Warne, Ali, & Pascoe, et al., 2003).
  - In general, the caliber of leadership within the settings studied was to be admired. The leaders and managers were innovative and they motivated and developed their staff, mainly by demonstrating that staff are highly valued and by acknowledging expertise and knowledge regardless of their pay or position. Another team building issue that emerged was that people were appreciative of informal "drop ins" by senior managers inquiring how they were doing. This "roving management" was said to contribute to better cohesion of teams, to promote system thinking, to help to focus on overall goals, and to facilitate communication and feedback.
  - "Team spirit" and "team cohesiveness" are both important values within the work culture and work ethic, nonetheless, there was nothing uniform about this in the settings studied. Some teams did not see the significance of their particular tasks to the overall goals of the organization. However, good examples of teamwork and team spirit were also evident. There were instances where teamwork was well integrated into daily work and where people worked collaboratively. Such teams were goal oriented and were not only teams in structure but in spirit and were led by a leader who saw his/her role as serving team members rather than just having the position of a leader (Warne et al., 2003).
  - For many employees, the performance cycle is annual and the outcome of a performance report often determines the prospects of one's career progression. Some felt somewhat uneasy as their performance evaluation was due relatively early into their posting cycle. A well planned performance appraisal system should help to make equitable and unbiased decisions regarding staff selection, placement, development, and training (Wood, 1989). Researchers were told that there was often a lack of clear communication about performance expectations. Also, an annual performance appraisal appears to be too long to wait for recognition of good work and too late to correct a performance problem. Morgan (1989) and Wood (1989) explain that to maximize positive results, the appraisal process should be two ways, it should facilitate and coach staff in doing their jobs effectively, and it should be frequent and informal.
  - It was observed that humor was used for smoothing discussions that were becoming heated and to stop the conflict from escalating whilst also enabling the conflicting subordinates to save face. At meetings, humor was used to assist in uniting people around common themes and to make criticism palatable.
  - One way of and increasing team and individual morale is to publicly acknowledge outstanding work. Making employees feel appreciated, and saying, "Thank you, we know that you are a good employee, we value you and your work," is a big factor in motivation (Mitchell, 2000). Key informants stated that public recognition of good work was scarce and that a written or verbal word of praise, a pat on the back often means more, for example, than a pay raise—"praise is better than money" and praise is needed at all levels.
  - Workplace design was seen to have impact on social learning. Staff located at small isolated outposts were at risk of feeling isolated and did not identify strongly with the parent organization. As stated earlier, outposted staff identified more with the workplace with which they were based than their Branch where they affiliated. This was further exacerbated by the fact that they often felt excluded by their colleagues.

- **Access to information:** The easy availability of corporate information in whatever format was observed to effect knowledge acquisition and generation of new knowledge and social learning. Motivators associated are: record keeping, networking, meetings, and information technology (IT) infrastructure.
  - The researchers observed that general familiarity with records keeping procedures was quite poor. Some people have developed their own

personal records keeping systems but there was little uniformity in these and no adherence to file naming conventions and standards. As some informants stated: "I believe that physical files in the … are no longer managed well because their management has been farmed out to outside bodies." or "I think we have problems with passing on information in the organization as a whole. We just don't do it very well." The issue of electronic records, particularly e-mail messages containing evidence of business transactions, posed problems not only in the setting studied but also in the ADO at large.

- Personal networks from previous postings as well as newly acquired contacts in the new environment play a vital role in knowledge construction and acquisition. New knowledge often begins with the individual and through conversations people discover what they know, what others know and in the process of sharing, new knowledge is created. Knowledge sharing depends on the quality of conversations, formal or informal, that people have. Sharing of information has a behavioural component and the emphasis is usually on one-to-one networking initiative and effort. It requires time and space (physical, cognitive and social) to develop the sense of safety and trust that is needed for information sharing. Webber (1993) aptly describes it "conversations—not rank, title, or the trappings of power—determine who is literally and figuratively 'in the loop' and who is not."
- Meetings are another means of accessing information and those that were observed varied significantly in format and the protocols in place. At the tactical headquarters, meetings that were mission related provided excellent opportunities for learning. Strict protocols were observed at these briefings (e.g., allowing participants to discuss errors or problems encountered during missions without assigning blame or shame to individuals). There were few equivalent meetings at the strategic headquarters, other than some induction sessions and briefings and it appeared that learning how to do one's job was not given quite the same priority.
- The researchers observed that information access due to failings in the IT infrastructure inhibited access to information within the strategic settings. Another issue that caused problems was the difficulty in finding information on the shared drive. Since there was no specific person responsible for maintaining the shared drive and for naming folders, it was left to the discretion of the document originator where information would be stored.

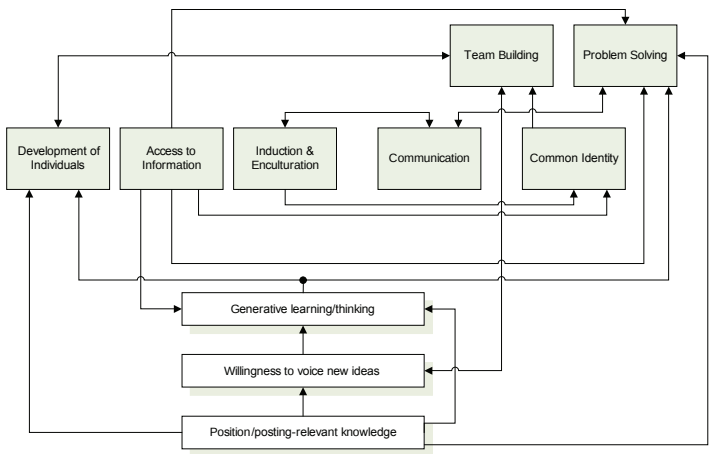
- **Development of individual expertise:** The acquisition and development of expertise was seen as an integral part of social learning. Motivators associated with this enabler are: career trajectories, professional currency, professional training, postings and promotion, and mentoring.
  - A career trajectory describes the positions, roles, and experience that individuals have accumulated, up to and including the position they currently hold. While not excluding personal experiences outside of a work or training context, a well designed career trajectory generally equips an individual with the skills, experience, maturity, and personal networks needed to successfully fill a particular posting.
  - The term professional currency has a somewhat different meaning within different environments. However, professional currency promotes social learning in the same way that appropriate career trajectories do so—by providing a foundation for the generation of new knowledge.
  - Appropriate professional training is a significant component of the development of individual expertise and, therefore, a fundamental for generating new knowledge. Training courses are important to furthering individuals' expertise, as well as for forming the personal networks that subsequently develop. However, in times of budgetary constraints, training money is often the first to go, with damaging consequences for the organization's ability to learn and manage their knowledge.
  - Mentoring is regarded as an effective method of assisting the development of individual expertise, especially for junior staff a degree of informal mentoring was seen to be built into elements of the training program in some of the settings studied. In terms of developing a career trajectory, the knowledge acquired through mentoring may also be important when individuals want to prepare themselves for specific roles in the future.
- **Communication:** Essential to effective learning within an organization and to effective social learning. Motivators associated with this enabler are: overall communication climate, formal and informal information flows, time for inquiry and reflection, use of humor, language, and workplace design.
  - Supportive communication climates are being positively linked to open and free exchange of information and constructive conflict management. Characteristics of a supportive commu-

nication climate include a culture of sharing knowledge, treating each other with respect, and generally behaving in a cooperative manner. Research has established the link between supportive organizational communication climates and generative learning (Bokeno, 2000; Ruppel, 2000) and with higher levels of organizational commitment (Guzley, 1992).

- An important element of generative learning is for organizational members to be able to engage in dialogue, which is open and is based on inquiry and reflection. A supportive communication climate is a prerequisite for such dialogue and it requires learning how to recognize defensive patterns of interaction that undermine learning (Senge, 1992).
- The issue of workplace design and its impact on teams, network building, and on accessing information arose repeatedly during the study. Physical location and proximity to each other had the potential to promote the transfer of pertinent knowledge. The point was made that in addition to more quickly obtaining answers to questions about particular tasks, an open plan workplace enabled one to tap into pertinent knowledge by overhearing others' conversations. Hutchins (1996) uses the term "horizon of observation" to describe the area of the task environment, which can be seen, and is therefore available as a context for learning by team members.

- **Induction and enculturation:** Facilitates social learning by providing a foundation upon which an individual can become fully productive. Issues associated with this enabler are: timeliness and comprehensiveness of the process, buddy/mentoring system, handovers and information packages, and training.
  - Good induction is more that just an introduction to new job and workmates; it is a way of helping people find their feet. Attitudes and expectations are shaped during the early days of new employment and work satisfaction is linked to well timed and conducted work orientation (Dunford, 1992; George & Cole, 1992). The interviews clearly indicated a relationship between meaningful and timely induction and subsequent job satisfaction. An interesting finding was that those who were not properly inducted or enculturated into the organization saw no need and responsibility to actually prepare any form of handover for anyone who may take over their position in the future.
  - Although highly desirable, it was not always feasible to conduct an induction program at the beginning of a new posting cycle. In the interim, a "buddy" or "mentoring" system could fill in the gap. A "buddy" would be an experienced workmate who could be available to answer questions and assist the orientation of new members during the initial few weeks. Some interviewees said that having a buddy when they started was invaluable to settling into a new job and to effective learning.
  - The researchers were repeatedly told that early training is an important part of effective induction and enculturation. It is an opportunity to learn the explicit knowledge that is taught as part of formal training. It is also an opportunity to be exposed to the attitude and cultural perceptions of colleagues and peers.

Figure 2. Enabling processes and their impact on social learning



These factors enabling social learning identified from our data are by no means exhaustive, however, based on the available data the research team could see a relationship between these enablers and social and generative learning. Figure 2 depicts these relationships and their impact on social learning.

FUTURE TRENDS

Whether by design or necessity, humans tend to collaborate to achieve set goals. In fact, this sharing of information and knowledge, and the willingness to cooperate, are key elements for learning, innovation and advancement in general. The progress and proliferation of information technology greatly facilitate this process. However, this widespread application of information technology and emphasis on sophisticated networks for information sharing and social learning leads to a false assumption that once all networks are in place the information will be shared and freely disseminated. The subtle difference between "the network" and "to network" is the key. "The network" is a noun, the information technology, and can only be the enabler. "To network" is the verb, the human behaviour, the action, and the main focus. Therefore, the future trends in the area of social and organisational learning must look beyond the acquisition of technical enablers to individual and organizational behaviour (e.g., organizational structure, processes, and tactics) in order to shift emphasis from a technology-centric approach to a people-centric capability, ensuring that people will get the systems they need and want.

CONCLUSION

Organizations seeking to improve information sharing and knowledge generation need to develop a greater awareness of the processes and strategies of organizational learning. Organizational knowledge is distributed across functional groups and its generation and continual existence is dependant on the overall communication climate which is embedded in the organizational culture. This study indicates that information sharing and subsequent knowledge generation would be successful when interactive environments are cultivated before other (e.g., technology-based solutions are implemented). Therefore, the communication strategy in any organization must take into account the role played by informal and personal networks and trust in information sharing to optimise the process of transferring critical data to facilitate speedier decision-making. Technology should only be designed and applied after a thorough investigation of the work practices and work preferences of the people and teams in the organization.

KEY TERMS

Career Trajectory: Describes the positions, roles, and experience that individuals have accumulated, up to and including the position they currently hold.

Common Identity: A common ground/understanding to which many people/groups can subscribe, and requires a shift from seeing oneself as separate to seeing oneself as connected to and part of an organizational unit.

Communication Climate: Extend to which there is an open and free exchange of information, transparency of decision-making, and how constructively conflict is managed.

Knowledge: An understanding gained through experience or learning: the sum, or a subset, of what has been perceived and discovered by an individual. Knowledge exists in the minds of individuals and is generated and shaped through interaction with others.

Knowledge Management: In an organizational setting, it must, *at the very least*, be about how knowledge is acquired, constructed, transferred, and otherwise shared with other members of the organization, in a way that seeks to achieve the organization's objectives.

Social Learning: Learning occurring in or by a cultural cluster and includes procedures for transmitting knowledge and practices across different work situations/settings and time.

Systemic Understanding: A holistic view of an organization and its inter-relationships, an understanding of the fabric of relationships and the likely effect of interrelated actions.

Socio-Cognitive Model of Trust

Rino Falcone
Institute for Cognitive Sciences and Technology, National Research Council of Italy, Italy

Cristiano Castelfranchi
Institute for Cognitive Sciences and Technology, National Research Council of Italy, Italy

INTRODUCTION

Humans have learned to cooperate in many ways and in many environments, on different tasks, and for achieving different and several goals. Collaboration and cooperation in their more general sense (and, in particular, negotiation, exchange, help, delegation, adoption, and so on) are important characteristics - or better, the most foundational aspects - of human societies (Tuomela, 1995).

In the evolution of cooperative models, a fundamental role has been played by diverse constructs of various kinds (purely interactional, technical-legal, organizational, socio-cognitive, etc.), opportunely introduced (or spontaneously emerged) to support decision making in collaborative situations.

The new scenarios we are destined to meet in the third millennium transfigure the old frame of reference, in that we have to consider new channels and infrastructures (i.e., the Internet), new artificial entities for cooperating with artificial or software agents, and new modalities of interaction (suggested/imposed by both the new channels and the new entities). In fact, it is changing the identification of the potential partners, the perception of the other agents, the space-temporal context in which interaction happen, the nature of the interaction traces, the kind and role of the authorities and guarantees, etc.

For coping with these scenarios, it will be necessary to update the traditional supporting decision-making constructs. This effort will be necessary especially to develop the new cyber-societies in such a way as not to miss some of the important cooperative characteristics that are so relevant in human societies.

BACKGROUND

Trust (Ganbetta, 1990; Luhmann, 1990; Dasgupta, 1990), in the general frame described above, might be considered as a socio-cognitive construct of main importance. In particular, trust building is always more recognized as a key factor for using and developing the new interactional paradigm.

Trust should not be made indistinct with security. The latter can be useful to protect – in the electronic domain - from the intrusiveness of an unknown agent, to guarantee an agent in the identification of its partner, to identify the sender of a message (for example, by verifying the origin of a received message; by verifying that a received message has not been modified in transit; by preventing that an agent who sent a message might be able to deny later that it sent the message [He, Sycara & Su, 2001]). With sophisticated cryptographic techniques, it is possible to give some solution to these security problems.

However, more complex is the issue of trust, that must give us tools for acting in a world that is in principle insecure (that cannot be considered 100% secure), where we have to make the decision to rely on someone in risky situations. (Consider the variety of cases in which it is necessary or useful to interact with agents whose identity, history or relationships are unknown, and/or it is only possible to make uncertain predictions on their future behaviors.)

Trust should not be made indistinct with reputation, too. In fact, communicated reputation (Conte & Paolucci, 2002) is one of the possible sources on which the trustier bases its decision to trust or not.

The more actual and important example of the usefulness of trust building is electronic commerce, but we must also consider other important domains of Multi Agent Systems and Agent Theory such as Agent Modeling, Human-Computer Interaction, Computer Supported Cooperative Work, Mixed Initiative and Adjustable Autonomy, Pervasive and Ubiquitous Computing. In fact, today many computer applications are open distributed systems (with many autonomous components that are spread throughout a network and interacting with each other). Given the impossibility to rule this kind of system by a centralized control regime (Marsh, 1994), it becomes essential to introduce local tools in order to choose the right partnership and at the same time reduce the uncertainty (deriving from the nature of an open distributed system) associated with that choice.

TRUST IN THE NEW TECHNOLOGICAL SCENARIOS

In fact, various different kinds of trust should be modeled, designed, and implemented:

- Trust in the environment and in the infrastructure (the socio-technical system)
- Trust in personal agents and in mediating agents
- Trust in potential partners
- Trust in sources
- Trust in warrantors and authorities.

Part of these different kinds of trust have a complementary relation with each other, that is, the final trust in a given system/process can be the result of various trust attributions to the different components. An exemplary case is one's trust in an agent that must achieve a task (and more specifically in its capabilities for realizing that task) as different from one's trust in the environment (hostile versus friendly) where that agent operates, or again as different from one's trust in a possible third party (arbitrator, mediator, normative systems, conventions, etc.) able to influence/constrain the trustee and representing a guaranty for the trustier (Castelfranchi & Falcone, 1998; Falcone & Castelfranchi, 2001).

Therefore, the "sufficient" trust value of one single component cannot be established before evaluating the value of the other components. In this regard, it is very interesting to characterize the relationships between trust and (partial) control (Castelfranchi & Falcone, 2000).

It is important to underline how trust is in general oriented towards not directly observable properties. It is, in fact, based on the ability to predict these properties and to rely or not to rely on them. Thus, it is quite complex to assess the real trustworthiness of an agent/system/process, not only because - as we have seen - there are many different components that contribute to this trustworthiness, but also because the latter is not directly observable (see [Bacharach & Gambetta, 2001] about signs of trust). The important thing is the perceived trustworthiness that is, in its turn, the result of different modalities of the trustier's reasoning about direct experience; categorization; inference, and communicated reputation.

SOCIO-COGNITIVE MODEL OF TRUST

The Socio-Cognitive model of trust is based on a portrait of the mental state of trust in cognitive terms (beliefs, goals). This is not a complete account of the psychological dimensions of trust. It represents the most explicit (reason-based) and conscious form. The model does not account for the more implicit forms of trust (for example, trust by default, not based upon explicit evaluations, beliefs, derived from previous experience or other sources) or for the affective dimensions of trust, based not on explicit evaluations but on emotional responses and an intuitive, unconscious appraisal (Thagard, 1998).

The word *trust* means different things, but they are systematically related with each other. In particular, three crucial concepts have been recognized and distinguished not only in natural language but also in the scientific literature. Trust is at the same time:

- A mere *mental attitude* (prediction and evaluation) toward another agent, a simple *disposition*;
- A *decision* to rely upon the other, i.e., an *intention* to delegate and to trust, which makes the trustier "vulnerable"(Mayer, Davis, & Schoorman, 1995);
- A *behavior*, i.e., the intentional *act* of trusting, and the consequent *relation* between the trustier and the trustee.

In each of the above concepts, different sets of cognitive ingredients are involved in the trustier's mind. The model is based on the BDI (Belief-Desire-Intention) approach for modeling mind that is inspired by Bratman's philosophical model (Bratman, 1987). First of all, in the trust model only an agent endowed with both goals and beliefs can "trust" another agent. Let us consider the trust of an agent *X* towards another agent *Y* about the (*Y*'s) behavior/action α relevant for the result (goal) *g* when:

- *X is the (relying) agent, who feels trust; it is a cognitive agent endowed with* internal explicit goals and beliefs (the *trustier*)
- *Y* is the agent or entity that is trusted (the *trustee*)
- *X* trusts *Y* about g/α and for g/α.

In the model *Y* is not necessarily a cognitive agent (for instance, an agent can - or cannot - trust a chair as far as to sustain his weight when he is seated on it). On the contrary, *X* must always be a cognitive agent: so, in the case of artificial agents we should be able to simulate these internal explicit goals and beliefs.

For all the three notions of trust defined above (*trust disposition*, *decision to trust*, and *trusting behavior*), we claim that someone trusts some other one only relatively to some goal (here the goal is intended as the general, basic teleonomic notion, any motivational representation in the agent: desires, motives, will, needs, objectives, duties, utopias, are kinds of goals). An unconcerned agent does not really "trust": he just has opinions and forecasts. Second, trust itself *consists of* beliefs.

Since *Y*'s action is useful to *X* (trust disposition), and *X* has decided to rely on it (decision to trust), this means that *X*

might delegate (act of trusting) some action/goal in his own plan to *Y*. This is the strict relation between trust disposition, decision to trust, and delegation.

The model includes two main basic beliefs (we are considering the trustee as a cognitive agent, too):

- *Competence Belief*: a *sufficient evaluation* of *Y*'s abilities is necessary. *X* should believe that *Y* is useful for this goal, that *Y* can produce/provide the expected result, and that *Y* can play such a role in *X*'s plan/action.
- *Willingness Belief*: *X* should think that *Y* not only is able and can do that action/task, but *Y* actually will do what *X* needs (under given circumstances). This belief makes the trustee's behavior predictable.

Another important basic belief for trust is:

- *Dependence Belief*: *X* believes -to trust *Y* and delegate to it- that either *X* needs it, *X* depends on it (*strong dependence*), or at least that it is better to *X* to rely on it, rather than not to rely on it (*weak dependence*). In other terms, when *X* trusts someone, *X* is in *a strategic situation*: *X* believes that there is interference and that his rewards, the results of his project, depend on the actions of another agent *Y*.

Obviously, the willingness belief hides a set of other beliefs on the trustee's reasons and motives for helping. In particular, *X* believes that *Y* has some motives for helping it (for adopting its goal), and that these motives will probably prevail -in case of conflict- on other motives, negative for it. Notice that motives inducing adoption are of several different kinds: from friendship to altruism, from morality to fear of sanctions, from exchange to common goal (cooperation), and so on. This is why, for example, it is important to have common culture, shared values, and the same acknowledged authorities between trustier and trustee.

Another important characteristic of the socio-cognitive model of trust is the distinction between trust "in" someone or something that has to act and produce a given performance thanks to its *internal characteristics*, and the global trust in the global event or process and its result, which is also affected by *external factors* like opportunities and interferences.

Trust in *Y* (for example, "social trust" in strict sense) seems to consists in the first two prototypical beliefs/evaluations identified as the basis for reliance: *ability/competence* (that with cognitive agents includes knowledge and self-confidence), and *disposition* (that with cognitive agents is based willingness, persistence, engagement, etc.). Evaluation about external opportunities is not really an evaluation about *Y* (at most the belief about its ability to recognize, exploit and create opportunities is part of our trust in *Y*). We should also add an evaluation about the probability and consistence of obstacles, adversities, and interferences.

Trust can be said to consist of or better to (either implicitly or explicitly) imply the *subjective probability* of the successful performance of a given behavior a, and it is on the basis of this subjective perception/evaluation of risk and opportunity that the agent decides to rely or not to rely on *Y*. However, the probability index is based on, and derives from those beliefs and evaluations. In other terms, the global, final probability of the realization of the goal *g*, i.e., of the successful performance of a, should be decomposed into the probability of *Y* performing the action well (*internal attribution*) and the probability of having the appropriate conditions (*external attribution*) for the performance and for its success, and of not having interferences and adversities (*external attribution*). This decomposition is important because:

a) The trustier's decision might be different with the same global probability or risk, depending on its composition (for example, for personality factors);
b) Trust composition (internal vs. external) produces completely different intervention strategies: to manipulate the external variables (circumstances, infrastructures) is completely different from manipulating internal parameters.

The idea that trust is gradable is usual (in common sense, in social sciences, in Artificial Intelligence). However, since no real definition and cognitive characterization of trust is given, the quantification of trust is quite *ad hoc* and arbitrary, and the introduction of this notion or predicate is semantically empty. On the contrary, in the socio-cognitive model of trust there is a strong coherence between the cognitive definition of trust, its mental ingredients, and, on the one side, its value, on the other side, its social functions. More precisely the latter are based on the former.

A degree of trust of *X* in *Y* is grounded on the cognitive components of *X*'s mental state of trust. More precisely *the degree of trust is a function of the subjective certainty of the pertinent beliefs*. The degree of trust is used to formalize a rational basis for the decision of relying and betting on *Y*. A "quantitative" aspect of another basic ingredient is relevant: the value or importance or utility of the goal (g). In sum, *the quantitative dimensions of trust are based on the quantitative dimensions of its cognitive constituents*.

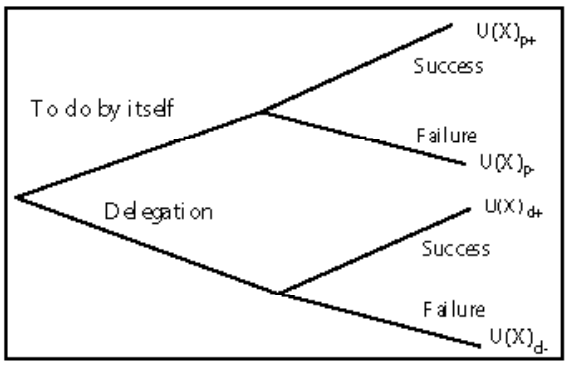
If we call $DoTXY\tau$ the degree of trust of an agent *X* about *Y* on the task $\tau=(\alpha,g)$ we have:

- $DoTXY\tau = DoCX[OppY(\alpha,g)] * DoCX[AbilityY(\alpha)] * DoCX[WillDoY(\alpha,g)]$

Where:

- $DoCX[OppY(\alpha,g)]$, is the degree of credibility of *X's* beliefs about *Y's* opportunity of performing α to realize *g;*

Figure 1.



- *DoCX[AbilityY(α)]*, the degree of credibility of *X's* beliefs about *Y's* ability/competence to perform α*;*
- *DoCX[WillDoY(α,g)]*, the degree of credibility of *X's* beliefs about *Y's* actual performance*;*
- *DoCX[WillDoY(α,g)] = DoCX[IntendY(α,g)] * DoCX[PersistY(α,g)]*
  (Given that *Y* is a cognitive agent)

In any circumstance, an agent *X* endowed with a given goal, has three main choices:

i) To try to achieve the goal by itself;
ii) To delegate the achievement of that goal to another agent, *Y*;
iii) To do nothing (relatively to this goal), renouncing.

Considering the simplified scenario in which only (i) and (ii) are the possible choices we have the Figure1.

Where if *U(X)* is the agent *X*'s utility function, more specifically:

- ***U(X)p+***, the utility of the *X*'s success performance;
- ***U(X)p-***, the utility of the *X*'s failure performance;
- ***U(X)d+***, the utility of a successful delegation (the utility due to the success of the delegated action);
- ***U(X)d-***, the utility of a failure delegation (the damage due to the failure of the delegated action).

In the previous scenario, in order to delegate we must have:

$$DoTXY\tau * U(X)d^{+} + (1 - DoTXY\tau)\, U(X)d^{-} > DoTXX\tau * U(X)p^{+} + (1 - DoTXX\tau)\, U(X)p^{-}$$

where $DoTXX\tau$ is the *selftrust* of *X* about τ.

More precisely, we have: $U(X)p^{+} = Value(g) + Cost[Performance(X)]$,

$U(X)p^{-} = Cost[Performance(X)] + Additional\ Damage\ for\ failure$

$U(X)d^{+} = Value(g) + Cost[Delegation(X\ Y)]$,

$U(X)d^{-} = Cost[Delegation(X\ Y)] + Additional\ Damage\ for\ failure$

Where it is supposed that it is possible to attribute a quantitative value (importance) to goals and where the costs of the actions (delegation and performance) are supposed to be negative.

FUTURE TRENDS

One of the main aspects that should be analyzed in the next few years is the dynamics of trust and the possibility of introducing all the dynamic aspects in the computational setting in which humans and machines will work together. Trust is a dynamic phenomenon in its intrinsic nature (Falcone & Castelfranchi, 2001). Trust changes with experience, with the modification of the different sources it is based on, with the emotional state of the trustier, with the modification of the environment in which the trustee is supposed to perform, and so on. But, trust is also influenced by trust, itself, in the same specific interaction: for example, how trust creates a reciprocal trust; how the fact that A trusts B can actually increase B's trustworthiness; and so on. In other words, in a computational model of trust relationships we have to consider all the dynamical aspects of the trust phenomenon.

CONCLUSION

The Socio-Cognitive model of trust analyzes the basic elements on which trust is founded in terms of the cognitive ingredients of the trustier. In fact, the richness of the referred model (trust is based on many different beliefs) allows us to distinguish between internal and external attributions (to the trustee) and for each of these two attributions it allows us to distinguish among several other sub-components such as: competence, disposition, un-harmfulness, and so on.

The model introduced a degree of trust instead of a simple probability factor since it permits us to evaluate trustfulness in a rational way.

In other words, if we understand what precisely the basic ingredients of trust are, we would be able to better model and build artificial systems in which this attitude should be present.

KEY TERMS

Cyber-Societies: The set of natural, artificial, and virtual agents connected and interacting with each others through natural and artificial infrastructures within virtual institutions.

Reputation: The estimated trustworthiness in an agent as derived from the communicated opinions of other parts (directly or indirectly received); the resulting and emergent "common opinion" about the agent's trustworthiness.

Task: An action and/or a goal an agent has to realize as delegated by another agent; thus – in the opposite perspective - the couple action/goal that an agent intentionally delegates to another agent; where at least the delegating agent knows one between the action and the goal.

Trust: The attitude of an agent to delegate a part of its own plan/goal to another agent and rely upon it in a risky situation (possible failure) on the basis of its own beliefs about the other agent and on the environment in which it operates.

Trustee: The trusted agent in the trust relationship.

Trustier: The trusting agent in the trust relationship.

Ubiquitous Computing: The trend of the technological development to integrate into any kind of object information processing and communication capabilities.

Sociological Insights in Structuring Australian Distance Education

Angela T. Ragusa
Charles Sturt University, Australia

INTRODUCTION

Sociology is well-known for analyzing institutions and social change (Holmes, Hughes, & Julian, 2007). Yet, a dearth of sociological research explores technology and distance education (DE) despite imperatives to include cultural issues (Jorgensen, 2002; Lum, 2006). Meta-analysis shows social studies scholars fail to prioritize technological research (Marri, 2007). Sociologists have examined Web-based instruction and anxiety levels (Gundy, Morton, Liu, & Kline, 2006), flaming (Lee, 2005) and the relationship between learning environment, pedagogy, social roles, relations (Jaffee, 2003) and unintended benefits of traditional classrooms using DE (Edwards, Cordray, & Dorbolo, 2000). This qualitative exploratory research looks at **asynchronous forum** (AF) and DE student experiences in Australia. Using social constructivism, learning is seen as *praxis*, or doing (Vygotsky, 1986) in contrast with ancient traditionalists' *tabula rasa*/"blank slate" understanding of learners waiting to be filled with knowledge (Palloff & Pratt, 2001). Case studies show how culture and learning environments affect **virtual communication** (VC) when *all* communication, student-teacher and student-student, is technologically mediated. Experiences from four 2005-2006 cohorts show social structure affects student perceptions' of learning, satisfaction and agency.

BACKGROUND

Knowledge is an interaction between learner and environment, subsequently reconfiguring both (Semple, 2000). What counts as knowledge is subjective and historically contingent. Advanced capitalistic societies are affected by information technologies (IT) in our "Information Age." In advanced capitalism, ownership and management of IT create global networks and change social interaction (Castells, 2000). This change affects education as technology increasingly facilitates dialogue across power structures and hierarchies (Sorenson, 2007). Virtual communities have emerged alongside, sometimes replacing, traditional communities. In e-**learning communities,** global citizens often use **virtual classrooms (VCM)**. "Globalization of the world's economies is leading to increased emphasis on internationalization of the curriculum" (Barjis, 2003, p. 1). AFs offer DE interaction opportunities that may be "an acceptable alternative to face-to-face [F2F] discussion" (Payne & Reinhart, 2008, p. 36). In VCM, **identity** is more complex than in F2F settings. Technology brings new cultural products and ways of thinking and acting. DE is a fragmented cultural product and pedagogic design and course management systems are contested as neutral (Payne & Reinhart, 2008; Sorensen, 2007).

The popularity of e-learning in post-2000 is growing. Technology has irrevocably altered business models and policies, including higher education worldwide (Stein, 2001). For example, the UK's OpenLearn project is "lead[ing] the learning revolution, experimenting with new models of content and technologies" as the introduction of tuition fees saw 15,000 less university entrances (NIACE, 2006, p. 4). E-learning is supplementing, and sometimes replacing, traditional classrooms as learners' age increases and universities add **flexible delivery**. In 2004, more than 130 countries were developing or offering DE courses, most using IT (Shields, Gil-Egui, & Stewart, 2004). By 2006, researchers claimed "Web-based distance learning environments is growing exponentially with no limits in sight" (Wijekumar & Spielvogel, p. 221). Adoption of IT for education exhibits great social change (Schifter, 2004) yet offers little consensus despite correspondence courses existing since the 1800s (Romeo, 2001). The global marketplace for e-learning varies widely among and within countries, courses offered and technologies available (Marcus, 2006) with DE shaped by cultural attitudes, communication, infrastructure and government policy (Bowles, 2004). Variation is compounded by multi-sector (education, corporate, government) involvement. As Ragusa (2007) cautions, excluding culture in the development, delivery and evaluation of education technologies poses undesirable learning, economic and communicative consequences.

In contrast with Webb, Jones, Barker, and van Schaik's (2004) quantitative analysis, much AF and DE research focuses on small numbers of graduate and professional experiences (Allan & Lewis, 2006; Beuchot & Bullen, 2005; Christopher, Thomas, & Tallent-Runnels, 2004; Marra, Moore, & Klimczak, 2004). Content analysis is common (Lee & Berter, 2007; Im & Lee, 2004; Marra et al, 2004; Marri, 2007; Zhu, 2006) and supplemented by surveys/interviews. Even when qualitative text analysis of

forum data is proclaimed among "the most valued analytic techniques" (Figaredo & Diaz, 2005, p. 4), much remains positivist. Quantitative analysis of student satisfaction in synchronous e-learning (Chen, Wu, & Yang, 2006) reveals social norms and socialization impact learning satisfaction more than technological systems and learning tasks. Structural change draws attention to the role of student agency in DE structures, an issue receiving little attention (van Aalst & Chan, 2007).

This research adds to proponents of case studies (Allan & Lewis, 2006; Hlapanis, Kordaki, & Dimitrakopoulou, 2006; Schrire, 2006) for analyzing VC to augment quantitative analyses (Beuchot & Bullen, 2005; Au-Yeung, Ha, & Au, 2004; Hawkey, 2004; Webb et al., 2004). Simultaneously, it addresses the common e-learning research limitation of inability to isolate "pure" e-learning, "learning that relies entirely on information and communication technologies" without supplementary F2F interaction which "is rare in Australia" (Bowles, 2004, pp. 25-26). In the U.S., Web-based technologies frequently supplement F2F classroom learning (Wijekumar & Spielvogel, 2006). However, research in Wales (Packham, Jones, Thomas, & Miller, 2006), and this study, demonstrates increasingly online university programs without F2F substantive learning. These structural changes foreground the timeliness and fruitfulness of contextualizing DE in organizational practices and procedures.

AF AND DE IN AUSTRALIA: PRACTICE-BASED EXPERIENCES

Descriptive surveys and qualitative secondary data from more than 800 2005-2007Australian DE undergraduates provide experiences, controversies and key issues on AF and VC. Anonymous student comments from two survey items (Q1 - *Aspects of this subject you found helpful to your learning* & Q2 - *Aspects of the subject you'd like to see changed*) a) reveal virtual realities are guided by communication norms/values and b) show identities are negotiated and recreated by computer-mediated communication set amid corporate policies and institutional cultures.

By comparing two DE environments, case studies show how social structure and culture impact perceptions, communication norms and identity formation. In Virtual Learning Environment 1 (VLE1) (2 cohorts: 2005, N=140 and 2006, N=15), students participated in instructor-driven AF with a peer-learning assessment item derived from their AF work. Virtual Learning Environment 2 (VLE2) (2 cohorts: 2005, N=280 and 2006, N=330) offered AF only as supplementary tool. This research argues VC *type* affects learner satisfaction, subject content and skills used. Findings are case-specific and nongeneralizable.

Main Findings

Research findings are presented in three general themes: 1) Structure and norms affect AF learning and dialogue; 2) AF require management of identities, cultural contests and unforeseen events; and 3) Variation in systemic practices affects AF success. Student perceptions and broader issues are presented by theme.

Structure and Norms Affect AF Learning and Dialogue

Variation in e-learning environments resulted in different learner practices (quantity and quality/type of forum postings, learning and teaching expectations and levels of professionalism). Examining responses from one 2006 third-year subject (N=15) in VLE1, 100% of respondents agreed: i) they enjoyed this form of online learning; ii) the subject forum was an appropriate way to support learning activities; and iii) their understanding of the subject improved because of the subject forum. This echoes experiences of 2005 first-year students (N=140). As one DE student and government employee wrote about her AF work, "this type of exercise mirrors how students would be asked to complete the work on campus and I think it's a really good learning tool" (2005, August 15). According to another, "it really makes a big difference and I am finding that what would normally be for me a very difficult subject [is] very stimulating" (2005, August 26). This adds to Webb et al.'s (2004) quantitative finding that participation in integral e-learning dialogue positively correlates with learning. This study lends qualitative support for the centrality of e-learning structure to student satisfaction and learner practices. Framed by Wenger's learning theory "as social participation in the process of active participation in communities of practice" (Sorenson, 2007, p. 165), students' experiences are part of a macrolevel participatory and reification process requiring adoption of microlevel competencies through online VC engagement.

Debate exists in the course management software (CMS) literature over social control and power in VCM, particularly classroom architectures as instructor/administrator-managed or learner-driven with integrated participation (Payne & Reinhart, 2008). The Australian experiences show dichotomizing learners and instructors/facilitators circumvents the complexity of "control" issues because variation in structural preference also exists between students. VLE1 and VLE2 were organized to specifically address issues of control and student ownership of learning. VLE1 evaluations show students supported highly structured AF assessment tasks. Comments such as "the assessments were extremely beneficial and enhanced learning in the subject" (Comment 1Q1, 2005) and "I found the student forum to be interactive

and reinforced learning of the subject" (2Q1, 2005) contrast with arguments for the centrality of dialogue to learning (Sorensen, 2007). Whereas VLE1 was structured to minimize impromptu student dialogue and student-driven discussion topics (in favor of instructor-determined objectives), VLE2 followed a social constructivist approach, enabling students to drive the nature/extent of virtual dialogue. Variation in computer literacy and AF preferences caused questioning of nonassessable forum discussions: "DE students are not all computer literate… I did not use forums…it never seemed to be the appropriate area to discuss a topic" (6Q2, 2006) with expectations differing by generation and younger generations exhibiting better computer knowledge.

In contrast to VLE1, VLE2 AF users produced little subject-related dialogue, primarily venting grievances with learning and life. In response to a student venting anger at the lecturer, another wrote "the student forum is not a chat room with people anonomously sending opinions and fantasy messages out to just see what happens or to vent without regard to others' feelings. The forum is in the real world and with real people: Would you have spoken to the person that way in front of the class of 170 people? You might say 'yes' but I would suggest you would instantly be very embarrassed if you did" (2005, June 30).

Student concern of supplemental AF usage continued in the 2006 VLE2 and yielded a number of negative comments. Noting the "appalling displays of bad manners on the forum" (25Q2, 2006) by other students one wrote, "I found the forums destructive to my learning. I frequently felt frustrated and annoyed by the attitude and online behavior of some of the other forum users. They did not seem to have a grasp of what was required of THEM at an academic level reducing the forum to a high school classroom. I frequently avoided using the forum for this reason" (2Q1, 2006). In VLE2, issues of quality management and structural arrangements led to debate over larger issues including freedom of speech, "from the 350 or so students enrolled in this [subject] it is unfair to the learning and teaching of this topic to have only ONE lecturer. At times it seemed that there was not enough control on the forums and when everything seemed to get out of hand the easiest way was to close the forum down. As a DE student this was seen as denying some students the freedom of speech" (3Q2, 2006).

While some interpreted AF moderation as censorship, others found moderation inadequate, asking for "stricter control over meaningless comments on the forums" (15Q2, 2006). Others said it was "a waste of time to read some of the students postings" noting "I am aware that it would be extremely helpful to talk about the topics…and this is the only way for DE students," but that "with such a huge workload, there is no time to communicate on the forum" (22Q2, 2006). Although netiquette guidelines were provided to VLE1 and VLE2, they did not meaningfully impact VC unless pedagogical guidelines and task-focused virtual learning were also supplied, as in VLE1, supporting Buelens, Deketelaere and Dierickx's (2007) AF research.

AF used for general communication with limited moderation in VLE2 fostered intolerance in the large, international and culturally diverse cohort. One student commented, "there were some really dumb people doing this subject. Maybe you could make people more patient?" (29Q2, 2006). Deciding whose perspective deserves legitimation is contentious. Virtual participants, equipped with multiple identities and knowledges (as professionals, in various locations with different social roles, etc.) used VC to act out real-world battles. Participants divided along political, ethnic, gender and class allegiances.

Perrotta (2006) argues social constructivism can help understand how culture affects identity production. Questioning how/why identity and tolerance develop, or flounder, via VC are issues these case examples raise, yet cannot solve. DE has potential to cultivate global citizenship, democratic skills and intercultural perspectives (Sorensen, 2007). In practice, learner variation stimulated "global awareness" but failed to promote tolerance, questioning whether building quality "online learning architectures" (Sorensen, 2007, p. 175) are sufficient for learners to work across cultural and geographical divides. Lifelong socialization fosters deeply-embedded norms and values, like nationalism, resilantly manifested in VC.

Despite negative VLE2 surveys, some positive evaluations reveal VC perceptions as highly individualistic. Positive comments stated "the forum was excellent, the lecturer made use of this communication very effectively" (7Q1, 2006), "the online forum is a must for DE" (10Q1, 2006), "great enthusiasm from lecturer and helpful hints regarding learning process" (1Q1, 2006) and "just reading the forum answered many queries" (18Q1, 2006). Student variation may explain how some could find the subject to have "a ridiculous amount in an introductory course" (9Q2, 2006) while others note "I have loved this course and the way in which it has been managed and taught… there has been feedback on the forums about the difficulty of some of the work. I sincerely hope that this kind of feedback will not lead to any kind of 'dumbing down'" (15Q2, 2006). Differences in social capital (Putnam, 2005) may explain such variation, offering insights for future sociological research.

In VLE2 62% of evaluating students agreed assessment tasks assisted their learning and 65% agreed supporting resources (i.e., online forums) facilitated learning. Eighty percent found DE provided adequate opportunities to communicate with the lecturer. Differences in AF quality and structure add to Jorgensen's (2002, p. 9) assertion "when students are actively involved in collaborative (group) learning online, the outcomes can be as good as or better than those for traditional classes, but when individuals are simply receiving posted material and sending back individual work, the results are poorer then in traditional classrooms."

Students in VLE2 and VLE1 raised competing life demands and perceived equity issues: "There was sometimes difficult[y] when other team members were shift workers, etc., and couldn't be online at the same time" (2Q2, 2005); "I would have really enjoyed the subject without the online forum weekly participation. I found that helpful but really hard to maintain with work and life commitments" (10Q2, 2005); "I would like to see the group forum a more equitable process" (5Q2, 2005). These contrast with arguments about nontraditional students being better suited to asynchronous technologies than F2F classrooms (Burgon & Williams, 2003). Still, VLE2 expressed broad agreement in DE technologies as beneficial with 88% agreeing assessment tasks assisted learning, 82% feeling online forums facilitated learning and 88% believing there were adequate communication opportunities with the lecturer.

AF Require Management of Identities, Cultural Contests and Unforeseen Events

The second theme is the importance of anticipating and managing unanticipated events. Unanticipated events may be technical (i.e., disrupted Internet service) or situational (i.e., outbreak of war). Regardless of event-type, AF can have a calm group of participants quickly turn into seething debaters (often outside business hours). Communication norms research (Palloff & Pratt, 2001) has used stage and systems theory to explain electronic group dynamics, including conflict and resolution. Management of unexpected dialogue often requires educators to quickly formulate solutions, put out "fires" or assume counseling roles. According to Lynch (2004, p. 109), "learning online supports dialogue and the collaborative development of understandings" while DE bridges individuals' life roles (Lynch, 2004). When engaging in AF, master statuses (gender, class, race, etc.) and social identities responsible for the enforcement of social norms are covert. VC's informal nature and transgression of traditional boundaries (geographical, social and economic) facilitate intimate dialogue among potentially isolated/segregated social groups creating potential for (politically incorrect) debate (Ragusa, 2007). The asynchronous and textual nature of VC dialogue poses unique challenges not experienced in F2F interactions:

- time to compile/access expertise from multiple resources for debate;
- lack of consensus regarding pre-established definitions (i.e., "indigenous" among more than 300 cross-cultural individuals);
- how to interpret meaning(s) of written text if intonation/context is lacking;
- uncertainty if anyone has heard/read one's contribution;
- lack of status symbols (i.e., uniform, job titles, credentials) to legitimate statements; and
- ability to affect/control the path of future dialogue.

Who has the right to speak is an epistemological and political issue (Roof & Wiegman, 1995)? Computers are more than IT tools; they are social artifacts mirroring self-images, encouraging reflection of self-presentation. How one defines situations is critical to the subjective meanings individuals attach to VC. According to Lynch (2004, p. 13), "when reading a typed message, there is a strong tendency to project—consciously or not—your own expectations, wishes, anxieties, and fears into what the person wrote. This may lead to further conflict and, because it is written, sometimes builds a feeling of resentment that lasts longer." VLE1 and VLE2 experiences showed VC encourages "self-talk," the thinking and rationalization process, to become public. Individuals often wrote "why" they advocated world views and reflected in writing for later review by all. Consequently, there is need for task clarity, focused collaboration and quick leadership intervention, if conflict arises for successful group functioning (McClure, 1998) and to diminish misinterpretion (Palloff & Pratt, 2001).

Variation in Systemic Practices Affects AF Success

The third theme is how systemic conditions impact delivery and quality of AF. Disgruntlment about educational design led individualist and capitalist comments, "I get nothing for my money... I feel completely ripped off" (11Q2, 2006). Statements like "I feel [the lecturer's] attempt to have the students take responsibility for their own learning may have been optimistic as it appeared many students were new to tertiary education and were overwhelmed by the need 'to think for themselves' (21Q1, 2006) articulate learners' comfort level with self-driven technologies and show to compare students' and instructors' perceptions (Mazzolini & Maddison, 2007). Students in both groups were unforgiving of IT failure (i.e., electronic assessment systems, incompatible files). Computer-generated reports led to outpours of computer-phobic sentiments and panic unique to VC. Structuring VLE1 with multiple educational technologies (CD readings, subforums, electronic lectures/student presentations, electronic exams, assignment submission) heightened potential for IT difficulty and elevated apprehension about IT inadequacies. Still, IT variation increased skill development and learning satisfaction, while practice virtual exercises reduced stress, and enhanced competence and willingness to use IT.

Student willingness to participate in AF is a key issue (Vredenburg, 2004). Vredenburg (2004) serendipitously found online minute papers enabled shy students to communicate with garrulous peers. Learners in VLE1 and VLE2

did not demonstrate similar behavior. "Students need to be encouraged to use the forum, would of [been] nice to hear from others instead of the same few" (7Q2, 2006). Making online tasks assessable made little difference to the garrulousness of students. Like F2F, AF had a few dominant voices interspersed by a quieter majority. This reveals resilience of social interaction norms. Research is needed to identify necessary conditions to enhance engagement. In contrast with Vredenburg (2004), all VLE1 and VLE2 learning was DE, yielding core and peripheral communicators. Deeper exploration of why/how individuals decide to participate, particularly where DE is the only learning mode, requires analysis. However, structuring learning environments so users can preselect when to contribute taught time management skills and empowered users to opt in/out of culturally sensitive issues (i.e., death, domestic violence).

FUTURE TRENDS

A number of trends emerge from this research. DE offers viable alternatives for higher education circumventing some infrastructure issues, such as lack of Australian rural universities. Yet, IT discrepancies among urbanites, rural and international students remain. Antiquated policies and systemic inconsistencies (i.e., postal return of assignments/grades coexisting with electronic exams) cause user frustration. In considering culture, one must transgress attitudes, behaviors and the social construction of sameness (Lum, 2006) to note how tacit knowledge, embedded in institutional culture, are acted out in policy. Infrastructural variation (i.e., slow mail delivery in Pipalatjara due to no rain in 2 years and by camel in the Sudan) are exacerbated by university policies.

Leaders in DE technologies must be aware of how socially created cleavages (culture, class, age, etc.) impact learning. Broader global adoption (Marcus, 2006) increases contact among individuals of divergent backgrounds. Diversity heightens culturally-contingency and interpretation in VC. As DE gains legitimacy and standing on par with F2F, new norms, customs and roles will develop from the unique group dynamics of virtual communities. Lacking the symbols and rituals of F2F (physical/verbal cues), mechanisms to manage unintended meanings, perceptions and consequences are needed because the frequency, depth and style of VC interactions differ. VC should not be left to ad hoc management, or postponed until convenient. VC requires active, consistent and flexible management, as learners are socialized to adopt communication norms and behaviors conducive to creating safe and supportive learning environments.

CONCLUSION

This research demonstrated culture is embedded in DE and fundamentally affects VC. Lack of sociological analysis was documented and arguments made for what socio-cultural analysis can offer DE organizations, participants, evaluators and planners. Experiences drawn from a large sample of Australian DE undergraduates in two differently-structured VLE highlighted key issues AF participants faced. The important role organization and management hold for satisfactory learning outcomes was revealed. The subjective nature of electronic communication was contrasted with the real-world impact of infrastructure limitations, both affecting social interaction norms. Potential and challenges of asynchronous communication was contextualized amid service delivery expectations in a consumerist world to argue changes necessitate re-evaluation of discursive practices and organizational policies. Findings reflect the complexity of virtual communication and how DE surpasses 18th-century correspondence courses. How VC structures affect social interaction in unique and patterned is argued to require further investigation.

KEY TERMS

Asynchronous Forum: Online communication billboard unconstrained by date/time. Users post statements for others' immediate or later review. Past postings stay viewable, depending on host server or project length.

E-Learning: E-learning uses technology to teach/learn and is a type of "distance education." University degrees via e-learning may use electronic assessments, virtual classrooms, and online resources.

Flexible Delivery: A mode of education more adaptable to time/geographical constraints than face-to-face classrooms. Often appeals to mature, rural/remote students or others with competing life demands (i.e., employment/child care).

Learning Communities: A social group sharing common experiences, cognitive boundaries, sense of belonging and geographical space (virtual or physical) who come together to learn.

Online Identity: Identity refers to a fluid social-psychological sense of "self" in relation to others. Online identities may be similar/different to "real world" identities.

Virtual Classrooms: Exist in contrast to face-to-face learning. Often used in distance education with asynchronous (consecutive) or synchronous ("real-time") communication.

Virtual Communication: Electronic information transfer between individuals/groups via the Internet. Can be text-based (e-mail, wikis, forums) or oral (podcasts). Meanings and communication norms differ from face-to-face communication.

Software Agents in E-Commerce Systems

Juergen Seitz
University of Cooperative Education Heidenheim, Germany

INTRODUCTION

The Internet introduces a new global marketplace for a large number of relatively unknown and not seldom small companies often offering substitutive or complimentary products and services. The merchants profit from reduced costs, reduced time, and unsold stocks. Customers are attracted by increasing convenience and fast fulfillment.

Merchants offering these products and services on this new marketplace need to acquire new customers and sustain ongoing relationships. Nowadays, most merchants' sites are passive catalogs of products and prices with mechanisms for orders (Dasgupta, Narasimhan, Moser, & Melliar-Smith, 1998). The pull strategy is also applied in auctions available over the Internet, where the seller waits passively for bids. The new push technologies for electronic commerce, like software agents, enable customers to compare a bewildering array of products efficiently, effectively, and automatically (Jennings, Sycara, & Wooldridge, 1998). Switching costs for customers and, thereby, their loyalty to previous suppliers in the marketplace decline (Phlips, 1989; Schwartz, 1999).

Using the Internet, the producers profit from reduced cost through direct, non-intermediated sales. The key elements to successful long-term relationships between merchants and customers will be the offering of personalized and value-added services, like one-to-one marketing services, discounts, guarantees, and savings coupons (Seitz, Stickel, & Woda, 2003).

In this article, we will analyze possible consequences of new push and pull technologies in electronic commerce for customer's loyalty, as well as the active technologies enabling customers to purchase efficiently and for the merchants to offer high personalized, value-added, and complimentary products and services. We will discuss some examples of such services and personalization techniques sustaining one-to-one relationships with customers and other actors involved.

BACKGROUND

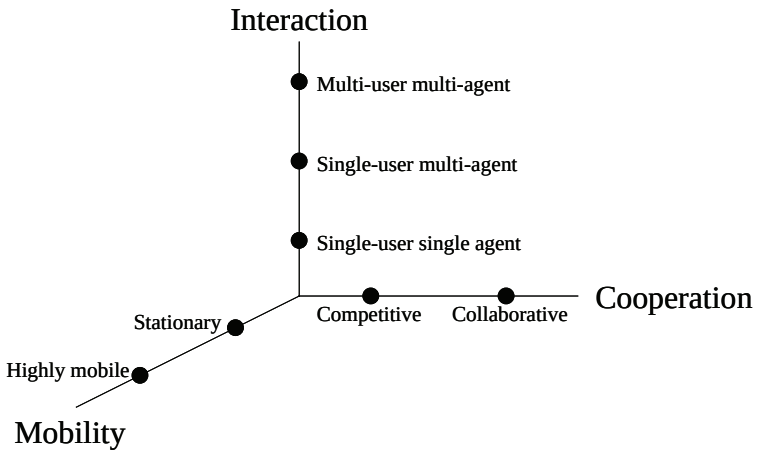
The World Wide Web provides a great opportunity to compare products and services. Customers as well as competitors may quickly gain detailed and up-to-date data. Especially, suppliers of digital goods are in fear of declining customer's loyalty. Customers compare catalogs of products of merchants and producers, and conduct transactions independently of their geographic localization. The crucial basic factors responsible for a limited loyalty of customers are convenience, time, and cost of fulfillment. So, an electronic commerce system should support the ability to embed intelligence to automate the decision process (Dasgupta et al., 1998). The system should not only compare products and prices, but also negotiate and finally purchase products (Teuteberg & Kurbel, 2002). Nowadays, most systems still involve a substantial human element, that is, from the consumer's perspective neither convenient nor efficient. The human involvement should be limited to transaction specification at the beginning of the process and to the buying or refusal decision at the end of the process (Chen, 2000). This means that an appropriate technology is necessary in the intermediate stages to coordinate between customers and suppliers (d'Inverno & Luck, 2003). Mobile software agents emerge as ideal mediators in electronic commerce and thereby as an appropriate technology for an automated procurement process. Customers may specify constraints on the features of products that enable mobile agents to select products from the merchants' catalogs and finally to determine the terms of the transaction. Otherwise, software agents may be used by suppliers as market surveyors to determine the current demand and an appropriate price for the good (Chernev, 2003; Fay, 2004; Hann & Terwiesch, 2003; Spann, Klein, Makhlouf, & Bernhardt, 2005; Spann, Skiera, & Schaefers, 2004; Spann & Tellis, 2006). Software agent technology also abolishes the problem of different technological standards, like hardware platforms and operating systems of remote computers. This means that geographical or technological barriers for customers are of no significant importance any more. The key factors are convenience, time, and cost of the procurement process.

AGENT-MEDIATED ELECTRONIC COMMERCE

Software agents are computer programs showing the following characteristics (Joshi & Ramesh, 1998):

- **Reactivity:** Agent perceives and reacts to environmental changes.
- **Autonomy:** Agent has its own program code, data, and execution state.

Figure 1. Classification of software agents (Joshi & Ramesh, 1998)



- **Proactivity:** Agent initiates changes to the environment.

The ability of an agent to travel around in networks enhances it to a mobile agent (Brenner, Zarnekow, & Wittig, 1998). Mobile software agents may be classified based on their attributes, like mobility, type of cooperation, and level of interactivity (see Figure 1) (Joshi & Ramesh, 1998). For further possible classifications see, for example, Nwana (1996), Sycara, Decker, Pannu, Williamson, and Zeng (1996), or Kurbel and Loutchko (2001).

Competitive agents, mostly single-agents, maximize the interests of their owners. Collaborative agents, on the contrary, share their knowledge and try to maximize benefits of the community on the whole (Joshi & Ramesh, 1998). Mobile agents differ also in terms of the ease of the mobility between remote computers. A continuously traveling nomadic agent, like mobile sales agents (containing information of the total quantity of the product to be sold, the initial price of the product, and the list of potential customers to visit), arrives at a customer's site and communicates with a stationary customer agent that determines the quantity to be purchased at a given price (Dasgupta et al., 1998). The customer agent uses market values and demand curves of the product for its decision. The sales agent has to adjust the price dynamically during negotiations in order to maximize the gross returns. The price for the product may not be settled too low (an agent sells all of his stock at a bargain price) or too high (a given quantity of the goods may be unsold). Such a supplier-driven electronic commerce system enables merchants to maximize their gross return, but also to identify quickly the customers' needs and finally to cultivate long-term relationships with them. The architecture of the supplier-driven system was presented by Dasgupta et al. (1998).

From a customer's perspective, software agents should be highly personalized, continuously running, and autonomous mediators that have to delegate some process management tasks (Guttman, Moukas, & Maes, 1998). A software agent should identify a customer's needs at first, then retrieve information about the product from the merchants' sites, compare the offers, and finally determine the terms of the transaction (Castro-Schez, Jennings, Luo, & Shadbolt, 2004). Nowadays, customer agents are mostly used for product and merchant brokerage and for negotiation (Guttman et al., 1998).

The price of a product may also be dynamically negotiated instead of being fixed (Phlips, 1989; Schwartz, 1999). For example, tête-à-tête agents cooperatively negotiate multiple terms of a transaction, like warranties, return policies, delivery times, and loan options (Guttman et al., 1998). The buyer agent in a tête-à-tête system negotiates toward a pareto-optimal deal with the sales agent (Fatima, Wooldridge, & Jennings, 2004). A system like this does not maximize gross returns to suppliers or price discounts for customers (Excelente-Toledo & Jennings, 2004; Rahwan et al., 2004). However, it takes into consideration the important value-added merchants' services (Weerakkody, Currie, & Ekanayaka, 2003).

Summarizing, software agents are helping customers to compare and to purchase goods in the Internet. Most of them are agents for a simple online product price comparison or for competitive negotiation over price without considering the value-added and post purchase services from merchants. Such agents decrease customers' loyalty to a merchant toward zero. However, additional services, like guarantees, return policies, loans, gifts, discounts, and insurance are of interest to customers. Therefore, they should rather use agents comparing or negotiation over multiple terms of a transaction (tête-à-tête). Otherwise, merchants may also send their

own sales agents to potential buyers in order to acquire new customers and remind the previous customers of new sales offerings (Dutta, Moreau, & Jennings, 2003).

FUTURE TRENDS

In general, software agents helping customers in the procurement process may minimize their loyalty to merchants. Suppliers who do not want to compete solely on the basis of price provide their customers with highly personalized and value-added services to sustain a long-term relationship.

Personalization and Privacy

Personalization is defined as the customization of a Web site to meet the particular needs of individual users (Chaffey, Mayer, & Johnston, 2000; Dean, 1998). The goals of personalization technology are to encourage repeated visits and to enhance user loyalty. The identification of customers' needs occurs through the observation of their behavior and the collection of data (filling out forms or following decision-tree sets of questions).

There exist some advanced techniques supporting personalization Web site contents, like rule-based matching and collaborative filtering. Using rule-base matching, users have to answer a set of yes/no or multiple choice questions to settle a set of user's criteria. Collaborative filtering methods combine the personal preferences of a user with preferences of like-minded people (Dean, 1998). In regard to personalization techniques, one-to-one-marketing should be noticed. This strategy enables targeting unique offers to specific customers (Chaffey et al., 2000). Institutions offering such individualized services have to dispose of accurate user profiles before.

A critical factor of personalization is the privacy issue. Filtering and customization techniques entail the collection and the use of personal data, like name, e-mail address, postal address, age, gender, income, Internet connection, and employment status, that must be protected from abuse (Dean, 1998). Furthermore, a lot of suppliers in the Internet deriving revenues mainly from advertising need to identify their users in order to better customize the content and to attract the advertisers being interested. Hence, the user should be informed by suppliers how they use the personal data and how they protect it. Nowadays, there are several initiatives and standardization projects for the privacy of personal data usage. Such initiatives increase user trust and confidence in electronic commerce. However, no organization or institution has the power to enforce it to the wide usage of suppliers.

Value-Added Services

Merchants who do not want to compete solely on the basis of prices often offer their customers value-added or complimentary services. Complimentary products imply higher benefits to the customer in the case he or she only buys the product he or she looks for (Seitz, Stickel, & Woda, 1999). Such products or services increase the value of the primary good to the customer. Examples of value-added services in electronic commerce are sales discounts, savings coupons, additional insurance and guarantees, gifts, and also free software to test. In general, value-added services enable customers to trade at favorable terms and with confidence. They increase the attractiveness of the merchant to present customers and attract new customers.

Reduced Financial Transaction Costs

Internet merchants might achieve additional reduction of transaction costs using electronic payment systems (Bakos, 1998). Electronic payment systems reduce cash handling costs for merchants and improve speed and convenience for customers. The aggregated cost of each payment consists of transformation costs, for example, the fees for conversion from assets to cash and vice versa, transport and storage costs, costs for safety measures, and search and time costs (Hakenberg, 1996).

CONCLUSION

This article discusses consequences of electronic commerce on customer's loyalty. Electronic commerce in the Internet offers the possibility to create a perfect marketplace. The intermediation in distribution will be reduced. This means lower costs for both suppliers and customers.

Software agents may be classified into different types with regard to their use on supporting electronic commerce. Most of the software agents only perform simple product price comparisons; some support the purchase of products. These software agents reduce customers' loyalty because the price is the only parameter. Quality and added values are not considered. Therefore, multi-agent systems allowing negotiation might be useful from a customer's perspective. Merchants may also send their own sales agents to potential buyers in order to remind previous customers of new sales offerings or to suppliers in order to maximize their gross return.

Personalization and customization of Web sites, value-added services, and the reduction of transaction costs are instruments for increasing customers' loyalty. Personalization techniques, like rule-based matching and collaborative filter-

ing, provide contents on Web sites that are appropriate to the customers' preferences or analyze past purchases and prior suggestions of other customers. One-to-one-marketing may be especially useful for sophisticated products demanding explanations or to enable cross selling of other products and services. User profiles allow merchants to make customer-oriented offers or build special offers including additional services. Value-added services attract the customer to trade at favorable terms. The usage of electronic payment systems may reduce transactions costs.

KEY TERMS

Collaborative Filtering: Collaborative filtering methods combine personal preferences of a user with preferences of like-minded people to guide the user.

Customer Loyalty: Because there is no existing ownership to service products, suppliers have to make special efforts to get long-standing customers.

Customer Profiling: Usage of the Web site to get information about the specific interests and characteristics of a customer.

Customization: The adjustment of products or services to individual needs. Basic characteristics are implemented in the product or service and may be controlled by parameters.

Disintermediation: The elimination of agents, like wholesale dealers or brokers, who built the former relationship between producer and consumer. Disintermediation allows the direct supply of the consumer.

One-to-One-Marketing: The direct dialog between a producer and an individual consumer or a group of consumers with similar needs.S

Personalization: Web-based personalization means providing customized content to individual users using Web sites, e-mails, and push technologies.

Software Agents: Computer programs that are characterized by reactivity, autonomy, and proactivity. Therefore, the software agent interacts with its environment.

Software and Systems Engineering Integration

Rick Gibson
American University, USA

INTRODUCTION

With software an increasingly significant component of most products, it is vital that teams of software and systems engineers collaborate effectively to build cost effective, reliable products. This article will identify the key aspects of software engineering and systems engineering in an effort to highlight areas of consensus and conflict to support current efforts by practitioners and academics in the both disciplines in redefining and integrating their professions and bodies of knowledge.

In response to increasing concerns about software development failures, the Software Engineering Institute (SEI) pioneered a software process improvement model in 1988, with the fully developed version of their Capability Maturity Model for Software (SW- CMMâ) appearing in 1993. Since the early nineties, there have been comparable improvement models introduced in the systems engineering community as well, some of which have been published and widely accepted include: Systems Engineering Capability Maturity Model (SE-CMM), also known as the Electronic Industries Alliance Interim Standard (EIA/IS) 731, Systems Engineering Capability Model (SECM), and the Integrated Product Development Capability Maturity Model (IPD-CMM). The resulting avalanche of models and standards has been described by Sarah Sheard (Software Productivity Consortium) as a "Framework Quagmire". In December of 2000, the SEI initiated the Capability Maturity Model–Integrated (CMMI^{SM}) project, which combines best practices from the systems and software engineering

Table1. Software and system engineering similarities and differences

Similarities	Differences
Definition and analysis involves manipulation of symbols.	Software is not subject to physical wear or fatigue.
Highly complex aggregation of functions, requiring satisfying (though not optimizing) multiple criteria.	Copies of software are less subject to imperfections or variations.
Decisions driven by need to satisfy quality attributes such as reliability, safety, security, and maintainability.	Software is not constrained by the laws of physics.
Easy and dangerous to suboptimize solutions around individual subsystem functions or quality attributes.	Software interfaces are conceptual, rather than physical—making them more difficult to visualize.
Increasing levels of complexity and interdependency.	Relative to hardware, software testing involves a larger number of distinct logic paths and entities to check.
	Unlike hardware, software errors arrive without notice or a period of graceful degradation.
	Hardware repair restores a system to its previous condition; repair of a software fault generally does not.
	Hardware engineering involves tooling, manufacturing, and longer lead times, while software involves rapid prototyping and fewer repeatable processes.

disciplines. (Note: CMMâ and CMMI℠ are copyrights and service marks of the Software Engineering Institute.)

Recent studies (Carter et al., 2003; Goldenson & Gibson, 2003) have validated the SEI's assertion the each of the disciplines benefit from incorporation of principles from the other. Moreover, there appears to be no fundamental differences between the disciplines that would prevent their integration.

BACKGROUND

There is great hope that the SEI imitative will provide the impetus to overcome some long-standing discipline boundaries. The nature of the systems and software engineering work has led to terminology differences rooted in the very descriptions of the disciplines. One important problem with software is the difficulty in understanding its inherent level of quality.

Issues and concerns regarding such an integration were articulated by Barry Boehm and Fred Brooks as early as 1975. Boehm suggested that the adoption of systems engineering reliability techniques by software engineers was counterproductive. Moreover, Brooks' Law suggests that a common systems engineering solution to schedule slippage (add more people) will only make late software projects even later.

More recently, Boehm (1994) expressed concerns that, in spite of the central function of software in modern systems, the two engineering disciplines have not been well integrated. Boehm articulated similarities and differences as shown in Table 1.

Software engineering, as defined by the Institute of Electrical and Electronics Engineers (IEEE, 2001), is: (1) the application of a systematic, disciplined, quantifiable approach to the development, operation, and maintenance of software; that is, that application of engineering to software; (2) The study of approaches as in (1)—and further identifies the body of knowledge for software engineering to be: software requirements, software design, software construction, software testing, software maintenance, software configuration management, software engineering management, software engineering process, software engineering tools and methods, and software quality.

A useful definition of systems engineering resides in an in-process body of knowledge document by the International Council on Systems Engineers (Leibrandt, 2001, p. 3), which defines systems engineering in terms of product and process: "…product oriented engineering discipline whose responsibility is to create and execute an interdisciplinary process to ensure that customer and stakeholder needs are satisfied in a high quality, trustworthy, cost effective and schedule compliant manner throughout a system's lifecycle". The process starts with customer needs, and consists of stating the problem, investigating alternatives, modeling, integrating, launching the system, and assessing performance. Moreover, the system engineer is responsible for pulling together all the disciplines to create a project team to meet customers' needs. The complete systems engineering process includes performance, testing, manufacturing, cost, schedule, training and support, and disposal. The body of knowledge recognizes that systems engineering processes often appear to overlap software and hardware development processes and project management. Thus, systems engineering is a discipline that focuses on processes; it develops structure, and efficient approaches to analysis and design to solve complex engineering problems. In response to concerns about integrated development of products, the system engineer plans and organizes technical projects and analyzes requirements, problems, alternatives, solutions and risks. Systems engineering processes are not specific to a particular discipline; they can be applied in any technical or engineering environment.

In short, software engineering is defined by IEEE Standard 610.12 as the application of a systematic, disciplined, quantifiable approach to the development, operation, and maintenance of software—that is, the application of engineering to software. Eisner (2002) adopts the International Council on Systems Engineering (INCOSE) definition of systems engineering as an interdisciplinary approach and means to enable the realization of successful systems.

When different process models are in place within developer groups, say for systems engineering and software engineering of an organization, the organizations will have communication problems, be unable to improve their processes, and if the combined performance of one advances beyond the other in capability, then the problems are even more profound (Johnson, 1998).

In 2002, the SEI released a single integrated capability model for systems engineering and software engineering, integrated product and process development and supplier sourcing. The new model, Capability Maturity Model Integrated (CMMI), is intended to improve organizations' development and maintenance of products. The CMMI will eventually replace the SEI's Software Capability Maturity

Model (Phillips, 2002). In the integrated model (SEI, 2002), CMMI, the categories and processes are:

One purpose of the CMMI was to evolve the software CMM while integrating the best features of the systems engineering capability models. The combination of the practices of the models into one single framework required more than just combining practices because of differences in interpretation, focus, and terminology. Compromises and intentional inefficiencies were required in order to integrate these models.

With the arrival of the CMMI, a wider continuum of the product life cycle has been targeted for possible enhancement, no longer limiting process improvement only to the development of software. This integrated approach provides a reduction in the redundancy and intricacy resulting from the use of multiple, separate process improvement models. For organizations that wish to assess their process improvement efforts against multiple disciplines, the CMMI provides some economies of scale in model training and assessment training. This one evaluation method can provide separate or combined results for the fields of software and systems engineering. Furthermore, software organizations can also focus on the amplifications for software engineering within the engineering shared process areas and take advantage of any systems engineering amplifications that are helpful. Although still subject to debate, a distinction is made between base and advanced engineering practices as model constructs. Adopting the continuous representation of CMMI not only forces software organizations to define business goals and choose process areas that should be implemented first to focus on these goals, but it also forces companies who are choosing a new subcontractor to do the same. One of the claimed benefits of a staged representation is that it facilitates comparisons among organizations (Shrum, 2000). While it may simplify comparisons, it does so at the loss of additional details. Using a continuous representation, the comparison can be done based on the process areas that are judged by the organization as important rather than simply comparing the organization's maturity score. When using a continuous representation, there is less likelihood that organizations will try to attain a specific level without reasons within their business to do so. It provides an incentive to address processes that would have the greatest impact on their business goals.

FUTURE TRENDS

Despite anticipated problems, bringing systems engineering best practices into the established software process improvement models is expected to be very beneficial. Boehm (1994) reminds us that an important reason to overcome or bridge these differences is to establish an adequate supply of people who can deal with complex systems problems. The Bureau of Labor Statistics (1997) estimates of anticipated growth in information technology jobs, shown in Table 2, provides further support for this concern.

Table 2. Anticipated employment growth 1996-2006

Type of Job	1996 Employment	2006 Employment	% Change
Database Administrators and Computer Support	212,000	461,000	118%
Computer Engineers	216,000	451,000	109%
Systems Analysts	506,000	1,025,000	103%
Data Processing Equipment Repair	80,000	121,000	52%
Engineering, Science, and Computer Systems *Managers*	343,000	498,000	45%

The final job type, managers, is a significant concern addressed by Jerry Weinberg in an interview (Layman, 2001). Weinberg explains that the software development problems are growing faster than individuals' levels of competence. Moreover, he asserts that the current state of practice is one where we need to apply a few fundamentals (e.g., requirements, reviews, configuration management); that is, things known to be useful, but not adopted in the sense of consistent application. Soloman (2002) provides guidelines for using the CMMI to improve earned value management.

It has been suggested that the systems engineering—hardware engineering interfaces have matured nicely over many years, but that the systems engineering—software engineering interface is not as mature as the various hardware engineering interfaces.

Meanwhile, the dependency on the systems engineering-software engineering interface has increased faster than it has matured. Specific concerns by discipline include:

The State of Systems Engineering

- Most successful projects rely on expertise established with similar systems.
- Lack of documented processes makes repeatability difficult.
- Development efforts for unprecedented or significantly different systems often encounter problems.

The State of Software Engineering

- The brief history of software development has been filled with problems of cost overruns, schedule slippage, and failure to achieve performance goals.
- Systems are increasingly dependent on software, yet hardware typically gets the most visibility.

CONCLUSION

Although Pierce (2000) suggests that the CMMI is more of a merged model than an integrated one, which may serve to prolong the separation of the disciplines, Rassa (2001) summarizes the benefits of the CMMI project as follows:

- Common, integrated vision of improvement for all organizational elements;
- Means of representing new discipline-specific information in a standard, proven process improvement context;
- Efficient, effective assessment and improvement across an organization's multiple process disciplines;
- Reduced training and assessment costs.

Although many software-only organizations remain adamant that they do not do systems engineering, all software must run on some computer system, and interface with others. This perceived separation of concerns exacerbates the difficulties associated with hardware/software/system tradeoff decisions, which are further complicated by terminology differences and disparate mental models. Interpretive guidance for CMMI implementation has been provided (e.g., Chrissis et al., 2003)

However, the integration potential of the CMMI[SM] can allow the system and software engineering communities to get the most out of their similarities. The CMMI[SM] allows organizations to tailor the model to mesh with their own mission and goal statements as well as their business objectives. Each individual project can use CMMI[SM] mod-

els for individual disciplines and discipline combinations because the architecture of the CMMI[SM] does not force the employment of every discipline for every organization implementing it. Before the CMMI[SM], the systems engineering models shared many of the same principles as the software version of CMM, but were written to address the needs and terminology of the systems engineering community. Because the CMMI[SM] includes the common and shared elements and best features of both software and system engineering together with discipline-specific elements, an organization can generate integrated capability maturity models or discipline-specific capability models. With CMMI[SM], an organization can still capitalize on these similarities and improve the efficiency of and the return on investment for process improvement. The resulting integrated capability models will adapt to an organization's business purposes.

The concept of an architecture continues to serve as a theoretical link for both the software/system tradeoffs and the integration of process improvement efforts. While respecting the legitimate differences in areas such as reliability testing, it is important to sustain the hope that overlapping or underlying theories will emerge regarding areas of common concern such as: requirements, security, safety, and performance.

In order to achieve true integration of software and system engineering practices into one process improvement model, the remaining differences of terminology and model construction have to be addressed. These two communities have well-developed disparate languages and methodologies that are reflected in their different origins, models and perspectives; differences that have become entrenched in their organizational cultures. With the adoption of an integrated process improvement model, an organization can assess both software and systems engineering functions, reduce conflict and increase consensus.

KEY TERMS

Capability Maturity Model (CMM): Contains the essential elements of effective processes for one or more disciplines. It also describes an evolutionary improvement path from ad hoc, immature processes to disciplined, mature processes with improved quality and effectiveness.

Process Architecture: Describes the ordering, interfaces, interdependencies, and other relationships among the process elements in a standard process. Process architecture also describes the interfaces, interdependencies, and other relationships between process elements and external processes (CMMI).

Process Improvement: A program of activities designed to improve the performance and maturity of the organization's processes, and the results of such a program.

Quality: The ability of a set of inherent characteristics of a product, product component, or process to fulfill requirements of customers.

Software Engineering: The software engineering discipline covers the development of software systems. Software engineers focus on applying systematic, disciplined, and quantifiable approaches to the development, operation, and maintenance of software.

Systems Engineering: The systems engineering discipline covers the development of total systems, which may or may not include software. Systems engineers focus on transforming customer needs, expectations, and constraints into product solutions and supporting those product solutions throughout the product life cycle.

The Software Industry in Egypt as a Potential Contributor to Economic Growth

Sherif Kamel
The American University in Cairo, Egypt

INTRODUCTION

During the 1960's computing was introduced to Egypt. Its use and applications was limited to the government and the public sector. During the 1980's the introduction and diffusion of computing was widespread following the global personal computer evolution. Personal computers effectively affected organizational development and growth due to the continuous developments in the information technology industry and caused by increasing hardware penetration, software innovations, and the build-up of the telecommunications and information infrastructures. This chapter assesses the recent developments in the software industry in Egypt, especially post to the establishment of the ministry of communications and information technology late in the 1990's as a major building block of the information technology industry and a possible active contributor to economic development at large through a strong, quality and much needed export-oriented software industry that could have concrete implications on the economy.

BACKGROUND

Although computing started in Egypt in the 1960's, it was only in 1985 that the active role played by the government caused a change in the way information technology was perceived as a vehicle for socioeconomic development and a tool to improve the decision making process (Kamel, 1999). This change was accelerated by the continuous development of new tools and techniques that had direct and concrete effects on socioeconomic development. Furthermore and after the establishment of a ministry for communications and information technology, Egypt's information society initiative (EISI) was launched in 2001 to provide a broad perspective on the strategic plan for information and communication technology diffusion in Egypt (Kamel, 2005). Therefore, it is perceived that the way developing countries will manage the computer driven process of change will influence whether its socioeconomic development goals will be promptly achieved. This will be bound to the continuous ability to invest in emerging technologies, the provision of skilled human resources and the completion of a state-of-the-art information and communication technology infrastructure. Many researchers have identified information technology as the combination of information, computing and communication technologies that through convergence could help the development process (The American Chamber of Commerce in Egypt, 2001).

Today, with the evolution and diffusion of the Internet, the integration of these technology elements is invaluable to societies around the world and strongly contributing to globalization. Moreover, newly evolving economies in the 21st century are mainly dependent on hardware to process information; communication that acquire and distribute information and software which helps manage the whole process. The importance of information technology has been greatly emphasized in most developing countries in a deliberate effort to ensure that they do not lag behind, with an emphasis on localization and adaptation to local community needs. In most developing nations, the government has played the most important role in the diffusion of information technology being the largest user of computers (Moussa & Schware, 1992) and through its policies, laws, and regulations it still exerts the largest influence on the diffusion of information technology throughout different organizations (Nidumolu & Goodman, 1993). Such concept has gradually started to change throughout the last decade through massive deregulation of the information and communication technology sector with a focus on telecommunications. For example, in the case of Egypt, the government used to be the primary user of information technology with an accumulated market share of 25% (Ministry of Communications and Information Technology, 2006). However, recently increasing use of information and communication technology has been greatly felt in the banking, health, employment, trade, and local administration and education sectors among others (CIT Egypt, 2006).

Since the establishment of Egypt's information society initiative in 2001 and its amendments in 2003 to cater for the changing local and global market needs, and through a public-private partnership (PPP), there has been a growing and effective role being played by the private sector through a win-win formula that is applied on a variety of information and communication technology projects that relates but not limited to (a) PC for every home, (b) free-subscription Internet model, (c) information technology clubs, (d) broadband diffusion, (e) mobile penetration, (f) electronic

government institutionalization, and (g) software incubation and development (Kamel & Ahmed, 2006).

Software as an integral element of the information and communication technology industry is attracting increasing attention of developing nations after many years where hardware was really the focal point. Moreover, it is important to note that the software industry is an excellent setting to understand the features of the knowledge-based economy (Seleim, Ashour & Bontis, 2004). It is also important for knowledge acquisition and transfer since the essence of software development is pure knowledge and the fact that 95% of software business is intangible capital (Grant, 2000; Hoch, Roeding, Purkert, Linder & Muller, 2000). India is a classical example with 6.5 billion US dollars industry and increasing steadily (Nasscom, 2000). In Egypt, the ICT market has been steadily increasing since the late 1990's (Economic News Bulletin, 2003). The software market according to the Egyptian Software Association (ESA) was estimated at 50 million US dollars in 1998 mainly locally developed with a focus on tailor-made applications and with an annual growth rate of 35% locally and expectation of 200% increase in exports annually (Harvard Consulting Group, 1999). During that time, the total market was estimated at being 140 million US dollars however with massive expectations of growth in the following years. It is also important to note that since the late 1980's, Egypt has been playing a leading role in software publishing in the Middle East and 80% of its software exports are regularly going to countries in the Gulf region and mainly Saudi Arabia (Arab Human Development Report, 2002). Table 1 demonstrates a number of elements that relates to the software industry in Egypt showing the different stakeholders, market outreach and the various applications whether customized or packaged.

IT FOR DEVELOPMENT

Egypt is the cradle of an ancient civilization dating back to 3000 BC. With a population of about 72 million, it is the most populous country in the region (Ministry of Communications and Information Technology, 2006). About 28% of its population is enrolled in education programs (schools and universities education), 58% are under the age of 25 and 19 million represent it workforce; around 6 million are working for the government sector (Information and Decision Support Center, 2003). Egypt is trying to expand its industrial base and modernize itself technologically with agriculture accounting for 17% of the gross domestic product, industry for 32% and a large service sector (51%) mainly built around tourism and transportation. A comprehensive economic reform program was implemented that enabled its current economic growth rate to stand at 6.1% annually with an inflation of 5.3% (Economic News Bulletin, 2003). Estimates show that unemployment is standing at 11% and the labor force is growing at around 2.7% annually (Information and Decision Support Center, 2003).

The government of Egypt is more determined than ever to build-up the national infrastructure and keeps pace with the IT evolution worldwide. Since 1999, the concerned ministry in collaboration with different stakeholders embarked on a master plan to build Egypt from an information and communication technology perspective that is based on the fact that as an emerging market, Egypt has already made considerable achievements in terms of economic development and is ready to move aggressively into the global market and the only vehicle to realize that objective is through a state-of-the-art information and communication technology infrastructure (Osman, 2000). There is no doubt that the information technology sector can act as a driving force behind a potential new economy for Egypt. With the growing size of the global

Table 1. Software industry elements

Industry Characteristics	
Stakeholders	Government Private sector Public sector Civil society organizations Individuals
Market Outreach	Europe Arab countries North America
Applications (customized and packaged)	Functional applications Educational applications Cultural applications Arabization of applications

software market, Egypt has promising potentials to compete in the middle market segment of companies because it cannot compete with the likes of India on the basis of prices. It can only compete based on the relatively low price of labor compared with the higher level of value added, business vision, and innovation (Rizk, 2002).

Developing the Software Industry

The software industry in Egypt has been gradually growing over the last few years. It is diverse and heterogeneous in nature with the presence of local vendors and multinationals like most mature markets. Most of the software development companies provide training services to support their products and clients. Overall, the number of information and communication technology companies grew since 1999 from 312 to 1,773 marking over 560% and employing over 35,000 compared to 6,000 in 2000 including managers, programmers, experts, consultants, and project managers mostly involved in the development and delivery of information systems to local and international markets (Ministry of Communications and Information Technology, 2006). The software industry is divided into four categories including (a) software tools, (b) packaged applications, (c) tailored applications and multimedia applications and (d) Arabization of applications. Software companies range in size between 1 to 5 staff member start-ups through to relatively mature firms with around 50 to 150 employees. The majority of firms are located in and around Cairo or Alexandria. However, recently, some of the new start-ups were located in the new industrial areas to benefit from the tax holidays they offer.

It is important to note that a growing number of firms since 2001 have been involved in a variety of business process outsourcing activities leading to expanding the outreach of these firms beyond the national borders and contributing to a healthy export-oriented software industry where playing a major part in such industry is companies like ITWorx, MNS, DMS, and Raya that are taking the lead among others. As an information technology-producing sector, the software industry can act as a driving force behind a potential new economy for Egypt. It is important to note that because of the cost structure of the industry that relies on information that is expensive to produce and inexpensive to reproduce; there are a variety of opportunities for economies of scale and increasing return on investment (Rizk, 2002). Respectively, given the important role of human capital in shaping an effective and rewarding software industry and Egypt's well-educated workforce it is important to highlight the importance of expanding investments in the information and communication technology sector and especially in the software industry.

Egypt's dream is to become a leading software exporter in the region with a global outreach which is relatively realistic considering the boom in the software industry in Egypt and the potentials in the regional marketplace with a growing need for Arabization in a market that totals over 300 million in population (International Telecommunication Union, 2006). The market for Arabized software is large in Egypt but there is also a great potential elsewhere throughout the Arabic speaking world that can be served with language-specific software produced in Egypt. In 2003, Egypt has put together a plan to lift its software exports to 2 billion US dollars within 5 years (AME Info, 2003). The plan presented by the Union of Egyptian Industries builds on the potential of the Egyptian software industry mainly in the domain of localization, customization and consulting although there were concerns for high taxation on IT imports as an obstacle to promoting a competitive software industry and a deterrent to investments in software research and development.

Capitalizing on over 160 software development houses and around 10,000 developers, Egypt has all the ingredients to become a regional leader in the domain of value-added services and localization (AME Info, 2003). The plan aimed at a cut on import taxes from 25% to 3% in order to make the industry more attractive and profitable. Lowering custom duties on imports would directly result in boosting the software industry by 300 million US dollars in the first year due to the decrease in cost of production. More importantly, the plan calls on the government of Egypt to include the software industry as a priority in trade agreements signed between Egypt and other countries.

While these numbers are not impressive if compared with more developed software industries, they do provide a foundation from which to start a serious development of the industry. Moreover, the ministry of communication and information technology has embarked since 2001 on a multiphases plan to train around 30,000 graduates to enter the labor market in the software industry and it the ministry has also allocated around 9 million US dollars for professionally qualifying them (Ministry of Communications and Information Technology, 2006). Egypt realizes that it must devote considerable resources to educating and training IT professionals to reach a reasonable critical mass that could act as agents of change and help create a healthy and strong software development platform that is an integral element of a high-tech industry and a contributing factor to the development of a knowledge-oriented and productive society. The plan aims to continuously increase and diversify the training of fresh graduates as well as IT professionals that could represent the core of the development of a high-tech industry (Osman, 2000). The expectation for growth in the domestic marketplace for IT products and services is expected to be in the range of 35% for services and products on annual basis for the many years to come.

The industry distribution channels in Egypt are still relatively underdeveloped with around 63% of software sales without intermediaries; 50% of tailored applications are sold

bundled with niche products and services. Moreover, software sales through system integrators are low because of limited subcontracting, technical cooperation, and interchange of skill and specialization's between local companies. Finally, function-oriented software is sold primarily through dealers (Seleim, Ashour & Khalil, 2005). With regard to software demand, the government purchases generate 25% of total software revenues, making it the largest demand segment with two major purchase determinants, which are quality and after-sales service for fear of system failure with cheaper systems (The American Chamber of Commerce in Egypt, 1998). However, only 6% of revenues are from sales to small office and homes, which is in part due to the widespread piracy rate of 86% that plagues this segment. This figure is gradually decreasing due to the newly introduced laws against violators of software piracy laws. Also, the number of software applications sold to households is increasing due to the boom in PC sales for household usage and the

Table 2. Software industry in Egypt SWOT analysis

Strengths	**Weaknesses**
▪ Well-educated graduates interested in ICT coupled with entrepreneurial skills ▪ Computer science schools in all national and private universities ▪ Basic and advanced training programs in IT management ▪ Growing technical skills in ICT ▪ Low and competitive labor costs ▪ Good command of English for dealing with overseas customers (other languages include French, German, and Spanish) ▪ Same time zone advantage with Europe and provides a second-shift for the United States (outsourcing services) ▪ Geographically well-located from most African and European cities and some Asian cities making it a hub for trading ▪ Encouragement of the government by facilitating procedures and logistics related to the software industry	▪ Technical skills are too broad and thin ▪ Lack of sufficient expertise in any one technology ▪ Software companies spend around 6 months to turn graduates into productive contributors ▪ Lack of project management, marketing, and managing start-ups skills ▪ Limited local demand for software ▪ Lack of management recognition to the value of using IT as a business vehicle ▪ Effective role of government still limited ▪ Infrastructure level and cost is high compared to the capacities of manufacturers and beneficiaries ▪ Government regulations needs to be firm and enforced ▪ Perception that software has little intrinsic value among commercial and government customers
Opportunities	**Threats**
▪ Creation of software business incubators such as the smart village model ▪ More proactive role played by educational institutions and training centers ▪ Internships and scholarships from software vendors both local and multinationals ▪ Promotional role played by software associations to activate the role of software development companies ▪ Government support role needs to be more at the macro and micro levels ▪ Changes in tax treatment, reduction on telephone tariffs and the introduction of new intellectual property laws ▪ Penetration of PC in homes and businesses is increasing	▪ Intellectual copyright violations ▪ Piracy rates are relatively high ▪ Lack of understanding for software products and their implications on business development ▪ Lack of market research in domestic and overseas markets that Egyptian companies could target ▪ Lack of financial support to the industry ▪ Limited distribution skills to serve the international software market

spread of Internet among younger generations due a few public-private partnership programs addressing the Internet diffusion and PC penetration in the society.

The competitive advantages of Egypt's domestic software production environment have attracted numerous international producers to subcontract programming of tailored applications. The industry was further boosted in 2004 with the establishment of the Information Technology Industry Development Authority (ITIDA) a governmental entity established through Law 15 and aiming at paving the way for the diffusion of the e-business services and supporting an export-oriented IT sector. This was coupled with a number of strong attributes that places Egypt as a potential center for offshore IT services such as (a) favorable technical staff and infrastructure costs, (b) language capabilities, (c) improving infrastructure, (d) pro-business governmental reforms, (e) strong government support for the IT sector and (f) a strategic geographic location.

With the presence of over 50 Internet service providers; there is an expected significant growth in services and software applications that are Internet-based contributing to the new economy with its driving forces and new rules. Additionally, there is an expected increase in the development of applications of a number of key sectors in the economy including the financial, petroleum, tourism, and health sectors (Loch, Straub & Kamel, 2000).

Software Industry SWOT Analysis

The software industry in Egypt is better analyzed through a SWOT analysis to be able to understand where it stands and where it is heading with an overview on its strengths and weaknesses and an identification of the opportunities available and the threats faced. Table 2 demonstrates the software industry in Egypt SWOT analysis.

FUTURE TRENDS

Based on the assessment of the software industry in Egypt, an action plan needs to be formulated in an attempt to capitalize on the opportunities available and overcome the challenges in the market. The plan can assist Egypt in improving its software industry performance and cope with the global trends and drivers especially in the domain of outsourcing. This could include (a) identifying and penetrating international target markets to realize growth, (b) investing in people to leverage the capacities of the key building block in the industry, (c) introducing incubator programs to link the industry to educational institutions and the government, (d) improving the infrastructure to ensure that firms have the vehicle to operate their business; and, (e) increasing government support role to demonstrate the value of software to Egypt's future (Kamel, 2003). Moreover, during 2005, the ICT sector, through public-private partnership programs have been focusing more on encouraging innovations and developments in ICT applications and in the development of the software industry with an emphasis on exports. Therefore, the government established four centers of excellence in data mining and computer modeling; wireless technologies, mobile and electronic services, and electronic design.

CONCLUSION

Egypt has an excellent opportunity to develop the ingredients of a small but effective software industry. The industry has high potential to be developed way beyond the current levels. All the efforts and support enabled by the government and backed by the industry, financial institutions and the educational system will ultimately determine the level of success of the industry making it profitable and active contributor to business and socioeconomic development. There is a wealth of opportunities for Egypt to improve all aspects of development for the software industry. Egypt could dramatically increase the level of revenue and growth in the software business with a relatively small investment and focus to be able to attain the levels of achievement realized in nations such as Ireland and India. Increasingly, Egyptian software companies are establishing partnerships with global software vendors offering complete and integrated solutions as well as customized applications designated for vertical markets. For example, since the establishment of the smart village, there has been a number of strategic alliances developed with the likes of IBM through the establishment of a software development center training 400+ skilled IT developers annually, Mentor Graphics established a design center training 170+ engineers, Intel established a regional platform definition center and a regional software development lab, HP established an imaging and printing technology center, Oracle established a global support center, Microsoft established a developer support center for software and a software innovation center, and finally Cisco established a core competency e-learning institute.

Egypt has all the resources to become a leading player in the regional industry and even to establish a global reputation as a software development center due to the growing presence of its manpower, skills, capacities and educational infrastructure. Such industry can benefit economic growth and work as a vehicle for knowledge acquisition and transfer which is an important element for societal development and building competitive advantages. The start could be the model of the smart village that could be replicated in different locations in Egypt. The smart village is a business park on 300 acres of land with a capacity of 67 companies' buildings, hosting 30,000 job openings with investment incentives like tax exemptions, high-speed network, host of a diversity of multinationals such as Microsoft, Alcatel,

Vodafone, and Ericsson among other as well as Egyptian companies and technology incubators; there are also areas available for SMEs and a plan to establish a financial district in which the Egyptian Stock Exchange and a number of financial institutions will be hosted.

RECOMMENDATIONS

Based on the development of the software industry worldwide and the potentials for the software industry in Egypt; there is a number of issues that need to be restructured to benefit from opportunities available both in Egypt and other countries in the region. These issues relate to (a) having a better link and coordination between the industry at large and academic establishments to cater for the growing needs in terms of human resource capacities as well as to enable an evaluation and feedback mechanism that relates both stakeholders; (b) enhancing the educational system to generate capacities ready to deliver the needs of local and international markets; (c) improving the salary scale in the industry to match other regional and relatively international markets to minimize the implications of brain-drain situations, (d) setting-up a regulatory authority to regulate the software industry, and (e) establishing a solid presence in the overseas markets through offshore business development and contact centers and benefit from a market for business development outsourcing that should reach 500 billion US dollars by 2008 (Ministry of Communications and Information Technology, 2006). The software firms in Egypt possess many elements that represents the platform for a growing, successful and competitive industry, however to have enable healthy and strong industry it is recommended to implement a number of steps that includes developing a strategy for the protection of intellectual property rights, providing a process for documentation of business practices and needs in the marketplace, and focusing on the needs of the regional markets for Arabic software and value-added applications such as e-government and Web-enabled government services.

KEY TERMS

Arabization: The transformation of software applications into the Arabic language in terms of usage as well as interface to be able to cater for a community that stands in 2003 at around 300 million people.

Building Blocks: Reflects all the critical success factors of the information technology industry and that include: hardware, software, human resources "humanware", networking and information.

Business Process Outsourcing: Means the use of outsourcing mechanisms locally or offshore for the design and/or development of software applications.

Diffusion of Information Technology: Reflects the spreading of information technology concepts among the society of implementation whether that could be within an organization or within the community at large.

Government-Private Sector Partnership: The teaming of different entities in the government and the private sector to realize a change and a transformation in the development of information technology at large and in the software industry in specific.

Incubator Programs: A form of collaboration usually between the industry, corporations, and the business community and the educational sector aiming at identifying industry and market needs, catering for these needs and creating employment opportunities for the society especially, young graduates.

Informatics Projects: The projects that involve in any way possible the use, design, delivery, implementation, and management of information technology irrespective of the element involved including software, hardware, and so forth.

Information Technology Industry: The accumulation of all elements of information technology design, delivery, and management.

Smart Village: Model technology park represented by a landscaped development usually comprising of high specification office space and retail developments, designed to encourage localization of high technology companies such as information technology and software development thereby giving each the benefit of economies of scale; usually located outside the city areas as these are quite land intensive in nature.

Software Industry: Focuses on the needs of the software development industry in terms of infrastructure, know-how, capacities, and development.

Tailored-Applications: Applications based on industry or organizational needs to complement the off-shelf software applications available in the marketplace.

Software Reuse in Hypermedia Applications

Roberto Paiano
University of Lecce, Italy

INTRODUCTION

Hypermedia applications were, at the beginning, hand-coded pages with "ad-hoc" links. This production method was acceptable until a few pages had to be produced, but it became rapidly unmanageable when several hundreds of pages with complex interactive objects had to be considered. In particular, two interwoven problems rapidly became relevant: how to ensure the "usability" of modern large hypermedia-applications (Garzotto, Matera & Paolini, 1999), and how to improve the efficiency of its production/maintenance process.

In good hypermedia applications, in fact, the reader should be able to effectively exploit the information contained in the application: that is, he or she should be able to quickly locate the objects of interest, to understand the inner structure of the objects and to easily navigate from one object to another. Several factors concur to the achievement of usability: one of the most important is to have a good structuring of the information objects and a good structuring of the navigation patterns.

BACKGROUND

Several authors have recently proposed the adoption of design models (Garzotto, Mainetti & Paolini, 1995; Isakowitz, Stohr & Balasubramanian, 1995; Schwabe & Rossi, 1995)and design patterns (Rossi, Schwabe & Lyardet, 1999), in order to improve the quality of hypermedia applications, at least for those aspects concerning structure and navigation. Other authors (Conallen, 1999; Schwabe & Rossi, 2000) have proposed the use of object oriented paradigm to model this kind of application, but the navigation structures are more simple. Design models provide, in fact, the primitives that allow structuring the information objects and the corresponding navigation patterns along regular and systematic features, improving consistency, predictability (for the user), robustness of the design, and therefore improving usability. The ancestor of these models can be traced to HDM (Garzotto, Paolini & Schwabe, 1993) and its evolution: W2000 Model (Baresi, Garzotto & Paolini, 2000).

The adoption of W2000 to design the internal structure and the navigational features of hypermedia applications is desirable for three reasons:

- resulting applications are usable;
- the production process can be decomposed into subproblems easy to manage;
- the application model can be "executed" by a suitable "interpreter" to create the application pages in a way that is independent from the specific application.

Furthermore, in several real-life projects we encountered the problem of dealing with application families. An application family is a set of applications sharing (part of) the content and also (part of the) conceptual design. The problem of application families is the typical situation where the application owner, after a successful first application, needs a second one very similar to the first one. At first it seems a simple problem of "reuse" of content: use the same pictures, use the same texts, use the same data, and so forth (Garzotto, Mainetti & Paolini, 1996). After a while it becomes apparent that not only content, but also (pieces of the) conceptual structure must be "reused". Then comes a third "similar" application, and so on. So, the truth emerges: the designer should have started from the beginning having in mind a family of applications, knowing that several specific applications could have resulted from it. In other words the designer should have optimized the activity of "carving out," from a family, a specific application, for a specific need.

Therefore it became clear that the design process, the design model and the design support system should adopt the notion of family of applications. Such kind of activity is made easily using a structured model.

BRIEF DESCRIPTION OF W2000 METHODOLOGY

The methodology was developed by the UWA Consortium (UWA), and specifically by Polytechnic of Milan.

W2000 methodology assumes that it is essential to make a clear distinction between the different aspects of the application that need to be observed during the design phase, in order to make the design itself a structured and easily controllable process, and to obtain clear modeling, suitable for different users and delivery devices.

After the Requirements Analysis phase, guided by a goal-oriented approach, the methodology suggests a sequence of steps that may be briefly summarized as follows:

- Information Design: the goal is to describe the information that the application is going to deal with, giving it a structured organization from the user's point of view.
- Navigation Design: this reconsiders the information and its organization from the viewpoint of its fruition, defining the navigational paths the user can follow.
- Publishing Design: the results of the previous steps must be complemented with considerations on presentation and organized into "pages" and "fruition units".

According to the previous description, a database can store the application components described by the model, and then a run-time engine can extract those components from the database to display it to the reader. This kind of engine, named WAPS, is application independent, so it is really reusable and it may be defined as a W2000 methodology Interpreter. It is the last evolution of a family of navigation engines according to the evolution both of methodology (Bochicchio & Paiano, 2000; Paiano & Pandurino, 2003) and available technology (Bochicchio & Paolini, 1998; Bochicchio, Paiano & Paolini, 1999).

A REUSABLE INTERPRETER

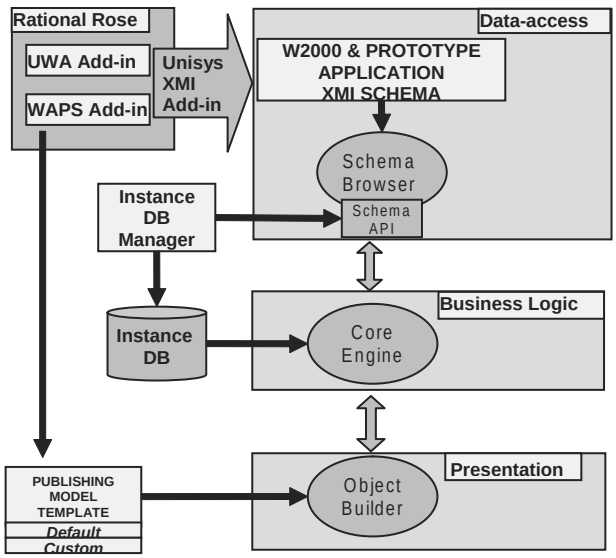
The run-time environment, the WAPS core, has the main task of creating a mock-up application starting from the W2000 model in XMI format.

In accordance with the modular structure of the W2000 methodology and the various aspects of WA, as shown in Figure 1, it is possible to identify a clear n-tier architecture for the WAPS run-time environment. This choice was highly suitable for the W2000 methodology: in order to manage the complexity, each architecture layer manages a single aspect and provides services to the other levels. All the data managed in the modules are in XML format; furthermore, all interaction between modules is in the same format according to the market trend and standard.

It allows the use of transformation parsing techniques like XSL in the visualization and processing phases, also allowing the following of the evolution of methodology.

- Rational Rose Add-in: Rose helps to design the WA in graphic format using standard UML notation, in accordance with W2000 methodology, in order to obtain a "machine readable" description. Another rational rose add-in: "Unisys Rose XML Tools," produced by Unisys, exports the UML diagram into a standard XMI output.
- Schema Browser: This module allows a unique entry point to the WA schema, hiding the complexity in order to manage the XMI in raw mode. The module provides a set of schema APIs (S-API) to navigate through the WA model via W2000 primitives, bypassing the UML MOF used by XMI.
- Core Engine: This module corresponds to the business level for a three-tier application. This module has the task of understanding the requests from the Object Builder, using the S-API of the schema browser to compose the reply schema that will contain the application data taken from the Instance DB. Since this module creates the reply schema, all design customizations take effect at this stage.

Figure 1. WAPS architecture



- Object Builder: This module is the door to WAPS systems: the user request comes in, the prototyped page goes out. The module moves the request to the Core Engine and receives the response in XML-like format. Its main task is to apply a template to make the page visible. WAPS uses the XSLT transformation to obtain HTML or WML pages.
- Instance DB: It is an E-R database that contains the data that will be shown to the user. The E-R schema is derived from the W2000 model; thus the schema is fixed and does not change with the domain of the WA being prototyped.
- Publishing Model Template: It is an E-R database that contains the references to the visualization template to create the page.

FUTURE TRENDS

We are now assisting the revival of MVC (Model View Controller) architecture applied to the Web. There are several frameworks oriented to the prototyping of Web applications, based on the MVC paradigm, but the Model site is not fully specified.

The next step of research in this area is to join the W2000 Model definitions with the Model site of these frameworks.

To achieve this goal, the SET Lab of University of Lecce is developing this kind of interface between W2000 model and Struts framework developed by Apache software Foundation, obtaining very interesting results.

CONCLUSION

The adoption of structured approaches and conceptual models, such as W2000, is an important step in the direction to improve the quality and the reusability of hypermedia applications, reducing at the same time the costs and the time required for their development.

The construction of a reusable engine for hypermedia application, based on the W2000 model, is the logical extension to the model-based approach. The reusable engine, in fact, is able to implement the needed hypermedia software in an application-independent way. The effectiveness of this approach is based on the ability of the model to describe a wide range of complex hypermedia applications.

KEY TERMS

HDM: Hypermedia Design Methodology, developed by Polytechnic of Milan (Italy). It is a methodology to design hypermedia applications.

Interpreter: The traditional definition in computer science is a program that translates and executes source language statements one line at a time. The meaning in this article is: a program that accesses the model to understand the requested navigation one user action at a time.

W2000: A methodology to conceptually design Web applications, developed by Polytechnic of Milan (Italy) in the UWA project.

WAPS: A reusable W2000 interpreter to prototype Web applications.

Web Application: An application that presents the characteristics and the issues of both hypermedia applications and traditional applications. In other words, this kind of application has the navigational issues of Web sites joint to the traditional operation issues.

XMI: XML Metadata Interchange is a widely used interchange format for sharing objects using XML. It is defined by OMG.

XML: EXtensible Markup Language is a mark-up language much like HTML designed to describe data using your own tags. It is a recommendation of W3C Consortium.

This work was previously published in Encyclopedia of Information Science and Technology, edited by M. Khosrow-Pour, pp. 2567-2570, copyright 2005 by Information Science Reference, formerly known as Idea Group Reference (an imprint of IGI Global).

Solutions for Wireless City Networks in Finland

Tommi Inkinen
University of Helsinki, Finland

Jussi S. Jauhiainen
University of Oulu, Finland

INTRODUCTION

Wireless urban networks can be approached from many perspectives. They are commonly studied on the basis of technology development (e.g., Chao, Uden, & Shih, 2005), business and service support (e.g., Friday, Davies, Wallbank, Catterall, & Pink, 2004; Jenisch, Orlamünder, Köstring, & Brügge, 2005), urban marketing and city image promotion (e.g., Dobers, 2004) or societal use of technology (e.g., Graham & Marvin, 1996; Rao & Parikh, 2003; Palm & Wihlborg, 2006).

This article gives a detailed outline of the provision and condition of public wireless local area networks (WLANs) in Finland. The cases of Oulu, Turku and Helsinki ("Arabianranta" residential area) are presented. These cities are relevant study locations because they have actively participated to the creation processes of public city WLANs. They are also using wireless networks as promotion tools in their image marketing. In addition, Finland has been regarded as one of the top "network ready" nations in the world and was ranked fourth in the latest Networked Readiness Index by WEF (2007) after Denmark, Sweden and Singapore.

BACKGROUND

Several relevant studies on wireless networks have been conducted recently (e.g., Harwit, 2005; Salkintzis, Pavlidou, Fitzek, & Varma, 2005; Zhuang, Gan, Loh, & Chua, 2003). For example, Tang and Baker (2002) analysed metropolitan area wireless networks in three locations in the U.S., including the San Francisco Bay Area, Washington D.C. and Seattle. They provided an extensive quantified analysis of network loading, activity and mobility patterns of data signals.

To generalise the work of Tang and Baker (2002), there are variations in 1) technologies, 2) organisational arrangements and 3) usage preferences related to WLANs. There are several "city networks" that could be studied here. First, several technical solutions exist for different purposes. Private radio access networks (RANs) and cellular wide area networks (WANs) are often deployed by public authorities (e.g., emergency units, police, maintenance) for the purpose of sharing and delivering information from their daily field operations. WLANs are the third typical solution structure for providing a higher bandwidth in outdoor conditions. WLANs are based on standardised industry technologies. Three main standards are used to define the communication protocol between the access point and the client. They are all variants of the IEEE 802.11 standard (802.11a, 802.11b and 802.11g). The (a) and (g) standards provide 54 Mbps rates and the (b) standard, 11 Mbps. However, in practice, the rates are considerably lower because of protocol overheads and distance decay between the client and the access device (Cisco, 2006).

A variety of interest groups are needed to realise a WLAN that provides services to the public, such as residents, tourists and business visitors. These include infrastructure providers, Internet service providers (ISPs), hardware providers and clearinghouse operators. In general, provision of a WLAN can be characterised either as a top-down approach in which network operators charge access fees, or as a bottom-up approach in which end-users are offered a free access on a noncommercial basis (Rao & Parikh, 2003). Thus, the main relationships are business-to-customer (B2C), business-to-business (B2B), business-to-government (B2G) and customer-to-government (C2G). Publicly provided noncommercial networks are often partly commercial, because their production and development usually requires outsourced services by collaborating partners. "Wireless city networks" are collections of networks under a same brand and they differ fundamentally from single actor networks (e.g., closed company network).

A second important issue of public and open access WLANs is information security and authentication. Commercial services always require an authentication procedure due to the need to charge for the service. From this viewpoint, noncommercial networks are more challenging because from the end user perspective, they can be either open access or ID-required networks. From the technical viewpoint, all connections have an "authentication" in the machine-to-machine interaction (requiring an IP address), but end user information is not included in open access networks.

Public organisations can provide two main elements for end-users: 1) the network access signal and 2) the access device. All other components and their provision are based on B2B or B2C arrangements. However, this is a generalised and spatially noncontextualised description of a WLAN provision. The issue becomes more complex when location-related specifics are included. For example, the physical attributes of the WLAN environment are important, because architecture (building heights and materials) and surface topology influence connection quality and speed.

The third, and perhaps the most problematic, field of WLAN analysis is human-to-computer interaction (see Davies, Cheverst, Friday, & Mitchell, 2002; Dawley & Anthony, 2003; Inkinen, 2006). This refers to user preferences, needs, contents and services of the Internet used via the WLAN connections. These include issues of P2P networking and distribution of copyrighted materials. Misuse of information networks is an identified problem of open access networks. Therefore, in most cases noncommercial freely accessible networks have an authentication system to prevent unwanted network behaviour. This implicates issues of network security and related protocols, for example, Wired Equivalency Privacy (WEP) that encrypts transmitted data. Also other security mechanisms, such as end-to-end encryption and virtual private networks (VPN) are tools that increase mobile workstation privacy and security.

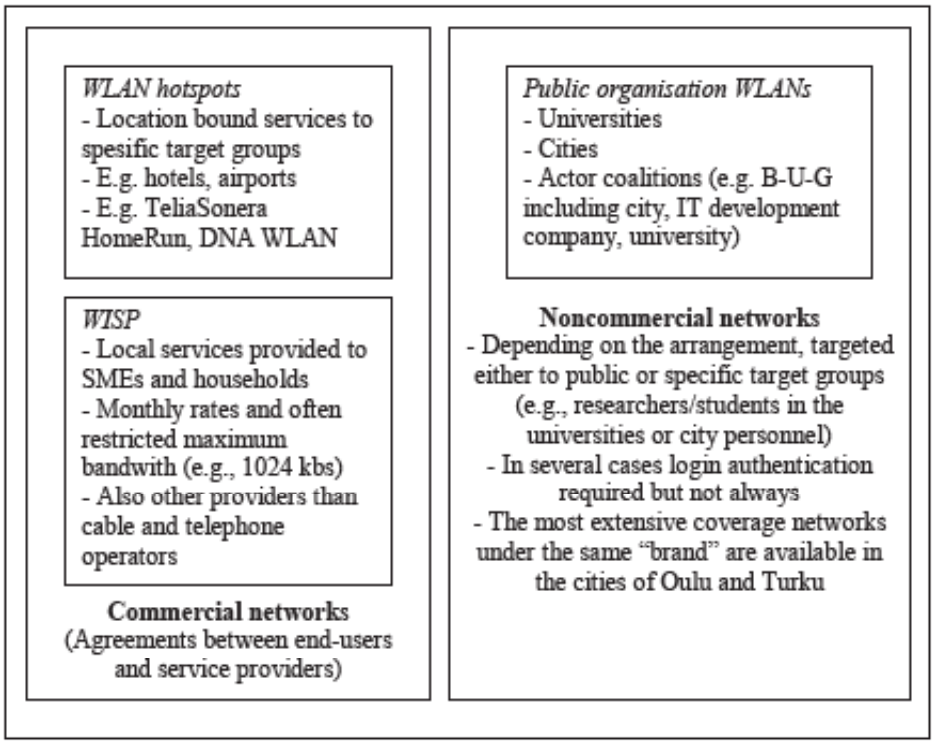
WIRELESS NETWORKS IN FINLAND

General Overview

Finnish public WLANs can be divided into three categories. First, there are commercial services provided by telephony operators, such as TeliaSonera (HomeRun) and Finnet Group (DNA WLAN). These services are provided on a "hot spot" principle, referring to spatially limited locations within a city space. Commercial hot spots are commonly located in hotels, airports, shopping malls, conference centres, restaurants and other gathering places in which the customer segment is expected to need wireless data transfer. These services have a charge, and depending on the tariff system, access can be obtained for minutes to weeks. Hot spot WLANs are targeted to professionals and they mainly serve the needs of business.

Second, there are WISP (Wireless Internet Service Provider) connections providing Internet access. These services

Figure 1. A characterisation of the public WLAN service provision in Finland



are provided mainly by local actors, in Finland commonly by electricity companies, telephone operators or cable-television operators. The target of these services is households and small companies. Compared to "hot spot" networks, WISP connections are less expensive for the end user.

Third, there are noncommercial WLANs providing Internet access in specific city locations. We use the term "city networks" mainly to refer to these noncommercial public WLANs provided or arranged by public sector. The extent of their network coverage varies, depending on the service provision arrangement. Commonly, noncommercial networks in Finland are developed and maintained by units of higher education, such as universities, or by public sector coalitions, including municipal organisations in cooperation with universities and local businesses. The triad cooperation between businesses, universities and government organisations is also called B-U-G cooperation (see terms and definitions). Generalised description of the available WLAN options is presented in the Figure 1.

In addition, it is possible to identify value-added WLAN services. They are private networks, but their provision is a complementary service (side product). Free-of-charge WLAN services in cafés, restaurants and hotels are examples of private noncommercial networks. In general, their provision is based on the consumption of another product (such as a beverage) in a location in which the WLAN service exists, and the role of the WLAN is to be a complimentary service for the customer. Moreover, these networks are commonly based on WISPs, so they can be regarded as realisations of the second category.

There are several solutions to building a cooperative network. Public noncommercial networks are implemented in the cities of Turku (Sparknet), Oulu (PanOulu) and Lappeenranta (WLPR). Sparknet and PanOulu cover the central areas of the respective cities, whereas WLPR is located at the university campus area outside the centre of Lappeenranta. Location-bound projects have also been implemented in Helsinki (e.g., Arabianranta WLAN) and Lahti (e.g., Wireless Lahti). In all cases, university institutions have a key role in the development and implementation of the networks. These networks are commonly segmented to certain user groups, requiring registration (authentication), which in most cases is based on the university network's user IDs. However, there are also exceptions in which authentication is not needed, as in the case of Oulu's RotuaariWLAN, which is a joint network within PanOulu.

A Closer Look: The Sparknet, PanOulu and Arabianranta networks

In the following, we focus on the cooperation arrangements of the noncommercial WLAN solutions in three case locations. PanOulu and Sparknet are actually "collections" of organisational networks and Arabianranta has a specifically built project solution. Thus, in several cases the noncommercial WLANs are themselves networks of networks consisting of various interest groups (see the background section and Figure 1). To combine these existing networks, cooperation is always required; there are business and social arrangements behind the pure technical interoperability. Outdoor WLAN provision in a city space is a multidimensional task that commonly requires efforts from several interest groups.

PanOulu is an open access network resulting from collaboration between the University of Oulu, the Oulu University of Applied Sciences, the City of Oulu and Oulu Telecom. The cooperation agreement was signed in October 2003. This shows that cooperation-based city WLANs are relatively new phenomena. Technically, PanOulu is a joint network including components from all the mentioned partner organisations. The available networks are "KampusWLAN," covering the university campus area and managed by the university; "OuluNet," which covers the area of the University of Applied Sciences; "OuKaWLAN," the network of the City of Oulu covering the city hall, the central library as well as cultural and science centres; and "RotuaariWLAN," an open-door network built cooperatively by university research teams and Oulu Telecom. The latter is an open access network without an authentication procedure (for details, see www.panoulu.net).

Sparknet is a collaboration network managed by ICT Turku Ltd, a local development company owned by the City of Turku in southwest Finland. Thus, the city's role is channelled through a nonprofit development company. The Spark WLAN was originally created by the University of Turku and MP-MasterPlanet Ltd. The City of Turku joined the consortium shortly after its launch in June, 2003. Thus, the city WLANs in Oulu and Turku were originated during the same time with different organisational structure. Currently, Sparknet is the largest and most widespread wireless network solution in Finland. Sparknet is used in both private and public sector organisations (for details, see www.sparknet.fi/en).

Sparknet is divided into two separate networks. The actual Sparknet brand is targeted to organisations, and "Openspark" is a community network mainly for individuals. Interestingly, Sparknet is based on a joint agreement to use the existing network infrastructures within the city. All Sparknet services require authentication. Business-targeted network services have a charge. Individuals are also able to register with Sparknet. Thus, for the "outsider," the Sparknet concept is similar to a commercial hot spot, but it allows substantially broader spatial coverage. The main operating principle is to provide extensive coverage for businesses with low investment costs.

The *Arabianranta network* is a spatially bound WLAN in the Arabianranta residential area (i.e., a local neighbourhood area network, NAN) in Helsinki, the capital of Finland. The Arabianranta WLAN project is mainly a publicly-funded

project operated by a private company. Thus, the Arabianranta network is a public-private partnership that supports attractiveness and economy in a particular location within the city space. The main target group comprises SMEs differentiating it from the resident-focused PanOulu.

Technically, two key elements are identified in the Arabianranta project: the WLAN and the "Helsinki Virtual Village" portal project. The project Web site states: "The fastest and most modern aerial network in Finland is located in Arabianranta. The speed of data transfer in the backbone network is as high as 1 Gbps" (Helsinki Virtual Village, 2006). The project has been implemented by Art and Design City Helsinki Ltd (ADC Ltd) in cooperation with the City of Helsinki and other local stakeholders. Helsinki Virtual Village portal is targeted to small and medium-size enterprises located on the area. The main user segment consists of various fields of business: design companies, media companies and support services for culture and travel. However, users must register themselves as individuals, not as organisations even though the individuals in the most cases represent organisations.

Discussion of WLAN Provision

There are similarities and differences in the urban WLAN solutions in Finland. First, the solutions vary in their provisional structure. All the described cases are joint actions, but the providers vary and actual service provision is mainly deployed by local businesses. Therefore, business-university-government cooperation and a combination of innovative actors within a city are essential in the creation of new services.

Because of their tight organisational relations, proximity and lower hierarchy, medium-sized cities normally have a better starting point for creating public noncommercial WLANs. Bureaucracy and hierarchical structures require unifying of administrative structures in the organisations of larger cities. The cases of Turku and Oulu show that both cities aim to provide an extensive "single service" WLAN in their central areas. Helsinki and its adjacent cities of Espoo and Vantaa have left WLAN provision to the markets and residential area driven development actions, such as Arabianranta.

Second, the target groups vary between cases. PanOulu is clearly targeted to inhabitants. It promotes the city's image of technological advance and openness, whereas the Arabianranta project is a business venture. Sparknet (including Openspark) has divided service provisions among the public and private segments through a separated arrangement. Marketing and "customer" identification are essential in public WLANs (see Davies et al., 2002). Also important are user and community involvement in the creation of the network. Creation of the information infrastructure is connected to the general definition of "information." Is it commodity priced or is it a public good, equally available to everyone?

Third, universities have an active role in WLAN provision in Finland. In the case of public noncommercial networks, universities have been the most important actors in the development of outdoor WLANs. All the universities in Finland are public nonprofit organisations, meaning that they have to gain something other than financial profit from WLAN cooperation. In addition, the absence of universities creates difficulties in providing low-cost WLANs in many cities. Voluntary-based nonprofit WLAN provisions may challenge the long-term robustness of the technology used (also Rao & Parikh, 2003).

One additional issue concerns the public-private operations and the use of public open space as a medium for information retrieval from the Internet. Creation of the information infrastructure, such as WLANs, is connected to the development of national, regional and local information societies (see Inkinen & Jauhiainen, 2006; Webster, 2002). Here, issues such as social division, digital divide and knowledge creation become relevant. They also include the legality of actions. For example, if public organisations take a strong position to promote open access WLANs, they must also consider security: if the infrastructure is misused due to poor information security, what are the responsibilities of the provider?

Last, but not least, is consideration of the spatial coverage of WLANs. This is becoming increasingly important because in the near future many people expect open access or payable WLANs to be available within cities. Various city organisations (tourist offices, business development, public relations) use a WLAN to attract "desired" individuals and businesses to the vicinity of the city. Areas of the city not covered by a WLAN may be seen as marginal or undeveloped urban space. Therefore, urban WLANs relate to urban segregation and differentiation resulting from economic and political relations and decision-making.

FUTURE TRENDS

Studied provision patterns in Finnish cities show that there are various ways to organise a noncommercial WLAN for wide user segments. Noncommercial WLAN service is commonly implemented as a cooperative effort by an organisation and the university and city authorities. The cases of Turku, Oulu and Arabianranta (Helsinki) show that public WLAN service provision includes the central issue of recognising the main service user groups. In addition, the expansion of WLAN coverage and service provision is increasing. This implies that technical proficiency has to be analysed jointly with business and customer segmenting; otherwise network expansion and long-term operability will suffer. Information security also continues to gain increasing attention. Database combining, user and consumer data and marketing have implications for privacy. There are unclear issues related to

composition and the pay-out logic of WLAN service provision. It will be interesting to see whether or not the business model, for example, the case of Sparknet, gains popularity elsewhere. Will one of the current models break through as the best practice for everyone?

There are several future challenges regarding the development and research of city WLANs. First, the development of technical solutions for new protocols and services continues to be an essential topic of engineering sciences. Especially, the emerging 4th generation mobile networks will challenge the short coverage of WLANs. Second, the economic questions of WLANs are gaining more attention by the research community. In particular, the practices and interconnections of cooperative networks need research on decision-making and management. Third, user-driven analysis of WLANs and the Internet is important. Individuals' and businesses' needs for services are relevant study topics for basic and applied research. Finally, the emergence of WLANs in public transportation systems such as trains and busses provides a field of further study of new business solutions taking advantage of wireless communication technologies.

CONCLUSION

This article provided an insight into local WLAN developments in Finland, technologically one of the most advanced countries. The following remarks concerning best practices, bottlenecks and challenges should be considered in similar efforts elsewhere:

- Recognition of the context: successful implementation of technology often requires knowledge of the target segment (consumers, organisations or locations and their particular technology solutions).
- Provision of free or low-charge WLAN solutions greatly depends on joint cooperation models between local organisations. The cases of Turku, Oulu and Arabianranta (Helsinki) are good examples of cooperative networking practices that combine the efforts of universities, city administrations and supportive private sector businesses.
- Selection of the technology employed should take into account the standardisation level of the technology. In several cases (e.g., public smart card traffic fare system in Helsinki), the selected technology does not comply with international standards, increasing the dependence of the whole structure on a single provider. This causes extensive losses if another provider must later reinstall large-scale systems.

Among the greatest challenges in the development of the information society and its technological solutions is interoperability. As discussed, it is not only about hardware-to-hardware, software-to-hardware or software-to-software interoperability, but also, and perhaps even more importantly, a question of human-to-human interaction and cooperative institutional arrangements. Target group identification is one practical example in the studied cases. Urban WLAN networks targeted to the masses (including all inhabitants) are likely to be more successful if their provision is based on wide cooperation between the stakeholders.

KEY TERMS

B-U-G Cooperation: An organisational cooperation model that includes partners from business, university and government. B-U-G co-operation is commonly locally based aiming to foster local development.

Public E-Service: A service available in digital form. Public e-services include all services provided by the public actor. These include Internet-based service solutions, other network-based solutions (also restricted), smart card solutions and other digitalised authentication methods targeted to users. Public e-services are provided by authorities of different spatial scales, including local actors (e.g., city organisations), regional actors (counties and districts), national and international actors (see Inkinen & Jauhiainen, 2006).

Public Noncommercial Wireless Network: A wireless network not based on market economy profit-making. Public organisations providing a wireless Internet connection without a charge or payment are noncommercial WLANs.

Public-Private Partnership: A joint agreement between public organisation and private business resulting into a product, service or development venture that is funded and operated through a cooperation of participating partners.

Wireless City Network: A location-bound WLAN provided by a public or a commercial organisation. Generally, a wireless city network can be used by anyone. The connection can be made with or without identification process by anyone located in the specified area. A city network can also be locally targeted inside the city to a certain location or it can be a full-coverage network.

Wireless Internet Service Provider (WISP): An actor providing wireless connection service to households and organisations. The WISP service customer (subscriber) gains access to network services within the vicinity of the server transmission range. These locations are called "hot spots" or "access points." WISPs provide basic service sets (BSS) and extended service sets (ESS) that are defined in the IEEE 802.11b specification.

Wireless Service End-User: A person or an organisation using the provided wireless Internet connection with a user interface that is commonly a lap-top computer, palm-top device such as a smart phone or other portable device.

Spatial Data Infrastructures

Clodoveu Augusto Davis, Jr.
Pontifical Catholic University of Minas Gerais, Brazil

INTRODUCTION

Spatial Data Infrastructures (SDI), also known as Spatial Information Infrastructures (SII), are a set of policies, technologies and standards that interconnect a community of spatial information users and related support activities for production and management of geographic information (Phillips, Williamson, & Ezigbalike, 1999). SDI reduces redundant effort and lowers production costs for new and existent datasets through interoperable information sharing, providing neutral means to access geographic data. Multiple information providers, commercial or public, may cover various interests and compete among themselves for clients.

SDIs present several challenges, at various levels of interaction. First, there is a societal and organizational level. Partners in a community should have convergent interests, agree on common rules, and be able to use information produced by others. Such agreements are not easy to achieve, and usually require long-term commitments. Within public organizations, it is usual to think in transnational terms, between national mapping agencies, but intranational relationships are also important.

Second, there are standardization issues. Guiding the technology standardization and defining the key elements for SDI, the Open Geospatial Consortium (OGC) has proposed a number of standards, through a framework called *OGC Reference Model* (Percivall, 2003).

Third, there are concerns on specific aspects of geographic information, such as scale (levels of detail, accuracy, uncertainty) and the need to integrate data from various sources. Geographic information from each source needs to be consolidated in order to be valuable to high-level decision-makers. In this case, SDI can be seen as a set of building blocks, in which hierarchies are built through the exchange and consolidation of information from corporate and local levels, to regional and global levels. In this hierarchy, lower levels (Davis & Alves, 2005) provide detailed information that helps to consolidate the upper, more general, levels (Rajabifard & Williamson, 2001). The integration problem also requires attention to semantics, because data produced by different organizations, for different needs, are not necessarily compatible, even if they refer to the same location or to the same real-world subject. In this particular issue, the development and use of ontologies may be required.

Finally, there is a technological level. The exchange of information can occur in several ways, but the most interesting one is the use of Web services, using a service-based architecture approach, thus achieving *loosely-coupled and distributed geographic information systems* (Bernard & Craglia, 2005; Davis & Alves, 2005). There are pending issues related to the compatibility between Web service standards defined by the OGC and by the World Wide Web Consortium (W3C), but there are already initiatives to bridge them (Bacharach, 2007; Kim, Kim, Lee, & Joo, 2005). There is also the need to define and propose higher-level services, so SDI can go beyond the simple discovery and download of geographic data, and provide solutions to location-related problems using multiple and distributed sources of information.

BACKGROUND

Creating geographic datasets is a complex and expensive undertaking. In the past, redundant efforts in dataset creation were commonplace: organizations with an interest in the same areas, therefore potential partners for sharing basic data, would not cooperate due to their diverse technological strategies, budgeting, and timing. Of course, such redundancy was undesirable, motivating the creation of cooperation efforts for data sharing.

An example of such an arrangement took place in Belo Horizonte, Brazil. A cooperation agreement, involving 29 different organizations, including government agencies, universities, and private-sector companies, has been active since 1994 (Davis & Fonseca, 2005). Even though political and organizational problems have been solved in this case, technologically there is still a lot to be done. Data for interchange reside in a FTP server, for download by authorized people in one of five different data formats. There is also a metadata sheet for each information class, presented as a simple and nonstandardized text file. Simple as it may seem, maintaining such a setting requires much effort by those who coordinate data gathering and distribution, because much work is performed manually or with little automation. Constant and efficient interpersonal communication is required, so that one organization's needs on some data can be informed to the organizations that generate that data. Thus, cooperative settings are a great improvement on the early approach to sharing, but their scalability potential is rather limited.

Data Transfer Standards

Large-scale off-line data sharing depends fundamentally on data translation, because each organization can use a different geographic information system (GIS). Many efforts in the past have tried to establish a neutral file format for exchange purposes, so that every GIS would only need translators to and from this common format (Lima, Câmara, & Monteiro, 2001).

In practice, commercial formats are used in most data transfer situations, reflecting the influence of the user community of a given GIS package. Regardless of using *de facto* or *de jure* standards, this approach addresses syntactic concerns only, avoiding semantic issues. Furthermore, data transfer formats are unsuitable for online access, maintaining the need for an export-import off-line cycle. Off-line sharing causes multiple copies of the same data to be distributed among interested parties at different times, causing serious synchronization problems.

Spatial Data Clearinghouses

From the establishment of a standard (or, at least, from some *de facto* standards), many national mapping agencies started to create *spatial data clearinghouses*, Internet-based settings that intend to facilitate access to spatial data. A centralized site, from which data from several sources can be found, is established, including services for searching, viewing, transferring, and ordering spatial data (Crompvoets, Bregt, Rajabifard, & Williamson, 2004). Clearinghouses allow data providers to make their offerings known by users, with descriptions (metadata) and instructions on how to access and use the data.

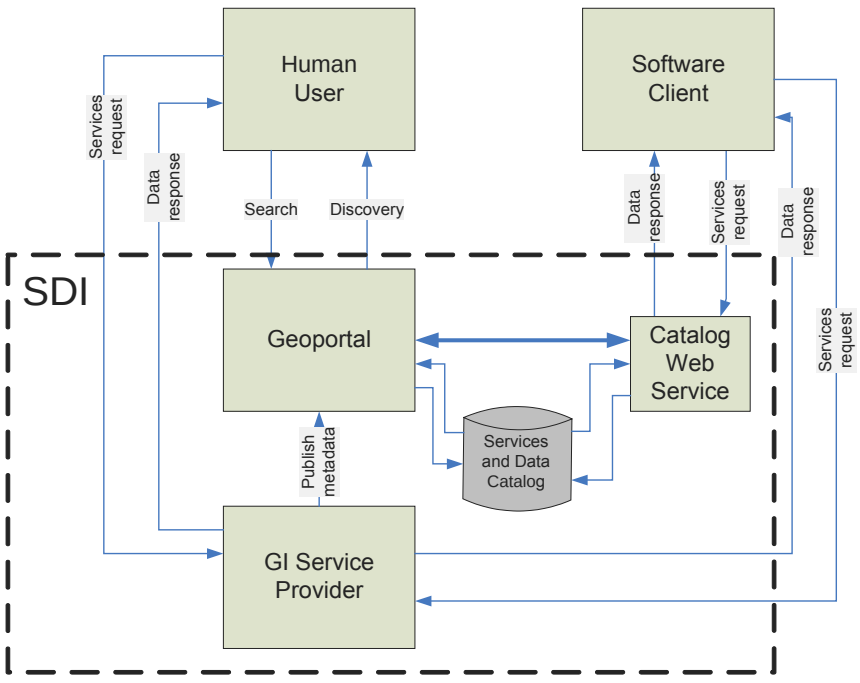
Clearinghouses have been more recently described as a kind of Web portal, that is, a site or a gateway through which commonly used services are offered (INSPIRE, 2002). The emphasis on services is recent, compared to previous implementations, which were mostly based on a combination of technical tools, institutional cooperation mechanisms, and commercial concerns, directed at "off-the-shelf" data dissemination (FGDC, 1997).

A recent study on clearinghouses (Crompvoets et al., 2004) showed that users are dissatisfied with their functionality, indicating that the focus should change from a data-oriented to a user- and application-oriented view. This can be achieved by using service-based architectures.

Early Spatial Data Infrastructures

The expression "spatial data infrastructure" was initially used to describe the provision of standardized access to geographic information (Maguire & Longley, 2005). Many clearinghouse initiatives evolved to what Masser (1999) calls "the first generation of national spatial data infrastructures," while observing that "infrastructure" implies the existence of some sort of coordination for policy formulation and implementa-

Figure 1. Geoportals and SDI



tion. This first generation of SDI focused on granting a broad thematic scope, which is consistent with the current analogy between SDI and other types of infrastructure: fostering economic development by granting access to publicly-available and multiple-use goods or services. By "publicly-available," we do not mean "government-supported." Even though SDIs are seen as drivers of economic development, some of the initiatives reviewed by Masser (1999) do not grant access to the private sector, or do so by charging an usage fee, as a means to recover some or all their costs.

Evolution from the first generation of SDI was made possible by the recent expansion of Web-based information systems. In the USA, the Geospatial One-Stop (GOS) Web portal was created to provide widespread access to geographic information[a], inaugurating the concept of *geoportals* (Maguire & Longley, 2005; Tait, 2005).

GeoPortals

The term "portal" has been widely used with the general meaning of an "entry point" for information and services available on the Web. Applying this concept to geoinformation, a geoportal is, therefore, a "Web site that presents an entry point to geographic content on the Web" (Tait, 2005). A geoportal includes the discovery of information sources and content, and online access to applications. Examples of geoportals include the previously mentioned Geospatial One-Stop from the USA, and the EU-Geoportal, a part of the INfrastructure for SPatial Information in Europe (INSPIRE) project (INSPIRE, 2002)[b].

It is important to distinguish between the concepts of SDI and geoportal. We consider that an SDI is formed by the confluence of (potentially) several geographic data providers, each of which grants data access through specific Web services. In order to select services to fulfill his needs, the user searches through a repository of metadata on available geographic data and services. In the case of a human user, searches are done interactively, through a geoportal, using search interfaces and other interactive tools; in the case of a software client, this can be done through a catalog Web service. Thus, we consider that a geoportal is a component of an SDI (Figure 1).

The use of Web services to grant direct access to data is the most important distinction between first- and second-generation SDIs. In fact, the numerous possibilities that arise from using services to encapsulate data from multiple sources, and thereby achieve interoperability, have led Bernard and Craglia (2005) to propose a new translation for the SDI acronym: *Service-driven Infrastructures*.

SPATIAL DATA INFRASTRUCTURES AND SERVICE-ORIENTED ARCHITECTURES

The most current view on spatial information infrastructures considers their insertion into the perspective of *service-based distributed system architectures*, which have been proposed as part of a strategy for developing complex information systems based on reusable components. One of the most interesting approaches in this field is the one of *service-oriented architectures* (SOA) (Papazoglou & Georgakopoulos, 2003).

Services, their descriptions and fundamental operations, such as *discovery*, *selection*, and *binding*, form the basis of SOA. SOA supports large applications with sharing of data and processing capacity, through network-based distributed allocation of applications and use of computational resources. In this architecture, services are self-contained, which means that information on the service's description, including its capabilities, interface, behavior, and quality, can be obtained from the service itself, through a standardized set of functions.

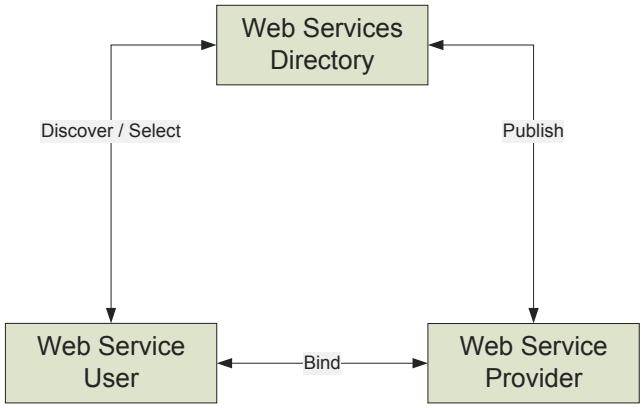
Service providers, service aggregators and service users are the actors that participate in this scenario. Providers implement and publish services, while aggregators design compositions of rules based on primary services. Available services should be listed in directories for user reference, or "discovery." Service users may be human or software clients, which need to access the services through the communications network.

Web Services

Web services are a particular class of services that use open Internet standards, such as connection and communication using the Hypertext Transfer Protocol (HTTP), identification using the Uniform Resource Identifier (URI), contents specification through the eXtensible Markup Language (XML), service descriptions expressed by the Web Services Definition Language (WSDL), and directory services using the Universal Description, Discovery and Integration (UDDI) protocol (W3C, 2002). Therefore, while services in general provide interoperability between different software components, Web services go a step further by facilitating cross-institutional interchange of data and services over the Internet, and by improving resources sharing among various data sources.

The main Web service operations are *publication*, *discovery*, *selection*, *binding*, and service *composition*.

Figure 2. Web service operations



Publication is performed by a service provider, and consists in creating a service description in WSDL and publishing it on Web-based discovery channels. These channels use the UDDI protocol to register the service, storing data that allow users to *discover* it. Users can then *select* services using UDDI to search through catalogs or directories, getting sets of URIs in response. Once the service descriptor is obtained (in WSDL) for the *binding* operation, client software initiates a direct communication with the service provider using HTTP, sending a request. The binding ends with the reception of the expected Web service response in XML (Figure 2). Finally, more complex services can be created by the *composition* (or *chaining*) of primary ones. In this case, service users access the composite services in the same way as simple services, but different results are possible. Thus, several alternatives in terms of service performance, costs and quality become feasible through the appropriate configuration of Web service chains.

OGC Web Services

The Open Geospatial Consortium (OGC) proposed the *OpenGIS Services Framework* (Percivall, 2003), an architecture for sharing of geographic data and functionality over the Internet, thus leading the standardization process on data formats, methods and interface specifications. The OpenGIS Services Framework does not necessarily employ the usual (W3C) Web services standards, such as the Simple Object Access Protocol (SOAP) and WSDL. Instead of using UDDI, the OGC proposes the use of catalog services for the implementation of the publication, discovery and selection operations. Moreover, OGC Web services have a particular interface for binding, which does not use service descriptors. This alternative poses difficulties for indexing and searching. OGC Web services use Geographic Markup Language (GML) to encode and transmit objects, while regular Web services use generic XML, but this is not actually a difference, because GML is based on XML. We observe that the main differences that exist between W3C and OGC Web services should be solved as soon as possible, in order to incentive the adoption of the proposed standards in a more universal way (Davis & Fonseca, 2005; Sonnet, 2004).

Some basic Web services were specified by OGC, as listed below:

- **Web Feature Service:** provides an interface for the insertion, selection, updating and removal of geographic features (objects).
- **Web Coverage Service:** provides access to geo-fields, much in the same manner of the Web Feature Service. Notice that this service does not return images of the geo-fields, but rather returns semantic details on them.
- **Web Gazetteer Service:** extends the Web Feature Service with resources for the implementation of interfaces to gazetteers.
- **Web Registry Service and OpenGIS Catalog Service (OCS):** implement an operational functionality similar to UDDI.
- **Web Coordinate Transformation Service:** provides an algorithm that converts coordinates for spatial objects between different spatial reference systems.
- **Web Map Service:** a service for the production of maps over the Web, or Web Maps. Maps, in this service, are renderings (presentations) of the reality, and do not include the actual geographic data.
- **Web Terrain Service:** similar to the Web Map Service, but geared toward three-dimensional renderings of surfaces.

OGC Web services may also be combined. A special OGC Web service, the Web Notification Service, can be used to send update notifications to registered clients that participate on a chain in which some Web service is to be altered. The

OpenGIS Services Framework shows the degree of commitment of the OGC with service-oriented architectures for interoperability purposes, which historically represent the core of OGC's purposes.

Such an open and flexible architecture will find its main uses in situations very similar to the ones presented in the discussion on SDI. Summing up our previous arguments, SDI must be distributed, must support multiple applications, multiple clients of several different types, multiple data sources, multiple data maintenance teams, under a heterogeneous computational environment. SDI must not force the adoption of specific products on their participants, but should instead provide an architectural view and determine a set of minimal standards. These standards should be as widely accepted as possible, and typical Internet standards as the ones we mentioned fill that description closely.

FUTURE TRENDS

It seems to be clear that the integration of the service approaches by the W3C and the OGC is desired by both groups and that could have a positive impact on future SDI initiatives. The differences only exist because the OGC, from its pioneering work on geoinformation integration, has conceived and implemented the concept of Web services even before the W3C, as the Web standards organization, reached that stage. This is a sign that information integration and interoperability problems that are being researched today have first arisen as significant concerns in the geoinformatics community.

Considering the tendency toward unification of the standards, SDI represents a new set of technologies that are central to a new generation of geographically distributed applications. SDIs are also a first step toward information availability through ubiquitous networking infrastructures.

CONCLUSION

A look at the OGC proposed Web services shows that most are concerned with data access, not with supplying problem-solving information. We consider that SDIs will benefit from the proposal of new services, in which actual information generation can be achieved. SDI, in the future, should deal with queries that are vague, if compared to what can be done using today's database query languages, and respond with information gathered from various distributed sources.

There is also potential for enabling the geographic information user as a "server" of various kinds of information. Information perceived directly by the user (Alves & Davis, 2007; Goodchild, 2007), along with previously collected data, perceived quality of information, ontologies about its interests, geographic position, and others, can be communicated to other users through services. However, additional studies concerning security and privacy in such applications are required.

ACKNOWLEDGMENT

The author wishes to acknowledge the support of his work receives from CNPq and FAPEMIG, Brazilian agencies in charge of fostering research and developement.

KEY TERMS

Geographic Information System (GIS): Information systems used to store, analyze, and manipulate geographic data, that is, data that represent objects or phenomena for which the geographic location is an important characteristic.

Geoportal: A Web site that presents an entry point to geographic content on the Web, used to discover and access geographic information and associated services on the Web.

GML: The Geography Markup Language is a XML grammar defined by the Open Geospatial Consortium (OGC) to adequately express and transfer, in a neutral way, the encoding of geographic features. Its purpose is to foster the integration of geographic data sources.

Service-Oriented Architectures (SOA): Information system architectures in which services encapsulate the exchange of data among modules, which can reside in different points throughout a computer network.

Spatial Data Clearinghouse: Internet-based components that intend to facilitate access to spatial data, by establishing a centralized site from which data from several sources can be found, and by providing complementary services, including searching, viewing, transferring, and ordering spatial data.

Web Services: Software applications from which interfaces and bindings are expressed in XML and that can be discovered using XML messages. In the W3C definition, Web services are "a software system designed to support interoperable machine-to-machine interaction over a network."

XML: The eXtensible Markup Language is a markup language developed to facilitate the sharing of structured data across different information systems.

INTRODUCTION

It is well known that documents available on the Web are extremely heterogeneous in several aspects, such as the use of various idioms, different formats to represent the contents, besides other external factors like source reputation, refresh frequency, and so forth (Page & Brin, 1998). Altogether, these factors increase the complexity of Web information retrieval systems.

Superficially, traditional search engines available on the Web nowadays consist of retrieving documents that contain keywords informed by users. Nevertheless, among the variety of search possibilities, it is evident that the user needs a process that involves more sophisticated analysis; for example, temporal or spatial contextualization might be considered. In these keyword-based search engines, for instance, a Web page containing the phrase "…due to the company arrival in London, a thousand java programming jobs will be open…" would not be found if the submitted search was "jobs programming England," unless the word "England" appeared in another phrase of the page. The explanation to this fact is that the term "London" is treated merely like another word, instead of regarding its geographical position. In a spatial search engine, the expected behavior would be to return the page described in the previous example, since the system shall have information indicating that the term "London" refers to a city located in a country referred to by the term "England." This result could only be feasible in a traditional search engine if the user repeatedly submitted searches for all possible England sub-regions (e.g., cities). In accordance with the example, it is reasonable that for several user searches, the most interesting results are those related to certain geographical regions. A variety of features extraction and automatic document classification techniques have been proposed, however, acquiring Web-page geographical features involves some peculiar complexities, such as ambiguity (e.g., many places with the same name, various names for a single place, things with place names, etc.). Moreover, a Web page can refer to a place that contains or is contained by the one informed in the user query, which implies knowing the different region topologies used by the system.

Many features related to geographical context can be added to the process of elaborating relevance ranking for returned documents. For example, a document can be more relevant than another one if its content refers to a place closer to the user location. Nonetheless, in spatial search engines, there are more complex issues to be considered because of the spatial dimension concerning on ranking elaboration. Jones, Alani, and Tudhope (2001) propose a combination of Euclidian distance between place centroids with hierarchical distances in order to generate a hybrid spatial distance that may be used in the relevance ranking elaboration of returned documents. Further important issues are the indexing mechanisms and query processing. In general, these solutions try to combine well-known textual indexing techniques (e.g., inverted files) with spatial indexing mechanisms. On the subject of user interface, spatial search engines are more complex, because users need to choose regions of interest, as well as possible spatial relationships, in addition to keywords. To visualize the results, it is pleasant to use digital map resources besides textual information.

BACKGROUND

Numerous contributions have been made in the information retrieval (IR) area since 1960's decade. Nevertheless, due to Web continuous growth, research in this field is still in infancy.

Baeza and Ribeiro (1999) say that IR brings some challenges, such as how to determine the real user needs, as well as supply their expectations through relevant document subsets. In IR systems, it is necessary to analyze both semantics and syntax of document contents, which may return imprecise results. According to Kowalsky (1997), the aim of an IR system is to minimize the overhead of finding the expected information. Classical IR models consider that a document is described by a set of indexed terms. Some of these models

also take into account different terms importance at the same document. This importance is called weight (w), and can be represented by a numeric value. The most well-known classical models are Boolean, probabilistic and vector. The vector one, proposed by Gerard Salton, has a greater acceptance between researchers and is the most utilized in current IR applications.

The Web brings new features and difficulties to the IR process, due to both the heterogeneity of the underlying documents and the approaches used to present them. Studies have demonstrated that a large amount of information disposed on the Internet has some kind of geographical context. For instance, the locale where the information was created, the referenced information locale, the place where most information consumers live, and so forth. However, traditional search engines do not consider this spatial context in their information organization and retrieval process.

The requirement for efficient information supported by the knowledge about a specific domain raised the concern on developing ontologies that model many associated concepts. Concerning geographical IR, the use of ontologies can be extremely important for geographical features representation of documents. Fu, Jones, and Abdelmoty (2005) suggest the existence of a primary ontological component, place ontology, that provides the terminology and geographical space structure modeling. Such ontology has a fundamental role, for instance, in user query interpretation, relevance ranking elaboration, and metadata extraction.

Surely, the relevance ranking elaboration is one of the main processes in a search engine, since it is directly related to user interest. In traditional systems, the ranking can be produced through a variety of techniques, for example, similarity measures between query and returned documents using the spatial-vector model (Baeza & Ribeiro, 1999). Currently, one of the most accepted methods is the PageRank (Page & Brin, 1999) that uses the Internet link structure to produce its ranking.

Research on spatial search engines is very incipient. It has addressed some information retrieval subareas aiming to develop efficient data structures and algorithms for space-textual indexing; to elaborate efficient approaches for relevance ranking using the geographic context; and to detect and model the geographic scope.

There are different approaches to extract geographic information from Web-crawled documents. Buyukkokten, Cho, Molina, Gravano, and Shivakumar (1999) associate domain name IP addresses to telephone code area, and by using postal code of the Web site, they enable to match place names to geographic coordinates. McCurley (2001) introduced the geocoding concept, which enables one to associate geographic coordinates to Web pages. McCurley also has used several terms that are useful to geocode a Web page, for instance, postal code, city names, and telephone numbers. Nonetheless, there is no discussion on techniques to extract and eliminate ambiguity. Gravano (Gravano, Hatzivassiloglou, & Lichtenstein, 2003) has implemented automatic geocoding.

More recently, some research projects have presented relevant results in this field, as, for example, the GeoTumba one (Chaves, Silva, & Martins, 2005). GeoTumba contains a repository based on a domain-independent metamodel to integrate geographical knowledge collected from several sources. Silva, Martins, Chaves, Afonso, and Cardoso (2006) focus on techniques for geographical features extraction from large collections of Web documents by using a method that involves the attribution of geographic scope through the GraphRank algorithm, which is inspired in the PageRank one (Page & Brin 1999). Silva et al. (2006) show three sets of heuristics used in the process of georeferencing Web pages.

Another important research project is the SPIRIT (*spatially-aware information retrieval on the Internet*), which focuses on geographic information retrieval and issues involving the semantic Web. This project proposes a multimodal interface that provides text and maps; spatially aware ontologies; query expansion and relevance ranking based on geographic ontologies; spatial indexes for the document collection; and a learning mechanism for extracting geographic context from Web documents that generates spatial metadata. An overview of this project can be found in Jones, Abdelmoty, Finch, Fu, and Vaid, 2004), which addresses the architecture, indexing mechanisms, and spatial ontologies.

Markowetz, Chen, Suel, Long, and Seeger (2005) use the geocoding concept divided into three steps: *geoextraction*, *geomatching and ge propagation*. Their work is inspired in Buyukkokten et al. (1999), and Ding, Gravano, and Shivakumar (2000). Markowetz, Brinkhoff, and Seeger (2004) propose a relevance ranking that may balance between text and spatial ranking.

TOWARD A SPATIAL SEARCH ENGINE

This section presents the GeoSEn, geographic search engine, project that has been developed in our laboratory, which may be accessed at http://www.lsi.dsc.ufcg.edu.br/geosen. GeoSEn is a Web spatial information retrieval system that uses geographical scope detection mechanisms (set of places that Web element contents can be associate) to better index Web documents.

Some studies have proposed a Web geographical information retrieval system. The major concern of these prototypes is to detect pages spatial features and represent them, providing documents retrieval according to a relevance ranking, elaborated considering the geographical location of the documents. However, the presented mechanisms for geographical scope detection and relevance ranking elaboration still have limitations and demand for innovative contributions.

Therefore, the main issue to be addressed in this research is to set the geographical scope of Web pages using more complex methods, and developing new techniques that are able to associate more flexible and complete contexts. The main contributions of the GeoSEn approach are:

- **Places associated by different factors:** besides administrative regions (e.g., cities, states), it will be possible to take, as valid places, regions formed by other factors such as weather (e.g., rainy or dried places), socioeconomic (e.g., countries with high level of violence), cultural (e.g., Paris Dakar rally places), and so forth.
- **Distinction between Web-page geographic scope and places of interest:** capability of distinguishing the places that are related to the page content and the places of interest of a particular page (Markowetz et al., 2004).
- **Multimodal interface:** the software interface should provide spatial, temporal, image, and textual interaction.
- **Multimedia information retrieval:** the system will be able to retrieve images and video based on their geographical scopes.
- **Innovative mechanism of Web page geographical scope attribution:** the proposed mechanism is capable of realizing analysis based on heuristics of document-referenced places distribution pattern, statistics about this distribution, many spatial relationships between places and weather, cultural and socioeconomic data. Moreover, well-known geographical references detection methods (Buyukkokten et al., 1999; Ding et al., 2000; Markowetz, Brinkhoff, & Seeger, 2005; Silva et al., 2006), as well as Web page link structure analyis techniques for geographical scope attribution (Buyukkokten et al., 1999; Markowetz et al., 2005) will be improved and used with the innovative methods developed.

After a particular page is captured by a Web crawler, it is parsed to find terms that can be mapped to some place name, for example, cities' names, zip codes, telephones, and so forth. Afterwards, these place names are associated with geographical coordinates, used internally by the system to manipulate the spatial information (e.g., gazetteer). Each identified place is associated to a certain level of trust. References to one or more places can be found in the same page, which allows the system to infer the document's geographical scope, thus, the region that the document is referenced. Hence, the system will take into account a variety of heuristics and specialized algorithms to combine features of discovered terms and different spatial relationship between analyzed regions. A major factor to be considered is the references distribution pattern. For example, suppose that a document has geographical references mapped to Brazilian states like Paraná, Santa Catarina, and Rio Grande do Sul. Thus, it is expected that the document is related to the Brazilian south region, once these three states are located at this region. Similarly, suppose a document that references many states at each of the five Brazilian Regions. It is possible that this document is associated to a national context.

Combined with this distribution pattern, GeoSEn utilizes several statistics to deduce geographical document scope. Still considering Brazil, suppose that two documents have references to 3 and 9 Brazilian swtates, respectively, from a total of 27. It is feasible that the second one is associated to a national context while the other is related to a restricted region. However, these many factors must be combined in order to obtain a more precise result. For instance, it is possible that all nine states referenced by the second document belong to the same region, whereas the first document references three states, where each one is from a different region, changing completely the initial hypothesis.

Regarding algorithms for document's geographical scope modeling, GeoSEn considers the various relationships between referenced places, for example, containment, distance, and adjacent properties. These relationships can be extremely useful, for instance, to detect regions that, even not belonging officially to a territorial division, are known by commercial trends, weather factors, and so forth.

- **URLs and WHOIS analyze:** besides checking the documents to search geographical references, the system analyzes URLs related to these documents and WHOIS (a set of public information that can be queried in a particular Internet domain).
- **External services interoperability:** in order to complement the geographical scope attribution and modeling necessary data involved in analysis, some external services are queried (e.g., gazetteers) via Web services.
- **Implementation issues:** after defining functional and nonfunctional requirements, 9 Web crawlers and 10 Web search engines, all of them open-source, were evaluated in order to choose the most appropriate to be extended with GeoSEn features. The final choice was the Nutch, from Apache Software Foundation. Details of the Nutch architecture can be seen at http://lucene.apache.org/nutch/. The main reasons for this choice were that it has shown great maturity when compared to the others; it is an active project that integrates, in one system, a Web crawler and a Web search engine; and it provides an easy extension mechanism due to its plug-in oriented architecture. Nutch is an extension of Lucene, a framework also from Apache that offers an API for textual indexing and the search system core. Hence, Nutch adds some functionality to Lucence, such as the capacity of retrieving Web pages (crawling) and

analyzing documents (parsing) from different formats. All mentioned software has been developed using the Java technology.

Users submit their queries and visualize the results through WebSearcher that delegates the search requests for GeoSEn and Nutch core. Both use their indices to find documents that satisfy the query, textually, in Nutch's case (Index) and geographically, in GeoSEn's case (GeoIndex). The Geodatabase stores a variety of geographical information essential to the spatial scope modeling and search process. In addition to Geodatabase information, GeoSEn accesses external services through Web services. Nutch offers several extension points, where some were chosen to access GeoSEn core functionalities, via API. Therefore, GeoSEn becomes independent from Nutch architecture, since its business layer is implemented in the core instead of directly in a plug-in. The GeoSEn plug-ins to be developed for Nutch are:

- **GeosenParser**, responsible for detecting geographical terms in the parsing process, the base for documents geographical scope analysis process;
- **GeosenOntology**, provides geographical semantics in the information retrieval process;
- **GeosenQueryFilter**, adds capacity of interpreting place descriptions in user queries;
- **GeoSenURLFilter**, offers geographical references and spatial relationships detection mechanisms in accessed URLs, during the crawling process.

The database that contains numerous place names and other information used by the parser (GeoDatabase) was implemented using the PostgreSQL database server, with its TSearch2 extension for indexing textual data. Currently, the parser capability of associating trust levels to place names functionality has been developed based on rules such as term frequency, abbreviation rate, and special terms existence in texts.

FUTURE TRENDS

The evolution of spatial search engines is directly related to the advances in spatiotemporal indexing, aiming scalability; more precise relevance ranking; and better extraction of the geographic scope in Web documents. It will be necessary for not only the advent of new techniques addressing those issues, but also the availability of spatially aware Web services. Hence, the service oriented architecture (SOA) will play an important role in the next generation of spatial search engines.

Another important issue to the geographical information system (GIR) area success is the definition of standards for place name ontologies and gazetteers, including a global scope and multilingual capabilities.

Other areas will continue to contribute to GIR, such as natural language processing, by promoting easy user interactions on spatial queries; and a strong and complete support for the temporal dimension, which will facilitate spatiotemporal interactions.

Lastly, the use of such spatial search engines in mobile devices will improve the quality of data manipulated by these devices; thus, an important research issue is how to integrate such spatial search engines with current location-based service architectures. Again, the use of SOA seems to be a good solution.

CONCLUSION

Search engines have become very popular nowadays and they are used ubiquitously by Web users. As most of the information available has a spatial footprint, the development of spatial search engines seems to be one of the next great waves in information retrieval techniques.

This chapter presents an overview of spatial search engines and discusses the GeoSEn prototype. We believe that by combining the ideas from traditional IR systems with those from geographical information systems will enhance the way of doing search on the Web.

KEY TERMS

Crawler: Also known as robot or spider, it is a module of a search engine that is responsible for visiting Web sites and extracting their content to be further indexed by the search engine.

Gazetteer: A dictionary that translates a set of spatial coordinates to a place name and vice-versa.

Geocoding: A technique to provide spatial coordinates to places.

Geographical Information System: Software, for implementing geoprocessing, that is able to store and manipulate spatial data.

Indexing: A data structure technique used to speed up querying in large datasets.

Multimodal Interface: User-centered interface in which the computer may process more than one mode of communication.

Search Engine: Software that enables one to find documents on the Web according to user query.

Sponsorship in IT Project Management

David Bryde
Liverpool John Moores University, UK

David Petie
Petie Ltd., UK

INTRODUCTION

Since the 1970s academics and practitioners in the discipline of project management have sought answers to two inter-related questions: How is project success defined and measured? What are the influences on project success? To answer the first question people have studied project success criteria/key performance indicators. To answer the second, studies have focused on project critical success factors. Daniel (1961) introduced the concept of "success factors," stating that "in most industries there are usually three to six factors that determine success; these key jobs must be done exceedingly well for a company to be successful" (p.116). Approaches to the management of information have been established using Daniel's concept. For example, Rockart (1979) developed a Critical Success Factor (CSF) method for meeting the information needs of top executives. This method focused on understanding the objectives and goals of the company and the factors (CSFs) critical to their achievement, and establishing information systems to report on performance in these two areas. A key challenge has been to integrate the definitions and measures of success with CSFs, and in this respect work has been carried out to develop frameworks linking models of success criteria (the measures of success) with CSFs (see, for example, van Veen-Dirks & Wijn, 2002). The concept of CSFs has also been applied to project environments, with project CSFs being "those inputs to the management system that lead directly or indirectly to the success of the project" (Cooke-Davies, 2002, p. 185). Project management theory has also looked for a holistic answer to the questions of "How is project success defined and measured?" and "What are the influences on project success?", through the development of models linking project success criteria and project CSFs (Westerveld, 2002; Bryde, 2003).

BACKGROUND

Sponsorship as a Project Critical Success Factor

In respect of individual project CSFs, the importance of project sponsorship to achieving successful project outcomes has long been recognized. In a review of previous studies of CSFs, the sponsorship of projects by top management was highlighted as one of 8 major influences on success (Pinto & Slevin, 1987) and confirmed in a later study by the same authors as one of 10 influences (Pinto & Slevin, 1989). The importance of sponsorship is recognized through the distinction made between Macro CSFs, which involves activities in the realm of the sponsoring organisation and Micro CSFs, which are carried out in the domain of the project team (DeWitt, 1988). This crucial role of sponsorship has been identified in various manufacturing and service-related business environments, such as defence (Tishler et al., 1996), construction (Black et al., 2000), research & development (Pinto & Slevin, 1989) and management consultancy (Jang & Lee, 1998). Studies of project CSFs in IT environments have confirmed the pivotal influence of project sponsorship (see, for example, Bytheway, 1999; Fui-Hoon Nah et al., 2001; Procacinno et al., 2002).

ROLES OF PROJECT SPONSOR AND PROJECT MANAGER

A key step to delivering successful outcomes is gaining an understanding of the perspectives of all stakeholders to the project, including the sponsor and other stakeholders (Wright, 1998; Wateridge, 1995). In IT environments a lack of understanding has contributed to projects being unsuccessful. A failure by project managers to understand that users emphasized longer-term criteria relating to delivering workable systems, rather than short-term criteria linked to meeting time and cost objectives was a characteristic of IT projects perceived to be unsuccessful (Wateridge, 1998). A necessary step in achieving understanding is defining and delineating the roles and responsibilities of the project spon-

Table 1. Role of the project sponsor

- Define the business benefit/requirements
- Understand the risks to benefit realisation
- Agree the project definition, including project objectives
- Develop the project strategy, including priorities
- Help define the project success criteria
- Specify any constraints
- Determine the relative priorities of cost, time and quality
- Monitor the project's business environment
- If necessary, re-define or cancel the project
- Monitor project performance
- Take delivery at project completion
- Monitor benefit realization
- Champion the project, including making resources available
- Support the project manager in their role

Table 2. Role of the project manager

- Develop an effective working relationship with sponsor
- Deliver the project to time and cost, quality objectives
- Evaluate the risk profile and advise the sponsor
- Meet the defined project success criteria
- Manage the sponsor's and other stakeholders' expectations
- Define the project
- Build and lead the project team
- Monitor and control project progress
- Keep sponsor informed of progress and problems
- If necessary, recommend redefining or canceling of the project
- Hand over to the sponsor on completion

sor and project manager (Belassi & Tukel, 1996). *Table 1* summarizes the role of the project sponsor, drawing from the following extant literature: Snowdon (1976), Kliem & Ludin (1992, pp.163-169), Morris (1994, pp.188-189, 258-259), Briner et al. (1999, pp.65-67), Turner (1999, pp.50-53), and Hall et al. (2003).

The role of the project manager is summarized in *Table 2*. This table was constructed with reference to Gaddis (1959), Middleton (1967), Mantel et al. (2001, pp. 27-34), Anderson & Merna (2003), and Kendra & Taplin (2004).

FUTURE TRENDS

Although the importance of the sponsor to achieving project success is now well established (see earlier section "Background - Sponsorship as a Project Critical Success Factor"), and the roles of the sponsor and project manager are fairly well defined in theory, there are a number of critical issues that still need to be addressed in the future.

Awareness Among Project Sponsors of Their Role in Benefit Realization

Firstly, in some project organizations the role of the sponsor, especially in relation to their relationship with the project manager, is not clearly understood. This can lead to problems. For example, the responsibility for monitoring benefit realization (a sponsor role shown in *Table 1*) is often abdicated (without any corresponding authority) to project managers. However, it must be remembered that project managers only deliver products. A failure by the sponsor to fulfill their role in relation to benefit realization will lead to sub-optimal performance from the strategic perspective of the organisation.

Integration of Project Sponsor and Project Manager Perspectives

Secondly, there is the practical difficulty of integrating the perspectives of the sponsor and the project manager. The

sponsor should be focused on the benefits of an IT system, its impacts on the organisation and its contribution to the company vision. However the project manager should be focused on delivering products, IS/IT functionality and how it will be used operationally. The need for such a strategic and tactical integration underpins work on the development of new models for the delivery of successful IT projects (for example, Byers & Blume, 1994; Ward & Elvin, 1999). Project managers, by their very nature, are backward looking and tend to focus on what has been done, what has been spent and the problems they have delivering the product. Sponsors, on the other hand, must be forward looking, trying to ensure that the benefits will be delivered and that nothing gets in the way of this.

Distinction Between "Executive" Project Sponsorship and the Sponsorship of Individual Projects

Finally there is the question of what is meant by executive sponsorship? There is a difference between the sponsorship provided by one person to an individual project and the sponsorship given by the organisation to enable a strategic vision to be linked with effective delivery of an IT system. This second type of sponsorship, which is a potentially new paradigm, involves company directors, senior executives and middle managers understanding how to lead and manage change. It focuses on ensuring the organisation is ready for a project to be undertaken. For example, an exploratory study showed that the greatest influence on achieving successful outcomes from business process re-engineering initiatives was the innovative capacity of the organisation (Teng et al., 1998). In a similar fashion, in the new paradigm, the sponsors of projects must ensure that organizational competency issues linked to project management, in such areas as programme management, benefits management, sponsoring individual projects, long-term planning and governance, training and support, are properly addressed.

To ensure success, most organizations intuitively restrict projects to a particular department or area, with little or no cross-functional interaction. This is purely a competency issue, largely relating to executive sponsorship rather than project management competencies. The line of least resistance is to manage work packages or small projects with limited impact on other areas of the business. However, successful organizations are able to manage complex and inter-related projects through effective sponsorship. It is not hard to appreciate that decisions made regarding a particular initiative will have ramifications in other parts of the business. These elements need to be managed by individuals who have the interests of the organisation as a whole at heart, rather than a specific initiative. Effective executive sponsorship achieves this. Project managers cannot be expected to manage these aspects as well as deliver the projects on time, to the right quality and at the right cost.

This executive sponsorship equates to demonstrating effective leadership and being a good corporate citizen. A real test of this is when projects get cancelled because the benefits cannot be realized or the risk profile is too great.

CONCLUSION

Over the last 30 years there has been much work carried out in establishing the importance of project sponsorship to achieving successful outcomes and in defining the theoretical roles of the project sponsor and the project manager. This has resulted in a "traditional" view of the project sponsor and project manager roles, which in the case of the sponsor tends to focus on the sponsorship of individual projects. A further element, which was discussed earlier, is that of "executive" sponsorship, which focuses on organizational competency issues linked to project management. Further study is needed to establish the extent to which the two types of sponsorship, "traditional" and "executive," are undertaken in practice and to explore the relationship between different types of sponsorship and project success. This will require the taking of a holistic view of "project success," that is, incorporating project management-related criteria (meeting cost, time and quality objectives), satisfaction-related criteria (for the customer, project team and user) and benefits-related criteria (tangible and intangible). From this holistic perspective it will be possible to investigate how variations in the nature of project sponsorship impacts on the different success criteria, with the most effective sponsorship being that which meets all three.

Another focus for future work in this area needs to be on how project sponsors and project managers work together to ensure that IT project performance is optimized and benefits are realized. To achieve such optimization it may also be necessary to redefine the sponsorship paradigm to focus on addressing organizational competency in project management. For this to be useful in terms of project management practice there will need to be accompanying education, training and awareness-raising activities of the broader sponsorship role.

KEY TERMS

Organisational Competency in Project Management: Ensuring that the organisation is in a ready state in order for projects to be able to deliver benefits.

Project Critical Success Factors: The influences on the success, or otherwise, of a project. A distinction can be made between the underlying factors, or causes of success or failure and the symptoms of an ineffective project management process. The lack of top management support is a typical project critical success factor, which can lead to a variety of symptoms, such as adequate resources not being made available to the project.

Project Manager: An individual with the responsibility of ensuring the project objectives are delivered.

Project Performance: The degree to which the project meets its overall objectives. This compares with *project management performance*, which is the degree to which the traditional objectives of cost, time and quality are met.

Project Sponsor: An individual or group with the responsibility and authority to ensure that the project benefits are realised.

Project Stakeholder: Any person or group that has an interest in the project. The interest could be in the project outcome, outputs or the project management process.

Project Success Criteria/Key Performance Indicators: The measures of success. The terms project success criteria and project key performance indicators are used interchangeably. Traditional measures are meeting cost, time and quality objectives. Other measures are linked to the attributes used by a stakeholder to judge whether their expectations have been met.

Spreadsheet End User Development and Knowledge Management

Anders Avdic
Örebro University, Sweden

INTRODUCTION

In the early days of computers, expertise was needed in order to use computers. As IT tools have become more powerful and user friendly, more and more people have been able to use computers and programs as tools when carrying out working tasks. Nowadays, it is possible for people without special IT training to develop Information Systems (IS) that only IT specialists could have done some years ago.

In this paper End User Development (EUD) using a Spreadsheet Program (SP) is discussed from a knowledge management perspective. *EUD* can be a part of an organization's effort to take advantage of existing, often tacit, knowledge or creating new knowledge. An end user is a person who acts both as a user and a systems developer. A typical feature of an end user is that he has a good (often unique) knowledge of the business and the work related to the IS in question, which is called the User Developed Application. It is the combination of these two sorts of knowledge which is the key to EUD as knowledge management.

The aim of this of this chapter is to relate EUD to knowledge management and, specifically, to describe how tacit knowledge can be audited when end users develop spreadsheet systems for their own domain of expertise. The main source is a set of qualitative case studies carried out between 1995 and 2005. (Avdic, 1999; Westin, Avdic & Roberts, 2005)

BACKGROUND

There are many reasons for professionals to use personal IT tools such as spreadsheet programs in their daily work. One is to increase their knowledge and understanding of their professional domain in a changing world. The use of spreadsheet programs in order to develop systems for decision making is an alternative to more traditional systems development, where IT specialists assist in specifying information needs and other requirements as a basis for a systems development process where the IT specialist is the developer. This "traditional" procedure is often the only option since developing the system, especially its technical parts, is complicated and not possible to carry out by non-IT specialists. When the technical dimensions are uncomplicated, there are some interesting benefits for professionals to develop their own systems.

End User Development is herein defined as "…the use of the adoption and use of information technology by personnel outside the information systems department to develop software applications in support of organizational tasks." (Brancheau & Brown, 1993) In our case studies, we have studied end users developing systems using spreadsheet programs. The end users have worked as controllers, administrators, civil servants, production planners, and managers in private companies and local government organizations. Some studies have been longitudinal, the longest one ten years. One thing they have had in common is that they are all professional experts in their domains. All of them have had the possibility, to a large extent, chose their own working situation and how to carry out the way they work.

Knowledge Management "is the name given to the set of systematic and disciplined actions that an organization can take to obtain the greatest value from the knowledge available to it." (Marwick, 2001) Focus here is more on "obtain greatest value" than "systematic and disciplined." The forms of EUD that are discussed here are often related to groups that could be described as *Communities of Practice* (Wenger, 1998) and whose development activities, to a large extent, are about making *tacit knowledge* explicit. (Polanyi, 1967) Among the practitioners' working situation and domain of expertise, there has been organized and disciplined activities in order to explore the knowledge domain by developing spreadsheet programs in various forms of cooperation with colleagues and peers. This is, to a large extent, an expression of social learning, which is a fundamental concept regarding communities of practice. (Wenger, 1998)

The knowledge management approach discussed in this chapter is more inductive than deductive in the sense that development activities are not planned or organized by the management but by the end user from his practitioner perspective. This is also a typical way for communities of practice to exist. The process of creating and sharing knowledge is complex, abstract, and subtle and, to a certain degree, a tacit process in itself. In accordance with Walsham (2001) we believe that knowledge management processes of the kind we discuss benefit from putting the human before IT.

Organizations where EUD activities take place are decentralized organizations where skilled practitioners have

the mandate and resources to independently develop various sorts of applications. Decentralization of decision making is a necessary condition "…when tacit and detailed knowledge is involved in opposite to explicit aggregated knowledge." (Grant, 1997)

The distinction between *tacit* and explicit *knowledge* is originally presented by Polanyi (1967) and is frequently used ever since. The notion of tacit knowledge refers to knowledge, experiences, and abilities that are not able to represent or codify, while explicit knowledge is possible to represent in, for example, books and computer programs. Some claim that most knowledge (50% - 95%) is tacit. (Awad & Ghaziri, 2004) Since tacit knowledge is not explicit, it is not possible to question. When end users make tacit knowledge explicit, it becomes, at the same time, open to inspection. This is an important part of EUD and the focus of this chapter.

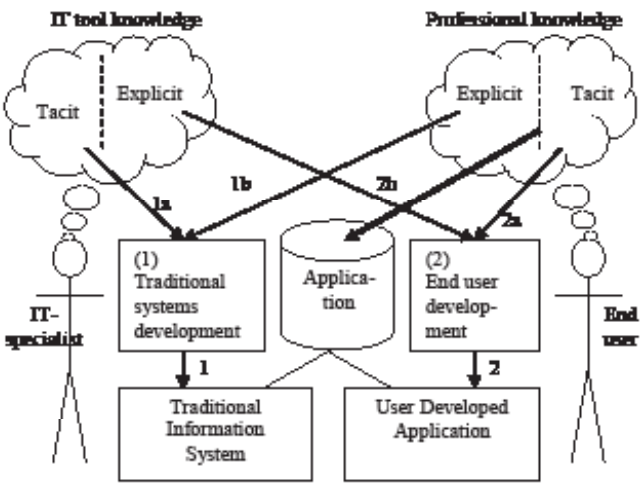
MANAGING KNOWLEDGE BY SPREADSHEET END USER DEVELOPMENT

Traditional and End User Systems Development

EUD is often compared to *systems development* carried out by IT specialists. This is not always relevant, but below we are applying the comparison in order to draw the attention to some central knowledge related properties inherent in EUD.

In Figure 1 the difference between traditional systems development (1) and EUD (2) is outlined. To the IT specialist, knowledge about systems development tools (e.g. methods, program languages) (1a) is in primary focus when developing an IS (1c). This is the core of his/her professional knowledge. Knowledge about business (1b) is, of course, essential but not primary. When the IT professional starts the next project, his/her basis is his/her IT specialist expertise but another business context is focused. To the end user, knowledge about business (2a) is of primary importance and knowledge about systems development tools (2b) is just a means to accomplish business-oriented tasks, eventually by developing user developed applications (2c). The IT specialist has access to knowledge about IS development tools that are hard to access for non-professionals, since they consist of tacit knowledge together with explicit knowledge. Some business knowledge is hard to access to the IT specialist, since this knowledge is not in the professional knowledge domain of the IT specialist. The end user, on the other hand, is the expert on business knowledge. His/her expertise depends on his/her knowledge about business. This professional knowledge also consists of tacit and explicit knowledge. No one can replace him/her in this matter. In order to perform EUD, the end user needs some knowledge about IS development tools. It is not possible, though, to have access to as much

Figure 1. The relation between knowledge and development



knowledge about IS development tools as the IT specialist has, since it is partly tacit.

To both the IT specialist and the end user, both kinds of knowledge are necessary. In order to make an IS though, the overall most important kind of knowledge is in general knowledge about business, since the IS is about the business and is supposed to be used in the business context. The bold arrow in Figure 1 demonstrates this circumstance.

In order to *develop information systems*, business specialists must share knowledge about business with IT specialists. This process is problematic since people have different frames of references. (Alter, 1996) The entire intention, closely related to professional ethics of the business specialist can, therefore, not be perceived by the IT specialist. The IT specialist can, therefore, not fulfill the requirements since he/she cannot completely understand the business specialist. Since the business specialist's knowledge about business to a certain extent is tacit, he/she cannot tell what he/she knows.

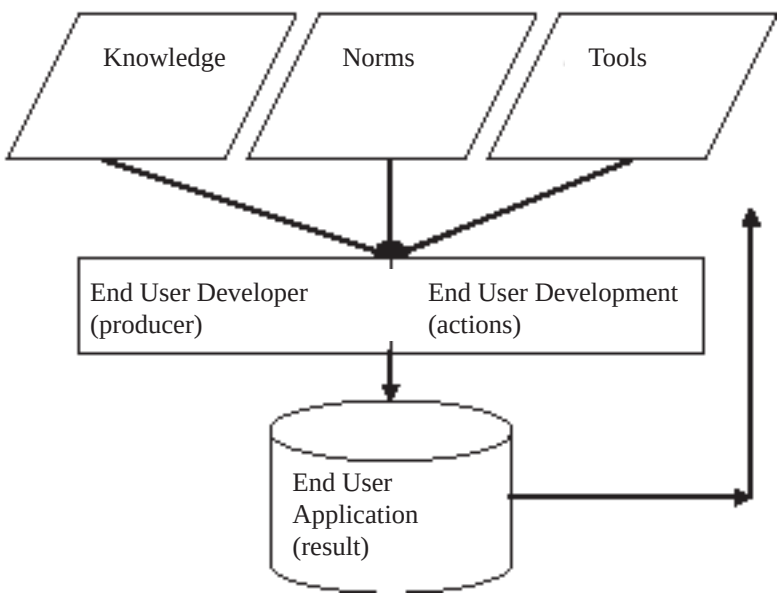
Even though the described problems of knowledge sharing are well known, complex systems development tasks still have to be performed the traditional way. The problem is addressed in various ways, for example, participative approaches or agile systems development methods. But as more powerful systems development tools are at hand, the possibilities to perform EUD are enhanced. Spreadsheet programs have properties that give the end user access to IS development features without the demands of being an IT specialist. The systems discussed here are often small and local, and thereby not suitable for traditional systems development projects.

The End User Development Practice

The practice of the end user is described below using the (modified) *model of generic practice* (the ToP model) (Goldkuhl, 2005) in order to systemize empirical findings and related theory. The model can be used to specify the conditions and result of a specific practice, for example, a controller practice or an IT specialist practice. The model consists of a set of conditional categories: *knowledge, norms, and tools.* The categories that express the specific practice are named *producers* and their *actions.* The last category is the *result* of the practice. When an end user develops an application he/she acts in at least two kinds of practices; the primary (e.g., controller) practice, and the secondary (developer's) practice. Each practice is related to a profession, for example, a controller and an IT specialist profession. The model makes it possible to separate the conditions of the different practices. It also makes it possible to discuss which parts of the developer's practice can improve the main practice without consulting an IT specialist. The nature of the categories is described in Figure 2 together with presentation of findings from the case studies.

A *user developed application* is an IS and an IS is a *result* of systems development. The difference between a

Figure 2. End user development as practice



traditional IS and a user developed application is mainly a question of how it is built. User developed applications are built by end users with a good knowledge of the business, while traditional information systems are built by IT specialists. (Avdic, 1999)

Traditional *Systems Development* can be characterized by the notion of the "Life Cycle", where tasks are specialized and activities are separated and systemized. *End User Development* (*actions*) and traditional development are profoundly different. EUD actions are seldom organized or planned. Specific work related tasks or problems make the end user aware of some information related requirements. EUD is by the end user perceived as work rather than systems development.

Risks are obvious when end users with limited IT skills start to develop systems that affect vital organizational decisions. Panko (2006) have shown that errors in spreadsheet systems are common and that there is a need for finding ways to prevent and find these errors.

An *end user* (*producer*) is a person with a deep knowledge of the business who develops user developed applications that support the end user in his/her work. The end user is primarily a professional (e.g., a controller) who integrates, to some extent, the role of one or more IT specialist, when performing EUD. The end user could have good knowledge about IS development tools. This does not disqualify him as an end user; it rather makes him even more efficient. When several end users work together with a common goal in order to understand and solve problems in their own domain, it can be described as a Community of Practice (Wenger, 1998).

When performing EUD, the *knowledge* necessary in the practice of the IT specialist practice to carry out the development, is divided between the end user and the tool (the spreadsheet program). IT-related knowledge that is not too complex, is formalized into the spreadsheet program (e.g., arguments of statistical functions and graph drawing) and can be used in the application. Other kinds of knowledge can be formalized by the end user into the application which is a knowledge condition of the business practice. Some kinds of knowledge (e.g., of critical evaluation of the relevance of formulas) cannot be formalized at all. Still, this kind of not-easily-formalized (sometimes tacit) knowledge can be taken into consideration when using the application, since the end user (with business knowledge) is the user of the system. We also claim that goals and norms, not easily formalized, can be taken into consideration when performing EUD.

Knowledge about tools can be used to deepen knowledge about business. End users make tacit knowledge explicit when developing EUD's, which in turn make it possible for others to evaluate and criticize the application and its output. One important aim of the end user is to articulate knowledge about business and EUD is one mean to do this.

Norms and knowledge are closely related and sometimes hard to keep apart. One set of norms that are central in a EUD context is professional ethics. Professional ethics are crucial to the end user, since the professionals' activities are monitored not by procedures but by professional and business ethics. Professional ethics as well as professional tacit knowledge cannot easily be transferred to IT specialists in systems development projects. Therefore, when EUD is performed by end users, professional ethics and tacit knowledge can be taken into consideration in a way not possible in traditional systems development. EUD can also change organizational norms. Ongoing questioning of business, using user developed applications, can implicitly or explicitly challenge existing models as well as their norms. (Avdic, 1999) This does not mean that revolutionary effects take place every time an end user develops an application. See also the section entitled "Processing the tacit".

EUD *tools* are closely related to norms and knowledge, since norms and knowledge are implemented in tools. The main tool when performing spreadsheet EUD is, of course, the *spreadsheet program*. The spreadsheet program integrates functions for input, output, storage, processing, and presentation. This integration results in interactive development and use. The open nature of the spreadsheet program can and does cause different kinds of errors. (Panko, 2006) Knowledge of business, tools, and design can prevent some of these errors. Another circumstance that makes spreadsheet programs suitable for EUD is the fact that they are very common. In Sweden, for example, almost all employees who might need it can have access to a spreadsheet program.

Because of the integrated nature of EUD, learning, using, and systems development take place at the same time. Learning applies to both the business and the tool. One conclusion of this is that training in the use of a tool can improve the quality of EUD, which in turn can improve business. One way for the management to support EUD, eventually in a Community of Practice, is to initiate and encourage end user-tailored training in the use of tools.

Processing the Tacit

Fahy & Murphy (1999) has shown that managers' ability to process their *tacit knowledge* by developing applications is rewarding in several ways. According to Fahy & Murphy (1999) managers are involved in "…activities that are characterized by high levels of tacit knowledge based on extensive experience." Development of systems is an important part of their efforts to understand and articulate their information requirements. "The process of developing systems provides managers with a mechanism for iterative analysis. This trial and error approach helps managers build up their understanding of the problem situation and allows them to be more explicit in describing and understanding the problem facing them." Göranzon (1990), on the other hand, shows evidence that when a professional domain (that of forest wardens) is formalized into a system that is

developed by someone else, there is a risk that professional knowledge disappears. He also states with examples from his study that the ability to calculate is closely related to the ability to assess and evaluate. This means that professional norms can be maintained by processing data.

According to Wulf & Jarke (2004), the initial costs for EUD exceeds those of traditional systems development. On the other hand, costs for "software adaptation in context of use" and, moreover, "costs for missed opportunities for appropriation" are larger for non-EUD applications. The reason for this is claimed to be the gap between domain experts and IT specialists.

FUTURE TRENDS

All over the world the use of computers, personal software, and Internet is increasing. More and more practitioners *develop end user applications*. According to Sutcliffe & Mehandijev, 2004) there were probably 55 million end users in USA 2005 in comparison to 2.75 million professional software developers. As knowledge of computer use is increasing, we can be sure that personal use of computers will increase. The growth of Internet use and maturity will promote an integration of Internet as an information source, which will open new possibilities for EUD.

A world that is changing faster and faster will put demands on managers and professional practitioners to explore how these changes affect their organization. To a certain extent this is possible with traditional systems, but due to the built-in inertia, these systems cannot provide means to explore aspects that are hard to define. Therefore, practitioners will have a need for personal IT tools like spreadsheet systems in the future as well. Actually, there are reasons to believe that organizations will more actively take advantage of communities of practice and support them (Wenger, 1998).

Finally, traditional systems development experts can benefit from EUD and integrate EUD in their development procedures in order to get access to tacit domain knowledge.

CONCLUSION

Organizational knowledge is to a large extent tacit. Due to ever ongoing changes in organizations and in the environment of organizations there is a need to understand current conditions in order to take decisions from what is as close as possible to the actual situation. Traditional *information systems* suffer from a certain inertia which sometimes makes them insufficient to produce current data. It is also rather obvious that existing systems cannot anticipate all future demands and there is, therefore, always a need for flexible and usable tools which make it possible for decision makers to collect, analyze, and present information in a not pre-specified way. Existing systems is a necessary condition but not always the most optimal way to serve as a tool for analyzing earlier, not explicitly known situations.

Increasing knowledge and decreasing costs of IT and IT tools have provided professionals with possibilities to process their explicit and tacit knowledge about their knowledge domain, their work, and their organization in order to create new knowledge and audit existing knowledge. EUD using *spreadsheet programs* provide opportunities to practitioners to explore and audit tacit knowledge.

KEY TERMS

Communities of Practice: Groups of people in organizations with common goals and a common repertoire of concepts and knowledge. They share what they know and learn from one each other regarding aspects of their work and provide a social context for that work.

End User Application: An information system developed by an end user developer in order to support him/her in his/her work.

End User Developer: A person with a deep knowledge of the business, who develops end user applications that supports him/her in his/her work.

End User Development: The adoption and use of information technology by personnel outside the information systems department to develop software applications in support of organizational tasks.

Explicit Knowledge: Codified knowledge.

Knowledge Management: A set of systematic and disciplined actions that an organization can take to obtain the greatest value from the knowledge available to it.

Tacit Knowledge: Knowledge, experiences, and abilities that are not articulated, represented or codified.

INTRODUCTION

The use of computers in education has been reported since the 1970s, but the Internet is fundamentally changing the way organizations operate, and these changes are spreading fast to educational organizations as they are eager to take advantage of the new possibilities.

In this context, new terms have been created to express new concepts related to the use of technology and following this trend, the term e-learning was coined. E-learning is an all-encompassing term generally used to refer to the use of technology in learning in a much broader sense than the computer-based training (CBT) or computer-aided instruction (CAI) of the 1980s. E-learning is extensively used and can include, just to name a few examples: educational Web sites; the use of hypermedia, discussion boards, e-mail, text chat, simulations and games in an educational context; computer-aided assessment; and learning management software. Although the term is not well defined and covers many possibilities, it has been mainly used when the Web is involved in the learning process.

The rapid growth in e-learning has led the community of designers, developers and users of learning resources to a point where they have an enormous variety of tools to support their work. However, if these tools use proprietary solutions, this would make the reuse of learning content outside the scope of the system where it was created difficult. It would also be hard to provide mechanisms for searching, accessing, reusing, and integrating such resources. One way to avoid these kinds of problems is the definition and use of open specifications and standards.

A standard is a set of technical definitions and guidelines for designers, manufacturers, and users, establishing the characteristics of a product, process, or service, such as dimensions, safety aspects, and performance requirements. Standards are written by experts with knowledge and expertise in a particular field (ASME, n.d). The Internet is a very good example of the importance of having standards to support the development and wide adoption of technology. It would have been impossible to connect so many different computers around the world if there were no standards to define the connections and communication protocols. This is also the case of e-learning technology, which needs standards in order to facilitate worldwide propagation.

Once e-learning standards are defined, accepted, and used, they will bring many advantages (Duval, 2004; MASSIE Centre, 2003):

- From the point of view of users, standards will prevent them from being locked-in to a particular vendor as it will be much easier to shift between tools and platforms and increase the reuse of existing resources.
- From the point of view of the tool vendor, they will not need to develop proprietary interfaces for other existing products lowering the cost and increasing the size of potential markets.
- From the point of view of content producers, they can use a standard format that will be understood by any delivery system conforming to the standards and increase the potential market of their products.

Above all, standards are a clear signal that a technology is mature and usually are seen as a first step towards a rapid growth phase and worldwide adoption.

BACKGROUND

It should be noted that there are different kinds of standards. *De facto* standards are developed by market—or technology-driven processes—and have come into use by general acceptance, custom, or convention, but have no formal recognition. When the standard is created by an accredited standard developing organization (SDO), it is called a *de jure* standard or an accredited standard and its scope can be national, regional, or international depending on the SDOs involved in its publication. Usually each country has a national standards body that is responsible for the adoption of standards within that country and that represents the country in international standards forums like ISO—International Standards Organization. ISO is a network of the national standards bodies of 157 countries, with one member per country and is a non-governmental organization with a Central Secretariat in Geneva, Switzerland (ISO, 2006).

When there is a product, which has been developed according to a standard, it is usually said to be conformant with the standard. If the product is tested by an external entity that verifies and attests the conformance (or conformity) of the

product to the standard, then it can be said to be certified.

The importance of a standard is usually measured by the extent of its actual acceptance and use. Nowadays, although accredited standards tend to have more credibility, *de facto* standards or even open specifications are commonly used as the need for standards is growing fast. This is the case in e-learning, where the most active standards groups are open consortia.

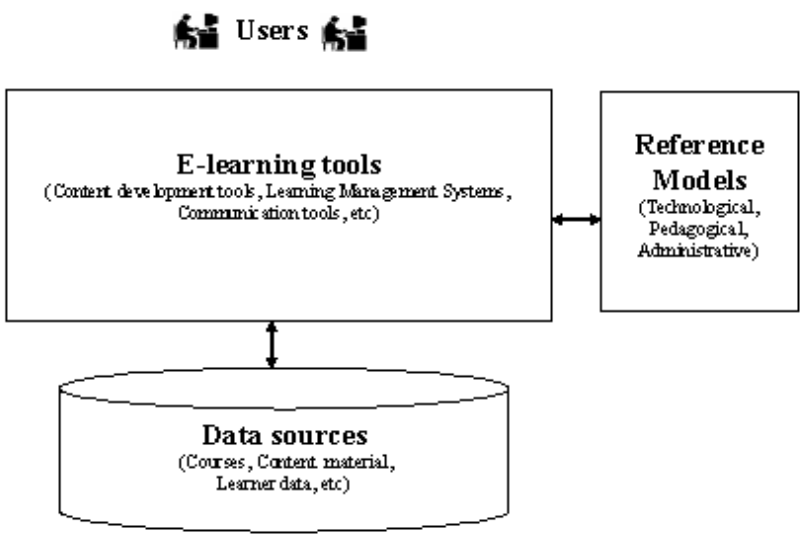
In e-learning, the development of standards usually follows four steps: specification, validation, standardization, and dissemination.

- In the specification phase, cooperating organizations develop initial specifications based on their analysis of the tasks accomplished during the learning process. All information exchanges and interfaces between components are specified, documented, and refined among all the participants.
- Based on the results gathered during the specification phase, pilot programs are developed to test the effectiveness of new products incorporating the initial specifications. This is the validation phase, where testbeds are established for validating conformance to the specifications and to reveal the existence of initial specifications that should be revised. Also, reference models are developed, showing how different specifications work together.
- The specifications that have been tested and proved to be valuable are then submitted for approval by accredited standards bodies that will refine, clarify, and follow the established procedures for reaching final accreditation of the specifications. In e-learning the bodies creating accredited standards are: IEEE Learning Technology Standards Committee (LTSC) (http://ieeeltsc.org/), ISO/IEC JTC 1/SC 36—Information Technology for Learning, Education, and Training (http://jtc1sc36.org/), and CEN/ISSS Learning Technologies Workshop (http://www.cen.eu). Within the bodies are working groups that address specific areas of e-learning and that coordinate all the internal process for reaching accreditation. Additional information about this process can be found in IEEE (2005).
- Finally, the last phase of the process is the dissemination of approved standards among all the stakeholders in e-learning, giving them support for understanding and correctly using the new standards.

CEN/ISSS Learning Technologies Workshop has created an observatory which reports the most important events in e-learning standardization available online at http://www.cen-ltso.net/.

To understand the relevant aspects that should be considered for standardization in e-learning, it is important to comprehend an e-learning environment. Figure 1 shows a simple model of the most important aspects of an e-learning environment. Users represent all the participants in the learning environment, including, for example, learners, teachers, content developers, and administrative staff. E-learning tools cover all the software and hardware systems that provide the necessary functionality for the environment and can include for instance such elements as a learning management system (LMS), content development tools, and communication tools. Data sources mean all the digital data that is needed to be able to fulfill the functionality of

Figure 1. A simplified framework of educational and training systems



the e-learning environment, including learner data such as personal data and grades, learning content materials, data about existing courses and conditions to be able to attend them, and so on. The reference models represent different administrative, pedagogical, and/or technological strategies, methods, and techniques adopted by the organization that can guide the learning processes. For instance, the pedagogical reference model could establish a learning approach based on an existing learning theory. Examples of the use of learning theories in online courses can be found in Modritscher (2006).

Considering this simplified framework of educational and training systems (Figure 1), it is possible to see how the different components play their part in an educational or training program. When starting the development of any educational or training program, the first step is to conduct a needs assessment. The developers can perform a needs assessment by accessing databases in order to find information revealing on which topics the students need more material, what professional or academic goals need further and/or deeper support and so on. Then, after choosing a new educational/training goal, knowledge about the audience must be acquired. This can be supported by a learner model and usually consists of accessing data from the learner's database. After this phase specific objectives are defined, and the system will support the design and development phases following the direction established by the course model and the pedagogical reference model.

If the needed content is not available, then its development will have to be considered. A widely accepted approach for authoring is related to grouping together pieces of information objects (Barritt & Lewis, 2001). This approach leads to the creation of what is generally called "learning objects" (LOs) and its main goal is to facilitate the development process and reuse of content. To fulfill this goal it is also essential to create metadata associated to the LOs. Metadata is simply defined as "data about data" and, in this case, it can be seen as structured, encoded data that describe characteristics of the LOs in order to allow faster search and easier access. It should be noted that authoring and composing tasks, in the LO approach, could be automated according to some special rules, allowing on-demand learning. In addition, there is the possibility that metadata could be automatically generated from the learning material. The learning content development process clearly includes the insertion of data and metadata into the content material database as well as possibly into the course database.

Another significant aspect connected to content development is the definition of learning activities. A learning activity may be loosely described as an instructional event or events related to content resources that will engage the student in executing a task that contributes to achieving learning objectives (Koper & Tattersall, 2005). The creation of learning activities is essential to achieve learning, and these activities should be tracked by e-learning tools and specified during educational or training program development.

Once an educational or training program is developed, there must be tools to allow its deployment. These tools are, of course, dependant on the teaching approach that was used during the design and development phases. In many educational and training systems the core functionality is to provide access to content material stored in the database on a previously specified sequence, following the visualization steps.

At this point, it is important to consider aspects such as user interface usability and information presentation, content hypermedia navigation, and content personalization and adaptation.

The goal of adaptation and personalization is to provide content according to the users' background and abilities which must be known by the tools and this capacity is now identified as an important factor in the improvement of pedagogical quality in e-learning (Brusilovsky & Peylo, 2003; Dagger, 2006; Paramythis & Loidl-Reisinger, 2004).

Another keyword is accessibility; this can be understood as the degree to which a system is usable by as many people as possible and now, in many countries, there are laws or regulations protecting users which specifically focus on people with disabilities and their access rights.

There are also systems based on constructivist principles. In this approach learning activities take a key role in the learning process, and there is a high degree of interaction among all the participants supported by communication and groupware tools. Other possible approaches include project-based learning, simulations, and educational games.

In addition, there are assessment tools that can be incorporated in the educational/training system in order to evaluate the students. Although assessment activities could be supported by groupware infrastructure or included as learning activities, it is interesting to consider specific assessment tools that could help teachers and students in the learning process.

Finally, security tasks and overall evaluation should be present on all the activities executed within the system. Course evaluation should lead to a revision on new iterations of the course while the evaluation of the educational and training system should lead to its development and improvement.

From this description it is easy to understand that data stored in the databases/data sources will be much more useful if standards exist. For instance, if the learner data has a standard format, all the tools that deal with this data can access that information regardless who originates it, who is maintaining it, or who uses it. In a more practical perspective, a learner having a standard learner data/profile can easily transfer this data from one environment to another conforming one. Therefore, the learner could have different personalized environments using and/or sharing the same learner profile.

From the point of view of the software tools, it is also possible to understand that it is essential that they are able to communicate and cooperate in order to provide all the services envisioned for the e-learning experience. This is equivalent of saying that interoperability is needed. Interoperability, according to ISO/IEC, is defined as follows: "The capability to communicate, execute programs, or transfer data among various functional units in a manner that requires the user to have little or no knowledge of the unique characteristics of those units" (ISO, 2003).

E-LEARNING STANDARDS AND ORGANIZATIONS

The presented description, although not fully exhaustive, allows establishing the most significant aspects that standards for e-learning must address. First, general standards for interoperability of software and hardware are clearly needed as in any other information system. They cover such areas as data exchange formats, communication protocols, and services. These standards are obviously created independently—that is separately from the application area and, because of the role that the Internet has, nowadays many important standards are produced within W3C (World Wide Web Consortium) (http://www.w3.org). This consortium develops relevant technical standards that are referenced and used within learning technologies such as: HTTP (Hypertext Transfer Protocol), URL (Uniform Resource Locator), HTML (HyperText Markup Language), XML (eXtensible Markup Language), RDF (Resource Description Framework), OWL (Web Ontology Language) and SOAP (Simple Object Access Protocol), just to name a few.

Besides these standards and specifications, there are those that specifically address the area of e-learning. In this case, two crucial aspects for achieving a more flexible and interoperable e-learning environment can be noticed: learning content and learner data.

Considering the learning content, the main aspects to be standardized are:

- **Metadata:** To describe useful characteristics of the content such as author, language, and title.
- **Content Distribution Information:** To specify how that content can be accessed by existing tools.
- **Content Assembling:** To state how different units of content can be assembled and used by existing tools.
- **Learning Activities:** To allow e-learning tools to allocate activities and their associated resources to participants that play the various roles, and coordinate the runtime flow.

Considering learner data, the main aspects to be standardized are:

- **Personal Data:** To identify the learner, including information such as name and address.
- **Qualifications:** To show the courses or other studies that the learner has pursued and the corresponding grades.
- **Competencies:** To describe learner's skill.
- **Accessibility:** To cater for special needs of the students connected with personal preferences or possible disabilities.

With the development of the e-learning industry, many organizations understood the usefulness of having standards and, then, addressed this problem. IEEE LTSC (http://ieeeltsc.org/), IMS Global Learning Consortium (http://www.imsglobal.org/), Advanced Distributed Learning (ADL) Initiative (http://www.adlnet.gov/index.cfm), Aviation Industry CBT Committee (AICC) (http://www.aicc.org/), and Association of Remote Instructional Authoring and Distribution Networks for Europe (ARIADNE) (http://www.ariadne-eu.org) are important players within the standardization process and are now working in collaboration.

From the learning content perspective, two main results are broadly accepted and have been adopted by many e-learning developers: IEEE LOM (Learning Object Metadata) and SCORM (Sharable Content Object Reference Model).

IEEE LOM (Draft Standard, 2002) specifies a conceptual data schema that defines the structure of a metadata instance for a learning object. This metadata instance describes relevant characteristics of the learning object to which it applies. Such characteristics are organized in a hierarchy of elements that are grouped into nine classification categories: general, life-cycle, meta-metadata, educational, technical, rights, relation, annotation, and classification. The purpose of this standard is to facilitate search, evaluation, acquisition, and use of learning objects. IEEE LOM was approved as a standard by IEEE LTSC in 2002 and this work has been extended by other standards through the specification of bindings of LOM data model in XML and RDF (W3C standard languages/data models for Web documents).

SCORM is a standards reference model concerning the development, packaging and delivery of learning objects. There have been previous versions and the latest one is the SCORM 2004 3rd edition. This edition is a collection of specifications and standards that defines the interrelationship of content objects, data models, and protocols such that objects are sharable across systems that conform to the model.

It is interesting to note that SCORM is built on existing standards and specifications proposed by other organizations. For instance, SCORM 2004 metadata is defined using IEEE 1484.12.1-2002 LOM Standard and IEEE 1484.12.3

Standard for Extensible Markup Language (XML) Binding for LOM Data Model.

Besides these two results, many other important specifications are also related to learning content:

- IMS Content Packaging is a specification for sending learning resources (or learning objects) from one program to another, facilitating easier delivery, reuse, and sharing of materials.
- IMS Simple Sequencing is a specification used to describe navigation paths through a collection of learning activities.
- IMS Learning Design is a specification used to describe learning scenarios. It allows these scenarios to be presented to learners online, and enables them to be shared between systems.
- IMS Question and Test Interoperability is designed to make it easier to transfer information such as questions, tests and results between different software applications.

Considering learner data, there are: IMS Learner Information Package (LIP) ("IMS Learner", 2005), IMS Accessibility for LIP (ACCLIP) ("IMS AccessForAll", 2004), IEEE Public and Private Information (PAPI) for Learners (PAPI Learner) ("PAPI Learner", 2002).

IMS LIP is designed to allow information about learners (including their progress and awards received) to be shared between different applications. Within the 11 defined categories, there is one for describing hobbies and recreational activities, and also an accessibility category for describing physical issues (e.g., large print) and/or technical preferences (such as the computer platform).

IMS ACCLIP provides a means to describe how learners can interact with an online learning environment based on their preferences and needs. These preferences will have an influence on the user interface of learning delivery tools and how content is selected and presented.

The PAPI Learner Standard is a data interchange specification that describes learner information for communication among cooperating systems. It is a multi-part standard that specifies the semantics and syntax of learner information. It defines and/or references elements for recording descriptive information about: knowledge acquisition, skills, abilities, personal contact information, learner relationships, security parameters, learner preferences and styles, learner performance, learner-created portfolios, and similar types of information. This standard permits different views of the learner information (perspectives: learner, teacher, parent, school, employer, etc.) and substantially addresses issues of privacy and security.

Finally, it is important to mention two interesting and more recent initiatives:

- The E-Learning Framework (ELF) project (http://www.elframework.org/): ELF is endorsed by important institutions in the e-learning arena such as the Australian Department of Education (DEST), the United Kingdom's Joint Information Systems Committee (JICS), and the U.S. Advanced Learning Initiative (ADL). It aims at providing both a common vocabulary and a roadmap for the development of the component services in an e-learning infrastructure. Besides the identification of necessary services, ELF also lists if there are standards and specifications that already support, at least partially, each of these services, and promotes the development of open source implementation toolkits to assist developers in implementing instances of the services.
- The Content Object Repository Discovery and Registration/Resolution Architecture (CORDRA) project aims to contribute to the solution of the problems related to the interchange of educational content between different repositories. As it is stated in literature, CORDRA is an open, standards-based model for how to design and implement software systems for the purpose of discovery, sharing, and reuse of learning content through the establishment of interoperable federations of learning content repositories (Rehak, Dodds, & Lannom, 2005).

To conclude, the issue should be raised as to whether these standards are perceived as useful for the development of the area. Several authors, in fact, report doubts about this (Dagger, 2006; Marshall, 2004; Modritscher, Gutl, Barrios, & Maurer, 2004; Paramythis & Loidl-Reisinger, 2004), but almost all of them acknowledge at least some advantages in having them. Marshall (2004) states that, "For some aspects of e-learning, it is clear that standards are useful, even necessary, and the impact of their utility is clearly measurable" (p. 601). Also, there are now many systems developed according to the existing standards that reflect the relevance/usefulness of the work done (Duval, 2004).

FUTURE TRENDS

The e-learning industry and research have matured to the point where there is a structured vision of an overall architecture (e.g., ELF) establishing the services that are needed and how they relate to one another. This is a fertile environment for standardization to grow as it offers a roadmap for standards development.

In the future, the issue of the creation of conformance tests to allow the certification of e-learning products must be tackled, as this will bring more credibility to products. Without well-established certification procedures, the claim

for conformance could be regarded as a mere marketing strategy and not necessarily as an indicator of quality.

CONCLUSION

E-learning technology grew largely with no e-learning standards and those that existed were initially developed without being widely adopted. The past few years have seen wider adoption of e-learning standards by the community of e-learning tool developers, especially in corporate training through the adoption of SCORM.

It is possible to notice that an e-learning courseware industry for corporate training (e.g., Skillsoft, NETg, DigitalThink, etc.) has, through the adoption of SCORM, had a rapid development which might otherwise been different if it had not been for this unifying standard which promotes interoperability.

Although important results have been achieved, many products still claiming conformance to standards do not really interoperate without adjustments. So, more specifications to cover all aspects of the identified services are needed.

As e-learning standards bodies are now aware of the importance of collaboration, it is expected that instead of developing overlapping specifications, they will work towards the common aim of having complete, non-redundant, and more reliable standards.

KEY TERMS

Accessibility: The degree to which a system is usable by as many people as possible.

Conformance: Adherence of an implementation to the requirements of one or more specific specifications or standards.

E-Learning: Refers to the use of technology in learning or training that can be deployed either locally or globally.

Interoperability: The capability to communicate, execute programs, or transfer data among various functional units in a manner that requires the user to have little or no knowledge of the unique characteristics of those units.

Learning Objects: Any digital resource that can be reused to support learning.

Metadata: Structured, encoded data that describe characteristics of an object.

Standard: A standard is a set of technical definitions and guidelines for designers, manufacturers, and users establishing the characteristics of a product, process or service.

User Profile: A set of characteristics describing a user.

Staying Up to Date with Changes in IT

Michael W. Dixon
Murdoch University, Australia

INTRODUCTION

Information and communications technology (ICT) has been changing rapidly over a long period and this rate of change is likely to continue or increase (Benamati & Lederer, 2001a; Lee & Xia, 2005). This rapid rate of change has produced many opportunities for organizations, but has also brought with it many challenges (Benamati & Lederer, 2001b). Among these challenges is the struggle for organizations to obtain personnel with the appropriate information technology (IT) knowledge and skills in order to meet their ICT needs (Byrd & Turner, 2001; Doke, 1999; Standbridge & Autrey, 2001). This is mirrored by the continual requirement for IT professionals to keep up to date with the skills required by organizations (Benamati et al., 2001a; Klobas & McGill, 1993; Moore, 2000).

Previous research has investigated the importance employers place on various skills and perceived deficiencies in these skills (e.g., Doke, 1999; Leitheiser, 1992; Nelson, 1991; Prabhakar, Litecky, & Arnett, 2005). While the call for improved communication and social skills has been consistent, the technical skills in demand have varied dramatically over time (Prabhakar et al., 2005; Van Slyke, Kittner, & Cheney, 1998). Less has been written about students' perceptions of the importance of various ICT skills, though this was addressed in a study that compared Australian and American students' perceptions of ICT job skills (von Hellens, Van Slyke, & Kittner, 2000). This article provides an overview of a project that investigated the channels of information that ICT students use to keep up to date with employers' needs.

BACKGROUND

Given that the skills required by IT professionals change over time, IT professionals need effective methods to keep up to date. The methods used by IT professionals to keep up to date were studied by Klobas et al. (1993). They identified the existence of a variety of information gathering strategies and noted that while IT professionals tended to be diligent in their efforts to keep up to date, a majority found it difficult to do so. In a more recent study, Benamati et al. (2001a) investigated the coping mechanisms adopted by IT professionals and noted that many mechanisms were not successful.

If it is difficult for experienced IT professionals to keep up to date, it is likely that it is even more difficult for ICT students to do so. New graduates require marketable IT skills in order to gain good employment, but the skills most in demand change regularly. Little is known about how ICT students keep informed of employers' requirements or about how they ensure that they can meet these requirements. Yet this knowledge would be of use to both educational institutions aiming to facilitate this process and to potential employers hoping to recruit students with the required skills.

Information about ICT skill requirements is available from a variety of sources in a variety of formats. Information sources include ICT suppliers, publishing companies, and universities. Formats include different types of publications, presentations, and personal contacts. The term "information channel" can be used to describe the various combinations of sources and formats of information.

HOW DO STUDENTS KEEP UP TO DATE?

Eighty-five information technology students at an Australian university were surveyed to investigate the channels of information that they use to keep up to date with employers' needs. Participants were recruited during class and completed a questionnaire on the spot.

The questionnaire listed information channels that may be used to keep up to date and asked participants firstly whether they had used each channel within the last three months, and also to rate the importance of each channel to them as a means of knowing what skills are in demand. Importance was measured on a 5 point scale ranging from (1) "Not important" to (5) "Vital." The initial list of channels of information was drawn from Klobas et al. (1993) report of the methods used by IT professionals to keep up to date with developments in ICT. Several additional channels were included after consultation with industry contacts. Table 1 lists the information channels included in the questionnaire.

Overall, the students appeared to be diligent in their efforts to keep up to date with employers' skill requirements. The average number of channels used by the students during the previous three months was 3.8 (and the most common number used was 5). Thirteen students (15.3%) had not made any attempt to keep up to date during this period and four (4.7%) had made use of all nine listed channels.

The information channels are ranked by frequency of use in Table 1. The most frequently consulted channels were newspaper employment and IT sections and Internet sources. University instructors had been consulted by about half of the participants during the previous three months. Other students had also been used as a source of information by quite a few students (40%). This high level of use of other students to provide information about employers' skill requirements is understandable given the easy accessibility of other students (Klobas et al., 1993). Work colleagues were ranked 7th overall, but as only around a third of the participants had ICT work experience this means that most of those with prior experience had consulted their colleagues (75% of those with prior ICT work experience had consulted their colleagues). The least used channels were books and vendor presentations. It is likely that students were conscious that information about employer skill requirements derived from books was not going to be sufficiently up to date to meet their needs.

Table 2 shows the importance rankings of the individual information channels. The most highly ranked information channel was Internet sources such as the Cisco and Lucent sites. As well as being frequently used, newspaper ICT sections and employment pages were also considered very important (ranked two and three). University instructors were ranked 4th in importance, which was consistent with their frequency of consultation by students. Although other students were consulted by many students they were not considered as an important channel of information (ranked 7th). This suggests that students recognize that although other students are an easily accessible source of information, they are not necessarily an accurate or reliable source. Both books and vendor presentations were considered of low importance. In future research, it would be interesting to determine how well student perceptions match those of employers.

In addition to the items about methods used to keep up to date, participants were also asked several questions that addressed whether they believed they were in fact obtaining the skills employers required. A majority of participants believed that their degree would provide the skills employers require (67.1% "yes," 5.9% "no," and 27.1% "not sure"). This high level of confidence suggests that although only around 50% of students had consulted their instructors about employer skill requirements during the previous three months (and instructors were only given a medium ranking of importance), students do implicitly accept that instructors know what skills students require. Industry certification was also seen as a very important means to ensure that students obtain the necessary skills (mean importance score was 4.18/5 for those students not yet working in the ICT industry). This is consistent with the results of a recent study on IT certification which found that students undertaking certification believe that the most important benefit of certification is that it provides "real world" experience (McGill & Dixon, 2005).

Are There Demographic Differences in Use and Importance?

Patterns of use and perceptions of importance were further examined to determine whether gender, level of study, or previous ICT work experience had an influence. Differences in use were explored using χ^2 tests and differences in importance were explored using independent sample t-tests. These factors had surprisingly little influence on patterns of use and perceived importance of information channels.

Table 1. Information channels ranked by frequency of use

Rank	Information channel	Number	Percentage
1	Newspaper employment pages	56	65.9
2	Newspaper ICT sections	52	61.2
3	Internet sources (e.g., Cisco, Lucent)	47	55.3
4	University instructors	43	50.6
5	Other students	34	40.0
6	ICT magazines (e.g., Packet Magazine)	29	34.1
7	Work colleagues	24	28.2
8	Books	20	23.5
9	Vendor presentations	17	20.0

Table 2. Information channels ranked by importance

Rank	Information channel	Mean	Standard deviation
1	Internet sources (e.g., Cisco, Lucent)	3.55	1.40
2	Newspaper IT sections	3.38	1.44
3	Newspaper employment pages	3.30	1.30
4	University instructors	2.88	1.42
5	ICT magazines	2.62	1.43
6	Work colleagues	2.54	1.43
7	Other students	2.41	1.13
8	Books	2.24	1.34
9	Vendor presentations	2.13	1.32

The first demographic factor considered was gender. No significant difference was found between the number of information channels used by male and female students. The only significant gender difference was for the levels of use and perceived importance of Internet sources. Male students used Internet sources more frequently and perceived them to be more important for keeping up to date with the skill requirements of employers.

The possible impact of previous ICT work experience was considered next. No significant difference was found between the number of information channels used by those with and those without previous ICT work experience. The only significant difference in usage of information channels was related to consultation with work colleagues and with other students. Those with previous work experience not surprisingly consulted with work colleagues more frequently, and appeared to consider work colleagues a more important channel of information. Presumably those with previous ICT experience would have received better quality information from their work colleagues, than would those without ICT work experience who would have been receiving information from a pool of people with perhaps limited direct ICT experience.

Those without ICT work experience consulted other students more frequently, but there was no difference in perceptions of the importance of other students between those with and those without previous ICT work experience. As previously mentioned, this suggests that other students are consulted because of their accessibility rather than their credibility as a source of information. Those with previous ICT experience have other accessible sources of more credible information and hence do not rely so heavily upon other students.

The differences between undergraduate and postgraduate students were similar to those between those with previous ICT work experience and those without. This is consistent with postgraduate students being more likely to have previous ICT work experience than are undergraduates (54.5% of postgraduates vs. 22% of undergraduates had previous ICT work experience). Undergraduate students consulted other students more frequently, but did not value their information more highly. Postgraduate students also consulted work colleagues more frequently, but they did not value their input more highly. This finding differs from the added importance given to work colleagues by those with previous ICT experience, but the means are in the same direction and the result may reflect the fact that 45.5% of the postgraduates did not have previous ICT work experience.

FUTURE TRENDS

The rapid rate of change in ICT is likely to continue (Benamati et al., 2001b; Lee et al., 2005), and in fact some authors believe that the rate of change is accelerating (Horn, 1999). This means that ICT students will continue to require access to up to date information about employers' ICT skill requirements. Given the increased role of electronic means of information dissemination (Bertot, 2003; Williams & Nicholas, 2001) it is likely that Internet sources of information will continue to be seen as the most important sources and that their frequency of use will increase rapidly so that Internet sources will soon be the most frequently used. Greater broadband access will enable delivery of richer content and greater interactivity. Convergence of information technologies such as notebooks, phones, and television and the development of pervasive computing will provided even greater flexibility to students who wish to keep up to date with employer skill requirements.

CONCLUSION

New graduates require marketable skills in order to gain good employment, but as the ICT industry is subject to rapid change, the skills most in demand change regularly. The study described in this article investigated the approaches that a group of ICT students used to keep up to date with employers' skill needs. Overall, they appeared to be diligent in their efforts to keep up to date with skill requirements. The most commonly used channels were newspaper employment and IT sections, and Internet sources. The same three channels were also rated most highly in terms of importance, with Internet sources being seen as most important.

Instructors were ranked relatively highly in terms of both frequency of consultation and importance and the results suggest an implicit confidence that the knowledge of instructors is up to date. Whilst students have a wide variety of information channels available to them and do indeed make use of them, instructors have a major role to play in providing up to date information about employers' needs. They need to be highly accessible and to ensure that their knowledge of employers' skill requirements remains current. Instructors should use studies of employers' requirements to assess their course offerings and to help guide their students.

KEY TERMS

Industry Certification: Certification involves passing a recognized standardized test (or set of tests) within particular subject areas. It intends to establish a standard of competency in defined areas. ICT industry certifications are designed to provide targeted skills that have immediate applicability in the workplace.

Information Channel: A term used to describe the various combinations of sources and formats of information.

Information Format: The arrangement and appearance of information. Format includes both the media used and the style of presentation.

Information Gathering Strategies: The approaches and processes used by information seekers. Information seeking behavior is influenced by previous experience, mental models, and preferences of information seekers.

Information Source: An organization or person from which information is obtained.

Information Technology Professionals: A term used to describe people for whom development and support of IT systems and related activities is their primary employment. The group includes people who design hardware, who develop and support information systems and who train end users. It does not include people who use ICT in the course of pursuing other professions.

Information Technology Skills: All IT professionals require some computer skills; these may include particular programming languages, database, or networking skills.

Strategic Alignment Between Business and Information Technology

Fernando José Barbin Laurindo

Tamio Shimizu
University of São Paolo, Brazil

INTRODUCTION

Information technology (IT) has assumed an important position in the strategic function of the leading companies in the competitive markets (Porter, 2001). Particularly, e-commerce and e-business have been highlighted among IT applications (Porter, 2001). Two basic points of view can be used for understanding IT's role: the acquisition of a competitive advantage at the value chain, and the creation and enhancement of core competencies (Porter & Millar, 1985; Duhan, Levy, & Powell, 2001).

Several problems have been discussed concerned with IT project results in effectiveness of their management. Effectiveness, in the context of this article, is the measurement of the capacity of the outputs of an information system or of an IT application to fulfill the requirements of the company and to achieve its goals, making this company more competitive (Shimizu, Carvalho, & Laurindo, 2006).

There is a general consensus about the difficulty of finding evidence of returns over the investments in IT (the "productivity paradox"), even though this problem can be satisfactorily explained (Farrell, 2003). Carr (2005) defends the idea that IT in itself has no more strategic value, since it is so widely disseminated that it could not be a source of strategic differentiation anymore.

In order to better use these investments, organizations should evaluate IT effectiveness, which allows the strategic alignment of objectives of implemented IT applications and their results with the company business vision (Shpilberg, Berez, Puryear, & Shah, 2007; Laurindo & Moraes, 2006). Besides, it must be highlighted that if IT applications are associated with changes in business processes, it is possible to notice greater impacts in business performance (Farrell, 2003).

According to Benko and McFarlan (2003), three aspects must be taken into account about IT strategic alignment: IT projects portfolio, business objectives, and the constantly changing situation of business environment.

Thus, the comparison and evaluation of business and IT strategies and between business and IT structures must be a continuous process, since the company situation is constantly changing to meet market realities and dynamics.

THEORETICAL BACKGROUND

Finding Strategic IT Applications

The discussion about the strategic impact of IT applications started in the 1970s, when technology began to provide more powerful alternatives not only for solving companies' problems but also for increasing their business competitiveness (Shimizu et al., 2006).

One of the first important proposals for studying the strategic role of IT was that of *critical success factors* (CSFs), which is still a widespread method used for linking IT applications to business goals, and for planning and prioritizing information systems projects. This method was proposed by Rockart (1979) and states that the information systems, especially executive and management information systems, are based on the current needs of the top executives. These information needs should focus on the CSFs.

Rockart defines CSFs as the areas where satisfactory results "ensure successful competitive performance for the organization." This author states that CSFs' prime sources are the structure of the industry, business (or competitive) strategy, industry position, geographic location, environment, and temporal factors.

Basically, the CSF method includes the analysis of the structure of the particular industry and the business strategy, and the goals of the organization and its competitors. This analysis is followed by two or three sessions of interviews with the executives, in order to identify the critical success factors related to business goals, define respective measures (quantitative or qualitative) for the CSFs, and define infor-

mation systems for controlling CSFs and their measures (Shimizu et al., 2006).

For Rockart, this process can be useful at each level of the company and should be repeated periodically, since CSFs can change through the time and also can differ from one individual executive to another.

The CSF method had an important impact on managerial and strategic planning practices, even though it was primarily conceived for information systems design, especially management and executive information systems.

Besides the utilization in information systems planning and information systems project management, it has been used in strategic planning and strategy implementation, management of change, and as a competitive analysis technique.

Furthermore, the continuous measurement of CSFs allows companies to identify strengths and weaknesses in their core areas, processes, and functions (Rockart, 1979).

More details of the process of implementation of the CSF method can be found in Rockart and Crescenzi (1984).

Understanding IT Strategic Role in Companies

McFarlan (1984) proposed the Strategic Grid that analyzes the impacts of IT-existent applications (present) and of an applications portfolio (future), defining four boxes, each one representing one possible role for IT in the enterprise: "Support," "Factory," "Turnaround," and "Strategic" (see Figure 1).

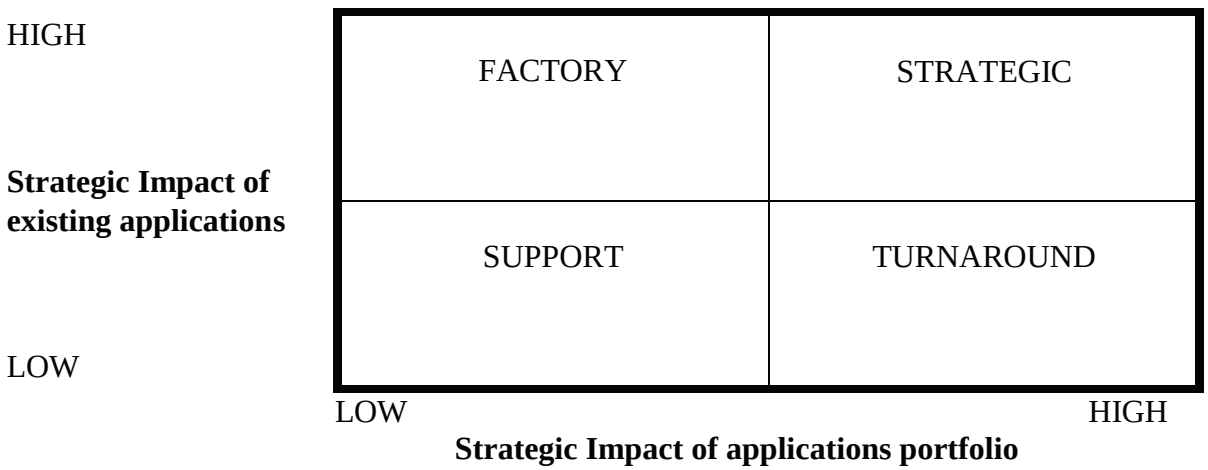
- *Support:* IT has little influence in present and future company strategies.
- *Factory:* Existent IT applications are important for the company's operations success, but there is no new strategic IT application planned for the future.
- *Turnaround:* IT is changing from one situation of little importance ("support" box) to a more important situation in business strategy.
- *Strategic:* IT is very important in business strategy in the present, and new planned applications will maintain this strategic importance of IT in the future.

In order to assess the strategic impact of IT, McFarlan proposed the analysis of five basic questions about IT applications, related to the competitive forces (Porter, 2008):

Can IT applications:

- build barriers to the entry of new competitors in the industry?
- build switching costs for suppliers?

Figure 1. Strategic grid of impacts of IT applications (McFarlan, 1984)



- change the basis of competition?
- change the balance of power in supplier relationships?
- create new products?

These questions should be answered considering both present and planned future situations.

Thus, IT may present a smaller or greater importance, according to the kind of company and industry operations. In a traditional manufacturing company, IT supports the operations, since the enterprise would keep on operating even when it could not count on its information systems. However, IT is strategic in a bank for business operations, since it is a source of competitive advantage and a bank cannot operate without its computerized IS.

Nolan and McFarlan (2005) have updated the Strategic Grid, changing the two "axes" for "Need for Reliable IT" (instead of "Present Impact") and "Need for New IT" (instead of "Future Impact"). These authors stated that companies in "Support" and "Factory" quadrants adopt a *defensive* approach regarding IT. On the other hand, companies classified in "Turnaround" and "Strategic" quadrants can be considered *offensive* in IT use. They also indicated the right policies in IT governance (Weil & Ross, 2005) for the board of directors' use in each of the four situations of the Strategic Grid.

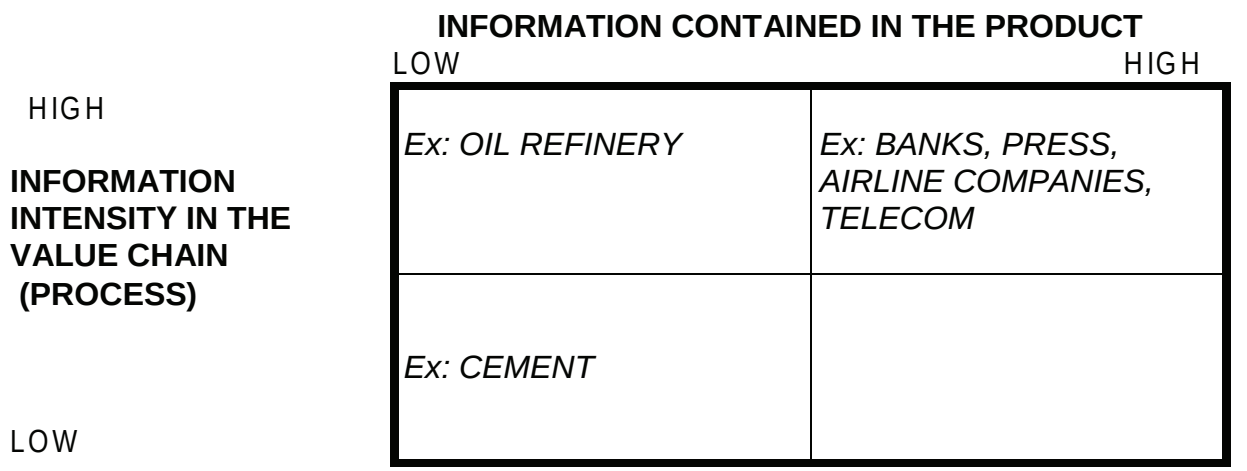
Porter and Miller (1985) highlight the concepts of the value chain (activities inside the company linked by connections and which have one physical component and another of information processing) and value systems (the set of value chains of an industry from the suppliers to the final consumer).

IT permeates the chains of value, changing the way of executing activities of value and also the nature of the connections among them and, therefore, IT can affect competition:

- by changing the structure of the sector since it has the ability to influence each of the five forces of competition (Porter, 2008);
- by creating new competitive advantages, reducing costs, increasing differentiation, and altering the scope of competition scope; and
- by generating completely new business.

The potential that IT has to make these changes varies according to the characteristics of the process (value chain) and of the product, regarding information needs. The "Information Intensity Matrix" considers the value chain and analyzes "how much" information is contained in the process and the product (see Figure 2). In companies whose products and processes contain a lot of information, information technology will be very important (Porter & Miller, 1985).

Figure 2. Information intensity matrix (adapted from Porter & Millar, 1985)



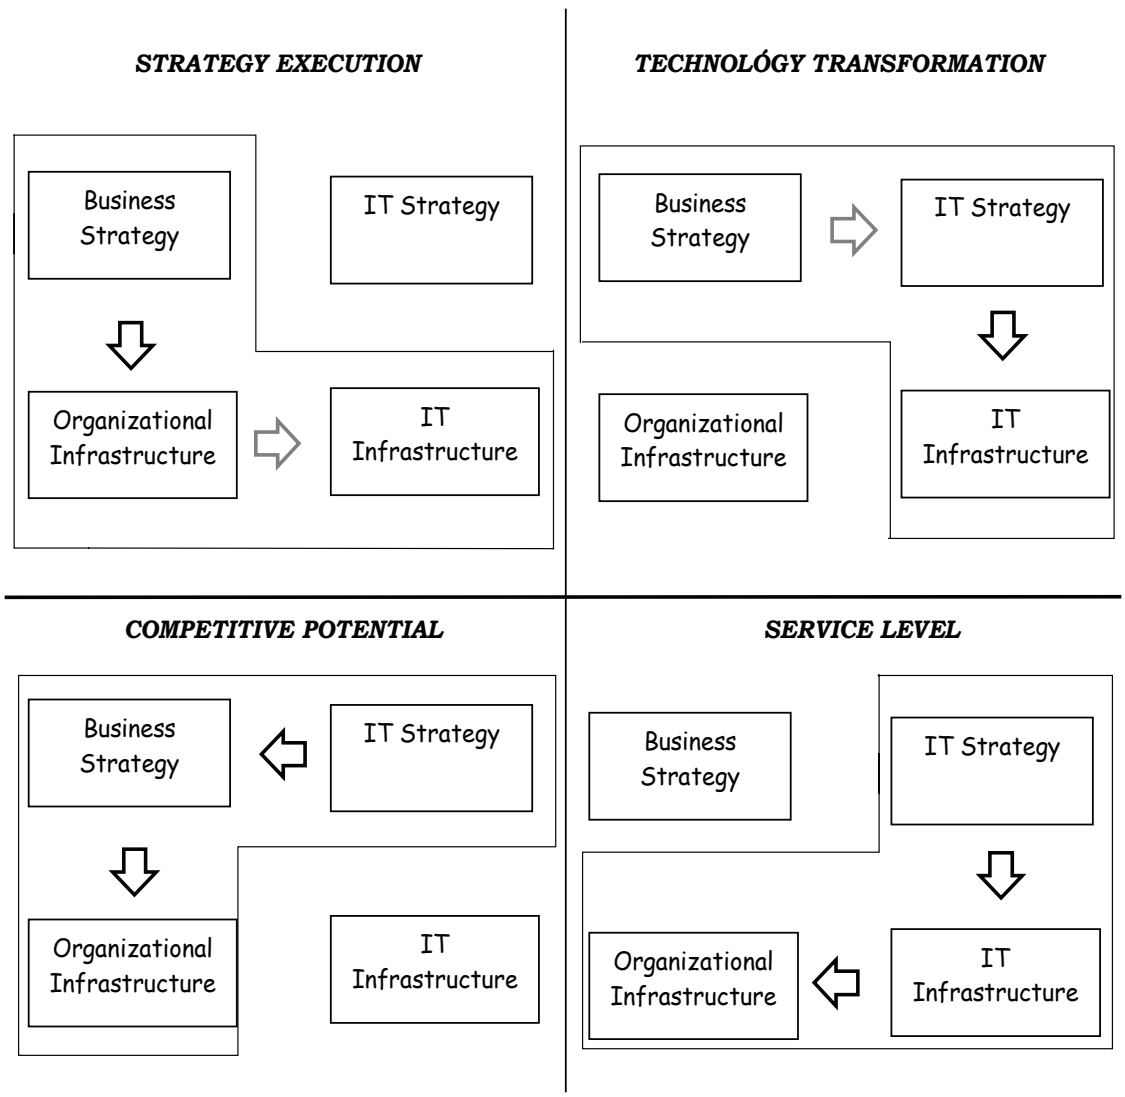
In their original article, Porter and Millar did not cite an example for "high information content in the product" or "low information intensity in the process" in the Information Intensity Matrix. However, for Duhan et al. (2001), this would be the case of educational and law firms, for consulting firms would also fit in this same quadrant.

Further according Duhan et al. (2001), an analysis of the value chain would be impaired in the case of knowledge-based companies (such as consulting firms) where it is hard to identify the value that is aggregated to each activity. In these situations, the authors propose that using the essential competencies would be more appropriate to plan the strategic use of information systems.

Henderson and Venkatraman (1993) proposed the "Strategic Alignment Model" that analyzes and emphasizes the strategic importance of IT in the enterprises. This model is based on both internal (company) and external (market) factors.

The authors emphasize that strategy should consider both internal and external domains of the company. Internal domain concerns administrative structure of the company; external domain concerns the market and the respective decisions of the company. Thus, according to this model, four factors (that the authors called domains) should be considered for planning IT:

Figure 3. Perspectives of strategic alignment (adapted from Henderson & Venkatraman, 1993)



1. business strategy,
2. IT strategy,
3. organizational infrastructure and processes, and
4. IS infrastructure and processes.

The Strategic Alignment Model brings the premise that the effective management of IT demands a balance among the decisions about those four domains above.

According to Henderson and Venkatraman, there are four main perspectives of Strategic Alignment, through the combination of the four factors, starting from business strategy or from IT strategy, as shown in Figure 3.

One important innovation of this model is that IT strategy could come first and change business strategy, instead of the usually general belief that business strategy comes before IT planning. This planning should be a continuous process, since external factors are in a permanent changing situation. If the company does not follow these changes, it will be in serious disadvantage in the fiercely competitive market. This is particularly true when a new technology is adopted by almost all companies in an industry, passing from a competitive advantage for those that have it to a disadvantage to those that do not use it. Thus, in this sense, the strategic alignment differs from the classic vision of the strategic plan, which does not present the same dynamic approach.

After the proposal of the four perspectives above, Luftman (1996) described four new perspectives that start in the infrastructure domains, instead of the strategies domains:

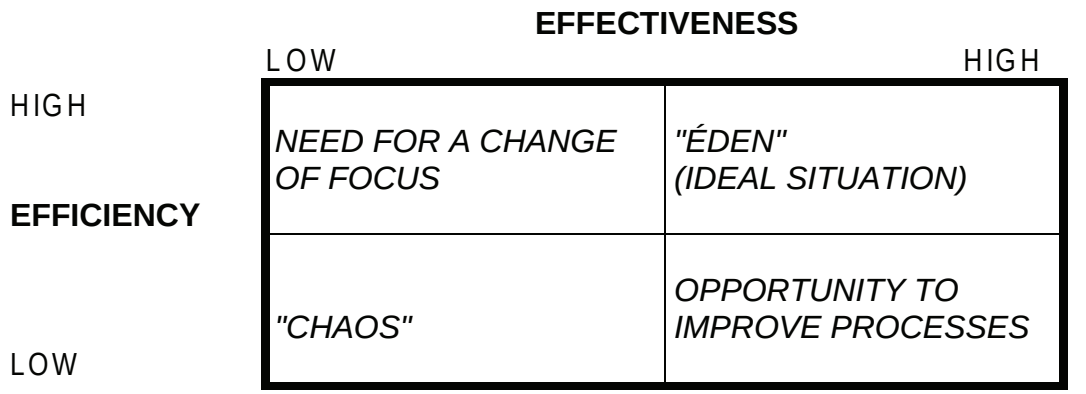
- *Organizational IT Infrastructure Perspective:* Organizational infrastructure → IT infrastructure → IT strategy
- *IT infrastructure Perspective:* IT infrastructure → IT strategy → Business strategy
- *IT Organizational Infrastructure Perspective:* IT infrastructure → Organizational infrastructure → Business strategy
- *Organizational Infrastructure Perspective:* Organizational infrastructure → Business strategy → IT strategy

Luftman (1996) also proposed that in some situations a fusion of two perspectives might occur. In these cases, two perspectives can be simultaneously assessed and impact the same domain: *IT Infrastructure Fusion, Organizational Infrastructure Fusion, Business Strategy Fusion, IT Strategy Fusion.*

Research has been developed in order to find the enablers of Strategic Alignment. Luftman (2001) listed five of them: senior executive support for IT; IT involved in strategy development; IT understands the business, business-IT partnership; well-prioritized IT projects; and IT demonstrates leadership. The absence or poor performance of these same factors are considered inhibitors of Strategic Alignment.

Some authors, like Ciborra (2004), state the strategic success of IT applications might be achieved through a tentative approach, rather than structured methods of strategic IT

Figure 4. Efficiency vs. effectiveness in IT applications (adapted from Shimizu et al., 2006)



planning. These authors argue that frequently the drivers of strategic IT applications are efficiency issues, instead of a result of a strategic IT plan. Some important and well-known successful information systems, with clear strategic impacts, do not present evidence of being previously planned, which seems to be in agreement with this kind of thinking (Eardley, Lewis, Avison, & Powell, 1996).

EFFICIENCY AND EFFECTIVENESS: DIAGNOSING THE ROLE OF IT IN COMPANIES

In this article the importance of focusing on the effectiveness of IT utilization has been emphasized, since frequently analysis is done only from the point of view of efficiency. However, this does not mean that being efficient is not positive; it means that one needs to be efficient in certain areas. In other words, once effectiveness is achieved, increased efficiency can result in important gains and there are many models that help to analyze and improve IT efficiency.

Figure 4 contains a proposed diagram for viewing the situations related to efficiency and effectiveness in the use of IT.

When companies demonstrate low efficiency and high effectiveness, they are in "Chaos"—in a critical situation. The first move to get out of this situation should be to aim at increased effectiveness, to align the IT strategy with the business strategy. If the company has low effectiveness, but high efficiency in the use of IT, it means that it should redirect its efforts, change the focus of its activities, in order to use its good capacity where it can add value to the company's competitiveness. In the case of a company with high effectiveness, but low efficiency in IT utilization, it is necessary to work to improve its processes, with a view to exploiting to the maximum the focus that is already on the right things, and which can contribute to the success of the company's strategy. Finally, a company that is efficient and effective in the use of IT will arrive in "Eden," the ideal situation, which should be the goal for all.

CONCLUSION

At present there are a series of applications that have captivated the attention of many and have opened up new possibilities. Both Knowledge Management and Customer Relationship Management have been closely associated to IT. In fact, without IT these concepts could hardly have been effectively used in companies. In this sense, one important example is the growing use of business intelligence applications.

Despite the failure of many virtual enterprises (the so-called "dot.coms"), e-business and e-commerce applications seems to have reached a new maturity level, especially B2B (business-to-business—the connection between companies via the Internet).

There are various success stories, and large companies are increasingly investing in this success. According to Porter (2001), the Internet is the IT tool that, up to the present, has shown the greatest potential of being a source of obtaining or stressing strategic advantages. Therefore, an appropriate analysis and evaluation of IT effectiveness can take on a fundamental role, enabling it to really become a powerful tool for competitiveness.

The concepts described above show the importance of a broad view for analyzing IT strategic alignment. Each of the described models (CSF, Strategic Grid, Information Intensity Matrix, and Strategic Alignment) focuses on specific aspect of this issue.

These widespread known models, in fact, have complementary characteristics, and concomitant use of them allows a better comprehension of the role of IT in an organization.

On the other hand, even the use of the three models does not solve the complexity of IT alignment in organizations. As highlighted by several authors, sometimes a tentative and evolutionary approach can be successfully adopted, in circumstances that structured methods do not work properly. By this continuous focus in the IT strategic alignment, the problems of the "productivity paradox" would be overcome.

Further studies would be necessary for a better and deeper understanding of the importance of IT effectiveness for the success of competitive companies. However, this chapter intended to help find a way for this understanding and to provide some tools.

KEY TERMS

Competitive Forces: According to Porter (2008), the state of the competition in a particular industry depends on five basic forces: new competitors, bargaining power of suppliers, bargaining power of customers, rivalry among current competitors, and substitute products or services.

Critical Success Factor (CSF): One of the areas where satisfactory results "ensure successful competitive performance for the organization," according to Rockart (1979).

Effectiveness: In the context of IT, the measurement of the capacity of the outputs of an information system or of an IT application to fulfill the requirements of the company and to achieve its goals, making this company more competitive. In other words, effectiveness can be understood as the ability of "do the right thing."

Productivity Paradox: The discussion about the lack of evidence about the return of investments on IT in the economy productivity indicators.

Strategic Alignment: The IT Strategic Alignment Model was proposed by Henderson and Venkatraman (1993) and consists of a framework for studying IT impacts on business and understanding how these impacts influence IT organization and strategy, as well as how it enables analysis of the market availabilities of new information technologies.

Strategic Grid: Nolan and McFarlan (2005) and McFarlan (1984) proposed the Strategic Grid, which allows the visualization of the relationship between IT strategy and business strategy and operations. This model analyzes the impacts of IT-existent applications (present) and of an applications portfolio (future), defining four boxes, each one representing one possible role for IT in the enterprise: "Support," "Factory," "Turnaround," and "Strategic."

Value Chain: According to Porter and Millar (1985), the set of technologically and economically distinct activities a company performs in order to do business.

Strategic IT Investment Decisions

INTRODUCTION

As many as half the decisions taken in organizations result in failure (Nutt, 1999). As information technology (IT) assumes a greater prominence in firms' strategic portfolios, managers need to pay more attention to managing the technology. However, while IT can have a significant impact on organizational performance, it can also be a major inhibitor of change and can be a resource-hungry investment that often disappoints. Organizations can best influence the success of IT projects at the decision stage by rejecting poor ones and accepting beneficial ones. This may enable better implementation, as Nutt (1999) suggests most decision failures are due to implementation failure that tends to be under managers' control.

However, little is known about IT decision processes. Research demonstrates the importance of managing strategic IT investment decisions (SITIDs) effectively. SITIDs form part of the wider range of corporate strategic investment decisions (SIDs) that cover all aspects in which the organization might wish to invest. Strategic investment decisions will have different degrees of IT intensity that may impact outcome. IT investment intensity is the degree to which IT is present in an investment decision. That is, some decisions will be wholly about IT investments while others will have little or no IT—most, though, will be blended programs of IT and non-IT elements. Here, IT investment intensity is defined as the ratio of IT spending to total investment. The higher the IT investment intensity, the more important IT is to the whole investment. For example, Chou, Dyson, and Powell (1997) find IT investment intensity to be negatively associated with SID effectiveness. The concept of IT intensity is similar to, but also somewhat different from, the concept of information intensity. Information intensity is the degree to which information is present in the product or service (Porter & Millar, 1985).

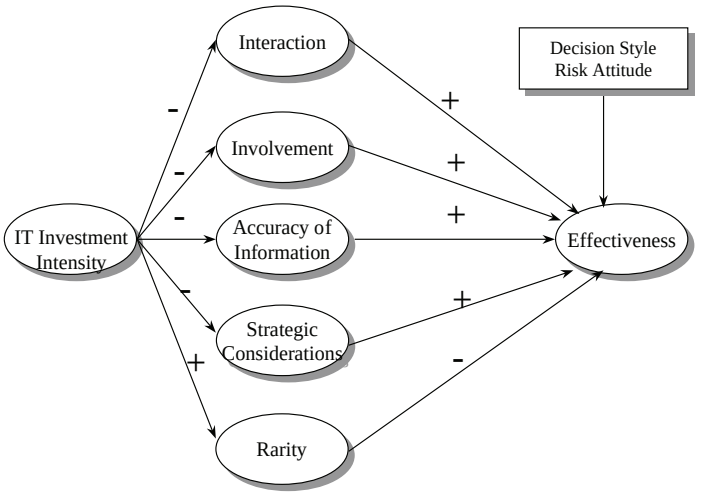
Management may use different processes in order to make different types of decisions (Dean & Sharfman, 1996). The link between decision process and outcome is so intimate that "the process is itself an outcome" (Mohr, 1982, p. 34). This may imply that the link between IT investment intensity and SID effectiveness is not direct but that the impact of IT investment intensity may be through the decision process. If different IT intensity in projects leads to different decision processes, leading to different outcomes, then it is important to know what factors act in this, in evaluating and managing SITIDs. This chapter presents an integrative framework for exploring the IT investment intensity-SID effectiveness relationship.

BACKGROUND

Studying decisions involves "contextualism" (Pettigrew, McKee, & Ferlie, 1988), which integrates process, content, and context, as all decisions need to be studied in context. Content refers to the decision itself, here exploring the nature and scope of SIDs. Process refers to actions, reactions, and interactions as managers allocate resources for the decision. The context includes the outer context of economic, political, and social actions, while the inner context involves ongoing strategy, structure, culture, management, and political processes.

Many researchers have investigated how strategic decisions are made, though most focus on the decision process rather than the implementation and the outcome. However, Hickson, Miller, and Wilson (2003) identify eight independent variables in decision implementation—familiarity, assessibility, specificity, resourcing, acceptability, structural facilitation, and priority—and uncover two distinct approaches—experience-based and readiness-based. The experience-based approach leads to acceptance of what is being done, while the readiness-based approach leads to implementation being given clear priority. Both approaches may be employed together. Hsu (2001) on the other hand introduces promethean rationality—the stealing back of order amid disorder. Sauer-Leroy (2004) argues that decision reality is much more complex than can ever be captured by

Figure 1. The theoretical model (adapted from Chou et al., 1997)



financial analysis and that projects often introduce inertia to the organization, as they are often irreversible. He stresses the role of subjective factors in strategic decisions.

In the IT investment intensity-SID effectiveness link, the roles of process, content, and context are unclear. Though unclear, it is likely that the links between variables are not direct; rather they are mediated or moderated by other variables or processes. Moderators and mediators are functions of third variables. A moderator "partitions a focal independent variable into subgroups that establish its domains of maximal effectiveness in regard to given dependent variables," while a mediator function "represents the generative mechanism through which the focal independent variable is able to influence the dependent variable of interest" (Baron & Kenny, 1986, p. 1174). Sambamurthy, Bharadwaj, and Grover (2003) employ the moderator concept in their work on reshaping agility through digital options. They, for example, see IT competence as an antecedent of firms' competitive actions, but the relationship is mediated by dynamic capabilities. Sambamurthy et al. (2003) demonstrate theoretically the IT investments and capabilities influence firm performance through organizational capabilities—agility, digital options, and entrepreneurial alertness, and through strategic processes involving capability building, entrepreneurial action, and co-evolutionary adaptation. This, they claim, is valid at the enterprise level, for business units and for processes. They finally call for empirical research that might validate their theoretical developments. This article takes a slightly different route as it focuses on IT at the project or at the decision level, and it is based on data that back up the model development.

Here, the proposal is that the impact of IT investment intensity on SID effectiveness is through decision processes. Accordingly, decision process constructs should have a mediating effect. Greater IT intensity in projects leads, inter alia, to a more technically orientated project that impacts SID effectiveness. The decision content has a mediating effect on the IT involvement-SID effectiveness link. The investment context impacts the outcome. Therefore, context constructs should act as covariances that impact SID effectiveness. Decision context, content, and process will involve many individual constructs, some unrelated to IT investment intensity. Two criteria can be employed in order to select the constructs of interest here. First, the decision construct is expected to vary with IT investment intensity. Second, it must impact at the decision level. Figure 1 outlines the basic model.

A hypothesized negative impact of IT investment intensity on several constructs suggests projects with high IT investment intensity are more challenging than those with low IT content. Effectiveness compares actual performance against planned target, outcomes, and policy objectives, measured by project success, correct choice, unexpected negative outcomes, learning, and satisfactory process (Butler, Davies, Pike, & Sharp, 1991).

Decision Context

The context of any investment is affected by many things, such as the firm's financial health, its market position, industry pressures, culture, and business strategy. SIDs often involve major change to the organization and environ-

ment. This suits managers with an innovative risk attitude. From a style perspective, decision quality is dependent on resources the leader is able to utilize. Consensus-driven management seems able to acquire more information than directive management, and leads to more effective decisions. Management's *attitude to risk* and *decision style* are predicted to relate to SID effectiveness, since other factors impact at an organizational level.

Decision Process

Strategic decision processes involve comprehensiveness, rational activity, participation, duration, and conflicts (Rajagopalan, Rasheed, & Datta, 1993). Comprehensiveness measures rationality and is the extent to which the organization attempts to be exhaustive in making and integrating strategic decisions. This includes formal meetings, assignment of primary responsibility, information-seeking and analytical activities, the systematic use of external sources, stakeholder involvement, use of consultants, reviews of historical data, functional expertise (Papadakis, 1995), and informal interaction. Hickson, Butler, Cray, Mallory, and Wilson (1986) define "politicality" as the degree to which influence is exerted on the outcome through a decision process. Strategic decision-making is not a matter of explicating alternatives and choosing on the basis of readily available criteria all participants perceive as appropriate (Fahey, 1981). It might be expected that interaction and involvement are related to IT investment intensity.

Interactions are contacts between people. Higher IT intensity reduces interaction and SID effectiveness. Decision-makers' IT knowledge, experience, and education are associated with alienated attitudes toward IT. Higher IT investment intensity leads to more technically oriented projects. Without IT knowledge, managers cannot discuss the project knowledgeably. It, therefore, reduces interaction and impacts decision quality. This article suggests that higher IT intensity reduces *involvement,* reducing SID effectiveness. Less involvement leads to less collective information and reduce decision effectiveness. This suggests that *IT investment intensity reduces interaction and adversely impacts decision effectiveness* and that *IT investment intensity reduces involvement and adversely impacts decision effectiveness.*

The evaluation process is important for investment decisions. An IT investment decision is problematic because the cost and benefits are hard to identify and quantify. Therefore, uncertainty of information used in evaluating IT investment is greater. The higher the information uncertainty, the lower the *information accuracy*. This article expects that lower accuracy of information reduces decision effectiveness, that is, *IT investment intensity reduces information accuracy and adversely impacts decision effectiveness.*

It can be argued that the IT evaluation problem is one of alignment. This article expects that management may fail to link IT's strategic purpose with organizational strategy, reducing decision effectiveness. This suggests that *IT investment intensity reduces strategic considerations and adversely impact decision effectiveness.*

Decision Content

A strategic decision is characterized by its novelty and complexity. Complexity relates to the number and variety of factors in the environment that impinge on decision-making behavior. SIDs evolve from the organizational context and have their own characteristics. Constructs that contribute to decision complexity include rarity and importance. Uncertainty is due to *rarity*. Rarity assesses the novelty of the decision to the firm. If a firm repeatedly makes similar decisions, then it will gain experience; conversely, a rare decision is likely to be more problematic. Importance is common to all SIDs irrespective of IT investment intensity, as they are all strategic. New technologies often require investments of a different nature because of high uncertainty, widespread organizational impact, and greater strategic importance. Even compared with other new technologies, the IT life cycle is short so that the IT component of projects is constantly changing, increasing rarity. Rarity inhibits effective feedback and learning. This article expects that the higher IT investment intensity, the higher decision rarity, reducing decision effectiveness; *IT investment intensity heightens decision rarity and adversely impacts decision effectiveness.*

In order to investigate these proposals, empirical work investigated a single strategic investment project in each if 80 Taiwanese manufacturers. IT investment intensity is measured by the ratio of IT spending to total investment in the project, while the measure of decision effectiveness is subjective. In order to capture the whole process from decision to outcome, only projects that were complete were researched. Thus each project had a decision process and an outcome to allow assessment of success.

DISCUSSION

A principal components factor analysis highlights five important factors in these decisions—information accuracy, strategic consideration, interaction, involvement, and rarity. However, only three proposed mediators, interaction, information accuracy, and strategic consideration are significant in predicting mediators.

The model as a whole is significant in predicting SID effectiveness. When contextual variables are added, IT investment intensity is still significant in predicting SID effectiveness. Interaction, information accuracy, and strategic consideration have a negative correlation with IT investment intensity, but a positive correlation with SID effectiveness. Hence, the impact of IT investment

intensity is transmitted to interaction, information accuracy, and strategic considerations and, through that, adversely impacts decision effectiveness. This suggests that *IT investment intensity does reduce interaction and adversely impacts decision effectiveness.* It is also the case that *IT investment intensity reduces information accuracy and adversely impacts decision effectiveness,* and that *IT investment intensity reduces strategic considerations and adversely impacts decision effectiveness*. However *IT investment intensity is not found to reduce involvement and adversely impacts decision effectiveness*, nor does *IT investment intensity heighten decision rarity and adversely impacts decision effectiveness*.

Three process-related constructs, interaction, strategic considerations, and information accuracy act as mediating factors in linking IT investment intensity and SID effectiveness, as they reduce the effects of IT investment intensity. Content-related constructs do not act as mediators. Although decision rarity is negatively associated with SID effectiveness, it is unrelated to IT intensity.

Interaction in the formulating process has a mediating effect on the linkage. Interaction is important in developing group behavior. IT investment intensity lowers interaction, reducing SID effectiveness.

Strategic considerations act as a mediating variable. The higher the IT intensity, the lower the strategic considerations, leading to reduced SID effectiveness. This demonstrates that the IT evaluation problem is really one of alignment.

Information accuracy acts as a mediating variable. The higher the IT investment intensity, the lower the information accuracy, reducing SID effectiveness. This supports Freeman and Hobbs (1991), who find managers ignoring reject signals given by capital budgeting techniques, and identify senior management's preference for qualitative information and IT investment as an "act of faith" (Powell, 1993). This suggests that high information uncertainty leads to a limited use of capital budgeting techniques.

IT investment intensity is still significant when interaction is tested as a mediator. This indirect transmission of influence from IT investment intensity to SID effectiveness via interaction shows that the effect of IT investment intensity on effectiveness is only partially mediated by interaction. The effect of IT investment intensity on SID effectiveness is completely mediated by strategic consideration and information accuracy—two evaluation-related constructs. This implies that, in seeking a better outcome of SITIDs, research that focuses on evaluation factors may be insufficient to capture the complexity of SITIDs.

FUTURE TRENDS

As demonstrated, the two evaluation-related constructs are highly correlated. From an IT investment perspective, alignment of IT and business strategy is problematic if there is a lack of accurate information for evaluation. However, evaluation of IT investments is problematic if there is a lack of alignment of IT and business strategy. To improve the effectiveness of IT investment, management needs to increase alignment of IT and business strategy and information accuracy for evaluation techniques simultaneously. This points to the issues to which management needs to attend in the future.

CONCLUSION

Much work on SITIDs ignores the continuous nature of decisions and the relationships between SITIDS and non-IT SIDs. This article proposed a model that explores mediators in the link between IT investment intensity and SID effectiveness. Survey data show that interaction, information accuracy, and strategic considerations are important factors that mediated the impact of IT investment intensity. Willcocks (1992) emphasizes that management faces a Catch-22 situation with IT investment. They know how important IT is, but they do not know how to evaluate IT projects. The implication is that managers need to pay special attention to the problematic nature of IT investment intensity in SIDs. They should focus on facilitating interaction, ensuring integration of IT strategy with corporate strategy, and improving information accuracy.

KEY TERMS

Contextualism: Integrates process, content, and context to study organizational decision-making.

Decision Content: Content refers to the particular decision under study. Content explores the basic nature and scope of decisions.

Decision Context: The context includes the outer context, which refers to the national economic, political, and social context for an organization, and the inner context, which is the ongoing strategy, structure, culture, management, and political process of the organization. Context helps to shape the process of decision-making.

Decision Process: The actions, reactions, and interactions of the various interested parties as they seek to make a commitment to allocate corporate resources. Process incorporates both the formulation and evaluation processes.

IT Investment Intensity: A concept similar to, but also somewhat different from, the concept of information intensity. Information intensity is the degree to which information is present in the product/service of a business. The degree to which IT is present in an investment decision reflects the IT level of intensity of that decision. Here, IT investment intensity is defined as the ratio of spending on IT to total investment.

Moderators and Mediators: In the social sciences, moderators and mediators have been identified as two functions of third variables. These are subgroups of independent variables that affect given dependent variables via a mediator function.

Strategic IT Investment Decisions: Significant, long-term decisions to invest in projects that have substantial information systems or information technology components. They form part of corporate strategic investment decisions.

Strategic Knowledge Management in Public Organizations

Ari-Veikko Anttiroiko
University of Tampere, Finland

INTRODUCTION

New public management and the more recent concept of new public governance have become the dominant management doctrines in the public sector. Public organizations have become increasingly network-like units with various governance relations with actors from the public, business, and voluntary sectors. Their organization is based more on networks than on traditional hierarchies, accompanied by a transition from the command-and-control type of management to initiate-and-coordinate type of governance.

Among the most critical factors in this transformation is knowledge, for most of what has happened has increased the overall demand to create and process knowledge, and to utilize it in the performance of governmental functions. The success of public organizations depends increasingly on how efficiently they utilize their knowledge assets and manage their knowledge processes in adjusting to local and contextual changes, as illustrated in Figure 1 (cf. Gupta, Sharma, & Hsu, 2004, p. 3; Skyrme, 1999, p. 34, Fletcher, 2003, pp. 82-83). This requires that special attention be paid to strategic knowledge management.

In the early organization theories of public administration, knowledge was predominantly conceptualized within the internal administrative processes, thus to be conceived of as bureaucratic procedures, rationalization of work processes, identification of administrative functions, and selected aspects of formal decision making. New perspectives emerged after World War II in the form of strategic planning and new management doctrines. The lesson learned from strategic thinking is that we need information on the external environment and changes therein in order to be able to adapt to and create new opportunities from these changes (see Ansoff, 1979; Bryson, 1995). As the complexity in societal life and related organizational interdependency has increased due to globalization and other trends, new challenges of managing organization-environment interaction also emerged (cf. Skyrme, 1999, p. 3).

Figure 1. The public organization as an institutional mediator (adopted from Anttiroiko, 2002, p. 272)

BACKGROUND

The branch of management doctrine that became known as knowledge management (KM) reflected actual changes and new ideas in the business world. Classic works that inspired later developments included Polanyi (1966) and Drucker (1969). During the 1980s knowledge became widely recognized as a source of competitiveness, and by the end of the 1990s, knowledge management had become a buzzword. Among the best-known thinkers who contributed to the rise of this field are Peter Senge (1990), Ikujiro Nonaka and Hirotaka Takeuchi (1995), Karl-Erik Sveiby (1997), and Thomas A. Stewart (1997). (For more on the evolution of knowledge management, see Barclay & Murray, 1997; Gupta et al., 2004, pp. 8-10.) It is becoming common understanding that in essence *knowledge management* is about governing the creation, dissemination, and utilization of knowledge in organizations (Gupta et al., 2004, p. 4; Lehaney, Clarke, Coakes, & Jack, 2004, p. 13).

Knowledge cannot be managed in the traditional sense of management. The processing and distribution of information can surely be managed, but it is only one part of the picture. The other concerns knowledge and especially managers' ability to create conditions which stimulate active and dynamic knowledge creation, learning, and knowledge sharing within the organization (e.g. Nonaka, Toyama, & Konno, 2000). To systematize this picture we may say that knowledge management includes four core areas (cf. Gupta et al., 2004; Lehaney et al., 2004):

- *Information Management:* Managing data and information, and designing information and knowledge systems
- *Intellectual Capital Management:* Creating and utilizing knowledge assets, innovations, and intellectual capital.
- *Knowledge Process Management:* Organizing, facilitating, and utilizing sense-making and other knowledge processes.
- *Organizational Learning:* Creating learning and knowledge sharing environments and practices.

Traditionally the most widely applied areas of knowledge management in public organizations used to be data and transaction processing systems, and management information systems serving mainly internal administrative functions. Yet, since the 1980s authorities started to facilitate the exchange of information by local area networks, followed by the Internet revolution of the 1990s. In the early 2000s the knowledge management agenda has focused increasingly on knowledge sharing and learning, and in inter-organizational network and partnership relations (e.g., Wright & Taylor, 2003). As reported by OECD (2003, p. 4), knowledge management ranks high on the management agenda of the great majority of central government organizations across OECD member countries, followed with some time lag by regional and local authorities. Many public organizations have even developed their own KM strategies. The leading countries in this respect include France, Sweden, Finland, and Canada (OECD, 2003, pp. 28-29).

As for more operational actions, there has been a wave of intranet projects at all levels of public administration since the late 1990s. The result is that some 90% of state agencies surveyed by OECD in the early 2000s had their intranets in place. Sectors that really stand out as being well above the OECD average include organizations in charge of finance and budget, of justice, and of trade and industry (OECD, 2003, pp. 20-30). Intranet projects in the public sector aim at creating an Internet-based computer network to securely share information or operations between politicians, administrators, and other employees. Extranet extends such a network outside the organization—that is, to users, partners, service providers, and other stakeholders. Many public organizations in different countries and at different institutional levels have set up such extranet and intranet projects. For example, New York City established in the early 2000s the Human Services Extranet (later renamed the Integrated Human Services Project) to link the city agencies with human service contractors. Similarly, in 2003 the Queensland Government, Australia, established a project aimed at enhancing the effectiveness of e-government service delivery, which was supported by a government-wide extranet. Such projects have been numerous in the public sector since the early 2000s, indicating a transition from information management towards genuine knowledge management. Yet, it is equally true that many public organizations have been slow to embrace knowledge management and knowledge technologies.

FOCUSING ON THE STRATEGIC ASPECT

Combining strategic thinking with knowledge management brings us to the very core of the life of organizations. *Strategic knowledge management* is a set of theories and guidelines that provides tools for managing an organization's knowledge assets and processes of strategic importance for the purpose of achieving organizational goals. It is in this sense about the development of an organization-wide knowledge management capability (Katsoulakos & Rutherford, 2005). The basic idea of strategic knowledge management in the public sector is to ensure that public organizations are capable of high performance by utilizing knowledge assets and knowledge processes when interacting with their environment.

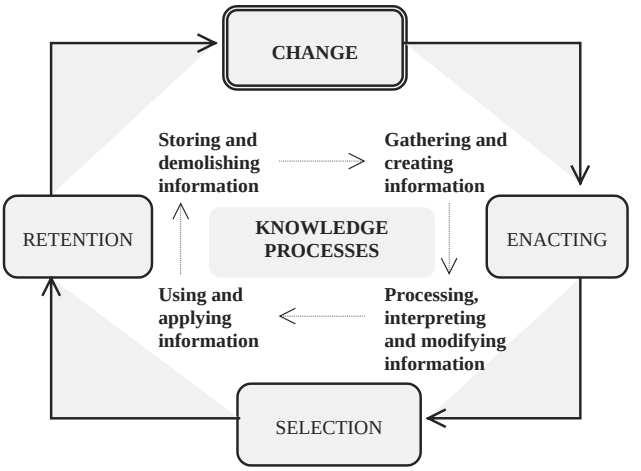
What is essential in strategic knowledge management is that it needs to be 'strategic' in the true sense of the word, as opposed to 'operational'. Public employees sometimes have a tendency to view their knowledge requirements from the point of view of their current work practices. At an organizational level, too, there is sometimes a temptation to map out the future on the basis of current strengths and well-defined short-term challenges. The strategic approach to knowledge aims to overcome such inertia and narrow perspectives by creative knowledge processes, which help to transform views from introspective to outward-looking, from resources to outcomes, and from formal duties to actual impacts and customer satisfaction.

In the knowledge management literature, knowledge has primarily been approached either as an object or a process (cf. Sveiby, 2001). The main focus of public organizations is on knowledge processes framed by certain institutional arrangements. Among the most important of these are the political dimension and democratic control and legally defined functions, competencies, and procedures within territorially defined jurisdictions (for more on KM in the public sector, see e.g. BSI, 2005). This theme will be discussed next.

FACILITATING STRATEGIC KNOWLEDGE PROCESSES

Public organizations possess and process a huge amount of information in their internal operations and external exchange relations. This is why the most important function of their knowledge management practice is to manage knowledge processes and to support knowledge-sharing practices.

Figure 2. Strategic sense-making and related knowledge process of the organization

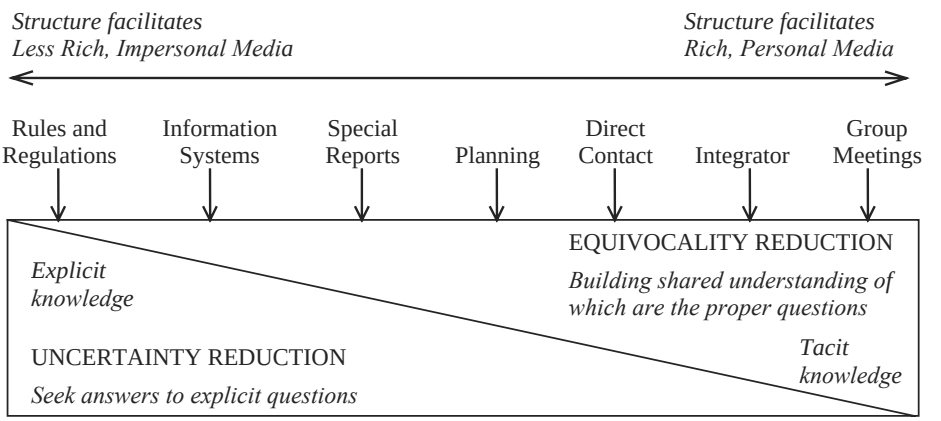


Nonaka (1994) considers an organization's ability to accomplish the task of acquiring, creating, exploiting, and accumulating new knowledge. This formulation takes us very close to how the knowledge process can be operationalized. The *knowledge process* can be defined as an organizational process in which information is gathered, created, processed, used, and dissolved in order to form an enriched orientation base for taking care of an organization's basic functions (cf. Gupta et al., 2004, p. 3; Mendes, Gomes, & Bátiz-Lazo, 2004, p. 153).

It is important to note that in the actual knowledge process, it is more or less meaningless to make a clear-cut distinction between knowledge and information, for both are processed in such a process. For example, knowledge is not simply extracted from information, for knowledge is possessed by human beings and serves as a background and built-in epistemic frame to deal with complexity, novelty, and the requirements of innovativeness (cf. Wiig, 2000). Thus, genuine aspects of the category of *knowledge* are in question when we deal with statements, assumptions, and understandings and such learning and communicative processes in which these knowledge assets can be shared, assessed, and enriched. Many theorists consider tacit knowledge in particular as the most challenging and important form of knowledge in organizations (Polanyi, 1966; Nonaka, 1994). It also needs to be stressed that it is not knowledge as something abstract, but a 'generative dance' or interplay between (a) *knowledge* we possess and (b) *knowing* as an epistemic aspect of the interaction with the world that generates organizational innovation and strategic understanding (Cook & Brown, 1999).

Strategic knowledge processes are those aspects of knowledge processes that have the most profound and far-reaching impact on an organization's adjustment to contextual changes and on its core competencies. A paradigmatic form of a strategic knowledge process is the *sense-making* or *strategy process* in which an organization devotes effort to analyzing its internal attributes and external conditions, and decides on that basis about the action lines in order to achieve its overall goals (cf. Weick, 1995). In such a strategic knowledge process, the organization seeks information on environmental changes and utilizes this in strategy formulation, in which such tools as SWOT analysis have traditionally been used. A basic model of the organizational knowledge-based adaptation process is presented in Figure 2 (Anttiroiko, 2002). This model serves as a heuristic tool to conceptualize knowledge processes. Yet, it is important to keep in mind that this is only a starting point. When taking this idea further, clear-cut sequential stages or phases of the KM lifecycle need to be 'recontextualized' as a set of continuous interdependent sub-processes (cf. Mendes et al., 2004, p. 165). Thus, context-related and situational aspects of knowledge need to be integrated with all essential connections to their environments into the key functions and operations of an organization in order to assess their meaning as a part of actual strategic adaptation and sense-making processes.

Figure 3. Continuum of knowledge facilitation mechanisms (Daft & Lengel, 1986)



Applying Daft and Lengel (1986), we may ask how organization structures and systems should be designed in order to meet the need to manage knowledge processes. Well-designed systems help to decrease the uncertainty and ambiguity faced by an organization by ordering the amount of relevant information and by enabling clarification of problems and challenges. Daft and Lengel (1986) propose seven structural mechanisms that can be used to deal with uncertainty and ambiguity in varying degrees, as illustrated in Figure 3. This model resembles the continuum of communication that has explicit knowledge and tacit knowledge as its extremities (Lehaney et al., 2004, p. 21).

The idea is that these mechanisms form a continuum starting from tools to be used to tackle well-defined problems and thus to reduce uncertainty, and proceeding towards more communicative mechanisms designed to facilitate sense-making processes that aim at reducing equivocality or ambiguity (Anttiroiko, 2002).

As stated, a paradigmatic case for strategic knowledge management is the strategy process of an organization (for more on strategy and information resources, see Fletcher, 2003, pp. 82-84). What is of utmost importance is that managers ensure that people feel involved in the strategy formulation process. The staff also needs to understand the meaning of strategy in their own situations. This would help to make strategy documents living guidance owned by all in the organization, as concluded by Wright and Taylor (2003, p. 198).

Another important premise relates to organization culture and work practices that often impede the development of knowledge management. For example, employees may resist a new knowledge management initiative if they perceive it only as extra work. Similarly, employees may be reluctant to share their knowledge if there are no rewards or tangible benefits for themselves or their organizations. In all, the 'human factor' is essential for improving KM practices, for most of the positive outcomes are the result of the commitment of all employees, successful structural changes in the organization, and the development of the organizational culture and climate (OECD, 2003, p. 4).

THE ROLE OF TECHNOLOGY

Information technology (IT) provides a range of tools that can be effectively used in knowledge management. Such applications are sometimes referred to as knowledge technologies. Relevant applications can support decision making, executive functions, planning, communication, and group work. Introduction of new knowledge technologies may be based on a stages of growth model for knowledge management technology, where organizations develop from the person-to-tools strategy, via the person-to-person strategy and the person-to-documents strategy, to the person-to-systems strategy (Gottschalk, 2005).

Tools and technologies available for knowledge management include generic communication tools (e.g., e-mail), blogs, computer-based information and decision support systems, document management systems, wikis, intranets and extranets, groupware, geographic information systems, help-desk technology, and a range of knowledge representation tools (Gupta et al., 2004, pp. 17-24; Grafton & Permaloff, 2003.) In general, the Internet may be suggested as the KM infrastructure due to its widespread availability, open architecture, and developed interfaces (Jennex, 2003, p., 138).

In real life, most of the tools applied in knowledge management are more or less conventional, such as training, seminars, meetings, and the like. Various KM-specific organizational arrangements had been adopted by about half of the organizations studied in the OECD survey on ministries, departments, and agencies of central government in the early 2000s. These measures include central coordination units for KM, quality groups, knowledge networks, and chief knowledge officers. Another important application area is the classification of information, referring to new filing mechanisms, e-archives, and new types of databases. In internal knowledge-sharing, intranet projects form the mainstream, combined with wide access to the Internet and having e-mail addresses for the staff. The external knowledge sharing goes largely hand in hand with the emergence of new practices of e-governance. These practices have increased the knowledge sharing in both local and wider governance processes (OECD, 2003, pp. 17-20; Anttiroiko, 2004).

FUTURE TRENDS

The future challenge for public organizations is to increase their responsiveness to stakeholders, especially to citizens. At the same time they need to be capable of strategic institutional mediation in the increasingly turbulent environment, thus bringing an element of continuity and stability to social life, and guaranteeing democratic and civic rights at different institutional levels.

Another trend that may change some premises of strategic knowledge management is the changing nature of media and information landscapes. One indication of this is Web 2.0, which refers to a second-generation of Internet-based services that allow people to collaborate and share information online in new ways (blogs, wikis, ubiquitous technologies, etc.). All this requires increasing capacity to manage knowledge of strategic importance and create innovations of knowledge management (see Montano, 2004).

CONCLUSION

Strategic knowledge management refers to the theory and practice of managing knowledge assets and processes of

strategic importance. Public organizations need to create favorable organization structures and environments for knowledge sharing, organizational learning, and other aspects of knowledge management in order to create all the knowledge they require in their adjustment and trend-setting processes.

A main return of strategic knowledge management is better capability to adjust to contextual changes. This is difficult to measure, even if such tools as Balanced Scorecard (BSC), the Intangible Assets Monitor (IAM), and Intellectual Capital Index (ICI) are available. This is because they provide only a partial picture of KM performance, as claimed by Chaudhry (2003, p. 63). What seems to be needed is more process-focused assessments that are able to analyze the steps of KM processes, thus highlighting the actual changes in organizational knowledge base, capacities, and processes. As usual, there is no measurement system that fits all organizations in all situations. Rather, measurement should be tailored to the actual needs of the organization.

KEY TERMS

Intellectual Capital (IC): Knowledge and know-how possessed by an individual or an organization that can be converted into value in markets. Roughly the same as the concept of intangible assets.

Intellectual Capital Management (ICM): A management of value creation through intangible assets. Close to the concept of knowledge management.

Intellectual Property (IP): Any product of the human intellect that is unique and has some value in the marketplace. It may be an idea, composition, invention, method, formula, computer software, or something similar. In practice, special attention is paid to such intellectual property that can be protected by the law (e.g., patent and copyright).

Knowledge Assets (KAs): Statements, assumptions, abstract models, and other forms of knowledge regarding the organization itself and its environment (markets, customers, etc.) that an organization possesses. These assets provide economic or other value to an organization when interacting within it or with its environment.

Knowledge Management (KM): Management theory and practice on managing intellectual capital and knowledge assets, and also the processes that act upon them. In a practical sense KM is about governing the creation, dissemination, and utilization of knowledge in organizations.

Knowledge Management System (KMS): Set of tools and processes used by knowledge workers to identify and transmit knowledge to the knowledge base contained in the organizational memory.

Organizational Learning (OL): An organizational process in which the intentional and unintentional processing of knowledge within a variety of structural arrangements is used to create an enriched knowledge and orientation base, and a better organizational capacity for the purpose of improving organizational action.

A Structured Approach to Developing a Business Case for New Enterprise Information Systems

Francisco Chia Cua
Otago Polytechnic, New Zealand

Tony C. Garrett
Korea University, Republic of Korea

INTRODUCTION

The term business case is used to describe both a process and a document. A business case exploits an initiative. Exploiting the initiative from awareness to implementation encompasses a process, referred to in the diffusion of innovation parlance, as the innovation-decision process. The development of a business case concerns this innovation-decision process. The individuals or the decision-making units pass through the innovation-decision process, gaining knowledge of a new idea, forming an attitude toward it, and deciding whether to adopt or reject it (Rogers, 2003, p 20). Gaining the knowledge triggers the awareness or enforces it. Then, it leads to setting the agenda. After the agenda-setting stage is the examination of the available options. Attributes of competing options are matched together, enabling attitude formation in favour or against a particular option. This results in the creation of a shortlist of two or three options. A decision is generally reached at this point. The decision is, therefore, part of the matching stage. However, this is not always true in an organisational setting. There is a third stage after the matching stage. It is the decision (aka, business case) stage. Organisations generally demand rigour in making the decision. A business case document embodies the rigour in the business case development. Consequently, the decision stage culminates with a completed business case document and the decision that results from it: to adopt or reject the innovation. The three stages, agenda setting, matching, and decision stages, compose the initiation phase. If the decision favours adoption, then the implementation phase proceeds. In the context of implementing the new enterprise information systems, the stages in the implementation phase consists of pre-production, production, post-production (that is, maintenance), and confirmation stages. In summary, the business case development is a means, and its end is a business case document.

A complete business case is a formal written argument and a detailed "point by point" analysis (Cannon, 2006, p 4; Carruth, 2001). It purports to justify the adoption or rejection of investing and thereby, implementing the new enterprise information systems. The analysis takes into consideration the stakeholders (Ministry of Health, March 2005), especially the decision-makers and the end-users. Consequently, a business case document is formal, detailed, and complex.

Using the parlance of "diffusion of innovations" (DOI) theory (Rogers, 1962, 2003), a business case document is a communication tool used to diffuse the new enterprise information systems, and to justify their adoption and implementation. Diffusion refers to the process by which the executive sponsor, who owns the innovation-decision process of the new enterprise information systems, communicates to the upper managers to get their approval of the project and funding.

Diffusion via a business case document for a technological product, such as an enterprise information system, must be directed at a single target audience to be effective. The upper managers represent a chasm that needs to be bridged (Moore, 1991). A completed business case document, containing relevant information for the managers, can serve as that bridge.

In addition to its relevance, a business case must also be responsible and credible. Therefore, the business case must bring relevance, reputation, and responsibility (the 3 Rs) into a number of issues and challenges during its development.

This chapter proposes a business case structure, with the 3Rs underlying it. It continues from the big picture of business case development in the article, *The Role of Business Case Development in the Diffusion of Innovations Theory for EISs* (hereinafter referred to as *The Role of Business Case Development...*). The structure, suggested in Table 2, delineates the context to the new enterprise information systems. However, prior to that, certain issues must be addressed:

- What is the purpose of a business case?
- What should a business case document contain?
- How should the business case be structured? How should it be written?

THE PURPOSE OF A BUSINESS CASE

A good business case must have a purpose that is clear, specific, and relevant to the organisation and the upper managers. *The Role of Business Case Development...* mentions "growth and sustainability" as a strategic goal. That term is too broad to be useful in a business case. A similar ambiguous construct is sustainable competitive advantage (Hammer, 1996; Monczka, Carter, Petersen, & McDowell, 2006, p 213). A single detailed statement is far more relevant to the organization than several broad statements. An actual case study reveals one objective of selecting and implementing a proven, up-to-date enterprise financial system. The chosen systems must have the capacity to meet likely future financial-related requirements and growth. This vague objective can be made clearer by citing sustainable competitive advantages that are strategically valuable to the organisation, taking into consideration certain guiding principles (Table 1).

Enterprise information systems are the enabling technologies that foster sustainable competitive advantages under certain guiding principles. Table 1 helps to develop the business case backward from the purpose, and includes ALL the planning activities, resources, and metrics that are critical to the goal (Ministry of Health, 2005, p 9). Recent research indicates that most successful organisations have a crystal clear notion of the organisation's strategy, and how deploying information technologies can help actualise that strategy.

A Business Case Is a Two-Sided Coin

The purpose of a business case is to reflect the rigour of planning relative to the level of investment being undertaken (Ministry of Health, 2005, p 3). This is one side of the coin. The other side relates to justifying the innovation discussed. On one side, there are sustainable competitive advantages or other reasons to justify the implementation of the innovation. On the other side is the purpose of the business case. Justifying the implementation and matching the best fit pertain to the what and the why questions. Thinking about the innovation-decision process and substantiating the process with the necessary rigour concern the how (and why) questions. In the context of the new enterprise information systems, the specific sustainable competitive advantage represents the primary goals. The enterprise information systems enable seamless integration (Table 1) of information across the whole organisation and its extended social systems. The systems empower the internal people in the organisation to provide the best performance with shared information systems. The systems help to identify and develop centres of excellence with resources and expertise prior to outsourcing. The systems also maximise return on information systems investment across the organisation, maximise the exploitation of opportunities, and minimise the risk associated with the new implementation. All these technological advantages are about the innovation. However, that is not the purpose of the business case, which is a reflection of the rigour on the innovation-decision process.

WHAT SHOULD A BUSINESS CASE DOCUMENT CONTAIN?

The Scope and Content of Business Cases Vary

Not only must the business case contain the justification of the innovation (what and why) and the rigour of the process

Table 1. Guiding principles and sustainable competitive advantages

Guiding principles	Sustainable competitive advantages
• E-business supply chain • Economic value-added focus • Globalisation • Satisfaction of the needs of customers • Total value management • Value/supply chain integration, productivity, and collaboration (operational excellence and process redesign)	• Seamless integration • Best performance: Quality, price, delivery, technology, cycle time (velocity, responsiveness, service), safety • Enhanced EVA (increase revenue by broadening the offerings and improving customer value, reduce internal and external cost structure, reduce assets, and improve asset utilization) • Enhanced EBIT, ROI, cash flows • Perceived highest customer value • Revenue generation • Time-to-market/breakeven

Adopted from Carruth (2001); Hammer (1996); Ministry of Health (2005), Monczka et al. (2006)

Table 2. Suggested structure of a business case

	Section	Caption	Remarks
E		Title Page	
E		Table of Contents	
E		Executive Summary	Prepare a sharp and compelling summary.
E	1	INTRODUCTION	Brief, purpose, scope, limitations
E		Terms of Reference or Background	State the brief (that is, who asks to do what?). What do the readers need to know? If the background is crucial, then there can be a separate Background section.
E		Purpose of the Report	Briefly explain the purpose of the report.
		Gaps Analysis	Describe the expected consequences (the strategic vision in refer to Section 4). Describe the assessment of the present state (refer to Section 4). Describe the gaps between the present state and the desired future state.
E		The Proposed Solutions and Its Strategic Value	Highlight the strategic value, the selling point, of the solution. Describe the relevant issues and their action plans (related to Section 7, the proposed project). Some questions to ponder are: Is the solution reactive or anticipatory (Figure 3 in *The Role of Business Case Development...*)? How does the proposed solution FIT into the big picture? If the solution is reactive, describe the urgency of the radical change. If the solution is anticipatory, explain the critical strategic area (Table 1 and strategic vision in Section 4 and Section 6). Why does the solution matter?
E		Project Ownership (and Consultant)	Corporate power dictates the level of detail this section requires (assumed). Who is the executive sponsor? How supportive is the executive sponsor to the business case? Who is the expert the executive sponsor has consulted?
E		Scope and Delimitation	Delineate the scope of the problem.
O		Methodology	Briefly describe the methods or methodology of Section 3.
E		Structure of the Business Case Document	Briefly outline how the business case is presented.
	2	CONCLUSIONS AND RECOMMENDATIONS	
E	2.1	Conclusions	How does the executive sponsor evaluate the Business Case (eg, cost-benefit analysis)? How logical or intuitive is the evaluation? Based on the financial and nonfinancial analysis, summarise briefly how the business case will impact positively and negatively on the organisation? What are the critical success factors? The critical failure factors? How are the options considered and documented?
O	2.2	Recommendations	Which option has the executive sponsor chosen and why? The Recommendations section (or the Proposed Project section) may attempt to answer further questions such as: How does the executive sponsor propose to rally the support, involvement, and usage? How does the executive sponsor ensure success?
O	3	METHODS	What are the contingency plans? How does the executive sponsor come about the plan? How reliable is the evidence used to develop the Business Case?
O	4	FACTS AND ASSUMPTIONS	This section may form part of the Introduction section.

Legend: E = Essential, O = Optional

continued on following page

Table 2. continued

	Section	Caption	Remarks
O		Strategic Vision	Identify the strategic vision, the guiding principles, and sustainable competitive advantages (Table 1). Assess the key strengths and weaknesses. This may be incorporated under the future state of the Introduction section.
O		Needs Analysis	Describe briefly the needs and relevant issues. This section may be incorporated under the Gaps Analysis of the Introduction section.
O		Options Analysis	Describe briefly the options considered in this business case. This section may be incorporated under the Proposed Solutions of the Introduction section.
	5	FINANCIAL ANALYSIS	How does the EXECUTIVE SPONSOR explore the sensitivity of key assumptions in the analysis?
E		Total Cost of Ownership (TCO)	Combine the net present value, discounted cash flows, and total cost of ownership in the financial analysis. Determine which option enhances the value to the organisation and not which option has the lowest TCO. Make sure to scrutinise all "hidden costs."
E		Business Risks	How does the EXECUTIVE SPONSOR identify, assess, and resolve the risks involved?
E	6	NONFINANCIAL ANALYSIS	What external factors drive the Business Case? How will the competitive advantage, macro environments, and stakeholders (competitors, customers, and vendors) impact the organisation? With what of key assumptions in the analysis?
E		Sustainable Competitive Advantage(s)	Describe in detail the innovation, its scope, its goals (the sustainable competitive advantages in Table 1), and the expected consequences. How does the innovation fit into, for example, the seamless alignment or the organisation's strategy? How does the innovation enhance the competitive advantage? How does it create the differentiation of the organisation from its competitors? What is the "compelling reason" why the innovation must be put into action? What value does the innovation provide?
E		Macro environments	
E		Stakeholder Analysis	St Gallen Management Model suggests two approaches. One is the "strategic stakeholder value." The other is the "ethically critical stakeholder value." The former approach assumes that a balanced consideration of the long-term interests of all stakeholders is the best way to maximise shareholder value. The latter approach evaluates all potential stakeholders equally toward "ethically justifiable legitimacy." (Rüegg-Stürm, 2005)
E	7	THE PROPOSED PROJECT	
		Project Plan	How does the project plan look like? What are the key milestones? How abstract or detailed is the project plan? How does the project plan mitigate the risks of occurrence of undesirable consequences (refer to Appendix A section)?
		The innovation-decision process	How did the executive sponsor conduct the initiation phase? What is the change strategy? How will the executive sponsor implement the new enterprise information systems? Reiterate the change strategy, costs, and risks?

Legend: E = Essential, O = Optional

continued on following page

Table 2. continued

	Section	Caption	Remarks
		Project Participants	How detailed has the Business Case been documented with regards to the resourcing requirements (that is, the capacity and capability requirements)? Specifically, what are the skills, experience, and time commitment required of the project team? What are the skills, experience, and time commitment required within the business after the completion of the innovation-decision process? How does the executive sponsor propose to manage the risks related to the resourcing requirements? How does the Business Case take into account the additional resourcing required through and after the implementation-decision phase?
E	Appendix A	UNDESIRABLE CONSEQUENCES TO AVOID	Refer to Project Plan section above.
E	Appendix B	REFERENCE SITES	

Legend: E = Essential, O = Optional

(how and why), it must be relevant to the stage of the innovation-decision process at which it is written. A business case written at the awareness stage (Stage 1) or matching stage (Stage 2) differs in scope and content with a business case written at the decision stage (Stage 3). For example, the Ministry of Health (2005) of New Zealand has issued guidelines for the investment in information technology. Its business case development is composed of three stages equivalent to the three stages in the initiation phase: the strategic analysis, options analysis, and completed business case. Respectively, the outputs are the needs and options analysis, both of which are part of the completed business case document. Each output is a specifically differentiated business case. The needs analysis is a business case. So is the options analysis. The needs analysis and options analysis represent a section in the completed business case document. The completed business case inevitably contains sections that correspond to the three stages of the business case development.

Analysis, Depth, and Quality

The keys to a successful business case are in-depth analysis and quality. A Risk-adverse organisation with an analytical bent will usually spend considerable time and effort in fully understanding all the aspects and implications of any significant investment (Carruth, 2001, p 10). Too much analysis is not cost effective. The content of the business case must limit and highlight few but crucial aspects that impact the organisation. Implementing new information systems affect the operation and well-being of the organisation concerned. The question is: Which of these "effects" give the greatest impacts to the organisation? Thus, there is a need to limit and highlight the critical factors. The focus is, therefore, on the quality of the information and the depth of analysis. Cannon (2006, pp. 2-4, 194-252) suggests 29 analytical tools, such as balanced scorecards, cost-benefit analysis, critical success factor, life-time cost analysis, risk analysis, sensitivity analysis, and SWOT analysis. The amount of analysis carried out is irrelevant. In a good business case, the analysis must reflect the right depth of a critical factor that impacts the organisation as a consequence of strategically investing or not investing the chosen option (Weill & Ross, 2004).

Managing Risk and Defining Undesirable Consequences

Aside from the in-depth quality analysis, the business case must identify important assumptions (also referred in Figure 1 of *The Role of Business Case Development...*). Risk-taking attitude, sustainable competitive advantages, organisational innovativeness, politics, cash flows, and total cost of ownership are examples of relevant assumptions.

Risk is foremost to these assumptions. The implementation of new enterprise information systems involves risk. How does the organisation react to risk? The answer can be found in the organisations past actions.Risk-seeking, innovative organisations exploit innovative opportunities which have potential for big returns. Risk-averse organisations are very late adopters of technology, and are less innovative. To risk-averse organisations, the business case must mention similar implementations undertaken by competitors or other organisations (refer to Appendix A section in Table 2).

Managing risk is simply gaining more power over the uncertainty brought about by the innovation-decision process. Borge (2001) suggests certain techniques to managing risk:

- Being aware of the risks by defining, at the start, the possible undesirable outcomes;
- Knowing that taking deliberate action can increase the odds of desirable consequence and decrease the chance of unexpected or undesirable consequences;
- Weighing risks vs. benefits

Defining all possible undesirable consequences is easily overlooked or taken for granted because, as Borge (2001) puts it, there is no universal definition of a bad outcome. Like the "new idea" to exploit, the "undesirable consequence" to avoid depends on the perspective of the people involved. Therefore, the undesirable consequence must be explicit in the business case. As mandated by the Sarbanes-Oxley Act, the executive sponsor and the project team members should be able to see the threat early, and understand them before they become clear and present dangers (Green, 2004).

Here is a last word on the risky business of managing risk. The rigour of developing a business case is NOT minimising the risk. It is balancing risk with opportunity to create the best overall value (for details, refer to the concept of "value at risk" by Borge).

Other Important Assumptions

The attitude to risk is not the only relevant assumption. There are other assumptions that need to be addressed and identified. For example, how do new enterprise information systems foster seamless alignment in the organisation? How does the proposed implementation fit into the organisation's strategy? Table 1 has suggested certain sustainable competitive advantages. Therefore, how does the business case describe in detail the innovation, its scope, its goals (the sustainable competitive advantages), and its objectives (the expected consequences)?

Corporate culture, specifically the power structure mentioned in the conceptual framework of *The Role of Business Case Development...*, is another basic assumption. A business case may rely more heavily on the opinions of the executive sponsor or any other leaders with powerful opinions. The mention of the "power" person or people gives credibility (or reputation, the second R) and responsibility (the third R) to the business case. If the business case is to diffuse successfully, the premise of the corporate culture dictates a disclosure of ownership of the implementation. Furthermore, IT governance essentially involves stating who is the executive sponsor who is responsible to making the IT decision and who will be accountable for diffusing its usage in the organisation (Weill & Ross, 2004; refer to project ownership in the Introduction section of Table 2).

NPV, DCF, and TCO

The net present value is an old measure that most accountants and financial professionals rely heavily on valuation to business decision making.

One related valuation method is the discounted cash flows (DCF) method. It estimates the current market dollar value of the new enterprise information systems. Based on expected future cash flows and discount rates, the DCF value drives capital budgeting and therefore, the innovation-decision process. For organisations with positive cash flows, the cash outflows for future periods can be estimated with a certain degree of reliability.

Another important concept is the total cost of ownership, or TCO for short. The traditional notion of cost is the money paid in exchange for tangible and intangible projects or services, where costs can be either direct or indirect. Before making the adoption decision, a capital budgeting analysis will be required. It involves breaking down the amounts to be paid. For example, with the enterprise information systems, the acquisition costs include initial software, hardware, installations, training, configuration, supporting, and consultation costs. Other cash outflows are used for maintenance, further training requirements, modifications, supports, and upgrades (Cua & Theivananthampillai , 2006; Piedad, 2001). The initial acquisition cost represents a capital expenditure. The subsequent ongoing costs are operating expenditures. These so-called operating "expenses" accumulate over time, and equate to at least a third of the initial acquisition cost (Schweitzer, 2003). They must be included in the total cost of ownership, otherwise, they will become hidden costs.

Combining the net present value, discounted cash flows, and total cost of ownership, give to financial analysis the much needed context as to valuation, strategy, finance, and corporate governance (Morin & Jarrell, 2001). There is one caveat. TCO is like air. Its absence is fatal, but it must remain discreet and in the background when present. Although determining the lowest TCO is good, deciding on the option with the lowest TCO puts emphasis on minimising the cost through TCO. It is, therefore, not wise. Instead, the question to ask is not which option has the lowest TCO? Rather, which option enhances the value to the organisation (Cua & Theivananthampillai, 2006; Morin & Jarrell, 2001)?

Planning for the Past, Present, and Future

In DOI, the innovation-decision process develops along a normal course. Imagine the whole project as a life cycle consisting of the two major phases (the initiation and implementation phases) with several stages in each phase. The completed business case (the third type of the business case) occurs in the decision stage of the first phase, and

effectively links the initiation phase to the implementation phase. Thus, a completed business case must contain the story of the past (what was done in the awareness stage and matching stage), the present (the available options and critical factors to make the decision), and a preview of the project management (Nokes, Greenwood, Major, & Goodman, 2004) with regards to the implementation of the new enterprise information systems.

Nonfinancial Factors

Other than the sustainable competitive advantages, there are other nonfinancial factors, such as the macro environments and the stakeholders. These are two of the six categories under the St Gallen Management Model (Rüegg-Stürm, 2005). The macro environments are particularly useful in weighing the external circumstances that can impact on organisation's growth and sustainability. Organisations often define their success by the degree to which they are able to meet the needs of the various stakeholders. Some stakeholders are the conditions to success. Others affect the creation of value. The purpose of stakeholders analysis is to maximise shareholder value in the longer-term (Morin & Jarrell, 2001; Rüegg-Stürm, 2005).

STRUCTURING AND WRITING THE BUSINESS CASE

Using a business report format, the business case (Table 2) identifies the gaps between the expected future state and the present state (Section 1). The conclusions on the business case, together with the recommendations, follow in Section 2. Subsequent sections are the methods (Section 3), facts and assumptions (Section 4), financial analysis (Section 5), nonfinancial analysis (Section 6), and the implementation plan (Section 7).

As business cases are complex, the executive summary becomes the most important part of the business case. Pugh and Bacon (2004) emphasise the "executive treatment," and suggest several approaches of diffusing the innovation via the executive summary. The upper managers are busy people. They have time to read a summary but not an entire proposal. They also have a crucial role in the final decision and therefore, they will form their "attitude" towards the business case in three quick steps: the executive summary (first step), the introduction (the second step), and the conclusions and recommendations (the third step). By the third step, they usually have an idea whether or not the executive sponsor has undertaken the necessary rigour in developing the business case, and whether or not the business case is worth investing.

CONCLUSIONS

The key points in the business case are the 3Rs (relevance, responsiblity, and reputation) of the strategic value of the new enterprise information systems. What value impacts the organisation the most? With the relevance brought about by the strategic value come the in-depth analysis and the quality (not quantity) of information. The project ownership in Section 1 and the stakeholder analysis in Table 2 concern responsibility, crucial to Sarbanes-Oxley Act and corporate/IT governance. Project ownership sets accountability for the decision and diffusing the usage of the new enterprise information systems. Stakeholders' analysis sets the social responsibility. The rigour of the business case development foster a mindset that the organisation is able to fully consider risks, and that the organisation is able to mitigate the risk concerned with the initiation and implementation of the new enterprise information systems. The reputation of the organisation is at stake in this instance.

Lastly, the proposed structure in Table 2 is a blueprint, but should not be used as a boilerplate.

KEY TERMS

Business Case: Completed business case document. Business case process.

B**usiness Case Development**: Walks through the initiation phase of the innovation-decision process and talks about the project plans that concern the implementation phase.

Completed Business Case Document: A formal written document that argues a course of action. It contains a point-by-point analysis to making a decision for a set of alternative courses of action to accomplish a specific goal.

Diffusion: Essentially communicating a new idea (aka, the innovation) within a social system (such as an organisation) with the intention that the audience of that communication adopts or use the innovation.

Diffusion of Innovations: Theory concerns the how, why, and at what rate the new idea (commonly referred to as innovation) diffuses.

Implementation Phase: Proceeding after the initiation phase, the implementation phase of enterprise information systems consists of pre-production, production, and post-production (also known as upgrade and maintenance). Refer to innovation-decision process.

Initiation Phase: Consists of awareness stage, matching stage, and lastly, the decision stage. It is the first phase of the innovation-decision process. The second phase is the implementation phase. Refer to innovation-decision process.

Innovation: Represents a product, a service, or an idea that is perceived, or should be perceived by the audience or the market in which this innovation is intended to be new and of value.

Innovation-Decision Process: Starts with an **initiation phase** through which the individuals or decision-making units move from knowing (understanding/identifying) the new idea (the innovation), to forming of an attitude toward the innovation, and subsequently, to deciding whether to adopt or reject the implementation and use of the new idea. The awareness stage is the agenda setting stage. The attitude formation stage is the matching stage. In addition, the decision stage to adopt or reject the innovation terminates the initiation phase. An adoption decision continues the process toward the **implementation phase**, which consists of the pre-production, production, post-production, and confirmation stages.

Risk: Connotes a possible negative impact to something of value. It symbolises the probability of a loss.

Total Cost of Ownership: Also known as TCO, is a rigorous and holistic methodology. It helps to estimate how much an investment will cost to operate over its lifetime. It takes into account all direct and indirect costs. The indirect costs are generally insignificant individually. However, they become very substantial when accumulated over time.

A Study of Image Engineering

Yu-Jin Zhang
Tsinghua University, Beijing, China

INTRODUCTION

Images are an important medium from which human beings observe the majority of the information they received from the real world. In its general sense, the word "image" could include all entities that can be visualized, such as a still image, video, animation, graphics, charts, drawings, even also text, and so forth. Nowadays, "image" rather than "picture" is used because computers store numerical images of a picture or scene. Image techniques, which are expanding over wider and wider application areas, have attracted more and more attention in recent years. Image engineering (IE), an integrated discipline/subject comprising the study of all the different branches of image techniques, is evolving quickly.

From 1969 to 2000, a well-known bibliography series had been developed to offer a convenient compendium of the research in picture processing until 1986, as well as in image processing and computer vision after 1986. This series has been ended in 2000 by the author after a total of 30 survey papers were published (Rosenfeld, 2000a). Some limitations of this series for the termination are (Zhang, 2002b):

1. No attempt is made to summarize the cited references for each year.
2. No attempt is made to analyze the distributions of the selected references from various sources.
3. No attempt is made to provide statistics about the classified references in each group.

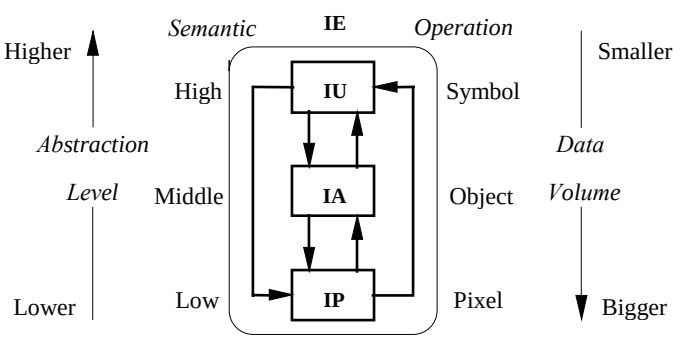
Another survey series, but on IE, has been started since 1996 (Zhang, 1996a, 1996b, 1996c, 1997, 1998, 1999, 2000a, 2001a, 2002a, 2003, 2004, 2005). The purpose of this survey work is mainly to capture the up-to-date development of IE, to make available a convenient means of literature searching facility for readers working in related areas, and to supply a useful reference for the editors of journals and potential authors of papers. This new series overcame the weakness of the earlier mentioned one by summarizing the cited references for each year, analyzing the distributions of the selected references from various sources, and providing various statistics about the classified references in each group. This new survey series has already made consecutively for ten years. This article will present an overview of this survey series by showing the idea behind and consideration on this work as well as the comprehensive statistics obtained from this work.

BACKGROUND

Image Engineering

IE, from a perspective more oriented to technique, could be referred to as the collection of three related and partially overlapped groups of image techniques, that is, image processing (IP), image analysis (IA), and image understanding (IU). In a structural sense, IP, IA, and IU build up three interconnected layers of IE as shown in Figure 1. Each of them operates on different elements (IP's operand is pixel, IA's operand is object, and IU's operand is symbol) and works with altered semantic levels (from low at IP to high at IU).

Figure 1. Three layers of image engineering



The three layers follow a progression of increasing abstractness and of decreasing compactness from IP to IU.

IP primarily includes the acquisition, representation, compression, enhancement, restoration, and reconstruction of images. While IP is concerned with the manipulation of an image to produce another (improved) image, IA is concerned with the extraction of information from an image. Compared to IP which takes an image as input and outputs also images, IA takes also an image as input but outputs data. Here, the extracted data can be the measurement results associated with specific image properties or the representative symbols of certain object attributes. Based on IA, IU refers to a body of knowledge used in transforming this extracted data into certain commonly understood descriptions and for making subsequent decisions and actions according to the interpretation of the images.

Related Subjects

IE is a broad subject encompassing studies of mathematics, physics, biology, physiology, psychology, electrical engineering, computer science, automation, and so forth. Its advances are closely related to the development of telecommunications, biomedical engineering, remote sensing, document processing, industrial applications, etc. (Zhang, 2002b).

According to different science politics/perspectives, various terms such as computer graphics (CG), pattern recognition (PR), computer vision (CV), scene analysis (SA) (just counted as another name of CV, see Rosenfeld, 2001) *etc*., are (partially) overlapped with IP, IA, and/or IU. A diagram describing the relationship among the earlier-mentioned subjects is given in Figure 2. Images are captured from the real world and processed to furnish the basis for IA or PR. The former produces data that can be visualized by CG techniques while the latter continually classifies them into one of several categories. Results produced by both of them can be further interpreted for human beings to understand the real world. The whole process aims to make computers capable of understanding environments from visual information, which is also the purpose of CV/SA.

THE CURRENT "PICTURE" OF IMAGE ENGINEERING

What is the current "picture" of IE? Answering this question is the foremost intention of the new survey series. For such a purpose, selection of reference source and classification of references according to contents are two important factors. Also for such a purpose, three statistics made by this survey are illustrated in the following.

Classification Scheme

The classification scheme used in the bibliography series should reflect the contents of references. A classification problem can be considered as a problem of partitioning a set into subsets. An appropriate classification of references into groups and/or sub-groups should satisfy the following four conditions:

1. Every reference must be in a group.
2. All groups together could include all references.
3. The references in the same group should have some common properties.
4. The references in different groups should have certain distinguishing properties.

Taking into consideration these conditions and the status of development in the field, a complete and compact classification of the theories and techniques of IE is proposed and listed in Table 1 (Zhang, 2002b). It is easy to verify that these conditions are fulfilled by this classification.

Figure 2. Image engineering and related subjects

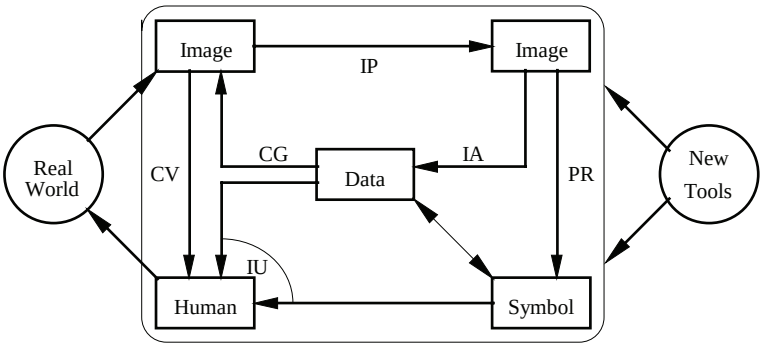


Table 1. Classification scheme of image engineering

Group	Sub-group
IP: Image Processing	P1: Image capturing and storage (including camera calibration) P2: Image reconstruction from projections P3: Filtering, transformation, enhancement, restoration P4: Image and/or video coding and standards P5: Image digital watermarking and image information hiding
IA: Image Analysis	A1: Edge detection, image segmentation A2: Representation, description, measurement (bi-level image) A3: Analysis of color, shape, texture, position, motion, etc. A4: (2-D) object recognition, extraction, tracking, classification A5: Human face and organ detection and location
IU: Image Understanding	U1: (Sequential, Volumetric) image registration and matching U2: 3-D modeling, representation and real world recovery U3: Image interpretation and reasoning (semantic, expert system) U4: Content-based image and video retrieval
TA: Technique Applications	T1: System and hardware (fast algorithm implementation) T2: Telecommunication, television T3: Documents (texts, digits, symbols) T4: Bio-medical imaging T5: Remote sensing, surveying and mapping T6: Others

Table 2. Selected journals and their abbreviations

#	Journal	Abbreviation.

15	Signal Processing	SP

Source Selection

As with any other emerging discipline, a large number of references related to IE have been published worldwide. The continued growth of the literature has already made it impractical to cover all of them in one survey (Rosenfeld, 1999). Though references have been dispersed across many resources, the most popular ones are conference proceedings, journals, and books. Considering the fast publishing rate, the conference proceedings would be ranked first followed by journals and books. Considering the comprehensiveness, the books would be ranked first followed by journals and conference proceedings. Considering the quality and coverage, journal articles would be ranked higher than that of conference proceedings and books. Combining all these considerations, journals would be the best choice for such a survey series.

Based on a careful selection of literature for providing an appropriate coverage in this area, 15 important journals (in the sense defined by Lin & Zhang, 1996) with high standard articles that are published in Chinese have been selected to limit the volume of references to a manageable size. All of the papers in these journals have titles, abstracts, and keywords in English. The list of journals is given in Table 2.

Summary Over Years

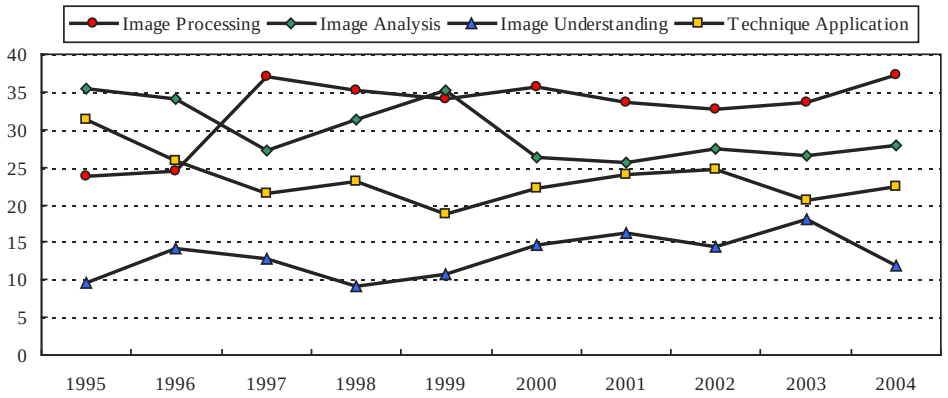
The first statistic made from this survey is a summary of the number of publications in the last ten years, as shown in Table 3. As in a survey of papers, the references have been classified into five groups: IP, IA, IU, TA and Survey. In Table 3, the total number of papers published in the selected journals (#T), the number of papers selected for survey as they are related to IE (#S), and the selection ratio (SR), which equals to #S/#T, for each year have been provided. In addition, the paper numbers for five groups (and their percentages in the year) are also listed.

Some interesting points can be noted from Table 3:

Table 3. Summary over the last 10 years

Year	#T	#S	SR	IP	IA	IU	TA	Survey
1995	997	147	14.74	35(23.8%)	52(35.4%)	14(9.52%)	46(31.3%)	
1996	1205	212	17.59	52(24.5%)	72(34.0%)	30(14.2%)	55(25.9%)	3(1.42%)
1997	1438	280	19.47	104(37.1%)	76(27.1%)	36(12.9%)	60(21.4%)	4(1.43%)
1998	1477	306	20.72	108(35.3%)	96(31.4%)	28(9.15%)	71(23.2%)	3(0.98%)
1999	2048	388	18.95	132(34.0%)	137(35.3%)	42(10.8%)	73(18.8%)	4(1.03%)
2000	2117	464	21.92	165(35.6%)	122(26.3%)	68(14.7%)	103(22.2%)	6(1.29%)
2001	2297	481	20.94	161(33.5%)	123(25.6%)	78(16.2%)	115(23.9%)	4(0.83%)
2002	2426	545	22.46	178(32.7%)	150(27.5%)	77(14.3%)	135(24.8%)	5(0.92%)
2003	2341	577	24.65	194(33.6%)	153(26.5%)	104(18.0%)	119(20.6%)	7(1.21%)
2004	2473	632	25.60	235(37.2%)	176(27.8%)	76(12.0%)	142(22.5%)	3(0.47%)
Total	18819	4032		1364(33.8%)	1157(28.7%)	553(13.7%)	919(22.8%)	39(9.67%)
Average	1882	403	21.44	136.4	115.7	55.3	91.9	3.9

Figure 3. Number variation of four groups in selected publications for last 10 years



1. This work has a quite large scale with nearly 19,000 papers involved and more than 4,000 papers selected and classified.
2. IE is an important topic for electronic engineering, computer science, and automation. The average SR is more than 1/5, which is remarkable considering the wide coverage of these journals.
3. IE publication evolves quite steadily. From Table 3, #S is increasing every year, and its value in 2004 is four times bigger than 10 years' ago. It is also noted that SRs in the recent three years are not only rising but also among the highest in ten years with SR > 1/4 for 2004.
4. The number of publications for IP and IA constitute 2/3 of the total number of IE publications. This shows the current research focus of IE. In contrast, research work on IU needs to be promoted.
5. The growing rates of publications for IP, IA, IU, and TA are comparable. To make it clear, Figure 3 shows the numbers of publications for these four groups graphically. The four curves in Figure 1 run quite smoothly and have not intercrossed in the last five years.

Distribution Analysis

The second statistic is the summary over the different journals (see Table 2), and the results are shown in Table 4. In Table 4, #I is the number of surveyed issues; #T and #S are now the total number of papers and the number of survey-selected papers, respectively. We also give the rank of the different journals according to their SR (selection ratio), and the rank of the different journals according to TR (total ratio, i.e., over all 15 journals). In Table 4, SR gives the relative frequency of IE publications in a journal. This relative frequency brings a measure of the probability of obtaining useful information from that journal. TR presents the relative contribution of each journal to IE publication and supplies a figure of importance of that journal among 15 journals. According to these rankings, readers could selectively scan the journal and judge the value of each journal.

From Table 4, the following observations can be made:

1. SR of a journal gives the probability of obtaining useful information from this journal. JIG has the highest SR among the 15 journals, and therefore, it should be checked frequently.
2. TR of a journal shows the contribution of this journal to IE publication. JIG has the highest TR among the 15 journals (and much higher than all competitors); therefore, it is evident that this journal offers a focused location for researchers in this field.
3. According to the scatter rule (Ding, 1993), most research papers of one discipline will be concentrated in a few number of journals, and other papers will be dispersed in a large number of journals. The leading five journals: JIG, AES, CJC, PRAI, and JEI, contained more than twice the number of IE papers compared to the other 10 journals.

Table 4. Summary over 15 journals

Journal	#I	#T	#S	SR (Rank)	TR (Rank)
AAS	60	1280	132	10.31% (14)	3.27% (10)
AES	88	3474	504	14.51% (11)	12.5% (2)
AGCS	40	592	95	16.04% (9)	2.36% (13)
CJBE	48	822	121	14.72% (10)	3.00% (11)
CJC	120	1946	319	16.39% (7)	7.91% (3)
CJSIA	36	488	111	22.75% (5)	2.75% (12)
CTTA	40	460	74	16.09% (8)	1.84% (14)
JCIC	106	2017	209	10.36% (13)	5.18% (8)
JDAP	40	971	211	21.73% (6)	5.23% (7)
JEI	84	2095	284	13.56% (12)	7.04% (5)
JEMI	40	565	57	10.09% (15)	1.41% (15)
JIG	102	1704	1223	71.77% (1)	30.3% (1)
JRS	48	639	155	24.26% (4)	3.84% (9)
PRAI	41	823	291	35.36% (2)	7.22% (4)
SP	48	943	246	26.09% (3)	6.10% (6)
Summary	941	18819	4032		

Detailed Classification Statistics

The third statistic is a detailed classification of IE publications in each sub-group and for each journal. The results are listed in Table 5.

Many commentaries could be made on Table 5; however, we only point out three important observations:

1. From the number of publications in different sub-groups, it seems that image compression (P4), image segmentation (A1), and object extraction (A4) are the most important research topics in all these years. Note that classes A1 and A4 are closely related but different. A1 is concentrated for separating an image into meaningful parts while A4 is more related to direct detection with object model; the former is more like an unsupervised task and the latter is more supervised.
2. The detailed classification shows that different journals have their different emphasis; some of them cover different sub-groups of IE (for example, AES, CJC, JDIP, JEI, JIG, PRAI) evenly, while some of them are more specialized in certain sub-groups of IE (for example, CJBE for T4, CTTA for P2, JCIC for P4 and T2, and JRS for T5). That information would be useful for potential authors.
3. The top two sub-groups are P4 and A1, respectively. Both of them contain about 1/8 of the total publications and thus indicate two hot research areas in IE. How-

Table 5. Detailed classification of references

Journal	P1	P2	P3	P4	P5	A1	A2	A3	A4	A5	U1	U2	U3	U4	T1	T2	T3	T4	T5	T6	S1

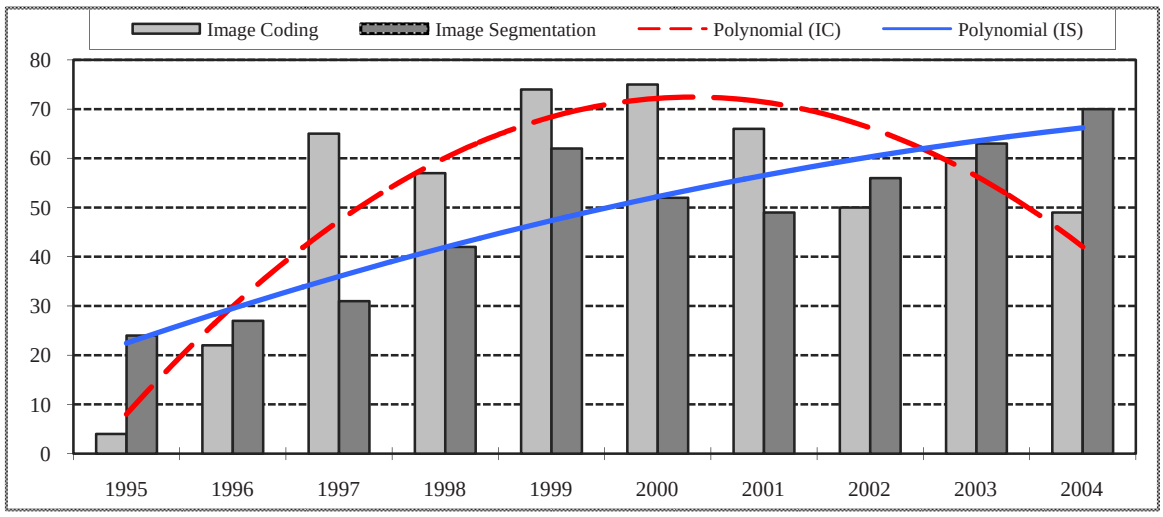
Summary	194	116	325	538	191	477	157	132	259	132	269	131	33	120	157	128	146	163	174	151	39

Figure 4. Comparisons of publication quantities for image coding and image segmentation in last 10 years



ever, a detailed comparison for each year, as shown in Figure 4, illustrates that they have had quite different developing trends. Image coding had been progressed mostly from 1997 to 2001 and decreased since than. This can be seen clearly by the polynomial (IC) curve (which is the polynomial approximation of the image coding curve for the last 10 years) in Figure 4. On the other side, image segmentation is progressing steadily all these years.

FUTURE TRENDS

The field of IE has changed enormously in recent years. Many techniques have been developed, exploited, or applied only in the last decade. We now see techniques for IE being implemented and used on a scale few would have predicted a decade ago. It is also likely that these techniques will find many new applications in the future.

Viewing the prospective of IE, the work for survey on IE could also be pushed deeply, at least, in two ways. First is that since this survey provides an up-to-date picture regarding IE and its research advance, so further research could be advanced and promoted in appropriate directions. Second is that according to the principles and methods of bibliometrics, a systematic investigation of the factors of the articles indexed in the survey series could be made. This can include the number of authors, the author productivity, the number of collaborative publications, the average number of authors per paper, the active author group, and the author variation ratio, and so forth. Some preliminary works have been performed (Zhang & Li, 2000b, 2001b); an up-to-date and completed version is in preparation. Such a work would reveal the level, status, and alteration of researchers in IE, as well as provide useful information for summarizing the development, progress, trends, and application areas of IE.

CONCLUSION

This article shows an overview of a survey series on IE made in the last 10 years. The idea behind and consideration on this survey, as well as a thorough summary of obtained statistics are illustrated and discussed. All these provide much of useful information regarding the 10 years' tendency of fast progresses of IE in China and worldwide.

Such a work not only provides a convenient means for literature searching in IE but also presents a detailed picture of hot research topics in the field. Moreover, it may be useful for publishers who want to quickly capture the general trends of development in IE and for potential authors who wish to disseminate widely their research results in the associated communities.

ACKNOWLEDGMENT

KEY TERMS

Image: An entity that was captured by some visual systems in looking at the real world and that can be sensed to produce perception. It is a representation, likeness, or imitation of an object or thing, a vivid or graphic description, something introduced to represent something else.

Image Analysis: One of three layers of image engineering, which is concerned with the extraction of information (by meaningful measurements with descriptive parameters) from an image (especially from interesting objects).

Image Coding: A process for representing an image with some other representations in view of reducing data for storage and/or transmission of this image.

Image Engineering: An integrated discipline/subject comprising the study of all the different branches of image and video techniques.

Image Processing: One of three layers of image engineering, which encompasses processes whose inputs and outputs are both images, with the outputs being improved version of inputs.

Image Segmentation: A process consists of subdividing an image into its constituent parts and extracting these parts of interest (objects) from the image.

Image Understanding: One of three layers of image engineering, which transforms data extracted from images into certain commonly understood descriptions, and makes subsequent decisions and actions according to the interpretation of the images.

Supporting E-Commerce Strategy through Web Initiatives

Ron Craig
Wilfrid Laurier University, Canada

INTRODUCTION

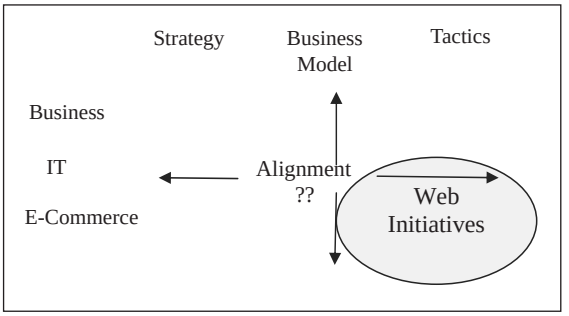
Our understanding of "the Web" and its e-commerce (EC) potential has grown rapidly during the past decade. While e-commerce has matured and is now mainstream, there continue to be opportunities to innovate as technology improves, the public is increasingly comfortable with and dependent up the e-approach, and new or enhanced applications appear. While historical roots of the Web go back several decades, it was only in the last two that business really started to embrace the Internet, and in the last one that commercial opportunities on the Web grew rapidly. Business use has gone from simple operational efficiencies (e-mail on the Internet, replacement of private EDI networks, etc.) to effectiveness (enhanced services, virtual products, and competitive advantage). Information and information products, available in digital form, and the ability to quickly transfer these from one party to another, have led to a paradigm shift in the way organizations operate. Many BPR (business process re-engineering) projects made use of the Web to streamline business processes and reduce or eliminate delays. Web self-service has emerged as a popular approach, with benefits for both customers and providers. Even governments have embraced the Web (e-government) for information and service delivery and interaction with citizens and businesses.

While the transition has followed the historical IT progression of automate, infomate, and transformate, the pace has been unprecedented. There have been successes and failures, with fortunes made and lost. After the dot-com boom/bust cycle, things settled down somewhat; yet the rapid pace of Web initiatives continues. At the forefront are innovators seeking competitive advantage. At the rear are laggards who can no longer ignore efficiencies provided by the Web and market requirements to be Web-enabled.

Paralleling the improvement in IT and the Internet has been a series of economic shifts including globalization, flattening of hierarchical organizations, outsourcing and off-shoring, increasing emphasis on knowledge work (contrasted with manual labor), plus growth in the service sector and information economy. IT has both hastened these economic shifts and provided a welcome means of addressing the accompanying pressures (often through EC or other Web initiatives).

To consider EC strategy and Web initiatives, one first needs to understand strategy and then extend this to the organization's business model and tactics. A firm's general business strategy includes, but is not limited to, its IT strategy (Figure 1). Similarly, EC strategy is a subset of IT strategy. Strategy should drive actions (tactics), through an appropriate business model. When strategy (business, IT, and EC) and tactics are closely aligned, and tactics are successfully executed, desirable results are obtained. Sometimes this normative view becomes reversed or otherwise changed. In the extreme, Web initiatives become the sole major focus (as was the case in the early days of the dot-com boom). However, without alignment between such tactics and the firm's strategy and business model, such an approach is either doomed to eventual failure or substantial modification.

Figure 1. Strategic alignment



In addition to commercial use of the Web, there are many non-commercial uses and non-commercial users (governments, educational institutions, medical organizations, etc.). The term e-business is often used to include both commercial and non-commercial activity on the Internet. In this article, the focus is on commercial activities (B2B and B2C). While e-government includes use of EC, governments are often driven by goals and responsibilities other than profit generation or cost reduction.

BACKGROUND: BUSINESS STRATEGY, IT STRATEGY, AND WEB INITIATIVES

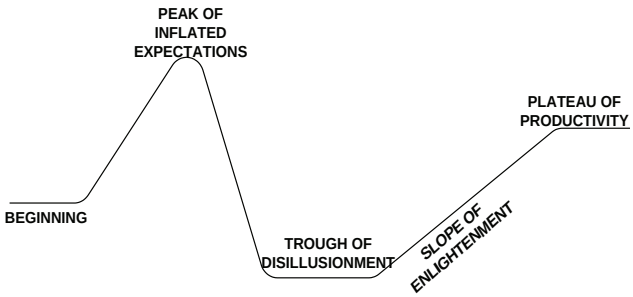
Business strategy and IT strategy have been extensively studied. The "strategic alignment model" of Henderson and Venkatraman (1993) identifies four domains of strategic

choice: business strategy, IT strategy, organizational infrastructure and processes, and IT infrastructure and processes. This model recognizes that a firm's IT operates within, and supports, a larger environment. As well, a firm's IT strategy can lead, lag, be independent of, or be aligned with a firm's business strategy. When alignment exists, there are significant payoffs (Tallon & Kraemer, 2003).

On the business strategy side, Porter provides several frameworks to guide firms in selecting their strategy and business model. His five-forces model, value chain network, and generic strategies (Porter, 1996) are useful frameworks when considering both business and IT strategies. In response to the question of whether or not the Internet renders established rules of strategy obsolete (as some had proposed), Porter answers that it makes strategy more vital than ever (Porter, 2001). He shows how the Internet has both positive and negative effects on industry structure, and identifies six principles of strategic positioning: (1) start with the right goal—superior long-term return on investment; (2) a firm's strategy enables it to deliver a value proposition, or set of benefits, that differentiates itself from competitors; (3) a firm's strategy is reflected in a distinctive value chain; (4) effective strategies require trade-offs; (5) strategy defines how all the elements of what a company does fit together; and (6) strategy involves continuity of direction. Porter (2001, p. 78) concludes, "In our quest to see how the Internet is different, we have failed to see how the Internet is the same." Today this conclusion seems almost self-evident, as our understanding of EC is much more comprehensive.

An extension to Porter's value chain is the virtual value chain (Rayport & Sviokla, 1995). Just as the physical value chain identifies the value-adding stages through which physical goods flow, the virtual value chain identifies the value-adding steps for information (gathering, organizing, selecting, synthesizing, and distributing). Firms can follow a three-stage development process: (1) visibility—improving ability to track operations more effectively, (2) mirroring—substituting virtual activities for physical, and (3) creating new customer relationships—using information to deliver value in new ways.

Figure 2. Technology hype cycle (Adapted from Gartner Group)



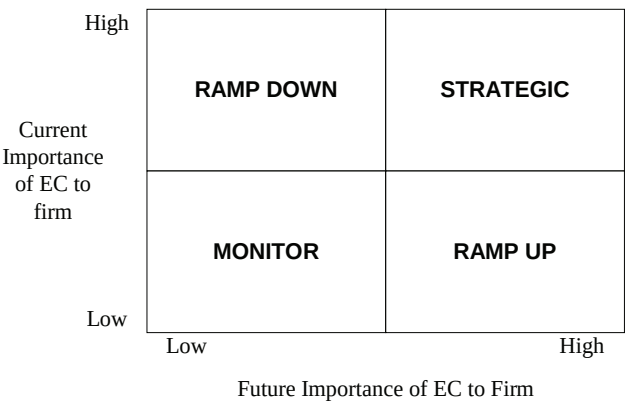
For virtual products and services, EC strategy and Web initiatives are especially important. EC usually takes advantage of both these value chains (the physical and the virtual). For example, supply chain management (SCM) initiatives have found that sharing information (virtual) about ultimate end-user demand with all members of the chain (physical) can result in significantly lower total chain costs along with improved delivery performance.

E-COMMERCE STRATEGY

During the rampant optimism of the mid to late 1990s, there seemed to be much more hype than reality concerning e-business. Statements were made that business was different now, that the Internet and Web changed everything, and that new e-business models were needed. The feeding frenzy among venture capitalists, eager to fund almost any start-up, allowed incomplete and ill-conceived concepts to be financed. It did not take long before reality took hold again, as the dot-com boom became the dot-com bust. The pendulum has now shifted from an overemphasis on "E" to a more balanced perspective on both "E" and "C." The Gartner Group Hype Cycle (Figure 2) provides a somewhat light-hearted, yet still realistic, view of this technology lifecycle. EC has gone through this cycle and emerged as an essential, productive process for most businesses.

Understanding an organization's strategic grid position (Figure 3) is critical for developing an appropriate IT and EC strategy and determining the requisite level of resources to commit. EC is not strategic to all firms, nor is all EC strategic. As Carr (2003) argues, much of IT today is a commodity-like service for many organizations, and can be managed as such (hence the popularity of IT outsourcing). Yet, EC and Web initiatives can be strategic. For firms transitioning from one quadrant to another within this grid

Figure 3. EC importance strategic grid



(i.e., changing their EC strategy) there are usually significant resource implications.

As stated earlier, an important component of corporate and e-commerce strategy is the business model used by a firm. As shown in the previous section, strategy is about making decisions and choices. For some firms, there will be much greater emphasis on the virtual side of their business; for others it will be the opposite. However, all firms need to consider the needs of their customers and the strategies (both business and IT) of their competitors, and be able to deliver required goods/services in a sustainable manner. Hence, the firm's business model must align with the strategy selected (be it EC strategy, IT strategy, or business strategy).

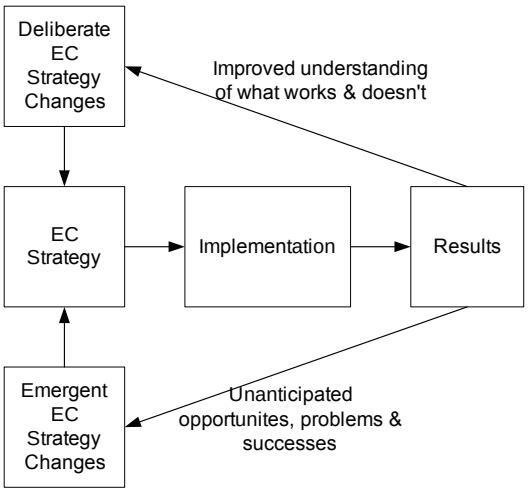
A business model is about much more than simply technology or the means of customer interaction. In the earlier days of the dot-com boom, there was an overemphasis on executing Web initiatives while ignoring the rest of the business model. Now, as the EC field matures, firms have a better understanding of the opportunities, the costs/benefits, risks, and the technology and applications to use. While technology is an important component, so are organizational characteristics (such as culture, interorganizational relationships, leadership, reward and control systems, staffing, and structure), resources (capabilities, financial, fixed assets, human, marketing, relationships, reputation and brand awareness, and technology), and managerial preferences (beliefs and values, personality and needs, job experience and context, leadership style, and political elements) (Crossan, Fry, & Killing, 2004).

An excellent discussion of business models is provided by Chesbrough and Rosenbloom (2002). They identify six functions:

- Articulates a customer value proposition
- Identifies a market segment (*who* will use the technology for *what* purpose; specifies the revenue generation process)
- Defines the venture's specific value chain structure
- Estimates the cost structure and profit potential
- Describes the venture's positioning within the value network linking suppliers and customers (includes identification of potential complementors and competitors)
- Formulates the venture's competitive strategy

Magretta (2002) identifies two tests for a powerful business model—the narrative test and the numbers test. The first test requires a logical, defendable explanation of who one's customers are, what they value, and how the firm will be profitable by providing that value. The second test requires evidence of ongoing financial viability, based on realistic assumptions and a financial analysis. Online auction giant eBay passed both these tests, as did Amazon. In contrast, most online grocery models failed because of false assumptions about what customers valued, and overly optimistic estimates of marketing, technology, and delivery cost. Another retailer, Lands' End, utilized Web initiatives and other IT to successfully pioneer mass customization for apparel (Ives & Piccoli, 2003).

Figure 4. Process by which EC strategy is defined & implemented (Adapted from Christensen & Raynor, 2003)



A business model can emerge quickly (e.g., for startups) or evolve slowly (as in a mature industry). The goal is to have a sustainable (profitable) business model. To develop this, components of the model (particularly business, IT, and EC strategy) may have to be changed. Christensen and Raynor's (2003) framework for strategy development can be applied to this process (Figure 4).

One question facing firms is when to use Web initiatives. Andal-Ancion, Cartwright, and Yip (2003) identify 10 drivers of new information technology (NIT), which also apply to Web initiatives. These different drivers determine the competitive advantages of deploying NIT, and fit under three general classifications: (1) Inherent characteristics of the product or service (electronic delivery, information intensity, customizability, and aggregation effects), (2) Interactions between a company and its customers (search costs, real-time interface, and contracting risk), and (3) Interactions between a company and its partners and competitors (network effects, standardization benefits, and missing competencies).

In their paper, they apply these drivers to various industries and firms, explaining the basis for disintermediation, remediation, or network-based mediation within an industry. These drivers should also be considered when a firm develops its EC strategy and considers Web initiatives.

A particular Internet benefit comes from its ability to integrate business processes across organizations, facilitated by the sharing of information between the various partners.

This is seen in B2B exchanges (whether private or public) and portals. After a rocky start with involvement in public exchanges (which tended to overemphasize price), many firms are now participating in, or hosting, private by-invitation-only exchanges (Hoffman, Keedy, & Roberts, 2002). Once again, it was lack of understanding of a sustainable B-model that resulted in so many failures. The original plan was to use the Internet's power and reach to form a more efficient marketplace. Most exchanges failed once their venture capital financing dried up. The strongest, surviving exchanges are those that added value for all participants (appropriate alignment, per Figure 1). Examples of successful industry exchanges include Covisint LLC (automotive, healthcare), Trade-Ranger Inc (energy/chemical), and Global Healthcare Exchange LLC (healthcare).

In the area of SCM, the sharing of information allows efficiency improvements all along the chain—firms can reduce inventory levels, increase the accuracy of their forecasting, and supply parts in a timely and cost-efficient manner. With the move from EDI to the Internet, even small firms can easily participate.

When developing an EC or Web initiative, there are many things to consider. A partial list includes the source and target (business, consumer, government), the focus (internal or external or both), whether the objective is efficiency or effectiveness, go it alone vs. partnership, proactive vs. reactive approach, targeting one-time vs. ongoing customers, physical vs. virtual goods, and single good/service vs. package.

From an ROI perspective, any investment in Web and e-commerce should provide a reasonable return. Yet, traditional investment analysis techniques may not be appropriate. Kohli, Sherer, and Baron (2003) discuss the unique challenges that e-business environments pose to the measurement of IT payoff. These include the productivity paradox, level of measurement, choice of metrics, and the measurement process. The authors identify four general areas for future research (appropriate metrics, the e-business environment, technology, and business process change).

FUTURE TRENDS

There is considerable uncertainty about predicting the future, particularly with IT and EC. Yet, there are current observable trends.

On the technology side, there is the gradual convergence of technical standards/protocols (although no single standard set has emerged). A benefit of collaborative consortiums is that a single protocol can be agreed upon by all participants. Certainly, the number of technologies and software capabilities will increase, and the move toward commoditization will continue, with the vendor community battling the Open Source community. For most firms, the problem will continue to be which technology to implement for what purpose. Overall, firms will continue to have more difficulty implementing technical initiatives because of non-technical issues. Usability of Web sites will continue to improve, as firms apply human factors analysis and other design procedures to implement better Web sites (see the Nielsen Norman group at www.useit.com). Research opportunities in this area will include empirical studies of how different types of organizations are using new technology, along with the study of implementation methods and challenges, and normative studies of how organizations should decide on which technologies to implement, when, and how.

Customer trends are also noticeable. Today's customers have heightened expectations. One proven approach to meeting these is through self-service applications (a "win/win" for both customers and the firm) for which Web initiatives are ideal. Self-service applications will proliferate.

The development and use of intra-organizational applications will continue to grow. Growing use of analytics will assist firms in segmenting their customers, more quickly becoming aware of demand shifts, and providing increased value at lower cost. Retail customers will have fewer Web site security concerns and continue to become more comfortable with Web purchasing of goods and services. Research opportunitities include developing better analytics and studying the behavior of early adopters, mainstreamers, and laggards.

At the firm level, several things are noticeable. As firms have gained experience with EC, many problems (such as channel conflict) have been identified and dealt with. SCM has led in consolidating firms into value chain networks. An increased understanding of the business levers for effective e-commerce strategies is leading to better decisions and standardization on "best practices" (which results in operational efficiency, but not necessarily in competitive advantage). In addition, there will be continued digitization of business processes; recent estimates were that only 20%-25% were currently digitized (Kalakota & Robinson, 2003). Smaller firms, facing resource scarcity, are likely to continue to lag in EC initiatives (Craig, 2002).

To date, m-commerce has not had the impact on EC that was expected. Yet the sheer number of mobile devices in the hands of consumers provides an attractive potential market. Okazaki (2005) provides an overview of m-commerce research, from both a past and future perspective. Xu and Gutierrez (2006) conducted a Delphi panel to identify potential "killer applications" for m-commerce. The panel results included SMS (short message service) and a killer portfolio (a package of applications designed to meet customer needs). In addition, four factors—convenience, ease of use, trust, and ubiquity—were identified as particularly important.

CONCLUSION

Business success comes from making difficult decisions about business, IT, and EC strategy, and then implementing these successfully, using appropriate resources. While spending on IT and EC will continue, it is possible to underspend, as well as overspend. Firms need to set priorities for investments, and ensure their business strategy aligns with their IT strategy (Farrell, Terwilliger, & Webb, 2003) and EC strategy. Sometimes this will result in being an IT and EC leader within an industry segment, and sometimes it will mean staying within the mainstream group or even lagging (Carr, 2003). This is an important choice for firms and should be made consciously, rather than by default.

Web initiatives, when undertaken as part of a firm's EC strategy, are only successfully implemented when adequate resources are provided for each project, and appropriate project management processes followed. For leading edge (bleeding edge?) projects, significant contingency allowances are important, and firms must be prepared for occasional failures (one could call these "learning experiences"). Risk management is necessary for all major IT projects, including Web initiatives.

Finally, firms should not overly focus on technology (Barua, Konana, Whinston, & Yin, 2001) when it comes to EC and Web initiatives. Good, appropriate technology (not necessarily the best), successfully implemented, will bring significant benefits at a reasonable cost.

KEY TERMS

Business Model: A specific arrangement of organizational strategies, goals, processes, resources (technologies,

finances, people, etc.), structures, products, and services that enable a firm to successfully compete in the market place. Many EC researchers have taken a narrower view, based on organizations involved (i.e., B2B, B2C, B2G, etc.), or specific framework used (i.e., hierarchy, hub, or intermediary for e-markets). While there is not yet a consensus about what makes up a business model, the trend is away from a narrower view.

E-Business Model: That subset of the general business model that supports e-business.

E-Commerce Strategy: A subset of general business and information technology strategy, focusing on Web-based commercial opportunities. It may dominate general strategy in some firms.

Electronic Commerce (E-Commerce): Commercial activities taking place over electronic networks (primarily the Internet); e-commerce is a subset of general commerce.

Mobile Commerce (M-Commerce): With wireless access to the Web.

Protocol: A set of rules and procedures that govern transmission between the components of an electronic network.

Strategy: The determination of the basic long term goals and objectives of an organization, and the adoption of courses of action and allocation of resources necessary for achieving these goals; major components of strategy include goals, product/market focus, business system focus, and competitive premise.

Web Initiative: Any use of the World Wide Web for a specific purpose.

Web Personalization: Customizing Web content, in real time, to a specific user.

Supporting Quality of Service for Internet Multimedia Applications

Yew-Hock Ang
Nanyang Technological University, Singapore

Zhonghua Yang
Nanyang Technological University, Singapore

INTRODUCTION

The Internet has gone from near-invisibility to near-ubiquity and penetrated into every aspect of society in the past decades (Department of Commerce, 1998). The application scenarios have also changed dramatically, and now demand a more sophisticated service model from the network. In the early 1990s, there was a large-scale experiment in sending digitized voice and video across the Internet through a packet-switched infrastructure (Braden, Clark, & Shenker, 1994). These highly-visible experiments have depended upon three enabling technologies: (1) Many modern workstations now come equipped with built-in multimedia hardware, (2) IP multicasting, which was not yet generally available in commercial routers, and (3) Highly-sophisticated digital audio and video applications have been developed. It became clear from these experiments that an important technical element of the Internet is still missing: multimedia, which dominate increasing proportion of today's data traffic, are not well supported on the Internet.

BACKGROUND

The Internet, as originally conceived, offers only best-effort service provided by the connectionless datagram service of IP (Internet Protocol). Such service does not promise whatsoever the end-to-end delay of packets nor about the variation of packet delay variation, and is not suitable for carrying multimedia traffic. To support multimedia services, the Internet must guarantee its transmission delay, delay variation, and loss according to the quality of service (QoS) required by multimedia applications and the service quality level expected by the Internet users. In other words, the Internet is to be QoS-aware of different service quality requirements for supporting multimedia applications and sensitive to the characteristics that are peculiar to multimedia data.

On the other hand, traditional networks are QoS-specific networks which were designed to support fixed classes of service; such as telephone networks for time-sensitive voice communication, cable networks for error-tolerant video streaming, and data networks for non real-time error-sensitive text messaging. The future Internet, however, is expected to be QoS-aware, and provide QoS guarantees to meet a wide range of QoS requirements for supporting multicast multimedia applications. In response to these expectations, the Internet Engineering Task Force (IETF) has specified three service models for supporting QoS on the Internet; namely, the Integrated Services (IntServ), Differentiated Services (DiffServ), and Multi-Protocol Label Switching (MPLS). This article discusses the design motivation, architecture and development of these service models for supporting QoS guarantees on the Internet.

PRINCIPLES FOR SUPPORTING MULTIMEDIA QOS

To support multimedia applications, the Internet service models must address the issue of quality of service that relates to the characteristics of multimedia data. These data characteristics are: (a) media type, (b) data synchrony, and (c) data persistency. The media type identifies the multimedia as one of image, video, audio, or text. Network services should be aware of different error susceptibilities of media types. For example, video data are handled by a QoS-aware network with a higher packet loss rate or treated with higher drop precedence than for error-sensitive audio data. Data synchrony defines the temporal synchronization of real-time data, such as interframe delay in video streams. A QoS-aware network must forward real-time data packets with higher priority than for non real-time data packets. Data persistency describes the transient nature of "live" data. Live data are not stored or buffered at its source; hence they are nonpersistent and are not retransmitted when received in error.

To be sensitive to QoS requirements of multimedia applications, a QoS-aware network must be designed according to the following four service principles and implemented with a corresponding set of traffic management/handling mechanisms:

1. *Service agreement*: a call admission mechanism to allow an application to negotiate for a service agreement

to share network resources or to operate at a required service level.

2. *Service specification*: a packet marking mechanism for the user or application to specify the application data type and a classification mechanism to allow routers to distinguish between different data specifications or classes of applications.
3. *Service conformance*: a traffic conditioning mechanism for flow policing and remarking of misbehaved packets so as to force application traffic to conform to service agreements.
4. *Service commitment*: a queue management and scheduling mechanism for QoS treatment of packets, while ensuring high resource utilization, to meet service agreements, and thereby fulfilling service commitments.

These service principles specify the manner a network is made aware of the service level requirements, specifications of traffic it is expected to handle, policing policies for service agreement enforcement, and service commitment to guarantee QoS of admitted flows. Accordingly, future Internet service models must all implement these principles for QoS-awareness.

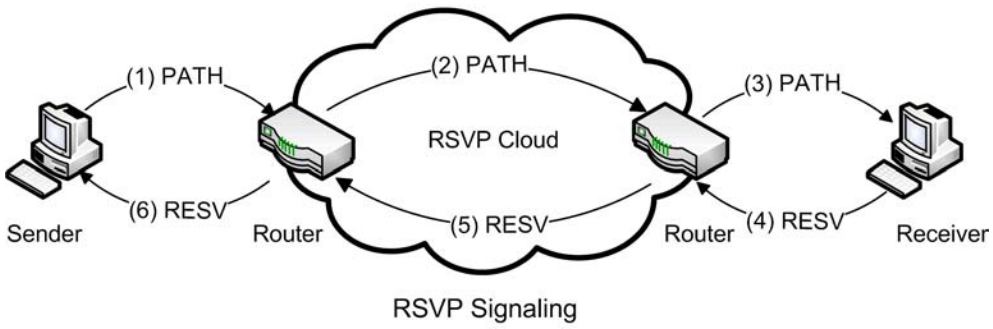
THE INTERNET INTEGRATED SERVICES (INTSERV) MODEL

The Integrated Services (IntServ) model extends the original connectionless point-to-point best-effort service of the Internet with a connection-oriented end-to-end QoS provisioned service (Braden et al., 1994). It achieves this by setting up a routed path between the endpoints with the necessary level of resources reserved along this path to guarantee end-to-end QoS on a per-flow basis (Figure 1).

Implementation of QoS support mechanisms for QoS guarantees in IntServ:

1. *Service agreement*: A call setup, using RSVP signaling (Braden, Zhang, Berson, Herzog, & Jamin, 1997) initiated by the application, requests for explicit resource reservation in routers to satisfy per-hop QoS requirements of an anticipated flow. The QoS requirements specified in a PATH message carries the *Sender_TSpec* and the *AdSpec* from the source toward the receiver. The *TSpec* contains the description of the traffic profile (traffic burst rate and average rate), while the *AdSpec* describes the properties of the data path and QoS requirements (packet delay and loss) of the sending application. The receiver responds to the service request with a RESV message for setting up the resources in the routers along the data path toward the sender.
2. *Service specification*: The RESV carries a *Flowspec* and a *Filterspec*. The *Flowspec* contains a *Receiver_TSpec* which describes the traffic profile, and *RSpec* (Reserved QoS spec) the QoS service level that each router along the routed path is expected to provide. The *Filterspec* provides the information required by the packet classifier in the router to identify packets belonging to a particular flow. Such flow-state information must be maintained in end-hosts and routers along the routed path for flow filtering and QoS packet treatment.
3. *Service conformance*: Packet classifiers in routers filter incoming flow packets based on the *Filterspec*. Packets identified as belonging to a provisioned flow are treated according to the reserved level of QoS. Flow packets not identified are treated on a best-effort basis.
4. *Service commitment*: Packet schedulers in routers handle a filtered flow according on its *TSpec* and service it such that its QoS commitments (*Rspec*) are met. The Token Bucket scheduler is typically used to service a flow carrying a *TSpec* of traffic burst rate, B bounded by the token bucket size, b; and its long-term traffic average rate, R bounded by the token arrival rate, r. The flow delay defined by b/R is guaranteed so long as the burst rate, B does not exceed the bucket size, b.

Figure 1. End-to-end QoS provisioning in Integrated Services Model



The key feature of the IntServ model is its ability to share available link capacity through explicit network resource reservation such that end-to-end QoS guarantee is maintained on a per-flow basis. However, large scale deployment of the IntServ model may be hampered in certain ways: (1) huge router memory required to maintain flow-state information which increases proportionally with the number of flows, (2) flow filtering and packet classification based on IP header multifield is computationally demanding, and (3) high implementation complexity is required as all QoS support mechanisms must be ubiquitously deployed in all routers and end hosts.

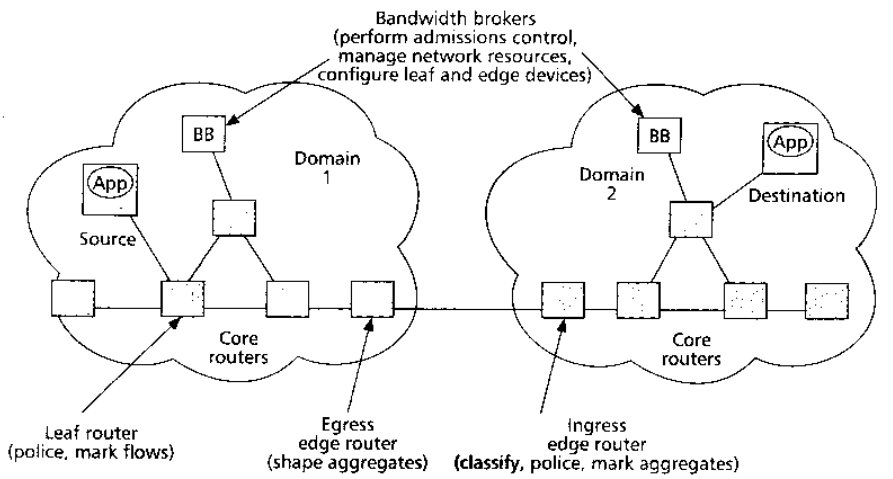
THE DIFFERENTIATED SERVICES (DIFFSERV) MODEL

The Differentiated Services (DiffServ) model provides per-class QoS service provisioning on a per-hop behavior (PHB) basis (Blake, Black, Carlson, Davies, Wang, & Weiss, 1998). Such per-class service avoided the scalability problem associated with per-flow QoS provisioning of IntServ. DiffServ allows flow packets to be marked differently by the application to receive different aggregate classes of service. It maintains edge-to-edge service commitments based on Service Level Agreement (SLA) and traffic conditioning at network edge (Figure 2).

Implementation of QoS support mechanisms for QoS guarantees in DiffServ:

1. *Service agreement*: An application initiates a SLA with the Bandwidth Broker (BB) for a service class and the traffic specifications it wants to be supported. The SLA includes a traffic conditioning agreement (TCA) which specifies the service level, traffic profile, and traffic conditioning policies. The service level is defined by a set of service performance parameters such as packet loss rate, and packet delay. The traffic profile describes the traffic peak rate and burst rate.
2. *Service specification*: Traffic entering the DiffServ domain are marked using the ToS field for differential service class treatment. ToS fields are mapped to behavioral aggregates (BAs) at leaf routers into Differentiated Service Code Points (DSCP). Packet classification into BAs using single DSCP value is far more efficient than multifield packet filtering in IntServ.
3. *Service conformance*: TCAs set up service classification and traffic conditioning policies in leaf and boundary routers for service conformance. BA flows exiting a DiffServ domain are shaped by egress routers to conform to contracted aggregate rate. Similarly, BA flows entering a DS domain are classified and conditioned to conform to TCA's traffic conditioning rules. Packets exceeding traffic profile are remarked as out-of-profile and could be potentially dropped.
4. *Service commitment*: Core routers maintain service commitments to BAs according to a set of service profiles on a per-hop behavior (PHB) basis. Service profiles define best-effort, assured forwarding, or expedited forwarding service classes and for each service class different packet drop precedence. BA reduces the number of service states needed to be maintained in the core routers; hence, a stateless core. Flow conditioning, policing, and conditioning are performed only at edge routers; hence, complexity at the network edge.

Figure 2. Per-hop behavior service in Differentiated Services Model



The DiffServ architectural framework has several advantageous features as compared to the IntServ model: (1) Stateless core allows high scalability of DiffServ domain, (2) Per-class aggregate SLA signaling is simpler than per-flow RSVP signaling, and (3) Efficient packet classification based on a single DSCP reference and forwarding based on a small number of states. However, DiffServ provides only PHB routing and no guarantee on end-to-end QoS. Traffic aggregation can potentially cause "hot spots" to form in the stateless core and hence disrupting end-to-end QoS guarantees; unless constraint based routing or traffic engineering has been used to even out "hot spots" and optimize resource utilization.

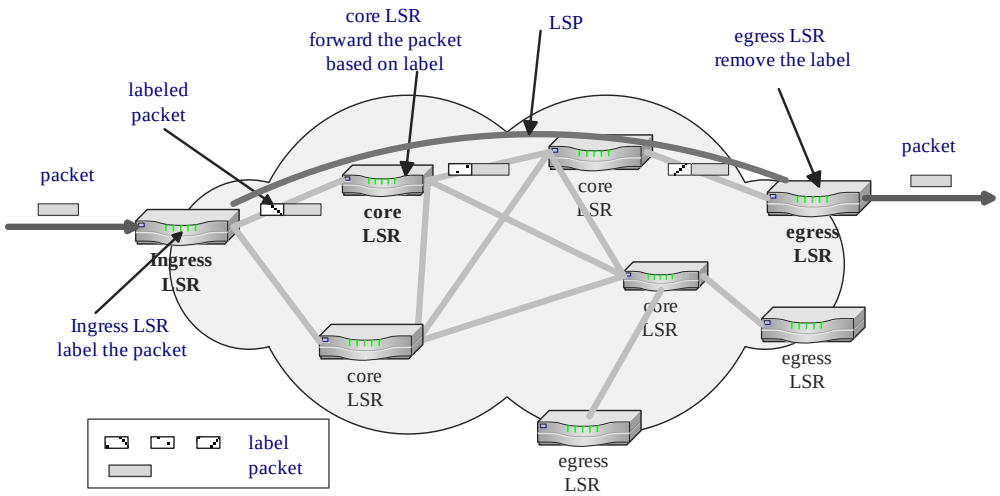
MULTI-PROTOCOL LABEL SWITCHING (MPLS)

Multi-Protocol Label Switching (MPLS) implements separate service control and forwarding functions (Rosen, Viswanathan, & Callon, 2001). Separate control allows the use of explicit routing or traffic engineering for QoS provisioning of label switched paths (LSPs) to achieve even distribution of traffic and optimized resource utilization. A LSP is end-to-end QoS provisioned and provides a forwarding equivalent class (FEC) service. Packets requiring the same QoS treatment are forwarded on a same FEC and switched along a LSP using label swapping (Figure 3).

Implementation of QoS support mechanisms for QoS guarantees in MPLS:

1. *Service agreement*: Explicit LSPs with labels are set up based on RSVP-TE (RSVP with Traffic Engineering extension) signaling (Awduche, Berger, Gan, Li, Srinivasan, & Swallow, 2001) or Label Distribution Protocol (LDP) (Andersson, Doolan, Feldman, Fredette, & Thomas, 2001). LSPs are QoS provisioned to support Forward Equivalent Classes (FECs) of service and are load balanced for high resource utilization. Label switched routers (LSRs) set up forwarding tables for packet forwarding using label swapping. An existing LSP of lower holding priority may be torn down for a new LSP with a higher setup priority to be established for a new FEC.
2. *Service specification*: An application flow is classified once at an ingress LSR into a particular FEC and assigned a label that binds the FEC to a QoS provisioned LSP. All packets in a FEC flow are treated in the same manner by intermediate LSRs along the routed LSP. Packet classification and forwarding uses a single-field MPLS label rather than IP header multifield filtering and longest-prefix address matching in IP routing. The experimental Class of Service (CoS) field in the MPLS header can also be used for microflow packet marking to provide PHB service integration with DiffServ. The CoS field may also be referred to as an EXP field and may be used for QoS bridging between MPLS and IEEE Layer-2 service (ANSI/IEEE Standard 802.1Q, 1988).
3. *Service conformance*: Ingress LSRs condition input flows to conform to FEC traffic specifications. Traffic conditioning in MPLS is done once at the ingress LSRs as compared to per-hop conditioning in IntServ.
4. *Service commitment*: QoS provisioned LSPs ensure end-to-end QoS guarantees of FEC and explicit routing of LSPs ensures load-balancing of FEC traffic for high resource utilization.

Figure 3. End-to-end packet forwarding in multiprotocol label switching



The MPLS architectural framework achieves several advantages over the IntServ and DiffServ service models: (1) Separation of service control and forwarding function allows efficient packet forwarding on explicit routed QoS provisioned LSPs, (2) Efficient flow filtering and packet forwarding using fixed-length label swapping, instead of multifield processing in IntServ, (3) Per-path QoS provisioning and end-to-end service guarantee; instead of per-hop service provisioning in DiffServ, and (4) Traffic engineered LSPs provides load-balancing of traffic and avoids network congestion.

THE FUTURE TRENDS

The IntServ, DiffServ, and MPLS, as described above, represent a generic class of service models for QoS support on the Internet. The intrinsic services they provide to different types of multimedia applications are characterized by the manner in which their service control and packet forwarding mechanisms are implemented (Table 1). These services provide QoS guarantees that match the QoS requirements of multimedia applications. For example:

- IntServ provides per-flow end-to-end service guarantee that matches QoS requirements of a dedicated flow of real-time audio stream.
- DiffServ provides per-class behavior aggregate service that matches different QoS requirements of intrastream class aggregates of I-, B-, and P-frames in a MPEG video stream. In such cases, I-frames are treated with the higher class of service and B-frames with the lowest class of service.
- MPLS provides per-path service guarantee that matches QoS requirements of a multiplexed audio/video stream. In this case, the EXP field in the MPLS header can be used to differentiate per-hop Class of Service (CoS) packet treatments that matches the distinct QoS requirements of audio and video flows in the multiplexed stream. Flow packets of the same EXP value are treated as a microflow with particular drop precedence.

Recently, research efforts have been directed at developing a framework for internetworking among the different service architectures to provide a truly integrated multiservice IP network. Such a framework includes the definitions of a common set of QoS parameters and a mechanism to map those QoS parameters across different service domains, which generally were composed of chains of multiple domains independently administered by different ISPs. A framework which provides end-to-end QoS in an IntServ-over-DiffServ architecture was proposed by extending the concept of PHB and treating each DiffServ domain as a Per-Domain Behavior (PDB) and a chains of DiffServ domains as a Per-Region Behavior (PRB), such that the QoS parameters of each of these behavioral domain/region can be externally defined and mapped between the user QoS requirements and the SLAs (Mammeri, 2005).

To facilitate the exchange and setting up of service agreements between the two domains, a set of Session Initiation Protocol (SIP) based description messages was proposed for establishing service agreements among end-to-end user terminals, policy servers, and edge routers. For IntServ-DiffServ interworking, the SIP descriptors declare the user traffic and QoS demands according to the SLA parameters and set the access control policies for traffic conditioning based on the status of resource reservation to guarantee seamless QoS connections (Cho, Shin, & Yoo, 2006). In fact, end-to-end QoS connections may also be guaranteed over any selected path that satisfies the user QoS constraint in the DiffServ domains by ensuring the residual resources in all servers along the selected path have sufficient capacity for the user request (Hsu, Tung, & Wu, 2007).

Interworking between per-hop DiffServ and per-path MPLS services can be implemented by mapping DSCP values onto specific QoS provisioned LSPs. The IETF, RFC

Table 1. Implementations of service control and packet forwarding functions in IntServ, DiffServ and MPLS service architectures

Service Model	Service Control	Packet Forwarding	Application Service/Type
IntServ	▪ Per-flow resource reservation ▪ End-to-end service	▪ flow filtering ▪ per-flow basis	▪ per-flow end-to-end QoS guarantee ▪ dedicated audio stream
DiffServ	▪ Per-class aggregates ▪ Per-hop behavior service	▪ packet classification ▪ per-class basis	▪ per-class QoS behavior aggregates ▪ MPEG video streams
MPLS	▪ Per-path provisioning ▪ Label swapping	▪ flow classification ▪ per-flow basis ▪ per-class basis	▪ per-path QoS guarantee ▪ per-hop CoS treatment ▪ Multiplexed streams

3270 (Wu, Davie, Davari, Vaananen, Krishnan, Cheval, & Heinanen, 2002) described two types of LSPs. An E-LSP which defines an EXP-Inferred per-hop scheduling class LSP, and a L-LSP which defines a normal Label-Inferred per-path scheduling class LSP and its PHB is determined from both the MPLS label and the EXP field. The E-LSP is useful for servicing microflows of I-, B-, and P-frames within a MPEG flow. For example, the DSCP values which define the per-hop aggregate class of services in DiffServ can be mapped to the EXP (or CoS) bits, and in turn mapped to the 3-bit user priority field in the Layer-2 MPLS (IEEE 802.1Q) frame to facilitate per-hop differential packet treatments of a FEC flow.

As QoS support on the Internet is becoming a reality there will be increasingly more demanding multimedia applications which require multicast services, such as in multimedia desktop collaboration, video conferencing, and network gaming. It was observed that further research work on multicast technologies were needed to develop multicast internetworking of IntServ, DiffServ, and MPLS into a practical solution (Agarwal, & Wang, 2003). In fact, practical developments to provide widespread interworking of service models have already begun at a Public Interoperability Event held at the MPLS World Congress 2006 on the interoperability of MPLS internetworked multicast services across many different MPLS vendors' equipments (Ganbar, Morin, Rossenhoevel, & Schrenk, 2006).

We believe that while cross domain QoS mappings are not yet widespread on the Internet, IntServ and DiffServ will continue to be the preferred service models for intranets and access networks implementations. However, as MPLS advances along with new protocols defined by the IETF, more devices will begin to include MPLS stacks. This will in turn push MPLS deployments closer to the edge and MPLS being adopted for access networks as well and as an integration model for widespread interworking of QoS-aware networks for supporting converged network services.

CONCLUSION

The Internet has evolved from a provider of the simple TCP/IP best effort service to an emerging QoS-aware network for supporting converged network services. The development of different service models, such as the IntServ, DiffServ, and MPLS forms the building blocks for a truly integrated multiservice IP network for supporting multicast multimedia applications over the Internet. These service models are characterized by a set of four common principles for supporting QoS guarantees and the implementation of their QoS support mechanisms led to unique characters of their service architectures for supporting different application services. With significant work and progress already completed over the last decade on the development of service architectures and network interoperability, it is anticipated that a truly integrated multiservice Internet may be realized sooner than later. Perhaps the MPLS architecture could well be the service model of choice because of its flexibility of service interoperability, end-to-end QoS guarantee, and high resource utilization.

KEY TERMS

Behavior Aggregate (BA): A collection of packets with the same DS codepoint crossing a link in a particular direction.

DSCP: A specific value of the DiffServ codepoint portion of DS field (same as in IPv4 header TOS field or the IPv6 Traffic Class field) used to select a PHB.

Forwarding Equivalence Class (FEC): A group of IP packets which are forwarded in the same manner (e.g., over the same path, with the same forwarding treatment).

Label Switched Path (LSP): The path through one or more LSRs at one level of the hierarchy followed by a packets in a particular FEC.

MPLS Label: A label which is carried in a packet header, and which represents the packet's FEC.

Multifield: IP header multifield defines the 5-tuplet fields in the IP header, comprising of the source and destination addresses, source and destination port numbers, and the protocol type.

Per-Hop-Behavior (PHB): The externally observable forwarding behavior applied at a DS-compliant node to a DS behavior aggregate.

QoS: Quality of service refers to the suitability of a packet delivery service for the needs of a particular application, as defined by parameters such as achieved bandwidth, packet delay, and packet loss rates.

RSpec: A Service Request Specification is a specification of the quality of service a flow desires from a network element. The service request specification is highly specific to a particular service; for example, it might contain information about bandwidth allocated to the flow, maximum delays, or packet loss rate.

RSVP: The Internet standard protocol: Resource ReSerVation Protocol (RSVP).

Service Level Agreement (SLA): A service contract between a customer and a service provider that specifies the forwarding service a customer should receive.

Service Model: Consists of a set of service commitments, in response to a service request the network commits to deliver some service.

Token Bucket: A particular form of traffic specification consisting of a "token rate" r and a "bucket size" b. Essentially, the r parameter specifies the continually sustainable data rate, while the b parameter specifies the extent to which the data rate can exceed the sustainable level for short periods of time.

TSpec: Traffic Specification containing descriptions of traffic characteristic such as packet arrival peak rate and burst rate.

Traffic Conditioning Agreement (TCA): An agreement specifying classifier rules and any corresponding traffic profiles and metering, marking, discarding or shaping rules which are to apply to the traffic streams.

Supporting Real-Time Services in Mobile Ad-Hoc Networks

INTRODUCTION

Mobile ad-hoc networks (MANETs) are well known by their flexibility and usefulness, being an ideal technology to support ubiquitous computing environments. Such environments are expected to support a plethora of applications, including real-time video and voice communications.

In terms of applications, this technology can be used whenever there is a lack of infrastructure for support, which typically occurs in rescue missions, areas affected by natural disasters, remote areas, war scenarios, and also in the underground. The use of real-time voice and video communications could allow, for example, firemen rescue teams to communicate seamlessly and for the head officer to remotely supervise their activity using different video channels.

The deployment of real-time services over mobile ad-hoc networks requires QoS (quality of service) support at different network layers. QoS support is understood as the network ability to offer some guarantees about the traffic being delivered. Within the scope of QoS we often define performance in terms of availability (uptime), bandwidth (throughput), latency (delay), delay jitter, and error rate.

Offering QoS support in mobile ad-hoc network environments is, nevertheless, quite difficult due to the innate complexity of these networks. The problems that impact mobile ad-hoc networks can be split according to the network layer affected.

At the physical layer, frequent topology changes—in conjunction with channel contention and unstable radio links—make real-time services support in such networks very hard to achieve (Georgiadis, Jacquet, & Mans, 2004).

At the Medium Access Control (MAC) layer, channel access is typically distributed, provoking the well-known hidden and exposed node problems, which complicate bandwidth reservation.

At the network layer, routing protocols have to deal with frequent topology changes and simultaneously discriminate among the available paths to meet QoS requirements.

At the application layer, awareness of the type of networks and technologies being used allows applications to adapt themselves according to path conditions and so improve performance.

This article discusses the aforementioned issues related to QoS challenges and solutions in mobile ad-hoc networks. It first includes some background information on the history of QoS support in computer networks. It then refers to the problematic of QoS support in mobile ad-hoc networks by referring MAC and routing layer solutions, along with QoS architectures for ad-hoc networks. To conclude the article there is reference to future trends in terms of QoS support in ad-hoc networks.

BACKGROUND

The first attempts at providing significant QoS support improvements in computer networks took place on the Internet in the early 1990s. The main problem faced by engineers was that the Internet was initially created to handle best-effort traffic alone. This means that its infrastructure was not designed considering QoS-related functionality such as resource reservation, and so all users compete for bandwidth. For this reason the Internet protocol (IP) is connectionless, requiring no set-up "signaling" for admission control.

When enhancements in terms of available bandwidth and a terminal's capabilities brought up the need for supporting new services on the Internet, preliminary evaluation studies showed that the performance of these new services was very poor due to the best-effort policy. There was, therefore, a need to enhance the Internet infrastructure in order to allow

performing resource reservations in a similar fashion to telephony networks. The RSVP protocol (Braden, Zhang, Berson, Herzog, & Jamin, 1997) was created to fulfill this need as part of the Internet's integrated services (IntServ) architecture (Braden, Clark, & Shenker, 1994). RSVP follows a receiver-based model since it is the responsibility of each receiver to choose its own level of reserved resources, initiating the reservation and keeping it active. The actual QoS control, though, occurs at the sender's end. The sender will try to establish and maintain resource reservations over a distribution tree. If a particular reservation is unsuccessful, the correspondent source is notified.

The IntServ architecture proved to be complex and required too many resources, suffering from scalability problems. So, the differentiated services (DiffServ) architecture (Blake, 1998) emerged as a more efficient alternative. In the latter, service-level agreements (SLA) are achieved between different domains. One of the main virtues of the DiffServ architecture is that it drops the traditional concept of signaling, no longer requiring the reservation of resources in all the network elements involved. The strategy consists of performing admission control on domain boundaries, and then treating them in a differentiated manner inside the domain according to packet tagging on the domain borders, which is a much faster and lightweight process.

QoS SUPPORT IN MOBILE AD-HOC NETWORKS

MANET environments differ greatly from the wired environments the DiffServ and IntServ models were created for. The difference stems not only from the new problems encountered in MANETs (mobility, collisions, variable channel conditions, etc.), but also because MANETs do not follow the client/service provider paradigm inherent to both IntServ and DiffServ models. In MANETs the network is typically formed by users that cooperate and, except in situations where there is some centralized management entity (e.g., Army), it depends on the good behavior of users and limited resource sharing. So, new proposals were presented in order to achieve reliable QoS support in MANETs.

In this section we present an overview of the different proposals available in the literature offering QoS improvements to mobile ad-hoc networks. We first introduce QoS proposals at the MAC layer. Then we refer to QoS solutions at the routing layer. Finally we refer to complete QoS architectures for MANETs.

QoS Support at the MAC Layer

Most of the MAC layer protocols for ad hoc networks are characterized by being distributed (there is no central entity regulating channel access) and contention-based (channel access is not deterministic, being that stations compete to gain access to it). These characteristics, along with the well-known hidden (Kleinrock & Tobagi, 1975) and exposed (Shukla, Chandran-Wadia, & Iyer, 2003) node problems that are prone to occur in wireless multi-hop environments, complicate the process of offering QoS support. In fact, in such wireless environments, it is impossible to offer strict QoS guarantees to users, and so statistical QoS is achieved instead.

Despite this is a novel research area, we can already find products in the market offering QoS support at the MAC layer. The most relevant technology available due to its widespread adoption is IEEE 802.11e, which is a new MAC standard proposed by the IEEE 802.11 Working Group (2005) to enhance WiFi networks with QoS support.

The IEEE 802.11e standard relies on a hybrid coordination function, HCF, which defines two medium access mechanisms: the HCF controlled channel access (HCCA) and the enhanced distributed channel access (EDCA). From these two, only EDCA applies to ad-hoc network environments, the former being reserved for access point operation.

QoS support through EDCA requires introducing different access categories (ACs) and their associated backoff entities. Contrarily to the legacy IEEE 802.11 stations, where all the packets received by the MAC layer have the same priority and are assigned to a single backoff entity, IEEE 802.11e stations have four backoff entities—one for each AC—so that packets are sorted according to their priority. Each backoff entity has an independent packet queue assigned to it, as well as a different parameter set.

Table 1. IEEE 802.11e MAC parameters for an IEEE 802.11a/g radio

Access Category	AIFSN	CWmin	CWmax	TXOPLimit (ms)
Background	7	15	1023	0
Best effort	3	15	1023	0
Video	2	7	15	3.008
Voice	2	3	7	1.504

Table 1 presents the default MAC parameter values for the different ACs introduced by IEEE 802.11e. Notice that smaller values for the AIFSN, CWmin, and CWmax parameters result in a higher priority when accessing the channel; relative to the TXOPLimit, higher values result in larger shares of capacity and, therefore, higher priority.

Works such as Romdhani, Ni, and Turletti (2003) propose enhancements to the IEEE 802.11e technology to offer relative priorities by adjusting the size of the contention window (CW) of each traffic class, taking into account both application requirements and network conditions. In the literature we can also find other works, such as Sobrinho and Krishnakumar (1999) and Sivavakeesar and Pavlou (2004), which propose alternate QoS MAC schemes designed specifically for ad hoc network environments.

QoS Support at the Routing Layer

The issue of QoS support at the routing layer is quite complex in the MANET field since different authors use different QoS metrics. Besides generic QoS metrics that typically apply to all environments—minimum bandwidth, maximum delay, maximum delay jitter, and maximum packet loss ratio—in MANETs there is another set of metrics that is also considered important. Among these we have residual link/path capacity, node buffer space, energy consumed per packet, node/route lifetime, and so forth.

Hanzo and Tafazolli (2007) survey the most relevant QoS routing solutions developed to date. That survey categorizes QoS routing solutions according to their interaction with the MAC layer. So, the authors define three different categories for QoS routing protocols in MANETs:

(1) MAC layer dependent/contention-free
(2) MAC layer dependent/contended
(3) MAC layer independent

Concerning proposals in the first category, Lin and Liu (1999) propose CCBR (channel capacity-based routing), a QoS routing protocol that includes end-to-end bandwidth calculation along with bandwidth allocation schemes. Chen and Nahrstedt (1999) propose TBR (ticket-based routing), defining a distributed QoS routing scheme that selects a network path with sufficient resources to satisfy a certain delay (or bandwidth) requirement, though not both at the same time.

An example of a routing layer proposal for the second category is CAAODV (Lei & Heinzelman, 2005), a QoS-aware routing protocol that incorporates admission control and feedback schemes to meet the QoS requirements of real-time applications by offering an estimate of available bandwidth. Also in this category we have AQOR (Xue & Ganz, 2003), a resource reservation-based routing and signaling algorithm that provides end-to-end QoS support in terms of bandwidth and delay.

An example of a routing protocol for the third category is IAR (Gupta, Jia, Tung, & Walrand, 2005), which offers throughput-constrained QoS routing based on knowledge of the interference between links.

QoS Architectures for MANETs

In the literature we find proposals focusing essentially on the MAC and routing layers, being that only a few authors have proposed complete QoS architectures for MANETs. We will describe three QoS architectures for ad-hoc network environments that we consider especially relevant: INSIGNIA (Lee, Gahng-Seop, Zhang, & Campbell, 2000), SWAN (Ahn, Campbell, Veres, & Sun, 2002), and DACME (Calafate, Oliver, Cano, Malumbres, & Manzoni, 2007).

INSIGNIA

The INSIGNIA architecture (Lee et al., 2000) is an attempt to adapt the IntServ model proposed for the Internet to MANET environments. It consists of an in-band signaling system that supports fast reservation, restoration, and adaptation algorithms. With INSIGNIA all flows require admission control, resource reservation, and maintenance at all intermediate stations between source and destination to provide end-to-end quality of service support.

One of the characteristics of INSIGNIA is that it relies on in-band commands. These are put inside the IP option field and include service mode, payload type, bandwidth indicator, and bandwidth request fields. When a reservation is being established, each node along the path checks INSIGNIA's IP option field to see if it can offer the maximum QoS requested. The destination will become aware of QoS availability on the path by obtaining the value of this field.

The INSIGNIA signaling system is designed to be lightweight in terms of the amount of bandwidth consumed for network control and to be capable of reacting to fast network dynamics such as rapid host mobility, wireless link degradation, intermittent session connectivity, and end-to-end quality of service conditions.

SWAN

SWAN (Ahn et al., 2002) is an approach to integrated services support in MANETs through a flexible signaling system. SWAN relies on plain IEEE 802.11 plus rate-control for best effort traffic. Rate control is done at every node and relies on an AIMD (additive increase/multiplicative decrease) algorithm based on feedback from the MAC layer.

The acceptance of real-time traffic is dependent on local bandwidth estimates and admission control probes. When

a new flow must be admitted into the network, the source station sends a probing request packet to assess end-to-end bandwidth availability. Each node along the path will update the bandwidth value if its locally available bandwidth is lower than the one stated on the packet. The destination node then sends a probing response packet back to the source node with the bottleneck field copied from the probing request message it received. Based on that value the source decides whether to admit the flow or not.

Mobility may cause traffic to be re-routed through new paths where there are no resources available to accommodate the new traffic. In the case of congestion, SWAN uses ECN (explicit congestion notification) so that intermediate nodes are able to mark packets.

DACME

Calafate et al. (2007) propose a QoS architecture for MANETs whose core element is DACME (distributed admission control for MANET environments). It consists of a probe-based admission control mechanism that, when combined with a QoS-enabled MAC layer (such as IEEE 802.11e) and an appropriate routing protocol—usually a reactive one such as AODV (Perkins & Royer, 1999)—conforms a full QoS framework for MANET environments offering statistical QoS guarantees.

The main element of DACME is a QoS measurement module that assesses the QoS conditions of an end-to-end path. Path conditions are measured in terms of end-to-end bandwidth availability, delay, and jitter. All measurements rely on probes between source and destination, though the strategy varies depending on what is being measured.

Admission control is based on all the values collected during the probing process. The source makes accept/deny decisions based on statistical indexes obtained from the different probes generated.

One of the main advantages of DACME's framework is that it does not impose any demand on the lower protocol layers, nor does it rely on any sort of resource reservation, thus offering soft QoS. Moreover, it operates correctly independently of the MAC or routing protocol being used, offering a great flexibility.

As a summary, in Table 2 we point out the main differences between the three architectures described in this section.

FUTURE TRENDS

Despite efforts from a great number of researchers worldwide, QoS support in mobile ad-hoc networks remains an area with much room for improvement. One of the current trends is breaking the boundaries between layers to achieve a real cross-layer architecture that is able to improve performance by allowing network protocols at any layer to gain awareness of everything that is going on underneath it. This means that, for example, the statistics gathered on the MAC layer about available channel resources and link quality towards each neighbor node are made available to upper layers (such as routing, admission control, or transport) which can help at finding better paths, better estimate end-to-end resources, and so forth. Another trend is to base QoS decisions on statistical inference instead of using hard values. Such technique avoids strict reservations, offering a better adaptability to the network dynamics.

Both techniques are expected to greatly boost the QoS performance of MANETs, and in the future we shall see several proposals in these lines of work.

CONCLUSION

Supporting QoS demanding applications in ad-hoc networks is a very challenging goal that can only be accomplished by enhancing the different network layers involved to support QoS restrictions.

At the MAC layer the most important issue to solve is how to offer prioritized channel access using distributed, contention-based algorithms.

In terms of QoS routing protocols, there was a clear

Table 2. Main differences between INSIGNIA, SWAN, and DACME architectures

Characteristic	INSIGNIA	SWAN	DACME
Relationship with existing Internet QoS models	Integrated services	Differentiated services	None
Resource reservation	Yes	No	No
Initial bandwidth estimation	Per node	Per-node	End-to-end
Support for delay/jitter constraints	No	No	Yes

evolution in the last few years, especially in the assumptions made about the MAC layer. Though initial protocols required a TDMA-based MAC, current ones are able to offer QoS support on top of CSMA/CA-based MAC layers such as IEEE 802.11. At the routing layer the most complicated issue to solve has to do with multi-constraint routing, which remains a very complex problem.

In terms of QoS architectures for MANETs, there is a trend towards solutions that minimize restrictions on the terminals and technologies used. We consider that the most relevant architectures currently available are INSIGNIA, SWAN, and DACME, where we can observe a progression towards soft QoS guarantees.

Due to the incipient nature of this research area, we expect to see novel solutions in the near future that are expected to greatly improve the QoS performance of mobile ad-hoc networks.

KEY TERMS

CSMA/CA: Stands for Carrier Sense Multiple Access with Collision Avoidance. The distributed channel access mechanism adopted by the IEEE 802.11 standard for operation.

DiffServ: Abbreviation that refers to Internet's Differentiated Services architecture.

IntServ: Abbreviation that refers to Internet's Integrated Services architecture.

Media Access Control (MAC): A communications protocol sub-layer that provides addressing and controls channel access to allow several terminals to communicate over a shared medium.

Mobile Ad-hoc NETwork (MANET): An autonomous type of network where terminals participate both as clients and routers, eliminating the need for any type of support infrastructure.

Resource ReSerVation Protocol (RSVP): A transport layer protocol designed to perform resource reservation on the Internet; one of the key elements in the integrated services architecture proposed for the Internet.

Service-Level Agreement (SLA): A formally negotiated agreement between customers and their service provider, or between service providers, which defines the expected standards in terms of services, priorities, responsibilities, guarantees, and so forth, which is usually referred to as the "level of service."

Supporting the Evaluation of Intelligent Sources

Dirk Vriens
Radboud University of Nijmegen, The Netherlands

INTRODUCTION

To survive, organizations need to produce and process information about their environment, for instance, about customers, competitors, suppliers, governments, or all kinds of socioeconomic and technological trends. The process of obtaining this information is often called competitive intelligence (cf Fleisher & Blenkhorn, 2001; Kahaner, 1997; Vriens, 2004). An important stage in the competitive intelligence process is the collection stage. In this stage, one has to determine relevant sources, access them, and retrieve data from them (cf Bernhardt, 1994; Kahaner). For each data class, many possible sources are available, and determining the right ones is often difficult. Moreover, accessing sources and retrieving data may require a lot of effort and may be problematic (cf Cook & Cook, 2000; Fuld, 1995; Kahaner, 1997). In this chapter, we present a tool for supporting the effective and efficient use of sources: the source map. In essence, a source map links data classes to sources and contains information about these links. This information indicates the adequacy of sources in terms of ease of access, ease of retrieval, and usefulness of the retrieved data. A source map can support the selection of appropriate sources and it can support the assessment of the overall adequacy of available sources.

BACKGROUND

The process of competitive intelligence is often described as a cycle of four stages (the intelligence cycle; see Kahaner, 1997; Vriens, 2004). This cycle comprises (a) the direction stage (in which the organization determines about what aspects in the environment data should be collected), (b) the collection stage (where sources are determined and data are collected), (c) the analysis stage (in which the data are analyzed to assess whether they are useful for strategic purposes), and (d) the dissemination stage (where the data are forwarded to decision makers; Bernhardt, 1994; Gilad & Gilad, 1988; Herring, 1999; Kahaner, 1997; Sammon, 1986). The collection stage is considered to be the most time-consuming stage (e.g., Chen, Chau, & Zeng, 2002) and if it is not performed carefully, many difficulties arise (e.g., too much time spent on search, collection stage leads to irrelevant data, information overload; see, for example, Cook & Cook, 2000; Chen et al.; Teo & Choo, 2001; Vriens & Philips, 1999). For successfully carrying out collection activities, knowledge about what sources contain what kind of data and knowledge about how to approach these sources (metaknowledge regarding the collection of data) would be very helpful. This chapter presents a tool to structure and deal with this metadata: the source map.

To collect data about the environment one has to

1. identify possible sources,
2. judge the value of the source (in terms of different criteria; e.g., does it contain relevant data? What are the costs of employing this source? Is it reliable?), and
3. use value judgments to select the appropriate sources.

Many authors discuss Step 1 by pointing to a variety of available sources (cf Fuld, 1995; Kahaner, 1997; Sammon, 1986). Typical sources include the Internet, online databases, sales representatives, internal or external experts, CEOs, journals, tradeshows, conferences, embassies, and so forth.

The literature treats the valuation step more implicitly. It discusses distinctions regarding sources, such as open versus closed sources, internal versus external sources, or primary versus secondary sources (Fleisher & Blenkhorn, 2001; Kahaner, 1997). These distinctions implicitly refer to criteria used in the valuation of sources. The distinction of open versus closed sources implicitly refers to, for instance, criteria such as ease in collection or relevance. The distinction of primary versus secondary sources implicitly refers to the criterion of the reliability of the data. In our view, it is possible to value sources more precisely when the valuation criteria are stated explicitly and not implicitly in the form of these distinctions.

The selection step is even more elusive in literature (and practice). This step integrates value judgments to select appropriate sources for collecting the required data. Few methods seem to be designed for source selection.

In this article, we propose a tool to structure and support the valuation and selection of sources: the source map. This tool builds on Fuld's (1995) intelligence maps and knowledge maps (e.g., Davenport & Prusak, 1998). The purpose of the source map is to help pin down the appropriate sources quickly and detect weaknesses in the available sources.

THE SOURCE MAP AS A TOOL FOR ASSESSING SOURCES

What is a Source Map?

A source map links data (or classes of data) to sources in such a way that the (most) appropriate sources can be selected for the collection of the requested data. If viewed as a matrix, the column entries may refer to data classes (e.g., products under development by competitor X) and the row entries to possible sources. Each column then indicates what sources may be used to gather the requested data (e.g., a patent database, economic journals, or the Internet site of competitor X). To determine what sources are (most) appropriate, the source map needs to contain information about criteria for appropriateness and their valuation. The cells in the source map (connecting the data classes to sources) should contain this information. To get this information, it should be clear (a) what the relevant criteria are, (b) how they can be given a value, and (c) how to integrate them into an overall judgment of the appropriateness of the sources. The next two sections deal with these issues.

Note that we treat the source map as a tool for supporting and structuring collection activities *given* the data classes. We assume that the data (classes) are already defined in the direction phase (the first phase of the intelligence cycle).

Criteria and Scores for Judging Sources

The criteria for assessing the appropriateness of sources link up with the three activities required to deal with sources. These activities are the following.

1. Accessing the source. Accessing means determining the exact location and approaching the source to prepare retrieval.
2. Retrieving (in interaction with the source) the data from the source.
3. Using the retrieved data in further processing (i.e., for the production of intelligence).

Referring to these activities, the appropriateness of sources depends on four dimensions: (a) ease of access, (b) ease of retrieval, (c) usefulness of the content of the retrieved data and processing ease, and (d) cost effectiveness. Below, we discuss criteria in these dimensions.

Criteria for Access and Retrieval

To assess the appropriateness of sources regarding access and retrieval, barriers in employing a source can function as criteria (cf Fuld, 1995; Davenport & Prusak, 1998). Examples of these barriers are as follows.

- A language barrier.
- A cultural barrier (i.e., a difference in culture between collector and source).
- An institutional barrier. In some (bureaucratic) organizations, it may be very hard to locate and approach certain people and documents.
- A personal barrier. Personal characteristics can make it difficult to approach and interact with someone.
- A geographical barrier. Some sources need to be dealt with on location.
- A technological barrier. Accessing some sources and retrieving data from them may sometimes be possible only by means of specific information and communications technology, requiring specific knowledge or skills.
- A fee barrier. For accessing some sources and/or retrieving data, a fee may be charged.
- A time barrier. For some sources, the response time may be very slow.
- A clarity barrier. This barrier refers to the effort one has to give to make sense of the data from the source. Factors that increase this barrier are the use of specific jargon and the lack of (requested) structure in the data.
- A stability barrier. This barrier refers to the stability of access to the source (some sources may cease to exist, some are not available at the expected moment, others may decide to stop providing their services, etc.).

In our view, these criteria can also be used to express the costs associated with using a particular source. We therefore prefer to deal with the above criteria, instead of using cost estimates that may be derived from them, because (a) it is difficult to translate the criteria into costs and (b) if only cost estimates are used, one loses information about the appropriateness of sources.

Using a barrier as a criterion to assess appropriateness, it can be scored on a five-point Likert scale where 1 means *very problematic* and 5 means *nonexistent*.

Criteria for the Use of Data

There are four criteria for assessing the appropriateness of sources regarding the use of the data for the production of intelligence. One of them is a processing criterion and three of them are content criteria.

The processing criterion refers to the ease of processing. This can be determined by the format in which the data are delivered; that is, does the source deliver the data in a format that can be used directly for the purposes of the collector or does it need reformatting? One may score this criterion on a five-point scale ranging from 1, *much reformatting needed*, to 5, *right format*.

The content criteria are completeness, reliability, and timeliness (cf O'Brien, 1998, for a summary of these criteria). When applied to the value of sources, these criteria mean the following.

- Completeness: The source can deliver all the data required to gain insight into the data class for which the source is used. This can, for instance, be measured in terms of the number of times the source was unable to deliver the requested data and/or the number of aspects of a data class for which the source could not provide data.
- Reliability: This refers to the reliability of the data from the source. It can be measured, for instance, in terms of the number of times the data from the source proved to be incorrect.
- Timeliness: The data from the source is up to date. It can be measured in terms of the number of times that the source delivered obsolete data.

In literature, one often finds relevance as an additional criterion to assess the content of data. Relevance then refers to the suitability of the data in gaining insight into the data class for which the source was used. However, relevance can be adequately expressed in terms of completeness, reliability, and timeliness. Completeness links the data provided by a source to the required data defined by the data class. Given the completeness, the data should further be correct and up to date to be relevant. Relevance, therefore, can be treated as an overarching concept, referring to the other three content criteria.

The content criteria can, again, be scored on a five-point scale, where 1 means *very incomplete*, *very unreliable*, and *very obsolete*, respectively, and 5 means *very reliable, very complete*, and *very timely*.

Content of Source Map Cells

The criteria for the appropriateness of sources and their scores should be put in the source map. To this end, each cell in a source map contains the following information (see also Figure 1).

1. General information about the source, consisting of the name of the source, the data-carrier (human, data or electronic) and (if known) the exact or default location.
2. Scores on the criteria for access, retrieval, content and processing of the (data from the) source.
3. Information about what data could not be delivered if the source was incomplete. This is useful for analyzing the appropriateness of the sources (see next section).
4. Remarks concerning one of the above aspects.

Using the Source Map

A source map allows for two different uses. First, it is used to find appropriate sources for a particular data class. Second, it is used to assess the overall adequacy of the sources. For both types of use, it is necessary to compare the sources. In this section, we discuss how to compare sources and how to use this method for comparison for the two different uses.

Comparing Sources

Sources can be compared using a single criterion (e.g., which source scores highest on completeness?). It is also possible to integrate the values of (several) individual criteria and

Figure 1. Content of cells in a source map (the shaded areas are not applicable)

Name:
Carrier:

	Language barrier	Cultural barrier	Institut. barrier	Personal barrier	Geogr. barrier	Techno. barrier	Time barrier	Fee barrier	Clarity barrier	Stability barrier
Access	1…5									
Retrieval										

Content:
Completeness: 1…5 If incomplete: What data could not be delivered?
Timeliness: 1…5
Reliability: 1…5

Process/format: 1…5

Remarks: …

compare these integrated scores. To integrate these values into an overall score, we propose the following procedure.

1. Define two classes of criteria: efficiency criteria and effectiveness criteria. The class of efficiency criteria consists of the access criteria, the retrieval criteria, and the ease-of-processing criterion. The class of effectiveness criteria consists of the criteria completeness, reliability, and timeliness.
2. Estimate weights for the criteria in the two classes. A possible way of determining the weights of the individual criteria is to have CI professionals produce a rank order of the criteria (in each of the two classes) expressing their ideas about the relative relevance of the criteria. Next, one could discuss the results and produce one rank order for each class. (This procedure could be supported by groupware, such as Group Systems; cf Nunamaker, Dennis, Valacich, Vogel, & George, 1991).
3. Compute, for each source, the overall scores for the two classes. For both classes, we suggest taking the weighted average score for the given criteria. To compute these scores, the scores on the individual criteria should be available. These scores might be obtained initially by asking CI professionals. From that moment on, they should be evaluated every time a source is used and updated when necessary.

Finding Appropriate Sources

The most straightforward use of the map is to find out what sources are available for a particular data class. A step beyond merely enumerating available sources is to give a judgment about the appropriateness of these sources in terms of the criteria presented in the previous section. To this end, we use the efficiency and effectiveness scores of the sources. For a particular data class, all the available sources can be plotted regarding these two scores (see Figure 2).

The figure states that Source 5 scores best on effectiveness, Source 4 best on efficiency, and Source 1 scores lowest on both classes of criteria.

Figures like the above can help in analyzing the appropriateness of a source for a particular data class. As a general heuristic for ranking the sources, we suggest that sources in the upper right quadrant should be preferred to those in the lower right quadrant, and these should be preferred to the ones in the upper left quadrant. Sources in the lower left quadrant should probably be discarded.

Sources that come up as appropriate should be checked for completeness. If they are complete, they can be added to the list with preferred sources. If they are incomplete, it is necessary to find out if there are sources that can compensate for this lack. To this end, information about what data the source is unable to deliver can be used. This information directs the search for an appropriate compensating source.

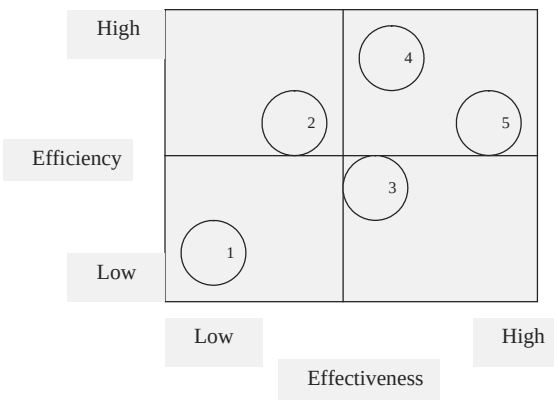
For sources that score high on effectiveness but low on efficiency (lower right quadrant), it should be examined (a) whether the relevance of the data class makes the effort (and costs) worthwhile and/or (b) whether measures can be taken to make the use of the source more efficient, for example, the efficiency of scale in gathering data (a subscription to an often-used online database).

For sources that score in the two left quadrants, it can be established what exactly causes the score. Dependent on the outcome of this investigation, it may be decided to stop using the source.

Assessing the Adequacy of Sources

To judge the overall adequacy of the sources, the map may help in answering the following questions.

Figure 2. Scores of five sources regarding their appropriateness for a particular data class (see text)



1. Do the sources cover all data classes?
2. Do we have adequate sources for the required data classes? If some data classes only have sources that have scores in the lower left quadrant of Figure 2, problems may arise. If a rank order of the data classes regarding their relevance exists, one can also establish whether the most relevant data classes are covered by appropriate sources.
3. Do we have enough different sources for the (most important) data classes? This question refers to the flexibility in collecting data. If a source is suddenly unavailable, one needs to have adequate alternatives. It is also useful to have different sources for the purpose of validating the data.

Answers to these questions help intelligence officers to identify weaknesses in the available sources and direct their efforts to repair them.

Implementing a Source Map

To build, maintain, and use a source map does not require exceptional resources. IT applications for implementing the map range from sophisticated applications to simple solutions. An example of a simple solution is an implementation of the map by means of Microsoft Excel sheets. However, it is also possible to use more sophisticated application, for instance, Web-based applications of the map. Making the map available via an intranet, for instance, can enhance its use and maintenance. In addition to these technological issues, it is important to define and allocate tasks and responsibilities regarding maintenance and use of the map. Finally, data collectors should be motivated to use the map to define their search strategies. In our experience, data collectors see the benefits of a good map and will be inclined to use and maintain it.

FUTURE TRENDS

To aid intelligence officers in their task to evaluate sources, the source map was introduced. Given the increasing need for organizations to collect data about their environment, it can be expected that the need for tools to evaluate sources (like the source map) will also increase. In order to deal with this, information technology tools may be tailored to support the implementation of source maps and the process of keeping them up to date (see, for instance, Philips, 2004).

CONCLUSION

To produce actionable intelligence, the efficient and effective use of sources is imperative. However, up until now, little attention has been paid to supporting the selection of sources. In this paper, we deal with this omission by presenting the source map as a support tool. Properly implemented source maps can be valuable instruments in the support of collection activities. In our view, they can aid in both the everyday use of sources and in the assessment of the overall adequacy of available sources.

KEY TERMS

Collection Stage: Stage of the intelligence cycle. In this stage, sources regarding the required environmental data are located and accessed, and the data are retrieved from them.

Competitive Intelligence: In the literature, two definitions are used: a product definition and a process definition. In the product definition, competitive intelligence is defined as information about the environment, relevant for strategic purposes. The process definition highlights producing and processing this environmental information. Process definitions often refer to the intelligence cycle.

Intelligence Cycle: Cycle of four stages (collections of intelligence activities). The stages are direction (also referred to as planning, in which the strategic information requirements are determined), collection (determining sources and retrieving data), analysis (assessing the strategic relevance of data), and dissemination (of the intelligence to strategic decision makers).

Source: Something or someone containing data and from which the data can be retrieved. Many distinctions regarding sources are given in the competitive intelligence literature, for instance, open versus closed sources, primary versus secondary sources, internal versus external sources, and a distinction referring to the carrier of the data (human, electronic, or paper).

Source Evaluation: The process of assessing the efficiency and effectiveness of a source or several sources, given certain criteria. The result of this process can be (a) a judgment about the usefulness of a particular source for collecting data and/or (b) an insight into the relative usefulness of all available sources. See also "Source map."

Source Identification: Identifying suitable sources (i.e., efficient and containing the relevant data) given a certain data need. See also "Source map."

Source Map: A source map is a matrix linking data classes to sources. In the cells of the matrix, the sources are valued according to different criteria (e.g., accessibility, costs, timeliness of the data, etc.).

Supporting the Mentoring Process

Karen Neville
University College Cork, Ireland

Ciara Heavin
University College Cork, Ireland

INTRODUCTION

While the concept of knowledge management (KM) is not new, the focus on knowledge management as a strategy has heightened in recent times as organizations realize the importance of knowledge as an intangible asset contributing to the enhancement of competitive advantage (Bolloju & Khalifa, 2000). In the 21st century, it is believed that successful companies are those that effectively acquire, create, retain, deploy, and leverage knowledge (Cecez-Kecmanovic, 2000). Knowledge work is the ability to create an understanding of nature, organizations, and processes, and to apply this understanding as a means of generating wealth in the organization. Evidently, the focus on knowledge management as a strategy has become central to organizations (Davenport & Prusak, 1998). Ichijo, Von Krogh, and Nonaka (1998) view knowledge as a resource that is unique and imperfectly imitable, allowing firms to sustain a competitive advantage. Additionally, many approaches to managing knowledge are marred by obstacles of sustainability (Kulkarni, Ravindran, & Freeze, 2006). As a direct result organizations fail to realize the expected returns on investment from knowledge management implementations or strategies (Zyngier, 2007). However, if knowledge management as a formalized organizational strategy is supported, it can be sustained. Therefore in an economic environment where organizations have been forced to take a step back and reevaluate their core competencies and ability to innovate, organizational knowledge has come to the forefront as a valuable strategic asset (Haghirian, 2003). It is the objective of this article to provide an example of knowledge workers and experts collaborating to implement successful training and learning programs to support knowledge management activities in their organization. The authors hope that the case discussed will inform researchers of an appropriate model in designing an interactive learning environment which enables a positive knowledge sharing environment and in turn contributes to the growth of an organization's memory.

BACKGROUND

The intensity of competition in the business market, advances in technology, and a strong shift towards a knowledge-based economy have each contributed to the demand for Web-based mentoring systems. "There is no knowledge that is not power," according to Emerson (1843), and the organization (public or private) that can utilize its knowledge resources more effectively than its competitor will persevere. An effective mentoring system between knowledge workers and experts can provide an organization with a strategic advantage in the market. Mentoring environments can help create and maintain skills, and therefore the corporate knowledge base. They both alleviate the strain on corporate resources and facilitate employees' changing training needs through knowledge sharing. Therefore the majority of organizations face the enormous challenge of supporting their employees' thirst for expanding their skill base and effectively their corporate assets, as "knowledge implies a knower; *the rest is just information.*" Some companies exploit the capabilities of Web technology to facilitate knowledge sharing at workgroup and company levels (Davenport, 1996). Recent evidence points to the deployment of organizational systems with the primary objectives of improving customer services, increasing revenue, containing costs, and improving internal processes—in other words, creating competitive advantage. In the case under consideration, the organization implemented a successful mentoring system in order to develop employee skills and knowledge in both IT and managerial issues such as knowledge management. This article is focused on the development of a Web-based mentoring system (WBMS) to mentor (Neville, Adam, & McCormack, 2002) workers and enhance learning. The case study indicates a strong requirement for the utilization of such an environment to both increase support for and collaboration between the knowledge workers.

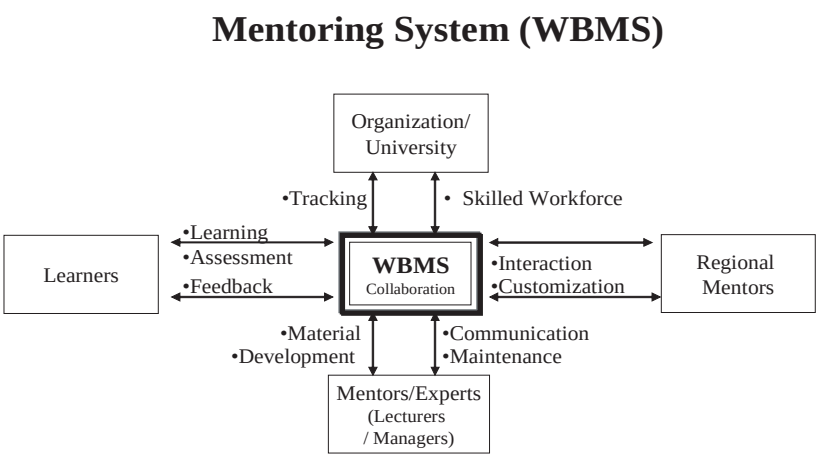
MAIN FOCUS OF THE ARTICLE

Mentoring is a traditional method of teaching that strengthens the concept and objectives of learning/training (Neville et

al., 2002; Heavin & Neville, 2006). The Oxford dictionary defines the word mentor as a "wise counselor, who tutors the learner in intellectual subjects." When this model is applied to a learning network, the student is called a teleapprentice who studies using appropriate methods. The teleapprentice reads messages, answers questions, participates in discussions, and conducts research online to master his or her subject. Mentorship is a method of teaching that has been used for hundreds of years; this design is incorporated into learning/knowledge networks to develop more effective learning and collaborating practices, and provide additional support and mediation to the learners/workers. 'Access to experts' is one of the many advantages provided through learning networks (Harasim, Hiltz, Teles, & Turoff, 1995; Hansen, Nohria, & Tierney, 1999). Networks are, in fact, modeled on this method (Harasim et al., 1995). Therefore, Web-based mentoring systems allow students/workers to communicate with experts in a field and collaborate with their peers. WBMSs can be described as learning delivery environments in which the WWW is its medium of delivery (Neville et al., 2002). The possibilities of WBMSs are limited only by constraints imposed by the university or organization in question, such as technological or managerial support (Neville, 2000). Innovative companies and universities are using this implementation for a number of reasons, specifically to keep employees or students abreast of emerging technologies in their fields, and to provide effective training to both staff and customers on new products and skills. Designing a WBMS requires a thorough investigation into the use of the Web as a medium for delivery (McCormack & Jones, 1997). The designer must be aware of the attributes of the WWW and the principles of instructional design to create a meaningful support environment (Gagne, Briggs, & Wagner, 1988). The Web-based training room is viewed as an innovative approach to teaching (Relan & Gillani, 1997). The virtual training room, like the traditional method, requires careful planning to be both effective and beneficial (Dick & Reiser, 1989). As stated by McCormack and Jones (1997), a Web-based classroom must do more than just distribute information; it should include resources such as discussion forums to support collaboration between learners and ultimately it should also support the needs of both the novice and advanced learner. A WBMS is composed of a number of components that are integral to the effective operation of the environment, for example the development of content, and the use of multimedia, Internet tools, hardware, and software (Reeves, 1993a). A developer must understand the capabilities of these components (search engines, feedback pages, and movie clips), as their use will determine the success or the failure of the learning environment. In this article we provide an example of a WBMS to help illustrate the main elements, issues, components, and problems encountered through the implementation of learning systems to enhance knowledge management in organizations.

The WBMS (see Figure 1) was constructed to support and develop knowledge sharing for personnel who seek to acquire and develop their knowledge management skills. Training material is available online, but in addition, a discussion forum enables both learners and experts to exchange ideas and add to the environment. This allows learners to provide feedback (anonymously, if desired) to the experts. It also enables them to pose queries, which other participants or the experts can answer. All participants are able to see the initial queries and the discussion stream of answers from

Figure 1. The Web-based mentoring system (WBMS)



other participants and the instructors. This further extends the reach of the training material, as employees can log on to the WBMS at home or at work and pose questions for which answers are available when they next log on. The facility also allows the learners to voice their satisfaction regarding the different elements of the environment. This provides the participants with the opportunity to take part in the ongoing design of the WBMS, and therefore increases user acceptance.

Figure 1 illustrates the opportunities available to the participants of the case. The system provides professional training to a range of employees, such as full-time staff at all levels including senior management. Its core aim is to develop further the knowledge and abilities of personnel so that they are increasingly aware of IT and management issues within the organization, with a particular focus on capturing, storing, disseminating, and creating knowledge. The course is designed on a distance-learning basis and is supported by a tutorial system. The main purposes of the tutorials are to facilitate the learning process, assist in the completion of interactive assignments, and encourage team playing within the group. Learners are presented with written modules, which act as 'the lecture', and the expert plays the role of the facilitator, enabling the students to combine the written materials with their own experiences. Feedback from the students identified the need to provide additional learning support through an online environment. The WBMS has provided an improved learning process and has enabled enhanced collaboration among employees. This article focuses on the development of these requirements through an interactive learning environment for employees, and the WBMS is designed or customized for the requirements of the individual learner. This approach accounts for the varying learning abilities of students and overcomes the limitations of traditional training environments, which are restricted to rules in order to adequately facilitate the group. The educator/expert instructs a class, but the level of both collaboration and the development of problem-solving skills can be directly correlated to class size. The greater the size of the group, the less attention individual learners gain or the more intimidated a student is to participate in discussions, thus reducing collaboration. The WBMS, when adequately designed, can reduce the limitations of the classroom and allow the learner to work at his or her own pace with structured support from both the educators and the other learners.

DESIGN CONSIDERATIONS

Harasim et al. (1995) describe knowledge networking as "the use of electronic linkages among different teaching and learning communities to facilitate information acquisition and knowledge building" (p. 10). Prime examples of knowledge networking are the thousands of discussion groups that exist on the Internet that exchange information and discuss a wide range of various different topics representing an "active forum of informal learning and information exchange: a knowledge network." "Knowledge networking is based on self-directed learning and growth through the pursuit of information, skills, and knowledge" (Harasim et al., 1995, p. 11), and learning occurs when experts/students/mentors/people interact with each other (for example by discussing a certain topic of interest). One of the main disadvantages to traditional distance education (characterized by "correspondence, paper-based assessment and tutor-student communication") is the "lack of immediacy and adequate communication" between mentors and knowledge workers or students (Louvieris & Lockwood, 2001). However, Louvieris and Lockwood (2001) argue that the use of ICT can enhance the mentor process, and that this is evident in the objectives of some higher education institutions who now "offer access to learning materials to students who are located geographically locally or remotely, facilitate support from their tutors/lecturers and also encourage participation in online activities while [taking] a course" (p. 1100).

Organizations are increasingly using and investing in Web technology as it can support all aspects of organizational work, including mentoring (Isakowitz, Bieber, & Vitali, 1998; Carstensen & Vogelsang, 2001), resulting in the fact that "higher education institutions are aiming to leverage both information and communication technologies, particularly the Internet, to redefine and/or extend their business scope in increasingly competitive global/international learner markets" (Louvieris & Lockwood, 2001, p. 1099).

Turoff and Hiltz (1998) argue that Web technology "is fundamentally a new medium of human communication" (p. 116). As students and mentors work together collaboratively, they form what Harasim et al. (1995) define as a 'learning community' that "can be both personally and educationally enriching," as the Web-based classroom offers the students more opportunities to voice their opinions or comments over the traditional classroom environment, so students feel that "online environments enable them to communicate with their colleagues more than in face-to-face classes." Learning through the Web is regarded as the 'silver bullet' solution to learning issues faced by both universities and organizations, despite little quantitative evidence to support claims of its effectiveness. Therefore, it is essential to define the characteristics of interactive education/mentoring that can be achieved through the WWW to promote learning. The identification of these characteristics is necessary to implement such a concept. Thus, this section reviews additional dimensions proposed by Reeves and Reeves (1993) for interactive training and collaboration including: (1) educational philosophy, (2) learning theory, (3) goal orientation, (4) task orientation, (5) source of motivation, (6) role of the teacher, (7) metacognitive support, (8) collaborative learning, (9) cultural sensitivity, and (10) structural flexibility.

The dimensions are proposed to describe the characteristics of a learning environment—the characteristics of a WBMS. Each of the dimensions identified are outlined in the following paragraphs:

1. *Educational philosophy* emphasizes the belief that learners build their cognitive strategies on previous knowledge and on the learning environment. Therefore a rich and stimulating environment is required to train the different adult learners. Thus, direct instruction is also replaced with challenging tasks.
2. The design of the environment should be based on researched *learning theories*. The two dominant theories identified in the design of training environments are behavioral and cognitive psychology. Behaviorists believe that the most important factors that should be taken into consideration are the arrangement of stimuli, responses, feedback, and reinforcement to shape the desirable behavior of the learners. By contrast, cognitive psychologists place more emphasis on internal mental states rather than on behavior. As a result, the WBMS design, using cognitive theory, will be based on direct instruction and practice exercises.
3. The *goals* for a WBMS can vary from sharply focused, where a specific environment is required, to a more general approach.
4. The orientation of *tasks* can range from academic to authentic. By contrast, an authentic design for adult education would require the learners to tackle job-related exercises or cases (tacit knowledge). The design orientation of a WBMS should support the transfer of skills to the learners.
5. *Motivation* is the main factor for the success of any learning environment. The source of motivation ranges from two extremes, from extrinsic (outside the learning environment) to intrinsic (a part of the learning environment).
6. Lecturers and tutors fulfill different *roles* from the traditional role of instructor (didactic) to the facilitative role.
7. *Metacognition* is described as the learner's ability to identify objectives, and plan and understand learning strategies. Thus, a WBMS can be designed to challenge the learner to solve course-related problems.
8. The *collaborative* learning dimension for a WBMS can also range from lack of support to the inclusion of facilities to support it.
9. Reeves et al. (1993) argue that all training environments have *cultural implications*. However, the development of a WBMS cannot be designed to adjust to every rule. Therefore, WBL should be designed to be as culturally aware as possible.
10. *Structural flexibility* describes a WBMS as either asynchronous or synchronous. Open or asynchronous environments refer to the use of such an environment at any particular time or from any location. However, synchronous refers to fixed environments that can only be used in the training room of an organization. The WWW provides educators and students alike with the opportunity to avail of resources from more open environments through which students are supported or mentored in the acquisition of both tacit and explicit knowledge.

The dimensions were used as an aid in the production of the generic WBMS (see Figure 1). Both the study of the different dimensions and the factors necessary for the collaboration and structure of learning provide valuable information and steps for the analysis and therefore the development of the solutions.

FUTURE TRENDS

Knowledge workers have praised the hands-on approach provided through this expert-driven system. As knowledge sharing has increasingly become a key organizational objective, this type of environment provides an extensive communication channel leveraging the technology to support a wide variety of knowledge-sharing activities. It also enables the experts and learners to collaborate, therefore providing 24-hour online support. This case is a prime example of a successful KM support tool that can and will continue to avail of technological advances to ensure ongoing success. Further research exploring the various pedagogy and technology mixes to produce a set of options, which would identify the integration of a particular pedagogy with an appropriate technology, would prove beneficial if WBM is to meet its full potential. Additionally, the WBMS illustrated in this chapter is primarily concerned with the downstream development process that incorporates key design and development considerations. Therefore, further research exploring the upstream development process would be worthwhile. This would involve exploring some of the development options that were identified in the development of off-the-shelf packages, and exploring the open source development option for a WBMS. These further studies may yield interesting results and therefore increase the level of understanding of the development of effective WBMSs.

CONCLUSION

Creating a knowledge or learning community is one of the major challenges for organizations and universities alike. Poe and Stassen (2002, p. 29) state:

"A sense of community—where students are able to work cooperatively with peers on course material, have the opportunity for positive interaction with the instructor, and where the learning environment is respectful and motivates students to do their best—is key to a positive and successful learning experience."

After an in-depth analysis it was apparent that the learners lacked an efficient online support system, which would complement alternative communication channels such as face-to-face encounters and traditional training classes as a means of knowledge sharing. An effective KM training support system can provide an organization with a strategic advantage in the market. Learning environments can help create and maintain skills and therefore increase the corporate knowledge base. They both alleviate the strain on corporate resources and facilitate employees' changing training needs. This article focuses on the design of a suitable environment to support knowledge workers and encourage collaboration. The research outlines the factors necessary for the successful implementation and use of the system. It also highlights the potential of the system to overcome the physical barriers of traditional knowledge sharing and learning channels. Interactive learning environments can, when properly mediated and structured, facilitate cooperation and enhanced learning practices, reduce conflict, and avail all of the benefits that technology can provide.

KEY TERMS

Explicit Knowledge: Information that has specific meaning and can be easily and clearly understood.

Knowledge Web: The use of electronic linkages among different teaching and learning communities to facilitate information acquisition and knowledge building.

Knowledge Work: The ability to create an understanding of nature, organizations, and processes, and to apply this understanding as a means of generating wealth in the organization.

Mentoring: A method of teaching that has been used for hundreds of years; this design is incorporated into learning networks to develop more effective learning practices and provide additional support to the learner.

Tacit Knowledge: Knowledge gained through an individual's own experiences.

System Dynamics Based Technology for Decision Support

Hassan Qudrat-Ullah
York University, Canada

INTRODUCTION

Managers face problems that are increasingly complex and dynamic. Decision support systems (DSS) are designed to assist them make better decisions. However, the empirical evidence concerning the impact of DSS on improved decision making and learning in dynamic tasks is equivocal at best (Klabbers, 2003; Sharda, Steve, Barr, & McDonnell, 1988; Sterman, 2000; Todd & Benbasat, 1999). Over four decades of dynamic decision making; studies have resulted in a general conclusion on why people perform poorly in dynamic tasks. In dynamic tasks, where a number of decisions are required rather than a single decision, decisions are interdependent, and the decision-making environment changes as a result of the decisions or autonomously or both (Edwards, 1962), most often the poor performance is attributed to subjects' misperceptions of feedback. That is, people perform poorly because they ignore time delays between their "actions and the consequences" (Sterman, 2000) and are insensitive to the feedback structure of the task system (Diehl & Sterman, 1995). Decision maker's mental models about the task are often inadequate and flawed (Kerstholt & Raaijmakers, 1997; Romme, 2004). In this paper we argue that system dynamics based interactive learning environments (ILEs) could provide effective decision support for dynamic tasks by reducing the misperceptions of feedback.

BACKGROUND

Dynamic Decision Making

Dynamic decision-making situations differ from those traditionally studied in static decision theory in at least three ways: (1) a number of decisions are required rather than a single decision, (2) decisions are interdependent, and (3) the environment changes, either as a result of decisions made or independently of them or both (Edwards, 1962). Recent research in system dynamics has characterized such tasks by feedback processes, time delays, and nonlinearities in the relationships between decision task variables (Romme, 2004). Driving a car, managing a firm, and controlling money supply are all dynamic tasks (Diehl & Sterman, 1995) In these tasks, contrary to static tasks such as lottery-type gambling, locating a park on a city map, and counting money, multiple and interactive decisions are made over several periods, whereby these decisions change the environment, giving rise to new information and leading to new decisions (Forrester, 1961; Sterman, 2000).

ILE

We use *ILEs* as a term sufficiently general to include microworlds, management flight simulators, DSS, learning laboratories, and any other computer simulation-based environment—the domain of these terms is all forms of action whose general goal is the facilitation of dynamic decision making. Based on the on-going work in the system dynamics discipline (Moxnes, 2004; Otto & Struben, 2004; Qudrat-Ullah, in press; Sterman, 2002), this conception of ILE embodies learning as the main purpose of an ILE. Under this definition of ILE, learning goals are made explicit to the decision makers. A computer simulation model is built to represent adequately the domain or issue under study with which the decision makers can experience and induce real world-like responses (Qudrat-Ullah, 2005). Human intervention refers to active keying in of the decisions by the decision makers into the computer simulation model via the interface of an ILE.

Performance in Dynamic Tasks

How well do people perform in dynamic tasks? The empirical evidence (Diehl & Sterman, 2000; Klabbers, 2003; Moxnes, 2004; Sterman, 2000) suggests almost a categorical answer: "very poorly." Very often the poor performance in dynamic tasks is attributed to subjects' misperceptions of feedback (Moxnes, 2004; Sterman, 2000). The misperception of feedback (MOF) perspective concludes that subjects perform poorly because they ignore time delays and are insensitive to feedback structure of the task system. The paramount question remains, are people inherently incapable of controlling system with time lags, nonlinearities, and feedback loops? Contrary to Sterman's MOF hypothesis, an objective scan of real-world decisions would suggest that experts can deal efficiently with highly complex dynamic systems in real life, such as, for example, maneuvering a ship through restricted waterways. The expertise of river

pilots, for example, seems to consist more of using specific knowledge (e.g., pile moorings, buoys, leading lines) that they have acquired over time than in being able to predict accurately a ship's movements (Schraagen, 1994). This example suggests that people are not inherently incapable of better performance in dynamic tasks. Instead, decision makers need to acquire the requisite expertise.

SUPPORTING DYNAMIC DECISION MAKING THROUGH ILES

There exists some fundamental barriers to developing expertise in dynamic tasks: (1) *dynamic complexity*: our limited ability to understand the impact of time delays between our actions and their consequences coupled with the interactions between feedback loops that are multiple and nonlinear in character and are ever present in the task systems we face in the real world, (2) *information availability limitations*: information we estimate, receive, and communicate is often oversimplified, distorted, delayed, biased, and ambiguous, (3) *information processing limitations*: when it comes to decision making people generally adopt an event-based, open-loop view of causality, ignore feedback processes; fail to appreciate time delays and are insensitive to nonlinearities present in the feedback loop structures of the task system; perceive flawed cognitive maps of the causal structure of the systems; make erroneous inferences even about the simplest possible feedback systems; and fall prey to judgmental errors and biases, defensive routines, and implementation failure (Sterman, 2000). The effective DSS, therefore, should allow the users to overcome such impediments to decision making and learning in dynamic tasks.

ILEs meet this challenge through the provisions of (1) a representative simulation model of the task system, (2) powerful interface, and (3) human tutor support—the three fundamental components of any ILE.

Decision Support Through the Simulation Model

The greatest strength and appeal of an ILE in supporting decision making and learning in dynamic tasks lies in its underlying simulation model. In an ILE, the simulation model is built on system dynamics methodology (Forrester, 1961). The fundamental premise of system dynamics methodology is that "the structure of the system drives its behavior." That structure consists of feedback loops; stocks and flows; and nonlinearities arising from the interaction of these basic structures (Oliva, 2003; Sterman, 2000). A typical system dynamics model allows that

- the interaction and feedback between the systems variables, over time, in and across various sectors (e.g., demand, supply, production, finances, etc.) of the task system be explicitly represented and the structural assumptions are made explicit and open;
- the disequilibrium framework for modeling be established, where the adjustments, say in the need for variable "A" in response to the changes in variable "B" to new equilibria typically create imbalances and transient behavior;
- delays and other distortions in perceiving the true value of the variables be explicitly modeled;
- desired and actual variable magnitudes be explicitly distinguished from real magnitudes in the model; and
- nonlinear responses to actions be explicitly represented.

The significance of the modeling capabilities of system dynamics methodology is its contribution to our understanding of the structure and behavior of complex, dynamic systems. An understanding of the relationship between the structure(s) and behavior(s) leads to the formulation of a better mental model of the task system (Sterman, 2002) and improved decision making (Brekke & Moxnes, 2003; Romme, 2004).

Decision Support Through the Interface Design

Dörner (1980) asserts that decisions makers in dynamic tasks must acquire some reasonably precise notions of relationships among key task variables and develop an understanding of the most influential delays and feedback loops in the task system. System dynamics methodology provides powerful tools to represent qualitatively the connections between structure and behavior of the task system through (1) causal loop diagrams and (2) stock and flow structures. Utilizing these tools together with advances in modern IT, powerful interface, whereby references to the underlying simulation model are facilitated interactively in an ILE, can be constructed (for an excellent illustration please see, Romme, 2004). In this way, ILEs aid decision making by allowing the learners to examine the structure-behavior relationship as and when needed in an ILE session.

Decision Support Through Tutor Support

Decisional aid in the form of human tutor support constitutes the distinguishing and fundamental component of an ILE model. In an ILE session, decisional aids can be provided at three levels: (1) pre-, (2) in-, and (3) post-task levels. Pre-task level decisional aids can be conceptualized as information

provided by the human tutor to a decision maker about the model of the task prior to performing the task (Corner, Buchanan, & Henig, 2001; Davidsen & Spector, 1997). In-task decisional aids attempt to improve the individuals' decision-making performance by (1) making the task goals explicit at early stages of learning, (2) helping them keep track of goals during the task, and (3) providing them with "diagnostic information" (Cox, 1992). Post-task level decisional aids aim at improving performance by providing the decision makers an opportunity to reflect on their experiences with task (Cox, 1992; Davidsen & Spector, 1997).

Thus, an ILE could support the user's understanding of dynamic tasks by offering the opportunity to, experimentally, design, test, and evaluate their decision strategies.

FUTURE TRENDS

Turning to the future, the most fundamental research question for dynamic decision-making research seems to be: How to acquire expertise in dynamic tasks? A solution to this question would effectively provide a way to improve dynamic decision making. We present a potential solution as shown in Figure 1. Our conceptual model presents an integrated approach to improve dynamic decision making.

In future studies, by utilizing our model, we could then compare results, build a cumulative knowledge base of effective decisional aids, and study the trade-offs among various kinds of decisional aids to dynamic decision making. Pursued vigorously and systematically, research on decisional aids such as ILEs should be beneficial to both dynamic decision-making researchers and practitioners.

CONCLUSION

Dynamic decision-making research is highly relevant to the managerial practice (Diehl & Sterman, 1995; Kerstholt & Raaijmakers, 1997). We need effective DSS to help the managers cope with the ever present dynamic tasks. We presented ILE as a viable decision support for dynamic tasks. Investigations regarding the overall effectiveness of ILEs, we believe, will advance our insights into the design conditions for an effective DSS to promote decision making and learning in dynamic tasks.

KEY TERMS

Behavior of System: The patterns of performance of the variable(s) of the system over time.

Diagnostic Information: Information that helps to understand why a particular consequence happened or did not happen.

Feedback: It is a process whereby an input variable is fed back by the output variable. For example, an increased (or decreased) customer base leads to an increase (or decrease) in sales from word of mouth which then is fed back to the customer base, increasingly (or decreasingly).

Mental Model: A mental model is the collection of concepts and relationships about the image of real world things we carry in our heads. For example, one does not have a house or a city or a gadget in his/her head but a mental model about these items.

Nonlinearity: A nonlinearity exists between a cause (decision) and effect (consequence), if effect is not proportional to cause.

Simulation Model: A simplified, computer, simulation-based construction (model) of some real world phenomenon (or the problem task).

Time Delays: Often the decisions and their consequences are not closely related in time. For instance, the response of gasoline sales to the changes in price involves time delays. If prices go up only after a while may sales drop.

Systems Thinking and the Internet from Independence to Interdependence

Kambiz E. Maani
The University of Queensland, Australia

INTRODUCTION

Despite our most impressive advances in sciences and technology, our prevailing worldview and the way we work and relate is deeply rooted in the thinking that emerged during the Renaissance of the 17th century! This thinking was influenced by the sciences of that era and in particular by Newtonian physics. Newton viewed the world as a *machine* that was created to serve its master–God, (Ackoff, 1993). The machine metaphor and the associated mechanistic (positivist) worldview, which was later extended to the economy, society, and the organization, has persisted until today and is evident in our thinking and vocabulary. The mechanistic view of the enterprise became less tenable in the 20th century partly due to the emergence of the corporation and the increasing prominence of human relation issues in the workplace. Today, this way of thinking has reached its useful life – The futurist, Alvin Toffler declared in 1991 "the Age of the Machine is screeching to a halt".

For well over a century, the western world has subscribed to a way of thinking known as analysis (Ackoff, 1995). In analysis, in order to understand things—a concept, a product, a law, an organization, human body—we break it into pieces and study the pieces *separately*. This approach tends to overlook the interdependencies and connections between the constituent parts, which are responsible for dynamic change in systems, say aging in human body.

On the one hand, this "divide and conquer" approach has served us well in the past. It has enabled efficient mass production of goods and services, which has brought a new social and economic order creating unprecedented wealth and standards of living in the industrialized world. On the other hand, this thinking has resulted in over-fragmentation and has created complexity and cross-purposes within organizations.

In the early part of the 20th century, a new breed of scientists, in particular quantum physicists such as Werner Heisenberg (Uncertainty Principle) and Norbert Weiner (Cybernetics) began to challenge the Newtonian precepts (Zohar & Marshal, 1994). In 1968, Austrian biologist Von Bertalanffy (1968) published "General Systems Theory"—a major departure from conventional fragmentation in science. Similarly, Jay Forrester of MIT introduced and demonstrated the applications of feedback theory in organizations (Forrester, 1958). Forrester's seminal work marks the birth of a new discipline known as System Dynamics. System Dynamics is concerned with applications of systems theory and computer modeling in complex problems in business, economics, and the environment. System Dynamics is the forerunner and the scientific foundation of Systems Thinking.

Today, biologist and physicists as well as social and cognitive scientists are working on new fields such as complexity and network theory, and Gaia theory. These emerging fields come under the broader umbrella of "systems theory" or "living systems" and "they are working in the systems sciences and are contributing to advancing the integrated, systemic understanding of life" (Capra, 2007).

BACKGROUND

The major intellectual and philosophical precepts that form the bedrock of our modern society, such as free-market economics, mass production, division of labor, and scientific management embed the following machine age characteristics (Zohar et al., 1994):

- The hierarchy
- Need for certainty, stability, and the absolute
- Treating organizations and the society as consisting of isolated, separate and interchangeable parts
- Relationships based on conflict and confrontation (rationality and self-interest)
- Desire for control and bureaucratic methods
- Persistence of "single points of view" leading to friction and polarisation
- Over-emphasis on specialist expertise, leading to fragmentation and loss of relevance

Machine-age thinking, still prevailing today, is based on the following notions, that:

- Complete understanding of the universe is possible
- All relationships can be described through simple (linear) cause-and-effect
- The world could be understood through analysis (breaking the wholes into pieces)

SYSTEMS THINKING

Systems Thinking (ST) is a discipline for understanding the dynamics of change and complexity underlying business, economic, scientific and social systems. Systems Thinking has three distinct but related dimensions: paradigm, language, and methodology. These dimensions are outlined next (Maani & Cavana, 2007):

- *Paradigm*: Systems Thinking is a way of thinking about the world and relationships. This paradigm relates to the dynamic relationships that influence the behaviour of complex systems. A number of expressions that we use in daily language reflect the Systems paradigm—vicious/virtuous cycle, ripple effect, snowballing, spiral effect, domino effect and chronic behaviour are among these.
- *Language*: As a language, Systems Thinking provides a tool for understanding complexity and group decision-making. The Systems Thinking language is known as Causal Loop Diagrams.
- *Methodology*: Systems Thinking provides a sophisticated computer modeling technology and associated learning environments for group interactions and learning.

Systems Thinking and the Internet

For centuries, knowledge was the preserve of the aristocrats and the clergy who controlled it to dominate and manipulate the masses. In the past century, the "knowledge" privilege extended to the teacher, the manager, and the boss who assumed this as part of their role and superiority. This knowledge divide, for its part, has strengthened the hierarchy and to some extent has widened the gap between the haves and have-nots.

In the past two decades, two movements have had a profound influence on the way we learn, think, communicate and do business—the Internet and Systems Thinking. Both are grounded in science and technology and complement each other in principle and practice. While one has become a daily necessity, the other is coming out of obscurity. The Internet was developed in military and academic quarters in the late 1960's. In the nineties, the Internet emerged in the public domain and rapidly became a mass movement. Today, the Internet is the engine driving the economy, globalization and convergence of various markets, services and industries (Query & Jin, 2003).

Systems Thinking also originated in scientific centers in the 1950's and is now growing rapidly in appeal and applications. It offers a way of thinking based on the primacy of the "whole" and relationships. Systems Thinking deals with hidden complexity, ambiguity, and mental models. It provides tools and techniques to leverage change and to create lasting interventions (Maani, 2001).

Although they may be regarded as purely technical advances, both Systems Thinking and the Internet challenge the age-old paradigms and the ways information and knowledge are disseminated. At a more fundamental level, they challenge the hierarchy and authority, power and leadership. In essence, the Internet has ushered in a new culture, social movements, and "new politics" around the globe (Webster, 2001). Through its unimpeded access and reach, the Internet has in effect brought down the boundaries that define business, trade, and even nationhood. For example, today, Facebook, an Internet portal, has over 100 million members—as a "nation" it would be the eighth largest "country" in the world (Bessant, 2007).

Likewise, Systems Thinking, through its unifying and compelling scientific principles, breaks down the superficial dichotomies of the whole vs the part, the individual vs. the collective, integration vs. autonomy, growth vs. sustainability, and nature vs. progress. Together, the Internet and Systems Thinking can provide powerful synergies blending new concepts, tools, and technologies.

Over the past 20 years, new management concepts and models have emerged that have dramatically challenged the prevailing assumptions and practices in business and organizations. Among these—the Just-in-Time philosophy and

Table 1. Why we need Systems Thinking (Maani & Cavana, 2007)

• Increasing complexity in our lives
• Growing interdependence of the world
• Revolutions in management theories and practice
• Increasing global consciousness and yet "local" decision-making
• Need for multistakeholder decision making and consensus building
• Increasing recognition of learning as a key organizational capability

techniques, total quality management, and, more recently, Supply Chain Management and Enterprise Systems. These paradigms have progressively removed the conventional boundaries between the organization, the customer, the supplier, and to some extent the competition.

Supply chain management (SCM) is an example of the Internet—Systems Thinking synergy. The conceptual underpinning of SCM is systemic in nature in that the "business" or organizational boundaries span to cover the entire chain of supply. In this model, the supply chain participants and stakeholders regard themselves as partners and collaborators in a "whole" where their good depends on the good of the whole. This notion stands in sharp contrast to the business models preceding it, which are characterized by competition, control, and optimization of the parts in isolation. For example in SCM, Internet companies extensively use the practice of drop-shipping, where the wholesaler stocks and owns the inventory and ships products directly to customers at retailers' request (Netessine & Rudi, 2006).

Concomitantly, the reach and speed of the Internet has enabled such cross boundary and integrative business models as supply chain management and e-business, e-commerce to rapidly grow and multiply. With the daily spread of globalization and e-commence there is a dire need for reliable and efficient ways to manage, monitor, and coordinate global large-scale initiatives which contain thousands of members and hundreds of organizations located at different sites. The terms "information exchange", "compatibility", and "interoperability" have become ubiquitous in this environment" (Badir, Founou, Stricker & Bourquin, 2003). To survive, companies will have to constantly develop innovative ways for selecting and managing information. These can be accomplished efficiently and effectively with Web-based models that automate the business processes and extend them beyond the organization.

The astronomical growth of the Internet is epitomized in China where, as of December 2004, 94 million people had gone online, making China the second largest Internet-user market in the world, behind only the US (Zhu & Wang, 2005). This, for example, has enabled over 50% of domestic Chinese insurance companies to offer policies on line (Query & Jin, 2003). However, the impact of the Internet goes well beyond business and economics and into cultural and political realms. This has sparked some serious questions in recent literature, such as, "Can the Internet open up a new public sphere that will foster democracy in China? To what extent will Internet communication erode the social and cultural fabrics and affect Chinese society negatively?" (Kang, 2004).

In summary, the Internet has steadily pushed our thinking and practice closer to a systemic model of the world and the enterprise. At a conceptual level, the accelerated interdependence and interconnectedness of the global economy, trade, and governance calls for a systemic (holistic) view of the global community, the environment, and nationhood. To this end, the Internet has substantially shifted the distribution of economic activity around the world through its impact on communication, information, uniform pricing, and marketing strategies that target individuals rather than regions, hence creating in essence a new "economic geography" (Anderson, Chatterjee & Lakshmanan, 2003) and "Invisible Continent" (Ohmae, 2004). Thus, Systems Thinking and the Internet can play a synergistic role in the transformation of social, cultural and political paradigms toward a unified global socioeconomic order. Given recent trends, this appears not only plausible but also inevitable.

FUTURE TRENDS

Agent based modeling (ABM) is an emerging technology, which draws its theories and techniques from complexity science (Rothfeder, 2003). While Systems Thinking/System Dynamics (SD) and Agent-Based Modeling (ABM) use different modeling philosophies and approaches, they can be used complementarily and synergistically.

System Dynamics focuses on modeling known structures (i.e., relationships, policies, strategies) that underlie behavior of systems. This may be viewed as a weakness of system dynamics approach in that behavior is assumed to be solely a function of structure (model relationships defined a priori). In contrast, in ABM, organizations are modelled as a system of semiautonomous decision-making elements—purposeful individuals called agents. In ABM, each agent individually assesses its situation and makes decisions based upon value hierarchies representing goals, preferences, and standards for behavior. Thus, macrobehavior is not modeled separately but emerges from the microdecisions of individual agents. In other words, in agent based modeling, "emergent" behavior unfolds as a result of agents' interactions. This is a key difference between the two approaches.

Recent advances in video game technology allow the development of multiagent, artificial "society" simulators with capabilities for modeling physiology, stress and emotion in decision-making (Silverman, 2002). While system dynamics acknowledges the critical role of individual and organizational mental models (e.g., motivations, values, norms, biases, etc.) it does not explicitly model them. System Dynamics utilizes factual data or "cold knowledge" and does not take into account decision makers "mood". In contrast, ABM attempts to capture warm knowledge, representing emotional and human context of decision-making.

At the simplest level, an agent-based model consists of a system of agents and their relationships. This new approach enables superior understanding of the complexity in organizations and their relevant business environments. This in turn provides an opportunity for new sophistications in learning environments that enhances decision-making.

Experience with agent-based modeling shows that even a simple agent-based model can exhibit complex behavior patterns and provide valuable information about the dynamics of the real world system that emulates them. "Agent-based complex systems are dynamic networks of many interacting agents; examples include ecosystems, financial markets, and cities. The search for general principles underlying the internal organization of such systems often uses bottom-up simulation models such as cellular automata and agent-based models" (**Grimm,** Revilla, Berger, Jeltsch, Mooij & Railsback**, 2005)**.

Despite their differences, SD and ABM can be used in a complementary fashion. Both ABM and SD are powerful tools for transforming information into knowledge and understanding leading to individual and group learning. Nonetheless, the transition from knowledge to understanding may not be immediate or transparent. This requires a deep shift in mental models through experimentation and group learning which is enabled by both SD and ABM.

CONCLUSION

The contemporary era is characterized by interdependence, change, complexity, speed, and a rapid breakdown of social and political norms. In order to succeed (or even survive) collectively, we need new paradigms and tools. According to Ackoff (1995), there is a progression from information to knowledge, to understanding and ultimately to wisdom. The Internet has facilitated part of this progression, namely, instant and free access to information and an un-impeding portal for global communication transcending conventional barriers of the past.

Systems Thinking, on the other hand, addresses a compelling need for a deeper understanding of the ever-increasing complexity and interdependence of the world and the human society. Systems Thinking and System Dynamics tool unravel forces shaping this interdependence. In social, organizational context, Systems Thinking makes it possible to:

- Examine and foresee the consequences of policy and strategic decisions;
- Implement fundamental solutions to chronic problems;
- Avoid mistakenly interpreting symptoms as causes;
- Test assumptions, hypotheses, and scenarios;
- Reconcile the dilemma of short vs. long term interventions
- Harmonize divergent mental models
- Create win-win solutions for complex multistakeholder problems
- Implement change management without adverse side effects.

The most urgent and fundamental dilemmas that we face today in the organization and in society alike require a collective will that comes from a deeper understanding of our place in history and our collective destiny towards an organic unity. Systems theory provides a scientific way of thinking about the world and relationships. It offers the art and the science of seeing the tree *and* the forest – it reconciles the superficial dichotomy between the individual and the collective and focuses attention on the common good. The principles of systems theory, collectively, provide a paradigm and a language for deeper understanding of the chronic issues besetting our times. Used appropriately and with care, they can transform our age-old views and assumptions and move us towards a shared understanding. In this respect, the challenge for the Internet is to transcend from an information repository and a business tool and become a channel to enhance understanding and goodwill. The evidence to date is promising—the Internet continues to break down national, political, and social barriers and boundaries thus bringing us closer to a holistic and systemic understanding of our global society.

KEY TERMS

Balancing (Counteracting) Feedback: A systemic pattern that is responsible for stability, balance and control. It represents adjusting, correcting and counteracting processes that resist, slow down or impede change and growth.

Causal Loop Diagram (CLD): A tool that captures the causal interrelationships amongst a set of variables. CLDs reveal systemic patterns underlying complex relationships and highlight hidden causes and unintended consequences.

Flow: or rate is the amount of change in a variable over time. Flow represents the change in the status of a variable over a specified time unit.

Leverage: Leverage knows which actions may yield long lasting outcomes. It knows where and when to intervene/influence a system to gain long lasting desired change using minimal effort and energy.

Reinforcing (Positive) Feedback: A systemic pattern that represents growth and self-feeding processes. It explains the dynamics underlying vicious and virtuous cycles with downward and upward spiral effects.

Stock: is the accumulation of a variable such as asset, debt, energy, morale, and reputation. Stock represents the status of a variable at a given point in time, that is, a snapshot of reality.

System Dynamics: Is a scientific tool which embodies principles from biology, ecology, psychology, mathematics, and computer science to model complex and dynamic systems.

System: Is a purposeful entity whose parts interact with each other to function as a whole. Thus, a system is not the sum of its parts—it is the product of their interactions (Ackoff, 1993). A system can be part of a larger system.

Systems Archetype: A generic pattern of relationships that occurs in a wide range of systems and circumstances, natural, biological, political, social, and economic—a powerful tool for seeing high-level dynamics.

Systems Delay: Is the time lapse between action and response. Delays often destabilize the system and slow a system down from reaching its goal. Systems delays often mask anticipated outcomes as well as unintended consequences of actions as the intervening time lapse is often longer than expected.

Systems Thinking: Is thinking holistically and conscientiously about the world by focusing on the interaction of the parts and their influence within and over the system.

Tacit Knowledge and Discourse Analysis

Michele Zappavigna-Lee
University of Sydney, Australia

Jon Patrick
University of Sydney, Australia

INTRODUCTION

Much of human experience is *below-view*, unattended to as we operate in the world, but integral to our performance as social creatures. The tacit knowledge involved in our practice allows us the experiential agility to be at once efficient and creative, to assimilate the novel and the familiar: in essence, to develop expertise. The possessors of skilful practice, the artisan, the witchdoctor or the physician, have occupied a position of both importance and mystery in most cultures since ancient times. Our interest over the ages in such hidden knowledge has caused us to mythologise expertise, placing it beyond the common by constructing it as unspeakable. Thus, in contemporary times it is not surprising that the dominant research perspective on tacit knowledge maintains that it is ineffable, that is, tacit knowledge cannot be understood by looking at what and how people communicate verbally. Indeed the word tacit has its origins in the Latin, *tacitus*, meaning silent.

As information technologies have begun to alter the way in which we think about our own processes while looking for ways to automate and retain our practices, we have been compelled to consider how the experience of the artisan mentioned above can engage with the constraints of the computational world. Capturing and sharing tacit knowledge has thus been a consistent problem in information systems and knowledge management research (Boisot, 1995; Nonaka & Takeuchi, 1995; Tsoukas, 2002; Wenger, 1998). Polanyi's Theory of Tacit Knowing (TTK) is the dominant theoretical perspective in this research. In this theory, Polanyi (1958) suggests that tacit knowledge is inherently personal, underlying our ability to perform tasks we find difficult to explain, such as facial recognition. Concepts in TTK have been made available to the information systems (IS) community largely through the work of Nonaka & Takeuchi (1995) who reinterpreted the theory, precipitating research directions in information systems that are misaligned with Polanyi's theses. A notable example is the movement in IS research to differentiate tacit and explicit knowledge (Johnson & Lundvall, 2001). In contradistinction, Polanyi asserts that explicit knowledge cannot be adequately separated from its tacit coefficient:

> *Now we see tacit knowledge opposed to explicit knowledge; but these two are not sharply divided. While tacit knowledge can be possessed by itself, explicit knowledge must rely on being tacitly understood and applied. Hence all knowledge is either tacit or rooted in tacit knowledge. A wholly explicit knowledge is unthinkable. (Polanyi, 1969, p. 144)*

The emphasis in information systems research is typically on converting tacit knowledge into explicit knowledge (Hershel, Nemati, & Steiger, 2001). Attention is also given to setting up a dichotomy of tacit and explicit knowledge in terms of articulation (can it be carried in language?), codification (can it be turned into an artifact?) or judgment (is it objective or subjective?).

This article is structured to critique the dominant position in information systems research that tacit knowledge is ineffable. The background section provides an introduction to the extensive interdisciplinary literature on tacit knowledge, providing context for the subsequent section that deconstructs the assumptions that this literature makes about what it means to, in Polanyi's (1966, p. 4) terms, "know more than we can tell." To conclude, the role of linguistic and semiotic analysis in realising the growing trend toward theorising "community knowing," rather than knowledge as an artifact, is suggested in the final sections.

BACKGROUND: UNDERSTANDING TACIT KNOWLEDGE, AN INTERDISCIPLINARY PURSUIT

Both prior and adjacent to the popularisation of Polanyi's TTK, there has been extensive interdisciplinary research in tacit knowledge and a very large body of research looking at the implicit, situated nature of practice. These disciplines include philosophy, psychology, linguistics, semiotics, sociology, history, philosophy of science, and, most recently, knowledge management. A theme running through all these domains is uncovering the below-view. For example, Freud's (1970) theory of psychoanalysis and his corresponding concept of the unconscious locates a significant aspect of human experience below the view of awareness. Similarly, a movement in psychology investigates implicit learning

(Reber, 1993), that is, learning that is below-view in the sense that it occurs without the attention of the subject on the process of learning. Recently, there have been attempts by psychologists to create psychological metrics for tacit knowledge. Wagner & Sternberg (2000) develop a method for measuring tacit knowledge in psychology and business management. Their "Tacit Knowledge in Management" (TKIM) inventory seeks to "identify individuals whose 'street smarts' indicate the potential for excellent performance in managerial and executive careers" (Wagner & Sternberg, 1991, p. 1). Conceiving of tacit knowledge as a facet of *practical intelligence*, they construct a triadic view of tacit knowledge as "managing self," "managing tasks" and "managing others," and test subjects in each area through multiple-choice responses to scenarios.

In the social sciences, the focus has been on identifying the implicit subject positions which have been naturalised by culture (Bernstein, 1971; Bourdieu, 1990). This naturalisation means that these positions remain below scrutiny. This is part of a research program that suggests that our experience is constructed through implicit social processes and parallels a body of research in psychology that claims that social behaviours are encoded automatically and without intention (Bargh, 1999). Bourdieu (1990) suggests that the individual internalises the cultural habitat in which they reside, their *habitus*. This means that they form dispositions to behave and construe their experience in certain ways. The acquisition of these structural constraints is a process of acculturation into specific socially-established groups or classes (Bourdieu, 1990, p. 130) and is akin to Bernstein's (1971) notion of *code orientation*. This is a different conceptualisation to the structuralist position, which argues that we follow unconscious rules in enacting our practice. Instead, it is a view of socially constructed dispositions that are inscribed in the habitus but which may shift with changes in context: "Agents to some extent fall into the practice that is theirs rather than freely choosing it or being impelled into it by mechanical constraints" (Bourdieu, 1990, p. 90).

Research in the history and philosophy of science examines science as a discipline that operates to efface the tacit component of its practice in order to maintain an ideology of objectivity (Collins, 1974, 2001a; Kuhn, 1962; Ravetz, 1971; Turner, 2001). In their investigation of science as a social practice, theorists in this domain have sought to reveal the tacit nature of the methods scientists employ. In fact, Polanyi's model of tacit knowledge itself was directed at critiquing the scientific method and to providing "a stable alternative to…[science's] ideal of objectivity" (Polanyi, 1966, p. 25). It provided a conceptual basis for understanding scientific activity as the practice of a craft (Ravetz, 1971). This is part of a program which deconstructs what Schuster (1984) refers to as the mythic construction of method. Method discourses in science typically try to generate the idea that they are systematic, explicit and objective (Collins, 2001a, 2001b; Ravetz, 1971). As such, they present themselves as incommensurable with other practices such as astrology, which they claim to be pseudoscience. Here we have an example of an institutional discourse, science, operating to efface the role of tacit knowing in the production of knowledge.

IS TACIT KNOWLEDGE INEFFABLE?

The attribute most consistently ascribed to tacit knowledge across the disciplines is ineffability (Baumard, 1999; Collins, 2001a; Nonaka & Takeuchi, 1995; Reber, 1993). The strong position is that tacit knowledge cannot be articulated in any linguistic form, while the weak position holds that it is difficult to articulate. Polanyi's (1966:4) widely cited suggestion that "we know more than we can tell" asserts the epistemological significance of tacit knowing in terms of its ineffability. In assessing this proposal, it is important to consider what it means "to tell." If telling means making explicit, codified artifacts that are directly transferred to the mind of the listener, then this kind of telling is not a possible means of exposing tacit knowledge. However, if we allow that telling involves processes of which the speaker is not necessarily aware and which are, in turn, subject to both unconscious and conscious interpretation by the listener, linguistic structure is reinstated as relevant to understanding tacit knowledge. These below-view processes are akin to Peirce's notion of the interpretant in semiosis, introduced in the previous section.

Thus, it appears that Polanyi's statement needs to be refined. We know more than we can tell only if we think about telling as making explicit knowledge. Such an assumption utilises an impoverished model of communication. This model, referred to as the mathematical model of communication (Shannon & Weaver, 1949), presupposes that meaning in communication is absolute and, as such, may be seamlessly transferred from the mind of the speaker to that of the listener. It applies what Reddy (1979) terms the *conduit metaphor*, that is, the notion that words are boxes with meanings inside that are unpacked by the person to which they are directed. Reddy (1979:287) argues that the metalingual resources of English privilege this kind of view, as the following examples suggest:

Whenever you have a good idea, practice capturing it in words

You have to put each concept into words very carefully

Just as in uttering the sentences above we are unlikely to focus on the presuppositions about communication that they presume, when we speak, that which we utter cannot be viewed as an overt object. We may well articulate what we know implicitly through patterns and features of language

to which we do not directly attend. This is an argument that articulation does not produce a form that by definition is explicit, or in alternative terms, that articulation is not the equivalent of codification. However, many studies in information systems research equate these two modes of meaning-making.

There is a substantial tradition within psychotherapy that has approached language as a way of understanding a person's unconscious experience (Ferrara, 1988, 1994; Freud, 1960; Labov & Fanshel, 1977; Lentine, 1988; Parker, 1995; Pittenger, Hockett, & Danehy, 1960). This notion is further specified in linguistics by Halliday & Webster (2002, p. 303) who assert the significance of the relationship between grammar and the unconscious. Meaning-making with grammar is, according to this view, implicit meaning-making:

Conscious language achieves its creative force mainly by lexical means; and lexical items are semantically close to experience. Unconscious language depends much more for its creative force on grammar – and grammatical categories are far removed from experience. (Halliday & Webster, 2002, p. 303)

This appears in accord with the argument that description of the grammatical features in a subject's discourse will give us insight into the nature of their unconscious experience. It follows from this, that if the features of a subject's grammar involving meanings that are effaced are explicated, then the knowledge to which they point may be elicited. In looking at implicit meaning, Hasan et al. (1996) introduce the notion of implicit style in discourse. They give the example of the clause, "they will," which they argue is an example of maximal implicitness as it does not contain a string that is not implicit. The clause raises the questions: whom "will" and what "will" they? Hasan et al. (1996, p. 194) argue that we may distinguish between implicit and explicit ways of saying and that, when an implicit style is adopted by a speaker, "precise meanings become available only if certain additional conditions are met; the average working knowledge of the language is necessary but not sufficient." It is at this point that we require the services of a linguist.

Zappavigna-Lee & Patrick (2004) present a method for eliciting tacit knowledge from the language of interviewees through a process of directed interviews based on a linguistic model of tacit knowledge. This process centers upon the interviewer identifying semantic and grammatical features in the interviewee's language that suggest knowledge that the participant possesses, which remains "below-view." The knowledge is below-view in the sense that the linguistic-choice that the interviewee has made indicates *under-representation*. Under-representation occurs when components of knowledge are effaced in discourse, as they have been automatised by the individual. For example, the agent in a clause may be omitted. In addition to simply being left out of discourse, the knowledge may be effaced through generalisation that construes it as unavailable for deconstruction. For example, a verb may be nominalised meaning that something that was a process with component steps is rendered as a static object This means that there is less potential for these steps to be analysed. Tacit knowledge is subsidiary in the sense that we do not attend to such obfuscation. The directed interview method entails:

1. Identifying the semantic feature that suggests knowledge that is under-represented in the interviewee's discourse and important for their current knowledge management task.
2. Asking a question that elicits a more delicate response from the interviewee and which prompts them to elaborate on this feature.

In applying this interview method in an on-going case study in an Australian broadcasting organisation, Zappavigna-Lee & Patrick (2004) demonstrate that identifying such features will contribute in eliciting a more delicate description of the interviewees' meaning than a strategy based solely on eliciting content. The description is more delicate not only in the sense of being more specific lexically, but also in the sense of being increasingly precise lexicogrammatically.

In a directed interview with a senior manager in the digital media division of the organisation the interviewer noted that the manager possessed tacit knowledge that was embedded in nominalizations. For example, the manager described his division as a "service area" that "provide[s] services including IT services." "Service" is the nominalisation of a range of processes involving understanding, communicating and delivering feedback to clients. An underlying component of these processes is negotiating shared cultural experience. Through elaborating this nominalisation in the directed phase of the interview the interviewer uncovered that the manager believed that the greater the shared cultural experience and active cultural processes that he was able to foster, the greater the shared knowledge and cohesion of his employees. This information was not elicited merely by asking the manager to be more specific, as this would simply have elicited a more detailed rendering of his explicit style. This may have merely produced a taxonomy of the IT services in the organisation. Instead, embedded phenomena about the manager's beliefs and practices were uncovered by analysing his implicit style. This phenomenon is more "specific" in a particular way: it is the elaboration of parts of the interviewee's language of which they were not aware. This is an exercise below the surface of the text, and below the content plane on which most interviews are conducted. As such it involves a richer elicitation of the interviewee's experience.

FUTURE TRENDS: TACIT KNOWING OR TACIT KNOWLEDGE?

There is a growing movement in the IS literature that argues that it is not possible to capture tacit knowledge but that we should instead manage processes which facilitate its social transfer (Boland & Tenkasi, 1995; Stenmark, 2001; Wenger, 1998). This is part of a movement which acknowledges that that knowledge is human and social rather than an artefact that can be abstracted in a database (Weick, 1995; Wenger, 1998). It suggests that tacit knowledge is dynamic and carried in communities of practice (Huysman, 2004; Wenger, 1998). Rather than taxonomising tacit knowledge as if it were an object, this movement adopts a community-oriented model of knowledge management in which IT services are aimed at connecting people with relevant experts rather than attempting to externalize and codify this expertise (Swan, Newell, Scarborough, & Hislop, 1999).

The community-oriented model is aligned with the post-critical epistemological orientation of Polanyi's thesis, which deals with "knowing" rather than "knowledge;" with a process rather than an object. This conceptual position is in accord with the movement in semiotics and other disciplines concerned with theorising knowledge, such as philosophy and linguistics, away from reification: that is, away from a constituency-based view of knowledge as an object, toward a view of knowledge as dynamically produced by human subjects. Future research adopting this kind of framework should seek to employ existing tools such as linguistic analysis to understand how humans "do knowing" as opposed to "construct knowledge."

CONCLUSION

Polanyi's maxim that "we know more than we can tell" remains the dominant perspective on tacit knowledge in information systems research. However, few studies consider what it means to "tell" and the implications this has on asserting the ineffability of tacit knowledge. As this research begins to shift to considering tacit knowledge a process rather than an object and draws upon the large body of existing scholarship in other disciplines, attention should be given to what kind of meaning-making tacit knowledge involves. Tacit knowledge is potentially not as taciturn as we have assumed.

KEY TERMS

Below-View: Elements of experience which are not available to direct inspection without applying some semiotic tool such as linguistic analysis.

Conduit Metaphor: A metaphor about communication, which suggests that an addresser's ideas are objects contained in packages, known as words, that are directly sent to the addressee.

Focal Awareness: Polanyi's term for conscious perception that the individual can directly access. Contrast with *subsidiary awareness*.

Habitus: Bourdieu's term for the cultural context in which an individual resides and which influences their practice.

Subsidiary Awareness: Polanyi's term for perception to which an individual does not have direct access, as it is not part of their focal awareness. Contrast with *focal awareness*.

Tacit: From the Latin *tacitus*, meaning silent.

Tacit Knowing, Tacit Integration: Polanyi's concept of the process of implicit integration of subsidiary and focal elements by an individual. The individual attends "from" the element in their subsidiary awareness "to" the element in their focal awareness.

Tacit Knowledge: Implicit understanding of which the individual is not directly aware and which is involved in their skilful practice.

Under-Representation: Zappavigna-Lee & Patrick's term for a set of specific linguistic features that indicates the presence of tacit knowledge in an individual's talk.

Taxonomy of C2C E-Commerce Venues

Kiku Jones
The University of Tulsa, USA

Lori N. K. Leonard
The University of Tulsa, USA

INTRODUCTION

Commerce can be conducted face-to-face or electronically. Electronic commerce (e-commerce) refers to buyers and sellers transacting online. As Figure 1 illustrates, businesses and individual consumers participate in various forms of this commerce, for example, business-to-business (B2B); business-to-consumer (B2C); and consumer-to-consumer (C2C). B2B e-commerce is the conducting of online transactions between businesses. It is the largest form of e-commerce being practiced today. B2C e-commerce is the conducting of online transactions between a business and a consumer. It is the largest form of e-commerce being researched and the second largest form of e-commerce being practiced. C2C e-commerce is the conducting of online transactions between consumers. It has not been researched as much as B2B or B2C e-commerce, but it is steadily catching up to B2C e-commerce, in practice. For example, online auction use is expected to reach $54 billion in 2007, which is a growth rate of 33% compounded annually since 2002 (Johnson, 2002). Even though more transactions are occurring, research in C2C e-commerce has not kept up in this growing field. Perhaps the reason for this lack of synchronization is that researchers are unaware of the many venues in which C2C e-commerce can and is being conducted.

The most cited and researched example of C2C e-commerce is through online auctions such as eBay. However, there are many other venues for conducting C2C e-commerce that should be explored that may not necessarily be apparent. As demonstrated by existing research in C2C e-commerce, researchers have focused their studies on venues in which C2C e-commerce is the specified purpose of a site. In addition to these venues, C2C e-commerce can be facilitated in places such as online communities, Web-based discussion forums, consumer blogs, and chat rooms. Each of these venues needs to be explored before a complete representation of C2C e-commerce can be made. Differences in how a consumer views each of the C2C e-commerce venues may be expected to alter the factors affecting his/her determination to participate in C2C e-commerce in the various venues.

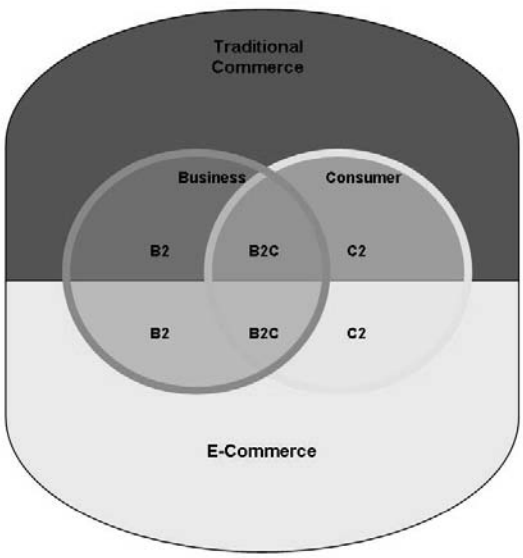
To help researchers in structuring the potential venues and classifying factors affecting participation, this article presents a taxonomy of the C2C e-commerce venues and a description of the types of venues found in the categories. The next section provides a background discussion of each venue discussed in the taxonomy. Following that will be the presentation of the taxonomy. Future trends and conclusions are provided at the end of the article.

BACKGROUND

C2C e-commerce has been examined in terms of trust, reputation systems, and value in communities. However, the venues for conducting C2C e-commerce have not been explored, nor have the multitude of venues available to conduct C2C e-commerce been recognized. This section will present potential C2C e-commerce venues and the relevant research to date for each venue.

Online auctions have been heavily researched in the literature. An online auction is designed to allow consumers to buy and sell from one another in a structured environment.

Figure 1. Commerce channels



In this venue, payment and product exchange mechanisms are established. One area of concern in online auctions is the reputation system. Many researchers have examined the impact of a seller's reputation (given that he/she may be anonymous) on the willingness of buyers to bid on and purchase items in an online auction (Lin, Li, Janamanchi, & Huang, 2006; Melnik & Alm, 2002). Online auctions have also been researched in many other ways, such as price setting (Bapna, Goes, & Gupta, 2001), bidding strategies (Ward & Clark, 2002), and trust (Klein & O'Keefe, 1999).

Third party listing services allow consumers to post items for sale as one would traditionally post in the classifieds. Third party listing services are also well structured and appear to be an established way to conduct C2C e-commerce; however, they have not been explored in the literature with regard to selling and purchasing. Currently, only the recognition of a third party in the buying/selling process has been studied as to its impact on consumer trust (Schneiderman, 2000).

Online communities offer consumers a venue to post comments regarding a topic of interest to the community. The feeling of being part of a "community" opens the online community up to more than just topical discussions. They offer the opportunity to post items for sale based on the community interest. The "community" feeling may make the member feel more comfortable with buying a product from another community member. Online communities have been greatly researched. Areas examined the most regarding online communities are: value (Armstrong & Hagel, 1996), design (Andrews, 2002; Lutters & Ackerman, 2003), success (Cothrel, 2000), and use in health care (Leimeister, Ebner, & Krcmar, 2005). However, research has not been conducted regarding the commerce that exists in online communities.

Web-based discussion forums are an online venue that allows individuals to post information related to a particular topic. Discussion forums are similar to online communities; however, individuals can be a part of an online forum without being a member of the online community. Web-based discussion forums have been researched in relation to rules of communication (Fayard, DeSanctis, & Roach, 2004), influence on consumer purchase decisions (Dellarocas, 2006), and learning (DeSanctis, Fayard, Roach, & Jiang, 2003).

Consumer blogs are online journal-like Web sites created by users to display their personal thoughts and ideas, much like a diary, and individuals that read the blog can leave messages which make this venue highly interactive. Therefore, blogs can be used for more than displaying journal entries; they can be utilized to conduct transactions. Research related to consumer blogging has currently been completed in relation to why people blog (Nardi, Schiano, Gumbrecht, & Swartz, 2004) and protecting bloggers (Robben, 2006), but blogging has yet to be studied in relation to C2C e-commerce.

Chat rooms offer a locale for individuals to meet and "chat" as often as they would like in real time. Chat rooms also offer the opportunity for consumers to meet and establish how a sale will take place; however, this aspect has yet to be explored in the literature. Chat rooms have been researched regarding information exchange (Shoham, 2004) and promotional chat where word-of-mouth and advertising is used (Mayzlin, 2006).

While research concerning commerce in these venues is lacking, anecdotal evidence suggests that all of these venues can be utilized to conduct C2C e-commerce. In order for researchers to fully study the venues, a taxonomy must first be established for guidance. The next section develops a taxonomy for C2C e-commerce venues.

C2C E-COMMERCE VENUES TAXONOMY

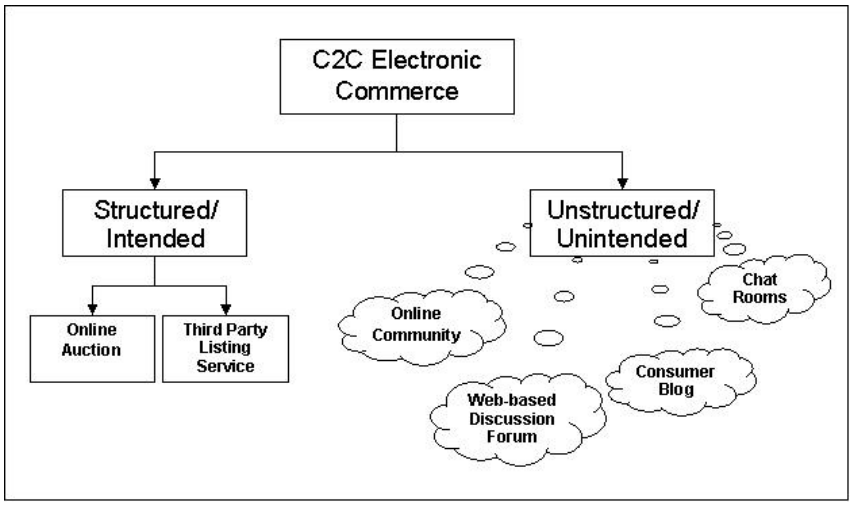
Taxonomies can help to better detail a particular phenomenon. When an area of research begins to blossom, it can be difficult to understand how research areas fit together. A taxonomy can help to structure current research, to identify holes in the existing literature for future research, and to build a roadmap for a given area of research. No such taxonomy exists for any aspect of C2C e-commerce. Without this valuable tool, researchers may find it difficult to see the connections among the current C2C e-commerce research and to develop future C2C e-commerce projects. This article develops a taxonomy of the venues in which C2C e-commerce can take place. Defining the characteristics of these various venues will help researchers to classify aspects of their C2C e-commerce research and begin to provide prescriptions to consumers participating in these various venues.

C2C e-commerce venues can broadly be broken into two main categories: Structured/Intended and Unstructured/Unintended (see Figure 2). Each of these two main categories can contain numerous venues where C2C e-commerce can be conducted. Below is a description of each of these categories.

Structured/Intended

The structured/intended category is made up of C2C e-commerce which is performed in a venue set up specifically for C2C e-commerce. For example, online auctions (e.g., eBay) and third party listing services (e.g., Half.com) are intended to facilitate C2C e-commerce. These venues may have other features available on the sites, but the main purpose for the site itself is to facilitate the exchange of goods and services. In order to participate on these sites consumers are required to adhere to various standards set forth by the third party hosting the site. The third party enforces its right to restrict consumers from participating if they do not adhere to the standards. These venues may or may not require payment

Figure 2. C2C electronic commerce venues taxonomy



from the seller in order to list on their site. The company governing the site provides consumers with information regarding what is and is not allowed to be exchanged on the site. The third party continually monitors the site to ensure that proper activities are being conducted. For example, the third party ensures that the buyer and seller of a transaction complete the given transaction under the terms agreed upon by the two parties. In many cases, the third party provides a guarantee or insurance to the buyer/seller.

These venues are very structured with formalized methods for the exchange of goods and services to and from consumers. Consumers are able to search the sites for specific products they wish to purchase or simply browse merchandise by category. They are then able to see the prices (or, in cases of auctions, the bids) of each item, description, method of payment accepted, and in most cases, pictures of the product. After a transaction takes place, consumers are able to rate one another regarding the transaction. The buyer's/seller's ratings are grouped together to provide a consumer with information regarding the number of positive and negative ratings received. This provides additional structured information for consumers to review and compare to other buyers/sellers.

Many factors can affect a consumer's willingness to participate in C2C e-commerce. For example, a consumer may feel that making purchases from consumers rather than businesses puts them at more risk of receiving defective products. C2C e-commerce conducted in the structured/intended venues may help to alleviate some of this feeling of risk by providing a third party to govern the transactions. While the consumer is still ultimately purchasing from another consumer, the structured and formal process of the venues in this category may provide more of a feeling of purchasing through a business entity.

Unstructured/Unintended

The unstructured/unintended category is made up of C2C e-commerce performed in a venue which was not created for the purpose of facilitating C2C e-commerce. For example, chat rooms are created for various purposes, such as exchanging information regarding a particular topic (more examples of venues in this category are discussed in the Background section and represented in Figure 2). These venues, while unintended, can still facilitate C2C e-commerce. To demonstrate, consider a participant in a "horror movies" themed chat room who entered the chat room to simply discuss the overall theme. While this participant is chatting in the room, the participant determines he/she doesn't have a copy of the current movie being discussed. In turn, he/she makes a request to the other participants to purchase a copy of the movie. Another participant indeed has an extra copy and informs the first participant of the price and acceptable method of payment (e.g., money order). Additional information such as name and address are then submitted by each participant. The payment and movie are then exchanged via postal mail. While the delivery of the payment and movie are not done online, the transaction was discussed, decided, and completed (in terms of the exchange of address information) through the chat room. So, while the intention of the chat room was not to facilitate C2C e-commerce, it was certainly a viable venue to conduct such a transaction.

Transactions performed under the unstructured/unintended category are done in an informal manner. While these venues can be hosted by a third party, there are no governing bodies to ensure that the transaction is completed as agreed. If one party submits payment and then does not receive the product/service, there are no guarantees that the individual will receive restitution. There are also no formalized payment methods set up on the venue itself. This may limit the ways in which consumers can send/receive payment. Compared

to the structured/intended venues, consumers may find it more difficult to search for items they wish to purchase. There are also no formalized rating systems for consumers to reference when determining if they want to transact with another consumer. Since the transactions in these venues are unintended, it may take longer for a consumer to receive information (i.e., description, price, comparison prices of other similar items, shipping cost, acceptable payments, etc.) regarding a particular product in order for the seller to gather and submit this information.

With this lack of structure and formalization may come a sense of distrust, which needs to be considered before a consumer feels comfortable in transacting with other consumers. Researchers will want to determine if there are differences not only between structured/intended and unstructured/unintended categories, but also between the various venues in the unstructured/unintended category regarding trust. For example, a consumer may feel more comfortable transacting with someone from their online community rather than someone who posted a product for sale on his blog.

FUTURE TRENDS

As C2C e-commerce continues to increase, so will the venues in which the phenomenon is occurring. Researchers will need to continue to study each aspect of these venues in order to determine the factors that will affect consumers in these areas. This article mainly discussed third party hosted sites with regard to both structured/intended and unstructured/unintended categories (with the exception of consumer blogs). One future trend might be that consumers begin holding online auctions on their own sites. In these cases, only the consumer owning the site would list items for sale. While the site would certainly contain aspects of the structured/intended (i.e., formality in auction, listing of payment methods, etc.), it would also have aspects of the unstructured/unintended category as well (i.e., any guarantees are only given by the consumer himself, and are not accountable for any standards set by a governing agency). In addition, consumers may wish to hold reverse auctions on their own sites. This, too, would fall somewhere between structured/intended and unstructured/unintended. In these cases, researchers will need to determine how that influences the factors affecting a consumer's decision to participate. Also, social networking sites, such as MySpace.com and FaceBook.com, will be used more for C2C e-commerce, if not already. Many businesses (B2C e-commerce) are currently advertising in this manner.

There is much to be done in the research area of C2C e-commerce. One factor of particular interest is trust. Many research studies have been conducted regarding trust on the Web, trust in B2C e-commerce, and related areas; however, little has been done in the area of C2C e-commerce trust beyond looking at online auctions. Additionally, satisfaction with C2C e-commerce should be explored, as well as satisfaction with C2C e-commerce venues, and how these venues transform from an area of discussion to an area for conducting commerce. The emotional draw of one consumer to another consumer in online commerce should be fully explored, examining aspects such as age, gender, and education.

CONCLUSION

The C2C e-commerce venues taxonomy provides a way for research to be organized in this valuable area. It also provides a roadmap to aid researchers in the areas not yet explored. The taxonomy includes structured/intended (online auctions and third party listing services) and unstructured/unintended (online communities, Web-based discussion forums, consumer blogs, and chat rooms) categories. C2C e-commerce venues offer consumers a multitude of ways to buy/sell from other consumers, beyond just online auctions. Researchers have yet to explore commerce in the venues classified as unstructured/unintended; however, commerce is indeed taking place in these venues. Additional research is needed in each venue to understand the factors that affect a consumer's decision to participate in C2C e-commerce.

KEY TERMS

C2C E-Commerce: Consumer-to-consumer electronic commerce, that is, the buying and/or selling of goods and services from one consumer to another consumer online.

C2C E-Commerce Venue: The place or format for which C2C e-commerce can be conducted.

Consumer Blog: A Web log that is created by a user to display journal-like entries.

Online Auction: An established online venue designed to allow consumers to buy and sell from one another.

Online Community: Otherwise known as a virtual community; an online venue that allows individuals with the same interests to interact, exchange ideas, and potentially determine the exchange of products.

Third Party Listing Service: An established online venue that is similar to using the classifieds; it allows consumers to post items online for sale and for other consumers to receive seller contact and product information so that a formal exchange can take place.

Web-Based Discussion Forum: An online venue that allows for the posting of and discussion of information related to a particular topic.

Technical Communication in an Information Society

John DiMarco
St. John's University, USA

INTRODUCTION

Historical analysis of technical communication elucidates an evolution of tools, techniques, and roles that are connected to the establishment and growth of the information society. The emergence of technical communication as an identifiable force in the matriculation of Western and Eastern information economies and societies has been quite evident. Historical literature provides accounts that point towards graphic communication taking 30,000 years to evolve (Meggs, 1998). From cave paintings during 15,000-10,000 BC, to the invention of writing with pictographs in Mesopotamia; through the evolution of illustrated manuscripts, into the invention of paper and Chinese relief printing; transitioning to the rise of late medieval illuminated manuscripts and into the breakthrough of movable type in Europe, the role of the technical communicator and the function of technical communication was born. Investigation of technical communication today, and during the last century, reveals patterns of technological, economic, occupational, spatial, and cultural developments that can be attributed to the creation of an information-driven economy and information society which relies on technical communication for stability and growth.

Gutenberg developed movable type and revolutionized communication. O'Hara (2001) makes identification that "from the fourteenth century on, the social system of science has depended on technical communication to describe, disseminate, criticize, use, and improve innovations and advances in science, medicine, and technology" (p.1). O'Hara's reference provides a clear pathway to further discussion and interpretation on the rapidly changing tools, techniques, and roles that have caused the permutation of technical communication from an original tool of science and medicine in the 1400s to an academic discipline and a universally desired societal skill set for all who engage the information society.

The purpose of this research is to identify the stature of technical communication in societies which engage heavily in information design, social technological product consumption, and publishing. This chapter addresses the past, present, and future issues, controversies, and roles that technical communication has had and will have on the information society.

BACKGROUND

On the broadest level, technical communication techniques can be defined as technical writing, research, information management, digital document design, Web design, and foremost, persuasive, action-based communication (Sheehan, 2005). A simple definition of the information society is a society that relies on information products and serves to thrive and prosper (Webster, 2002). Investigation of the history of technical communication and the birth of the information society, revealed some interesting research questions. The connection between technical communication and the information society provides a pathway to gaining a deeper understanding of the role of technical communication within modern day society. To clarify the connections, I explored and answered two research questions. First, how do the tools, techniques, and roles of technical communication enable an information society to exist? Second, are there metaphors that may be translated into predictable analogies that can be uncovered that connect technical communication as a driving force in the information society? Answering these questions revealed commonality, pattern, and evolution within the tools, techniques, and roles of technical communication as they relate to the information society.

Historical Connections

The proliferation of technical communication into disciplinary maturity has occurred over the past sixty years and has yielded academic programs and a body of innovative research (Staples, 1999). Pringle and Williams (2005, p. 362) explain that "evidence exists, in fact, that traces technical and scientific writing back to ancient times where anonymous technical writers wrote on tablets in Babylon". The rise of moveable type and the English renaissance enabled technical writing to emerge as a "by-product of print technology and literacy" (Pringle and Williams, 2005, p. 362). This historical plateau in technical communication gave rise to the 1800s and the rise of technical writing in England. Pringle and Williams (2005) explain that the first works were "books that provided instruction on performing work in a broad range of fields such as medicine, agriculture, navigation, and military science" (*Ibid.* 362). These pre-industrial revolution and pre-war events helped to structure and enable the

foundations of technical communication, technical writing, and technology.

Technical Writing Connection

"Technical" occupations in the early 1890s through the 1940s, before the title and designation of technical communication practitioner ever existed, meant serving the tools, techniques, and roles of technical writing. The evolution of technical writing as a staple skill and a staple role within the context of technical communication has bred innovation and fostered change in the information society on economic, occupational, and cultural levels. Connors (1982) describes the early years as being established by the need for engineering education soon after the passage of the two Morrill Acts in 1862 and 1877. These laws provided land grant opportunities for agricultural and mechanical colleges (A&M) which made college education possible for large numbers of people in the later nineteenth century. This economic and cultural development initiated the birth of colleges which had engineering students going through freshman composition within an English department. In the period from 1880-1905 or so, Connors (1982) explains that this education in writing was thought to be adequate for the engineer of the day. However, this was not the case and in response, many engineering schools opened separate English Departments to cater to teaching not only freshman level English courses, but also advanced upper level composition courses which addressed the needs of student engineers. The metamorphosis of Engineering and English collaboration into technical writing brought the role of technical writing into both the arenas of science and humanities, and provided new occupational purposes for people to learn and communicate. These purposes were driven by technological needs of the day such as world war and post world war development of the defense industry. O'Hara (2001) points out that specifically during the war, technical writers were used to write "standardized procedure documents, definitions, descriptions, instructions, and training". These skills were transferred into writing proposals and other military procurement documentation when war was over and the national defense sector evolved into a prominent player within the US government.

Technology Connection

After the postwar development of the transistor by Shockley, Bardeen, and Brattain (O'Hara, 2001) the United States, the most prominent ubiquitous application that has evolved from printed circuit board technology, is the personal computer (O'Hara, 2001). Having a computer on your own desktop, a personal computer, changed the nature of technical communication by complementing the technical writing skill set and knowledge base of technical communicators with the unbridled creative power of digital tools. This caused a paradigm shift in the tools, techniques, and roles of technical communication in the late 1950s through the new millennium. Hardware and software pioneered by Microsoft, IBM, Apple, Aldus (now Adobe), Macromind (formerly Macromedia, now Adobe) helped usher in technical communication as a profession and an academic discipline that went beyond technical writing and digital tools towards research, design, development, publishing, and presentation.

The tools and technologies of today are not only specific to technical communication practitioners, students, and academics, but to all people who need to live, work, and survive in the information society. Steiner (1999, p. 389), looks to Heidegger's definition of communication and argues against it by calling for innovation and individuality. Steiner (1999) explains that Heidegger finds no place for the technical specialist because he or she is part of an objective world in which there is no humanity to share. Therefore, Heidegger believes that "scientist, engineers, and technologists have no humanity to share" (*Ibid.* 389). Technical communication for the everyday person, professional, and academic will become cross functional as a commodity in the form of unlimited data content, information development based on needs and wants, and knowledge development based on problems and processes. Using e-mail, PDA's, iPods, kiosks, interactive television, video games, and personal computers have become the technical communications tools, techniques, and roles of everyday life. These everyday technical communication activities drive the information society in the form of ubiquitous technology, occupational shifts, economic realities, spatial communication methods, and cultural identity changes.

TECHNICAL COMMUNICATION WITHIN THE INFORMATION SOCIETY

Literature review of technical communication theories and histories, graphic design histories, the various schools of thought behind the information society, and professional technical communication practices were interpreted to decipher connections between past, present, and future events. These connections are presented in a series of definitions and an interpretive narrative.

Communication and Technical Communication

To begin the investigation, quantification of the term technical communication needs to be established. Severin and Tankard (1979, p. 5) reinforce the idea that the definition of communication has been extended by a plethora of scholarly articles and numerous schools of thought. To establish meanings for this communication research project, several notable

definitions on the terms, communication, and technical that stress sharing and influence will be discussed. Commonality and sharing are two active features of communication noted by scholars. These features play a role in the life of the technical communicator through creating a common thread of information for all to follow and sharing data with others so that it evolves into information or knowledge within each receiver's individual experiences. Severin and Tankard (1979) quote Alexander Gode's definition of communication "It [communication] is a process that makes common to two or several what was the monopoly of one or some" (p. 6). Schramm (1971) describes communication in terms of "sharing informational signs" (p. 13), which is quite evident in everyday technical communication activities that people share with their new media devices, such as e-mailing each other images and text, or downloading and burning mp3 files, to an Apple iPod that may be redistributed to others later.

The root of technical communication activity is purely communication driven. This includes persuasion, which has been essential to the definition of communication by many scholars. Berlo (1960, p. 16) provided a definition of communication that stated: "All communication behavior has as its purpose the eliciting of a specific response from a specific person (or group of persons)." This idea that persuasion is central to communication is consistent with the goals of technical communication being a facilitator to understanding and action.

Technical meanings serve as an adjunct to context and content, as well as to tools and techniques. Severin and Tankard (1979, p. 6) discuss the meaning of communication through looking at the etymology of the word, or the words in other languages from which it was derived. In the case of communication, the Latin word is *communicare* which means "to make common" (p. 6). Common experience of information is something that technical communicators facilitate. Technical communicators who develop detailed animations depicting natural and mechanical disasters provide visual elements that make understanding complex occurrences "common". On such example is the heavily shown 911 animation which explained to the American people and the world how the steel infrastructure of the Twin Towers in New York City failed from the massive heat brought on by raging, jet fuel driven fire. Although disturbing, the animation helped people come to a common understanding of what happened, even if they did not have a background in structural engineering.

Examination of the word "technical" takes us to the realm of several important distinctions. DiMarco (2004) explained that the modern day word "technical" comes from the Greek word *technikos* which means "of art" and "of or relating to a technique". The term also carries the meaning of "having special knowledge of a mechanical or scientific subject" (DiMarco, 2004, p. vii).

Establishing a definition of technical communication, through both academic and professional lenses, begins with looking at historical documentation from the Society of Technical Communication. The STC was born in 1971 with the merger of technical writing and technical editing organizations. STC "helps professionals design effective communication for a technical world". Understanding technological ubiquity, STC encourages the development of better-educated professionals whose jobs are to make complicated information usable by many (http://www.stc.org). In its early years, "STC was primarily made up of engineers who wrote instructions and descriptions of how electrical and mechanical products worked" (http://www.stc.org/about/history01.asp). The STC and the field of technical communication adapted as "profound change took place as the pervasiveness of technology and the need to understand it became an integral part of our everyday lives" (http://www.stc.org/about/history01.asp). The emergence of the Internet and online communication within the information society has caused the need for all people to be technical communication savvy. This socio-technological need stems from the desire and societal lifeline enabled by creation through navigation and understanding of ubiquitous and professional technologies and applications.

Richard Johnson-Sheehan's introductory textbook: *Technical Communication Today* (2005) defines technical communication based on the role of technical communication as a critical information management activity. Sheehan states, (p. 6) "Technical communication is a process of managing technical information in ways that allow people to take action".

A synthesis of the terms "technical" and "communication", based on prominent scholarly viewpoints, produces a comprehensive definition of technical communication as *techniques involving special knowledge of a mechanical or scientific subject for the purpose of sharing informational signs to make them common, to evoke shared experiences, and to persuade people to act*. A real life example of this proposed definition can be seen in assembly product instructions used when we buy a product that "assembly is required" and we are directed to "read this first". Taking furniture assembly and translating it into a series of steps supported by graphics and language which take the form of informational signs (the parts of the furniture) and make them common to all (everyone who buys the furniture), and then persuades the reader to (act) begin to put the furniture together.

We also see the common person, or someone who is assumed to not be a technical communication practitioner, use *"everyday technical communication skills & activities"* to share informational signs to evoke shared experiences. This is clear in video games. When a young teen (or someone 35 years old) plays a true to life video game such as Tiger Woods Golf, the player has the option to choose the distinct

characteristics of their virtual golfer. When the player does this, he or she is using everyday technical communication skills including menu navigation, scrolling, and visual communication to create a virtual player. That virtual player will become part of a gaming experience which was enabled by technical communication and creativity on the part of the game developers and the game players. The teenager uses the created golfer to "act out" the experience of virtually playing professional golf against modern day athletes who exhibit their own unique traits within game play.

INFORMATION SOCIETY CONNECTIONS

Many scholars cite Webster's debate that questions the notion of an information society. Webster explains that information society theorists contend that "technological innovation produces social change" (Webster 2002, p. 264). On the other side of the debate, of which Webster is a staunch proponent, scholars charge that no information society exists and that information and technology are simply following a path of continuity with historical change. More importantly, Webster (p. 6) makes the distinction that many scholars occupy various points along the continuum of both constructs. Webster explains that there exist five criteria (technological, economic, occupational, spatial, and cultural) for definitions of an information society. The criteria for these definitions are driven by the thought that quantitative changes in information are evoking qualitative changes in society, thus contributing the notion of an information society (Webster 2002, p. 9). By repurposing Webster's five criteria for defining the information society and translating it into the context of technical communication, the connection between technical communication and an information society become more evident.

Technological

It seems obvious from its name that technical communication has technological foundations attached to it. With technological innovation comes societal change. To clarify this, Webster (2002, p. 10) highlights the 1980 suggestions of Alvin Toffler and the three waves of technological innovations. The three waves Toffler refers to are the agricultural revolution, the industrial revolution, and the information revolution (Webster, 2002). These waves are seen by scholars as periods of change both in commercial, professional, and academic circles, but also in societal measures. Webster points to several pieces of evidence that technology is an integral part of the social systems that we occupy. He exemplifies that many studies show that R & D departments have engaged society's needs and wants by providing technologically savvy products that focus on helping establish identity and social comfort for the user. Such products include the Apple IPod and downloadable ring tones, both customizable technologies that provide a sense of identity.

Another such example is creating a Web portfolio. DiMarco (2005) explained that a Web portfolio is a collection of artifacts that is organized and presented in a Web site. A Web site, once considered a high end professional project, requires technical communication skills including Web design, digital imaging, and information organization abilities which have become more common in technologically savvy societies.

Economic

The work of Machulup (1962) has focused on establishing the idea that information business is central to the economies of a specific nation and that each sector of an economy can be categorized into informational and non-informational elements and counted to assess the weight information based activities hold in an economy. By assessing informational and non-informational activities within an economy, a distinction can be made that an economy heavily weighted in information services and products can be seen as an information economy (Webster, 2002). An information society is one in which information economy drives public and private sectors. How is technical communication connected? Technical communication activities are based on managing, manipulating, and publishing information. Therefore, as economic dependence on information based elements grows, so does the economic stake of the technical communications practitioners and academics. The value of technical communication in an information economy is built around the need for dissemination of information that stimulates the economy. Dissemination occurs through many public and private media vehicles. These vehicles and activities drive society to experience, learn, understand, and act.

Occupational

Discussing the work of post industrial society theorist Daniel Bell, Webster (2002) references the evidence that "in western Europe, Japan and North America over 70 percent of the workforce is now found in the service sector of the economy, and the white collar jobs are now in the majority" (p. 14). Webster points out that Bell evidence provides evidence that insists that the information society must exist because "predominant group [of occupations] consists of information workers" (p. 14). Technical communication activities contribute to this trend. As the information society grows, so will the unyielding need for technical communication skills in all occupations that involve service. Whether it is using a PDA for recording package deliveries or designing e-learning for aeronautics training, technical communica-

tion skill is present in all levels of occupation within the information society.

Spatial

Castells (1996) identified spatial boundaries in the information society by explaining that with the network society, the boundaries of the clock have disappeared. Technical communication on everyday and professional levels uses information networks to relinquish boundaries of time and space. One such example is that of e-mail. It is an everyday act executed by many people and is also relied upon heavily in the professional and business world for dynamic communication.

Cultural

In organizations, there are many people who prefer to create their own presentations using PowerPoint. This is positive from an empowerment standpoint but can be devastating from a communication standpoint. As seen in Edward Tufte's 2003 manifesto on the evils of bad presentation design, "The Cognitive Style of PowerPoint", Tufte exalts that the tools are not the content. The content is the content and those who create content must take care of how it is presented in the form of quantity, style, pace, and, most importantly, message. Technical communication specialists who are formally trained in design, writing, interactive multimedia, and presentation technology can decipher between weak and strong communication and utilize tools for achieving a goal other than simply to use a tool. Myspace.com is cultural example of technical communication. A myspace.com Web account allows you to upload text and graphics to a Web page that appears under your specific profile. Creating Web pages and uploading them to myspace.com and the Internet through templates is a technical communication activity. It involves special knowledge to evoke shared experiences and persuade the visitor to act by providing feedback via chat or e-mail.

FUTURE TRENDS

As the future serves more information and more information manipulation devices, building the context of the information society into the definition of technical communication will be critical to keeping a true measurement of the impact of the discipline. Investigation of the connection between technical communication and the information society is suggested as a topic for further historical, ethnographic, and action research.

Reliance on information based skills, products, and services will continue as society grows more attached to socio-technological ways of life. Using tools and processes in technical communication in everyday life will require, as well as foster, information literacy across populations. The growth of information literacy and skill building will be a necessity for prosperity in information based economies worldwide. Further research in the value of technical communication in the information society is suggested to enable continued growth of technical communication as a social science that reveals ubiquitous communication challenges to evaluating, understanding, designing, publishing, and presenting information for professionals, academics, and everyday people.

CONCLUSIONS

A interweaved definition technical communication has been established in this paper as techniques (technical writing, research, information management, digital document design, Web design) involving special knowledge of a mechanical or scientific subject for the purpose of sharing informational signs to make them common, to evoke shared experiences, and to persuade people to act as developer, producer, receiver, or user.

Finally, this paper identifies technical communication as evolving as a critical societal skill set for professional or ubiquitous contexts and all who live in an information society.

KEY TERMS

Communication: A transactional process that involves the exchange of information by sharing and evaluating informational signs which include verbal (auditory), non-verbal (visual), written, and mass (radio, television, print, and Web medias) message types.

Everyday Technical Communication Activities: Activities that require technical communication skills. (playing video games, operating cell phone, using a digital camera).

Everyday Technical Communication Skills: Technical communication skills (menu navigation, scrolling, visual communication) used to share informational signs to evoke shared experiences in the execution of everyday technological activities.

Information Society: A society that relies on information products and serves to thrive and prosper.

New Media: Media characterized by digital content, development, and delivery. New media includes digital video, computer animation, 3d Modeling, video games, motion graphics, kiosks, PDA, iPod, and Web sites.

Technical Communication: (1)Techniques (technical writing, research, information management, digital document design, Web design) involving special knowledge of a mechanical or scientific subject for the purpose of sharing informational signs to make them common, to evoke shared experiences, and to persuade people to act. Technical communication can occur within the contexts of developer, producer, receiver, and user because of the dynamic, ubiquitous nature of technical communication tools, techniques, and roles. (2) An academic discipline focusing on technical writing, research, information management, digital document design, and Web design.

Technical Writing: Writing medical or technology based materials which include: standardized procedure documents, definitions, descriptions, instructions, and training.

Ubiquitous Technology/Ubiquitous Computing: Microprocessor based devices that people to use in everyday personal life. Examples of ubiquitous computing are IPods, cell phones, and automobile navigation systems.

Technological and Social Issues of E-Collaboration Support Systems

Nikos Karacapilidis
University of Patras, Greece

INTRODUCTION

Removal of communication impediments and provision for techniques that systematically direct the pattern, timing, and content of cooperative processes are two key prerequisites in the contemporary organization. Their establishment has been proven to facilitate the solution of ill-structured problems by a set of individuals working together as a team, through the interactive sharing of information between them. *E-collaboration* involves a variety of both communication and cooperation issues, in that it leverages the connective powers of a computer network to coordinate the efforts of a group of people. By using e-collaborative capabilities in an organization, people can operate as a single business entity, thus making joint decisions of added value.

At the same time, the representation and visualization of social structures and interaction in a collaborative environment is also of major importance. This is associated to the perception and modeling of actors, groups and organizations in the diversity of collaborative contexts. A problem to be addressed is to provide the means to represent and manage user and group profiles, as well as social relationships in a collaborative context. Neither relationships nor contexts are static; they are emerging and change over time, which necessitates the development of adaptive services. Furthermore, social relationships are diverse and of different intensity. What is required is development and utilization of appropriate mechanisms that perceive given structures in order to extract implicit information.

Issues to be addressed in the establishment of an e-collaboration environment should have a strong *organizational focus*. These include work structuring in order to improve coordination, use of communication technology to make collaboration more efficient and effective, enforcing of rules and procedures for achieving consistency, exploitation of social structures and interaction, and automation of data processing in data intensive situations (Angehrn and Jelassi, 1994).

BACKGROUND

The environment in which a collaborative process takes place sets a series of important requirements. Issues to be taken into account in the design and implementation of an e-collaboration system include:

- The *spatial distance* between team members. This refers to whether full face-to-face communication among them is possible. Depending on the group size and the proximity of members during a decision making procedure, various settings have been identified (DeSanctis and Gallupe, 1987).
- The *temporal distance* among the activities performed by the individual group members. This refers to whether collaboration is taking place through meetings at a particular time, such as in conventional meeting or teleconferencing environments, or whether participants submit their input at different points in time, based on electronic mail, bulletin boards, newsgroups, and computerized conferencing concepts.
- The *type of participants' goals* distinguishes between an environment in which a group wants to solve its common problem cooperatively, and another, in which bargaining takes place. Issues arisen in the first case concern knowledge sharing, preference aggregation, and negotiation support.
- The type of *control* over the collaborative process. There may be cases where the participants follow a democratic process in order to reach a solution, and cases where the system is supported by a human group leader or *mediator*.
- *Separating people from the problem.* The system designer has to evaluate the individual and group characteristics of the participants, as well as their motivations, disagreements, and conflicts, in order to reduce (if not avoid) the negative impact that misunderstandings, emotions and bad communication may have.
- *User modeling.* The term user modeling refers to the process of acquiring knowledge about a user in order to provide adapted services or information to his/her specific needs (McTear, 1993). By having the characteristics of users explicitly represented within a system, it can be used as a resource in various types of computations and services in order to bring user-tailored services. User modeling is in general motivated by the observations that different users have different

needs. The user model is an essential component when considering personalized interaction and adaptive filtering in information systems. It provides the means to control and confront important problems such as cognitive overhead.

- *Social networking.* Social structures, relationships and interaction should be represented and visualized in a way that makes it possible to reflect on them in their context. In order to provide this, appropriate structure representations and visualizations must be provided. Specialized applications for representing social structure and relationships are usually known as *social network applications* (Atzenbeck and Tzagarakis, 2007).
- The *type of communication* between the participants. Collaborative environments can be based either on *point-to-point communications*, or on *broadcasting* of messages.

Furthermore, approaches for the development of a framework for e-collaboration have to address both behavioral and technical aspects (Zigurs, Poole, and DeSanctis, 1988). Behavioral issues reported concern the diffusion of responsibility, pressures toward group consensus and problems of coordination.

COMPUTER SUPPORTED COOPERATIVE WORK

Computer-supported cooperative work (CSCW) has been defined as computer-assisted coordinated activity, such as communication and problem solving, carried out by a group of collaborating individuals (Greenberg, 1991). The multi-user software supporting CSCW is known as *groupware* (Ellis, Gibbs and Rein, 1991). CSCW may also be viewed as the emerging scientific discipline that guides the thoughtful and appropriate design and development of groupware (Greenberg, 1991). Key issues of CSCW are group awareness, multi-user interfaces, concurrency control, communication and coordination within the group, shared information space, and the support of a heterogeneous, open environment which integrates existing single-user applications.

A principal aim for the designer of an e-collaboration framework is to apply state-of-the-art telematics and groupware technology to provide advanced support for the users over wide area networks, in particular the Internet. Generally speaking, CSCW tools can harness the complexity of the social and knowledge processes involved, thus providing benefits in terms of speed and accuracy, and facilitating the development of business policies. Such tools can be used to support the group reasoning processes, that is, to facilitate the evaluation of proposed solutions and their support, to structure the decision-making process through the implementation of specific methodologies, and to help group members in reaching a shared understanding of the issue by supporting knowledge elicitation, knowledge sharing and knowledge construction. Moreover, by exploiting intranet or Internet technologies, they can connect participants with similar interests, encouraging dialogue and stimulating the exchange of knowledge.

A plethora of systems that support capturing of decision rationale and argumentation for different types of user groups and application areas has been already developed. For instance, *QuestMap* (Conklin and Begeman, 1987) can capture the key issues and ideas during meetings and attempts to create a shared understanding by placing all messages, documents and reference material for a project on a "whiteboard", while *Sibyl* (Lee, 1990) is a system that provides services for the management of dependency, uncertainty, viewpoints and precedents. Generally speaking, this category of systems meets the collaboration requirements concerning the type of control, conflict resolution, and behavioral issues, by providing a cognitive argumentation environment that stimulates reflection and discussion among participants. However, issues related to temporal and spatial distances are not fully addressed. These systems do not exploit any network infrastructure, thus users can work in an asynchronous way only through a human mediator who receives their contributions and appropriately deploys them to the system. Most important, this category of systems does not integrate any reasoning mechanisms to (semi)automate the underlying decision making and negotiation processes.

Increasing interest has been also developed in implementing Web-based conferencing systems, such as *AltaVista Forum Center*, *Open Meeting* and *NetForum*. Such systems exploit the platform-independent communication framework of the Web, as well as its associated facilities for data representation, transmission and access. They usually provide means for discussion structuring and user administration tools, while the more sophisticated ones allow for sharing of documents, on-line calendars, and embedded e-mail and chat tools. Discussion is structured via a variety of links, such as simple responses or different comment types to a previous message. This category of systems meets fully the requirements that are related to the spatial and temporal distances between members of a team. However, these systems merely provide threaded discussion forums, where messages are linked passively. This usually leads to an unsorted collection of vaguely associated comments. As pointed out by the developers of *Open Meeting*, there is a lack of consensus seeking abilities and decision-making methods (Hurwitz and Mallery, 1995). Moreover, as in the previous category of systems, issues related to the appropriate storage of knowledge in order to be exploited in future collaboration settings are not addressed.

This last category of systems belongs to the family of *social media*. Social media have increased in popularity

during the last few years, due to the development of capable web technologies and the growth of a wider and more mature user community discovering the potential of user-created content and many-to-many communications. Hence, large virtual communities are today formed around a multitude of subjects, collaborate through wikis, express and comment through blogs, share material through resource sharing sites (such as *delicio.us* for bookmarks, *Flickr* for photos, and *YouTube* for videos), and use forums for structured discussions. The usefulness of these systems with respect to large virtual communities is in many cases evident, as they are successful and have a large user base. However, with respect to capturing collaborative discourses, there is a range of weaknesses as far as the inherent needs of communities are concerned.

In parallel to the growth of social media, tools and methodologies for supporting collaborative discourses have been matured. One example is the *Compendium* tool (http://www.compendiuminstitute.org/), which supports various concept mapping paradigms and dialogue mapping. The approach followed originates from IBIS (Issue Based Information System), introduced back in 1970 (Kunz and Rittel, 1970). Also building on IBIS concepts, the *Hermes* system (Karacapilidis and Papadias, 2001) supports collaborative decision making through formal argumentative discourse acts. Another example is *Conzilla* (http://www.conzilla.org/), a tool that works with "context-maps", which are collaborative crafted contexts or presentational layers on top of semantic information. Finally, *CoPe_it!* (http://copeit.cti.gr/) is an innovative Web-based system that attempts to assist and augment collaboration being held among members of Communities of Practice by facilitating the creation, leveraging and utilization of the relevant knowledge (Karacapilidis and Tzagarakis, 2007).

SOCIAL NETWORK APPLICATIONS

Social network applications support users in jointly keeping track of their connections to others. Examples can be found for various domains, such as business (e.g., LinkedIn.com, Xing.com), students (e.g., studiVZ.net), or entertainment (e.g., MySpace.com). Many research projects deal with representing social structures. Examples include studies on large distributed organizations (Hinds and McGrath, 2006) or surveys on various special groups, such as researchers (Spence, Reddy and Hall, 2005) or software developers (Elliott and Scacchi, 2003). A recent survey on selected social network or contact management software has shown that their structures are based on simple syntax and semantics (Atzenbeck and Tzagarakis, 2007). They mostly represent social relationships apart from their contexts, for example, their connections to assets or the intensity of relations. This makes structure representations highly abstract.

Dealing with human and intellectual capital can be also approached by social network analysis, because organizations function by way of a social network of employees influencing, giving, hoarding, or accumulating data. From this network sprout the innovations that will produce the next revenue generating or cost saving product or service. Although no organization can survive without such a network, some organizations are beginning to realize that they can profit by analyzing these invisible - sometimes described as tacit - communication links. Real working knowledge lies in the relationships between employees. Many companies confuse hierarchical structure with their social network, but a hierarchical tool such as an organizational chart reflects procedural, not social knowledge.

Communities' activities concerning collaborative asset production is a special form of technologically embedded social networks. Various research from the social sciences has to be acknowledged in order to respect special roles, hierarchies, and positions within an organization. In network organizations (Castells, 2004), new forms of links between the individual level and the organizational level, namely networked links in project teams, do have several implications for software design, especially concerning the management of knowledge (Elmholdt, 2004). Of special relevance for the use of asset management applications are power differences in collaborative teams. Research shows that team members with insufficient formal power have difficulties with such work (Cabrera and Cabrera, 2002). Moreover, computer-mediated communication over long distances in worldwide working teams has been proven to often lead to new adjusted roles, hierarchies and individual timetables (Licoppe and Smoreda, 2005).

Finally, attempts to address collaborative behavior modeling have been confined in terms of generality and flexibility. In the proposed approaches, a participant's intentions and plans are identified by the system based on the behavior and intentions regarding a particular issue in hand (Introne and Alterman, 2006).

FUTURE TRENDS

We argue that services to be provided in a contemporary e-collaboration framework can be classified in four levels:

- The *information services* should deal with the interoperability of proprietary systems, providing efficient and cost-effective access to multimedia data in heterogeneous, distributed databases over wide-area networks. In particular, services should be included for finding relevant data and converting proprietary data to standard formats for data interchange. Additionally, these services should include ways of controlling remote servers from within compound documents

and general-purpose electronic mail, conferencing systems, and hypermedia systems, such as the World Wide Web. Another major issue here concerns the provision for customized solutions, which adapt to a team member's profile according to his/her preferences, abilities, experience, and collaboration mode, as well as aspects related to technical specifications of his/her platform, software available, and network connection. In order to be effective, such solutions have to remove barriers imposed by non-interoperable collaboration tools, inadequate infrastructure, undefined data sharing policies and standards, and differing priorities for presentation formats. What is often required is generation of customized content through approaches such as document transformation, dynamic documents generation, adaptive hypermedia, and provision for personalized collaboration tools, based on adaptive learning techniques, that track a team member's activity and interactions with the system, analyze the feedback, and accordingly identify his/her needs or interests.

- The *documentation services* should provide a "shared workspace" for storing and retrieving the documents and messages of the participants, using appropriate document formats, such as XML. As argued in (Prahalad and Hamel, 1990), an organization's only advantage in today's business environment is its ability to leverage and utilize its knowledge. While a firm comprises individuals and a set of objectified resources, its most strategically important feature is its body of collective knowledge (Spender, 1996). Such knowledge resides in an evolving set of assets including the employees, structure, culture, and processes of the organization. Of these, employee knowledge, and, particularly, tacit knowledge is identified as the dominant one, which is decisive at all mental levels and has to be fully exploited (Nonaka, 1994). Security and privacy issues should be also addressed here. Moreover, controlled experimentation by simulation may augment the quality of a collaborative process by providing insight into the dynamic interactions and feedback loops formed by the problem elements (Sterman, 2000). A simulation model can map organizational knowledge onto appropriate graphs quantifying the problem under consideration, thus providing a clearer understanding of which alternative solution seems to be more prominent at the moment. Finally, databases containing project documents may also become part of the *collective memory* of a community, facilitating the design and re-use of plans.
- The *social network services* should satisfy requirements related to the user and group modeling, as well as to the associated social structures, interactions and relationships. First of all, user (group) modeling requires an explicit representation of the notion of user (group), usually called the *profile*. This takes usually the form of a predefined attribute hierarchy that characterizes the user (group) in a particular system. The associated attributes are usually specific to the domain of the application. They can be categorized, depending on how they are populated and who may modify them, as explicit (their values are provided by users themselves and include personal data such as name, address, birth date, preferences, competencies, skills etc.) or implicit (their values are not provided by users explicitly, but implicitly, by observing their behavior within the system). User (group) modeling is also associated with *mechanisms for the acquisition of user (group) related information.* The role of these mechanisms is to acquire the implicit information of users (groups) that has been mentioned above. They observe and log the operations and discourse moves of users within the system and record them in the user's profile. Finally, user (group) modeling services need to offer *inference engines.* The role of these engines is to analyze all data present in the profile and either extract new information about a user (group) or take appropriate actions towards adapting the software according to the user's (group's) current state. One important aspect that most *user modeling* approaches have in common is that they focus on individual users and can provide their advanced services only on the user level; thus, they do not deal at all – or deal marginally - with the community-related aspects (i.e. relationships between individual users and relationships between users and knowledge artifacts). While this may be acceptable in situations where the individual is of prime importance, such as in e-commerce and learning systems, it is not adequate in collaboration environments, where the emphasis is on the community and not on the individual. In such situations, adaptation and role management at the community – rather than at the individual – level is required.

  Management of social structures, interactions and relationships is also critical in a contemporary e-collaboration framework. As mentioned in the previous section, many applications and projects dealing with social relationships mainly support explicit and abstract structures. However, social structures may gain from the expertise of structure domain research, including various structure abstractions or ways for implicit structuring. Another issue to be addressed concerns the elaboration of social relationships in their contexts, that is, how they relate to assets, locations, or change over time. Social network analysis has to be extensively used to find who is depending on whom in a network. Such an analysis will also help to detect hidden hierarchy of social networks. Finally, another service of this category concerns the (semi)automatic

role-specific cognitive mapping for each participant, based on his/her overall behavior (with respect to the knowledge content of every issue of concern and his/her issue-specific collaborative behavior), as well as development of (cognitive map related) complexity, centrality, and collaboration metrics, which will be associated to the context-sensitive and collaborative use of assets.

- The *mediation services* should regulate the group's activities and facilitate the underlying decision making processes. Commercial workflow systems can be used to support well-defined, formal administrative procedures within organizations. Decisions should be considered as pieces of descriptive or procedural knowledge referring to an action commitment. In such a way, the decision making process is able to produce new knowledge, such as evidence justifying or challenging an alternative or practices to be followed or avoided after the evaluation of a decision, thus providing a refined understanding of the problem. On the other hand, in a decision making context the knowledge base of facts and routines alters, since it has to reflect the ever-changing external environment and internal structures of the organization (Bhatt and Zaveri, 2002). Knowledge management activities such as knowledge elicitation, representation and distribution influence the creation of the decision models to be adopted, thus enhancing the decision making process (Bolloju, Khalifa and Turban, 2002).

CONCLUSION

We have summarized a series of technological and social issues to be considered in the development of systems supporting e-collaboration in the contemporary organization. Services to be provided by such systems have been classified in four levels, namely, information, documentation, social network, and mediation services. We argue that more research and applied work needs to be carried out on issues concerning the synergy of knowledge management and decision making, while this should be further enhanced by providing advanced argumentation, visualization and experimentation features.

KEY TERMS

Computer-Supported Cooperative Work (CSCW): A computer-assisted coordinated activity, such as communication and problem solving, carried out by a group of collaborating individuals.

E-Collaboration: The process in which a set of individuals communicate through an intranet or Internet to coordinate their efforts towards the solution of a problem.

Group Decision Support System: An interactive, computer-based system that aids a set of decision makers working together as a group in solving ill-structured problems. It enables decision makers to analyze problem situations and perform group decision-making tasks.

Groupware: The multi-user software supporting CSCW. Sometimes this term is broadened to incorporate the styles and practices that are essential for any collaborative activity to succeed, whether or not it is supported by computer.

Knowledge Management: The active management of the expertise in an organization involving collection, categorization, and dissemination of knowledge; the activity of representing and processing knowledge.

Social Network Applications: Specialized applications for representing social structure and relationships.

User Modeling: The process of acquiring knowledge about a user in order to provide adapted services or information to his/her specific needs.

Technologies for Information Access and Knowledge Management

Thomas Mandl
University of Hildesheim, Germany

INTRODUCTION

Internet search engines established themselves as an everyday technology for many users. Search engines provide the main access to information on the Internet. According to estimates, some 500 million queries are sent to search engines every day (http://searchenginewatch.com/reports/article.php/2156461) in order to find the most relevant pages among the billions of pages on the Internet. The underlying technology for search engines is provided by information retrieval (IR), which is a key technology in the knowledge society.

IR deals with the search for information and the representation, storage, and organisation of knowledge. Information retrieval is concerned with search processes in which a user needs to identify a subset of information that is relevant for his or her information need within a large amount of knowledge.

For many years, information retrieval systems were mainly used by professional database hosts that provide online access to bibliographic references. Most knowledge objects were manually (or intellectually) indexed. This means that the representation in the form of index terms is selected by human information specialists usually out of a controlled vocabulary. The dominant retrieval model was the Boolean model that advocates an exact match between query and documents, which is inspired by set theory.

In the 1960s, automatic indexing methods for texts were developed. They had already implemented the "bag-of-words" approach, which still prevails. Although automatic indexing is widely used today, many information providers and even Internet services still rely on human information work.

In the 1970s, research shifted its interest to partial-match retrieval models and proved their superiority over Boolean retrieval models. Vector-space and later probabilistic retrieval models were developed. However, it took until the 1990s for partial-match models to succeed in the market. The Internet played a great role in this success. All Web search engines were based on partial-match models and provided ranked lists as results rather than unordered sets of documents. Consumers got used to this kind of search systems, and all big search engines included partial-match functionality. However, there are many niches in which Boolean methods still dominate, for example, patent retrieval.

The basis for information retrieval systems may be pictures, graphics, videos, music objects, structured documents, or combinations thereof. This article is mainly concerned with information retrieval for text documents.

BACKGROUND

The user is in the center of the information retrieval process. Nevertheless, most research tends either to be more user oriented or more algorithm and system oriented. User-oriented research tries to pursue a holistic view of the process whereas system-oriented research is concerned with measuring the effect of system components and tries to resolve efficiency issues.

The information retrieval process is inherently vague. In most systems, documents and queries traditionally contain natural language. The content of these documents needs to be analyzed, which is a hard task for computers. Robust semantic analysis for large text collections or even multimedia objects has yet to be developed. Therefore, text documents are represented by natural-language terms mostly without syntactic or semantic context. This is often referred to as the bag-of-words approach. These keywords or terms can only imperfectly represent an object because their context and relations to other terms are lost.

As information retrieval needs to deal with vague knowledge, exact processing methods are not appropriate. Vague retrieval models like the probabilistic model are more suitable. As a consequence, the performance of a retrieval system cannot be predicted but must be determined in evaluations. Evaluation plays a key role in information retrieval. Evaluation needs to investigate how well a system supports the user in solving his or her knowledge problem (Baeza-Yates & Ribeiro-Neto, 1999).

Web search engines take the information retrieval process to the Internet. They need to contain the following modules (Arasu, Cho, Garcia-Molina, Paepcke, & Raghavan, 2001).

- A crawler collects pages on the Web by starting from known pages, following the links encountered in these seed pages, and iteratively following all links found in further pages (Baeza-Yates & Castillo, 2002).

- An indexer builds a representation of the pages passed on by the indexer. Well-known information retrieval technology is used for this process including linguistic preprocessing and weighting schemes dealing with several occurrences of the same term.
- The user interface (usually a Web client) allows the user to enter queries, presents the results, and should support user strategies like iterative retrieval.
- The query processor analyzes the queries and compares them to the pages represented in the index. Based on the similarity between page and query, a ranking is produced.

Except for the crawler, the other modules are necessary for any information retrieval system and will be introduced in the following sections.

REPRESENTATION AND RETRIEVAL OF TEXT DOCUMENTS

Information retrieval deals with the storage and representation of knowledge and the retrieval of information relevant for a specific user information need. The information seeker formulates a query trying to describe the information need. The query is compared to document representations that were extracted during the indexing phase. The representations of documents and queries are typically matched by a similarity function such as the cosine. The most similar documents are presented to the users, who can evaluate the relevance with respect to their problem.

Representation

Indexing is a process during which words describing the content of a document are chosen as content representation of this document. During automatic indexing, algorithms assign keywords to documents. The indexing process for natural-language documents typically consists of the following steps.

- Word segmentation
- Elimination of stop words
- Stemming
- Compound analysis (for some languages)

Linguistic preprocessing is limited to the level lexemes and morphology. Syntax and semantics are not analyzed because current technology is not able to achieve satisfying quality for mass data. Consequently, the word provides the core for the content representation. The meaning of a text is seen as a set of basic word forms of words that occur in the text. Each word contains its meaning; however, the specific meaning within the text or a sentence can be reconstructed based on the information in the index.

Segmentation is defining the boundaries between the individual words. In European languages, most boundaries can be found by considering blanks. However, other characters need to be considered additionally. In Asian languages, where words are not segmented by blanks, segmentation is a difficult task.

Subsequently, many words that occur frequently are eliminated. These are called stop words and comprise usually articles, prepositions, pronouns, and conjunctions. These words obviously do have meaning; however, because the content is represented following the bag-of-words method, the words are isolated and taken out of their context. Stop words cannot be used for representation in such an approach. In addition, few users would post queries containing stop words. The elimination of stop words also reduces the corpus size typically by 30% and thus leads to higher efficiency (Savoy, 1999).

The most important operation during linguistic preprocessing is stemming. It maps conjugated word forms to their basic form or their stem (e.g., runs -> run, walking -> walk). Morphological variations of words fulfill their function only within their grammatical context. In a bag-of-words approach, all variations can be reduced to their basic form. Stemming improves efficiency also. Three main methods are used for stemming.

- Rule based
- Lexicon based
- Similarity based

The most important algorithms are rule based. The rules describe which steps are necessary in order to obtain the stem from a word form. The number of rules necessary is still under debate (Savoy, 2006).

All index terms are stored in an inverted list from which the documents belonging to a term can be easily accessed.

Weighting

Weighting determines the importance of a term for a document. A term weight measures how well the term represents a document. These weights mirror different levels of relevance. First, the frequency of each term is counted. Weighting assumes that words occurring more often are better representatives for a document. The relationship is not modeled as linearly increasing but is governed by a logarithmic function. The second important parameter of weighting systems is the frequency of a term in the whole collection. Very frequent words contain little discriminative power. Rare words better

distinguish between documents. This assumption is formalized in the inverse document frequency (IDF) formula for weighting (Sparck Jones, 2004). Weighting also needs to perform length normalization; otherwise, longer documents would be more likely to be encountered than short ones. Currently, advanced weighting schemes take the average and maximum length of all documents into account. Other formulas like OKAPI consider even the query terms. OKAPI has led to excellent results (Robertson, Walker, Jones, Hancock-Beaulieu, & Gatford, 1995).

Similarity Calculation

Once the representation has been created, users can post queries to a system. First, the words in the query are preprocessed as the words in the documents. The comparison of the representation of the query to the representation of the documents is the central part of the matching process. The documents most similar to the query will be returned. The system calculates a retrieval status value (RSV) or system relevance, which is a measure for the similarity between document and query.

The Boolean model allows only the similarity values 1 and 0. A document either belongs to the relevant set or not. The ranking or partial-match systems allow different degrees of similarity and order the result documents according to the similarity or relevance. An example for a partial-match model is the vector-space model, which interprets the retrieval process using a spatial metaphor. All documents and the query are points in a high-dimensional space. Closeness is seen as similarity. The retrieval status value can be calculated as a measure of the distance between the documents, which can be determined, for example, by the Euclidian distance. The axes in the model are defined by the terms, and the weights define the exact position of a document.

Other typical similarity functions like the cosine similarity exploit the direction of the vector, which each document defines. The angle between document and query denotes the degree of relevance. When both vectors point toward the same direction, the angle is small. The cosine function returns a high value for such an angle and a small similarity value for a large vector.

In Web retrieval, systems often take noncontent factors into account. A popular way to add additional terms to the representation is the analysis of link labels. How do other pages refer to a certain page? This text is added to the model. An additional way to calculate the similarity is the consideration of authority by link analysis. Algorithms for link analysis take the number of links that point to a page as a measure for their quality or authority. This absolute value of a page is used during the similarity calculation (Thelwall, 2004).

EVALUATION

Information retrieval systems can be implemented in many ways by selecting a model and specific language processing tools. They interact in a complex system and their performance for a specific data collection cannot be predicted. As a consequence, the empirical evaluation of the performance is a central concern in information retrieval research.

A holistic evaluation of a system is difficult and needs to set the satisfaction of the user as the yardstick. The user is satisfied when the initial information need is stilled. A holistic evaluation would need to consider the user interface, the speed of the system, as well as adaptivity. In order to achieve such an evaluation, individual and subjective factors as well as the context need to be considered. However, such results may be of little value for situations different from the one studied.

As a consequence, information retrieval research has adopted an evaluation scheme that tries to ignore subjective differences between users in order to be able to compare systems and algorithms. The user is replaced by a prototypical and constant user. Relevance judgments are carried out by domain experts who evaluate the relevance of a document independent of subjective influences. This approach is called the Cranfield paradigm after one early evaluation study (Robertson, 1982). Current research shows that the Cranfield paradigm leads to reliable results for comparing systems (Buckley & Voorhees, 2005).

The most important measures are recall und precision. Recall shows how good a system is in finding relevant documents whereas precision measures how good a system is in finding only relevant documents without ballast.

Important experiments are carried out within evaluation initiatives. The three major evaluation initiatives are historically connected. TREC (http://trec.nist.gov) was the first large effort, which started in 1992 (Voorhees & Buckland, 2005). Subsequently, CLEF (http://www.clef-campaign.org; Peters et al., 2006) and NTCIR (Kando, 2005) adopted the TREC methodology and developed specific tasks for multilingual and crosslinguistic searches. TREC achieved a high level of comparability of system evaluations for the first time in information science. The test data and collections have stimulated research and are still a valuable resource for development. The initial TREC collections for ad hoc retrieval were newspaper and newswire articles. In the first few years, the effectiveness of the systems approximately doubled. In order to cope with the new requirements and the changing necessities of different domains and information needs, new tasks were continuously established (Mandl, in press). Evaluation initiatives provide collections of documents and topics as descriptions of information needs, and after the experiments of the participating research groups,

they organise the intellectual relevance assessments and publish comparative results.

OPTIMIZATION APPROACHES

The most important technique to improve the quality of a retrieval system for a specific query is relevance feedback and subsequent iterative retrieval. Relevance feedback requires activity by the user, who needs to specify which of the documents presented in the initial result list are relevant. The system can exploit this information as an additional knowledge source and can modify the query to better suit the information need. Frequent terms in the documents judged as relevant are added to the query. Terms of documents judged as irrelevant may be omitted or weighted lower.

Although relevance feedback has proved to lead to very good results, few systems offer it because many users are unwilling to provide relevance judgments. The technique is mimicked by so-called blind relevance feedback, where the system assumes that the top documents are relevant and initiates another retrieval step. The results are presented to the user after only one iteration.

There were two main directions of research on relevance feedback: first, to reweight terms automatically depending on their distribution over relevant and irrelevant documents, and second, to provide term expansion within the initial query (Harman, 1992). Later on, the community paid attention to more detailed aspects, namely, the relation between the modification of weights and query expansion, the selection of further query terms, the effectiveness of the number of iterations, and so forth.

Many evaluation studies have shown that the results of similarly well-performing information retrieval systems often differ. This means that while the systems find the same percentage of relevant documents, the overlap between their results is sometimes low. Therefore, fusion seems to be a promising approach and has been applied to retrieval (McCabe, Chowdhury, Grossman, & Frieder, 1999). Fusion methods combine different perspectives of representation and query-document matching. They delegate a task to different systems and integrate the results into one final result. Fusion requires the integration of different probabilities for the relevance of a document. Such approaches are also referred to as polyrepresentation (Ingwersen, 1994).

FUTURE TRENDS

The integration of information resources is an important trend. Integration tries to combine several data sources under one virtual system so that users need to interact only with one interface for querying all collections. This often leads to semantic heterogeneity, which can lead to a degradation of the quality from the perspective of the user. Consequences may be that the user's terminology does not match the terminology of the system, or the cognitive landscape he or she has formed of a domain does not match the structures presented within an interface. Heterogeneous ontologies occur in many areas. The most typical attempt to resolve this problem is standardization and concentration on one ontology. However, this may not always be possible, and aspects of and perspectives on the domain may get lost. As a consequence, heterogeneity treatment is necessary to overcome the incompatibilities between different ordering systems. A traditional but expensive approach is the creation of concordances. Currently, automatic systems based on machine learning are being developed (Hellweg et al., 2001).

More and more collections contain documents written in different natural languages. Multilingual or crosslinguistic information retrieval (CLIR) is concerned with the retrieval of documents in other languages than the query language. This is of importance if the user has only passive knowledge of a language that enables him to read a document. However, in many cases, users lack the active knowledge to formulate a good query. CLIR needs to bridge language borders and applies several methods from natural-language processing. Often, machine translation is used to translate the query. In these cases, the translation quality is not the most important factor. Sometimes, a bad translation may still lead to good retrieval results. Other approaches include statistic transfer methods without an explicit translation step (Oard, 1997).

Apart from text documents, other media types are collected in large amounts as well. Image, music, and video collections require content-based retrieval also. So far, the content of a picture cannot be extracted fully automatically. The identification of objects or faces in pictures and the classification of similar images is an active research area. Current systems can retrieve documents based on color, texture, forms, objects, and spatial relationships between objects. Still, much research is needed to achieve systems in which the user can naturally query for images (Bimbo, 1999).

Information retrieval systems often offer value-added tools in order to support the user. These tools may provide personalization, geographic constraints on queries, support during query formulation, or the display of relationships between documents.

CONCLUSION

Information retrieval is a technology that guarantees access to large collection of unstructured text. It is the basic technology behind Web search engines and, as such, is an everyday technology for many Web users.

Information retrieval deals with the storage and representation of knowledge and the retrieval of information relevant for a specific user problem. Information retrieval systems

need to process queries that typically contain a few words. The query is compared to document representations that were extracted during indexing. The most similar documents are presented to the users.

KEY TERMS

Indexing: Indexing is the assignment of terms (words) that represent a document. Indexing can be carried out manually or automatically. Automatic indexing requires the elimination of stop words and stemming.

Information Retrieval: Information retrieval is concerned with the representation of knowledge and subsequent search for relevant information within these knowledge sources. Information retrieval provides the technology behind search engines.

Inverse Document Frequency (IDF): IDF is a traditional weighting scheme for terms. It can be calculated as the logarithm of the term frequency in the document divided by the frequency of the term in the whole collection.

Link Analysis: The links between pages on the Web are a large knowledge source that is exploited by link analysis algorithms for many ends. Many algorithms similar to PageRank determine a quality or authority score based on the number of incoming links of a page. Furthermore, link analysis is applied to identify thematically similar pages, Web communities, and other social structures.

Precision: Precision is a quality measure for information retrieval evaluation. It gives the percentage of relevant documents within the document set. Precision can be calculated by dividing the number of relevant documents that were found by the number of documents found.

Recall: Recall is a quality measure for information retrieval evaluation. It can be calculated by dividing the number of relevant documents that were found by the number of relevant documents in the collection. The second figure can often only be estimated.

Stemming: Stemming refers to the mapping of word forms to stems or basic word forms. Word forms may differ from stems due to morphological changes necessary for grammatical reasons. The plural versions of English nouns, for example, are mostly constructed by adding an *s* to the basic noun. In most European languages, stemming needs to strip suffixes from word forms.

Term Weighting: Weighting determines the importance of a term for a document. Weights are calculated by many different formulas that consider the frequency of each term in a document and in the collection, as well as the length of the document and the average or maximum length of any document in the collection.

Technologies in Support of Knowledge Management Systems

Murray E. Jennex
San Diego State University, USA

INTRODUCTION

Knowledge management systems (KMSs) support the various knowledge management (KM) functions of knowledge capture, storage, search, retrieval, and use. To do this, KMSs utilize a variety of technologies and enterprise systems. This chapter surveys the various technologies and enterprise systems. Specific attention is placed on enterprise systems that integrate KM into organizational business processes, and technologies that enhance the effectiveness of these implementations. The chapter is based primarily on research summarized in *Case Studies in Knowledge Management* (Jennex, 2005a) and articles published by the Knowledge Management Track at the Hawaii International Conference on System Sciences (HICSS).

BACKGROUND

Knowledge

Davenport and Prusak (1998) view knowledge as an evolving mix of framed experience, values, contextual information, and expert insight that provides a framework for evaluating and incorporating new experiences and information. They found that in organizations, knowledge often becomes embedded in artifacts such as documents, video, audio, or repositories and in organizational routines, processes, practices, and norms. They also say that for knowledge to have value, it must include the human additions of context, culture, experience, and interpretation. Nonaka (1994) expands this view by stating that knowledge is about meaning in the sense that it is context specific. This implies that users of knowledge must understand and have experience with the context, or surrounding conditions and influences in which the knowledge is generated and used for it to have meaning to them. This also implies that for a knowledge repository to be useful, it must also store the context in which the knowledge was generated. That knowledge is context specific argues against the idea that knowledge can be applied universally, however it does not argue against the concept of organizational knowledge. Organizational knowledge is considered to be an integral component of what organizational members remember and use, meaning that knowledge is actionable.

Polanyi (1967) and Nonaka and Takeuchi (1995) describe two types of knowledge, tacit and explicit. Tacit knowledge is that which is understood within a knower's mind, and which cannot be directly expressed by data or knowledge representations and is commonly understood as unstructured knowledge. Explicit knowledge on the other hand is that knowledge which can be directly expressed by knowledge representations and is commonly known as structured knowledge. Current thought has knowledge existing as neither purely tacit nor purely explicit. Rather, knowledge is a mix of tacit and explicit, with the amount of explicitness (only one dimension needs to be measured) varying with each user. This is the knowledge continuum where purely tacit and purely explicit form the end points, with knowledge existing somewhere on the continuum between the two end points. Smolnik, Kremer, and Kolbe (2005) have an individual position of knowledge on the continuum through context explication, where context explication reflects the experience and background of the individual. Nissen and Jennex (2005) expand knowledge into a multidimensional view by adding the dimensions of reach (social aggregation), lifecycle (stage of the knowledge lifecycle), and flow time (timeliness) to explicitness. Research is continuing to refine the concept of knowledge and its dimensions.

Knowledge Management

Jennex (2005c) utilized an expert panel, the editorial review board of the *International Journal of Knowledge Management*, to generate a definition of KM as the practice of selectively applying knowledge from previous experiences of decision making to current and future decision-making activities, with the express purpose of improving the organization's effectiveness. Another key definition of KM includes Holsapple and Joshi (2004) who consider KM as an entity's systematic and deliberate efforts to expand, cultivate, and apply available knowledge in ways that add value to the entity, in the sense of positive results in accomplishing its objectives or fulfilling its purpose. Finally, Alavi and Leidner (2001) concluded that KM involves distinct but interdependent processes of knowledge creation, knowledge storage and retrieval, knowledge transfer, and knowledge application. Taken in context, these definitions of KM focus on the key elements of KM: a focus on using knowledge for

decision making and selective knowledge capture. This is important as the selective focus on knowledge capture separates KM from library science, which attempts to organize all knowledge and information, and the decision-making focus emphasizes that KM is an action discipline focused on moving knowledge to where it can be applied. Ultimately, KM may best be described by the phrase, "getting the right knowledge to the right people at the right time," and can be viewed as a knowledge cycle of acquisition, storing, evaluating, dissemination, and application.

Knowledge Management Systems

Jennex (2005c) views a KM system as that system created to facilitate the capture, storage, retrieval, transfer, and reuse of knowledge. The perception of KM and KMSs is that they holistically combine organizational and technical solutions to achieve the goals of knowledge retention and reuse to ultimately improve organizational and individual decision making. This is a Churchman (1979) view of KM that allows KMSs to take whatever form necessary to accomplish these goals. Alavi and Leidner (2001, p. 114) defined KMSs as "IT-based systems developed to support and enhance the organizational processes of knowledge creation, storage/retrieval, transfer, and application." They observed that not all KM initiatives will implement an IT solution, but they support IT as an enabler of KM. Maier (2002) expanded on the IT concept for the KMS by calling it an information and communication technology (ICT) system that supported the functions of knowledge creation, construction, identification, capturing, acquisition, selection, valuation, organization, linking, structuring, formalization, visualization, distribution, retention, maintenance, refinement, evolution, accessing, search, and application. Stein and Zwass (1995) define an organizational memory information system (OMS) as the processes and IT components necessary to capture, store, and apply knowledge created in the past on decisions currently being made. Jennex and Olfman (2006) expanded this definition by incorporating the OMS into the KMS, and adding strategy and service components to the KMS.

INTERNET KMS

Discussion

One of the most commonly cited KMS success factors (Jennex & Olfman, 2005) is having an integrated technical infrastructure including networks, databases/repositories, computers, software, and KMS experts. KM designers are using the Internet to obtain this integrated network and are using browsers as common software. Various approaches are being utilized by KMS designers to achieve common databases and repositories. Common taxonomies and ontologies are being used to organize storage of unstructured knowledge files and to facilitate knowledge retrieval, while other Internet-based KMSs serve as interfaces to large enterprise databases or data warehouses. Some Internet KMSs are being used to facilitate communication and knowledge transfer between groups. Knowledge portals are being used by organizations to push knowledge to workers and be communities of practice (CoPs) to facilitate communication and share knowledge between community members. The following section describes some examples of Internet-based KMSs.

Internet networks can be scaled to fit any size KMS. Browsers can be tailored to fit processes as desired. Taxonomies can be created that support unstructured knowledge sharing for any size KMS. The following examples illustrate this flexibility as the examples include a project KMS, an industry-wide project KMS, and an enterprise KMS. Knowledge portals can be scaled to fit either form of KMS but are more commonly used for enterprise KMS. A community of practice KMS is a variation of process/task KMSs.

Examples of Internet-Based KMSs

Project-Based KMS for a Single Organization

Jennex (2000) discussed an intranet-based KMS used to manage knowledge for a virtual Y2K project team. This KMS used two different site designs over the life of the project. The purpose of the initial site was to facilitate project formation by generating awareness and providing basic information on issues the project was designed to solve. The design of this site was based on Jennex and Olfman (2002), who suggested a structure providing linkages to expertise, and lessons learned were the knowledge needed by knowledge workers. This was accomplished by providing hot links to sites that contained Y2K knowledge, a project team roster that indicated the areas of expertise for each of the project team members and additional entries for individuals with expertise important to the project, and some basic answers to frequently asked questions. This site was accessed from the corporate intranet site through the special projects section of the IT division page. This made the site hard to find for those who did not know where to look, forcing the project team leadership to provide direction to the site through e-mail directions. The site did not contain guidelines and accumulated knowledge as reflected in test plans, test results, inventories of assets referenced to the division who owned them, and general project knowledge such as project performance data, meeting minutes and decisions, presentations, and other project documentation. This information had not

been generated at the time the site was implemented. Once generated, this information was stored on network servers with shared access to acknowledged project team members. This was done due to a lack of resources allocated to the initial site. No dedicated personnel or special technologies were allocated for the design or maintenance of the site. This site was in effect from early 1998 through mid-1998.

As the project team formed and began to perform its tasks, the requirements for the intranet site changed from generating awareness to supporting knowledge sharing. The site was redesigned and expanded to include detailed frequently asked questions (FAQs), example documents, templates, meeting minutes, an asset database, guidelines for specific functions that included lessons learned, and so forth. The knowledge content of the site was distributed into the other components of the site, and persons were identified as being responsible for the information and knowledge content of their responsible areas. Additionally, access to the site was enhanced by the addition of a hot link to the Y2K site placed and prominently displayed on the corporate intranet homepage. The basic layout of the site provided for access to seven specific sub-sites: Major Initiatives, Contacts, Documents, What's New, Hot Links, Issues and Questions, and Y2K MIS.

Access to this site was granted to all employees; however, several of the sub-sites were password protected for restricted use. Most of the knowledge contained on the site was contained in these protected sub-sites. The knowledge from the initial site was rolled over into the Hot Links and Contacts sub-sites. Additionally, information that had been previously stored on network servers was left on those sites, but access was provided through the intranet site. The network structure was expanded to include more sub-structures for storing more documents, information, and knowledge.

The effectiveness of the two sites was considered good. The first site was successful in generating interest and starting the project. The second site succeeded in taking a project that was performing in the bottom third of projects to being a leading project within six months after its release. Effectiveness of the sites was established using the model in Figure 2 and by ensuring the information quality was high and the system quality, especially the search, retrieval, and infrastructure, was good. Use of both sites was established by ensuring the sites met the needs of the project team and the company.

Project-Based KMS for an Industry

This example is the extranet site used by the utility industry for Y2K (Jennex, 2000). Its purpose was to facilitate information/knowledge sharing between industry members. It initially provided documents, procedures, and guidelines for getting projects started. It also provided an electronic forum for questions and answers. As projects progressed, more test data became available and this information was posted. Finally, this site provided links to other important sites and sources of information.

The effectiveness of the site was limited. A great deal of knowledge was stored on the site, but searching was difficult and time consuming, reducing system quality. The consensus of the Nuclear and Non-Nuclear Generation Y2K project personnel was that the site provided little benefit as many companies did not post test results, thus reducing information quality. The Substation Controls Y2K project personnel also found it limited, except they did use the knowledge to put together a statistically valid test sample as requested by the North American Electric Reliability Council (NERC). Industry consensus was that the site had limited knowledge value. A redesign of the site with more emphasis on knowledge search and retrieval was not available until after most projects were complete. It was anticipated the new site would be available for the expected onslaught of lawsuits following the rollover to 2000, which of course did not happen. A further inhibitor to effectiveness was that the member companies did not categorize equipment and system information in the same format. This lack of a shared ontology contributed to the search and retrieval difficulties and made understanding the posted information and knowledge more difficult to users from other companies.

KMS as a Knowledge Portal

This example, from Cross and Baird (2000), is an intranet site built by Andersen Consulting. Consulting firms have had a long tradition of brokering their knowledge into business. In the early 1990s, Andersen Consulting began to produce global best practices CDs for distribution to project personnel. This evolved into the development of a intranet site called KnowledgeSpace, which provided consultants with various forms of knowledge including methodologies and tools, best practices, reports from previous like engagements, and marketing presentations. Support was also provided for online communications for online communities of practice and virtual project teams. The site was effective for personnel with access to the Internet and adequate bandwidth. It should be noted that current modem technology and improved dial-in access, as well as the proliferation of broadband connections, have made sites such as this much more effective for field or remote personnel.

The second example, from Bartczak (2005), describes the system used by the United States Air Force to support the Material Command called the AFKM Hub. The AFKM Hub is the primary Web site for the AF Lessons Learned utility. Although the Web site has evolved, Lessons Learned are still the centerpiece of the Hub. Lessons Learned have been captured and categorized by subject area and provide valu-

able knowledge about past processes and events. The AFKM Hub also acts as a portal for all other AFKM components and, as such, also serves as the default AFKM homepage. The AFKM Hub provides a conduit to select relevant information and knowledge resources, and provides an avenue for creating a knowledge-sharing organization. The AFMC Help Center of the AFKM Hub allows AFMC customers to perform a natural language or keyword search of over 130 AFMC Web sites and selected databases. It connects AFMC customers throughout the Air Force and Department of Defense with the appropriate AFMC information source or point of contact. The search engine used dynamically creates a unique results page separated into four categories: ranked list of related Web documents and links, top priority Major Command issues, bulletin board discussion entries, and contact information for the AFMC command liaisons and topic area points of contact The CoP Workspace supports the growing number of Air Force communities of practice. A community of practice is a network of people who share a common goal. CoP workspaces are virtual environments where members of these CoPs can exchange information to complete work tasks and solve problems. Each CoP serves a specific customer set. The AFKM Hub provides workspaces for a variety of CoPs and supports more than 1,300 active CoPs. The effectiveness of the AFKM Hub has also been mixed. Air Force leadership sees the value in KM, and many examples of successful uses of knowledge have been recorded. However, articulating a knowledge and KM strategy has been difficult and has allowed for wasted effort in supporting Air Force KM needs.

KMS as a Topic Map

The last examples come from Eppler (2001). There are five types of knowledge maps: source, asset, structure, application, and development. A multimedia company intranet site is used to illustrate a knowledge source map. This site provides graphical buttons representing individuals with specific expertise color-coded to indicate the expert's office location. The Knowledge Asset map provides a visual balance sheet of an organization's capabilities of a skills directory or core competency tree. Colors are used to indicate knowledge domains, while the size of symbols indicates level of expertise. Knowledge Structure maps divide knowledge domains into logical blocks that are then broken into specific knowledge areas. The Knowledge Application map breaks an organization's value chain into its components parts and then indicates what knowledge, tools, or techniques are needed to implement the component part.

The last example is a Knowledge Development map. This map is used to plot the activities needed to acquire the indicated knowledge competence. Clicking on the displayed competence displays the steps needed to develop the competence. Effectiveness of these maps has only been determined for the Knowledge Asset map. This map, developed for a telecommunications consultant firm, was found to be very useful for the planning of training activities and for identifying experts quickly when required during an emergency. It should be noted that knowledge maps enhance the linkage aspects of information quality.

ENTERPRISE SYSTEM SUPPORT FOR KMS

Discussion

As organizations strive to improve their competitive position/advantage, they are implementing enterprise-wide systems. These systems integrate processes and data/information/knowledge across the enterprise, and in many cases with suppliers and customers to improve efficiency and effectiveness (Koch, 2002). This usually results in lowered operating costs and improved response times, economies of scale, and user satisfaction. Typical of these systems are enterprise resource planning (ERP), customer relationship management (CRM), supply chain management (SCM), and data warehouse implementations. As these systems are refined and improved, organizations are finding that incorporating knowledge and KM into them improves system performance. Additionally, KMS designers are finding that enterprise systems satisfy several KMS success factors including: a knowledge strategy (meeting the needs of the enterprise system processes); a common enterprise-wide knowledge structure (inherent in the enterprise systems); a clear goal and purpose for the KMS (supporting the enterprise system); search, retrieval, and visualization functions of the KMS support easy knowledge use (they are built into the enterprise system); and work processes are designed that incorporate knowledge capture and use (also inherent in the enterprise system work processes). Unfortunately, there are also several issues involved in successfully using enterprise systems to support KM; chief among these are organizational culture issues. Many enterprises suffer from fragmentation, meaning that many organizations within the enterprise own and use their own data and systems. Enterprise systems seek to integrate these systems, but to be successful they must overcome issues of ownership and a reluctance to share data, information, and knowledge. This issue is usually characterized by the presence of "silos" in the enterprise. Corral, Griffen, and Jennex (2005) discuss this issue with respect to integrating data warehouses and KM. This is considered the principal issue affecting successful integration of enterprise systems and KM. The following examples describe how enterprise systems and KMSs are being fused together.

Enterprise systems support primarily infrastructure/generic KMSs, as the primary reason for using these systems is to integrate data, information, and knowledge and to create a common infrastructure. However, data warehouse systems can be used to support process/task KMSs through the use of data marts, and CRM and ERP can be used as transitional technologies. Transitional technologies preserve the process/task KMS while converting their stored knowledge into generic knowledge through back-office operations. The issue in doing this is in getting the process/task users to agree to knowledge capture process changes that incorporate capturing supporting context and culture data and information.

Examples of Enterprise System Support for KMS

ERP and KMS

Li, Yezhuang, and Ping (2005) describe an ERP implementation in a Chinese paper manufacturing company. The ERP was implemented to help the company respond to market and customer changes more rapidly by integrating enterprise data information and knowledge and centralizing process control. Unfortunately, China lacked experience with ERP implementation (although it has experience with MRP) and is not overly familiar with western concepts of centralized data, information, and knowledge management. This was an issue in getting the ERP implemented and utilized. Once this was accomplished, decision making was greatly enhanced through improved knowledge transfer provided by the ERP's integration of organizational data, information, and knowledge into a single accessible location. Other issues faced in implementing the ERP were management support of the various sub organizations being integrated into the ERP and creating a culture that used data, information, and knowledge in the expected way.

White and Croasdell (2005) describe ERP implementations in Nestle, Colgate-Palmolive, and Chevron-Texaco. Each of these implementations was performed to improve data, information, and knowledge integration, with an expectation of improved decision making and transfer of key knowledge such as lessons learned and process improvements. All three implementations were ultimately successful after initial difficulties, including cost overruns due to unrealistic project estimates of schedule and cost, and overcoming employee resistance to changing to new processes and merging data, information, and knowledge ownership. These examples also incorporated the KMS success factor of metrics for measuring success and illustrate the importance of measuring KMS performance.

CRM and KMS

Al-Shammari (2005) describes a knowledge-enabled customer relationship management (KCRM) system in a large middle-eastern telecommunications company. The KCRM was composed of three major parts: enterprise data warehouse (EDW), operational customer relationship management (CRM), and analytical CRM. The KCRM initiative was designed to automate and streamline business processes across sales, service, and fulfillment channels. The KCRM initiative was targeted at achieving an integrated view of customers, maintaining long-term customer relationships, and enabling a more customer-centric and efficient go-to-market strategy. The driver for the initiative was that the company faced deregulation after many years of monopoly. The company initiated a customer-centric knowledge management program, and pursued understanding customers' needs and forming relationships with customers, instead of only pushing products and services to the market. Unfortunately, the KCRM program ended as an ICT project. The company did not succeed in implementing KCRM as a business strategy, but did succeed in implementing the KCRM as a transactional processing system. Several challenges and problems were faced during and after the implementation phase. Notable among these is that the CRM project complexity and responsibilities were underestimated, and as a result, the operational CRM solution was not mature enough to effectively and efficiently automate CRM processes. Changing organizational culture was also a tremendous effort in terms of moving towards customer-centric strategy, policy, and procedures, as well as sharing of knowledge in a big organization with lots of business 'silos'. Employee resistance to change posed a great challenge to the project. Ultimately, this project failed to achieve expectations.

Data Warehouse, Enterprise Databases, and KMS

White and Croasdell (2005) describe Xerox's use of an enterprise database to facilitate the sharing of experience knowledge across the company. Xerox had difficulty in fostering best practice among its group of printer maintenance employees. The problem centered on an inability to circulate employee expertise using existing organizational infrastructure. To help the maintenance technicians share their experience and expertise, Xerox created a database to hold top repair ideas in order to share those ideas with other technicians in all areas. This strategy called for only the most favored ideas to be kept within the database, as it often occurred that what one person thought useful, others found absurd or redundant. Xerox also realized that many

databases had been created by managers who filled the databases with information they thought would be useful for their employees. However, most of those databases were rarely used by the employees. When Xerox created the Eureka database, it also formed a process for entering and updating the ideas within the database. The process is based on a peer review system. Within this practice the representatives, not the organization, supply and evaluate tips. In this way a local expert would work with the representative to refine the tip. Representatives and engineers evaluate the tips, calling in experts where appropriate. As of July of 2000 the Eureka database held nearly 30,000 ideas and was being utilized by 15,000 Xerox technicians who answered a quarter-million repair calls per year. The shared knowledge in Eureka saved Xerox about $11 million in 2000, and customers also saved money in terms of the reduction in downtime.

Eureka later extended the role of the Eureka database to collect, share, and reuse solutions to software and network problems as well as those involving hardware. Additionally, Xerox Web-enabled, or made available over the Web, the Eureka database system, allowing technicians to gain access to the system from anywhere in the world though the Internet. The system added features including a search function, called "Search Light," and a wizard that aids in searching for tips, including those waiting to be validated. The technicians trust the Eureka system and constantly use the system because it helps them get any problem fixed quickly. In the old process many technicians would have to call a specialist to find solutions to problems they could not solve themselves.

As mentioned above, Al-Shammari (2005) describes the use of a data warehouse with its KCRM implementation. The data warehouse became the primary repository of data, information, and knowledge for the KCRM implementation and was designed using knowledge of customer needs and questions. Data mining tools were provided to support KCRM users in discovering knowledge contained in the data warehouse. Also as discussed above, key issues in implementing a data warehouse with KM were organizational culture as reflected in a "silo" mentality, and overall data, information, and knowledge ownership.

ADVANCED TECHNOLOGIES

Discussion

Although there is strong support for using the Internet as a knowledge infrastructure, there are concerns. Chief among these concerns is the difficulty in organizing, searching, and retrieving unstructured knowledge artifacts. Ezingeard, Leigh, and Chandler-Wilde (2000) point out that Ernst & Young UK in the beginning of 2000 had in excess of one million documents in its KMS. Another concern is the tendency to not use the system. Cross and Baird (2000) discuss this tendency but come to the conclusion that repositories are essential. Jennex (2007) found that use and importance for knowledge do not correlate, suggesting that use is not a true measure of the value of a KMS. Jennex and Olfman (2002) found that voluntary use is enhanced if the system provides near and long-term job benefits, is not too complex, and the organization's culture supports sharing and using knowledge and the system. Stenmark (2002) found that if the Internet is visualized as a system for increasing awareness of knowledge and the KMS, a system for retaining and sharing knowledge, and as a system for enhancing communication and collaboration between teams and knowledge experts and users, then it should be successful as a KMS. In all cases, researchers are experimenting with technologies that improve the handling of unstructured knowledge. These are discussed in the following paragraphs.

Technologies

Newman and Conrad (2000) propose a framework for characterizing KM methods, practices, and technologies. This framework looks at how tools can impact the flow of knowledge within an organization, its role in manipulating knowledge artifacts, and the organizational behavior most likely to be affected. The framework also looks at the part of the KM process the tool works in. The Activity phase looks at the utilization, transfer, retention, and creation of knowledge. This framework can be used to show that Internet and browser-based KMS tools are effective.

Gandon, Dieng, Corby, and Giboin (2000) propose using XML to encode memory and knowledge, and suggest using a multi-agent system that can exploit this technology. The proposed system would have improved search capabilities and would improve the disorganization and poor search capability normally associated with Internet systems. Chamberlin et al. (2001) and Robie, Lapp, and Schach (1998) discuss using XML query language to search and retrieve XML-encoded documents.

Dunlop (2000) proposes using clustering techniques to group people around critical knowledge links. As individual links go dead due to people leaving the organization, the clustered links will provide a linkage to people who are familiar with the knowledge of the departed employee. This technique would improve the reliability of the links to knowledge called for in Figure 2. Lindgren (2002) proposes the use of Competence Visualizer to track skills and competencies of teams and organizations.

Te'eni and Feldman (2001) propose using task-adapted Web sites to facilitate searches. This approach requires the site be used specifically for a KMS. Research has shown that some tailored sites, such as the ones dedicated to products or

communities, have been highly effective. This approach is incorporated in the examples in this article with the exception of the use of dynamic adaptation.

Eppler (2001), Smolnik, and Nastansky (2002) and Abramowicz, Kowalkiewicz, and Zawadzki (2002) discuss the use of knowledge maps to graphically display knowledge architecture. This technique uses an intranet hypertext clickable map to visually display the architecture of a knowledge domain. Knowledge maps are also known as *topic maps* and *skill maps.* Knowledge maps are useful as they create an easy-to-use standard graphical interface for intranet users and an easily understandable directory to the knowledge.

The use of ontologies and taxonomies to classify and organize knowledge domains is growing. Zhou, Booker, and Zhang (2002) propose the use of Rapid Ontology Development (ROD) as a means of developing an ontology for an undeveloped knowledge domain.

Making sense of seemingly unrelated structured data, information, and knowledge can also be difficult. Data mining is being used as a method for identifying patterns in this data, information, and knowledge that can then be assessed for meaning. Zaima and Kashner (2003) describe data mining as an iterative process that uses algorithms to find statistically significant patterns in structured data, information, and knowledge. These patterns are then analyzed by business process experts to determine if they actually have meaning in the business process context. CRM tends to use this technology the most, as illustrated by the example from Al-Shammari (2005).

Organizing and visualizing data and information into usable knowledge is a challenge that digital dashboard technologies are seeking to solve. Few (2005) describes dashboards as providing single-screen summaries of critical data and information. The key to developing effective dashboards is the use of KM to identify critical knowledge for key decision making and then linking it to the appropriate context data and information that indicates the status of the key knowledge. Dashboards can be used with a Internet browser or any other KMS infrastructure.

FUTURE TRENDS IN KNOWLEDGE MANAGEMENT

KM is a young and evolving discipline. The last section of this chapter looks at some of the emerging future trends affecting the discipline. Many of these trends have been discussed in relative detail in previous sections so they will just be summarized. The first trend is towards more formal measurement of KM success and performance. This is an indicator of discipline maturity, organizations are moving from "it's a good idea to do KM" to "KM has this impact on our performance."

A newer trend is a set of technologies used to empower knowledge groups such as communities of practice. KM was initially viewed as a formal process for managing organizational knowledge; this is still true, but it is also being recognized that KM can enable groups and teams to self-manage their knowledge. CoPs are groups that may or may not be in the same organization. What makes them a CoP is a shared common interest in a knowledge domain. CoPs have a shared context of understanding and may or may not share culture. CoPs self-identify critical knowledge and transfer it to those in the CoP that need it. Finally, CoPs need technology that facilitates CoP communication and collaboration. Wikis and other open source tools as well as knowledge portals are examples of technology used by CoPs. Murphy and Jennex (2006) illustrate how these tools in the hands of a CoP can lead to leaderless development in times of emergency and the quick creation of KM-enabled systems.

Finally, the Internet itself is changing. Efforts to improve the Internet's ability to facilitate collaboration and handle unstructured data, information, and knowledge, both by users and by software agents, is leading to the development of the Web 2.0 and Web 3.0/semantic Web. Web 2.0 refers to improving the Web to handle social networking sites and collaborative technologies such as Wikis, blogs, and other community-based sites (such as Craigslist, Skype, etc.). Web 3.0/semantic Web is predicted to be an environment where data, information, and knowledge can be understood and used by any user and software agent. Technologies used include Resource Description Framework (RDF), Web Ontology Language (OWL), and the Extensible Markup Language (XML). Both of these developments will improve the ability of the Web to store, search, and retrieve knowledge and to facilitate knowledge transfer.

CONCLUSION

The conclusion is that the Internet, data warehouse, CRM, and ERP are effective infrastructures for a KMS. However, there are issues associated with using these technologies that KMS designers need to be aware of. Chief among these are knowledge representation and search. Several tools such as Knowledge Maps, XML, adaptive Web sites, clustering, and dashboards are being developed to address these issues. However, as knowledge bases grow, designers need to be aware of increasing search times as well as a variety of knowledge artifacts. This is perhaps the most important area for future research. Developing ontologies and taxonomies to aid in classifying and structuring knowledge domains is critical.

KEY TERMS

Knowledge: An evolving mix of framed experience, values, contextual information, and expert insight that provides a framework for evaluating and incorporating new experiences and information (Davenport & Prusak, 1998).

Knowledge Management: The process established to capture and use specific knowledge in an organization for the purpose of improving organizational performance.

Knowledge Management System: The system created for users to interact with the organizational memory system.

Knowledge Map: An intranet hypertext-clickable map to visually display the architecture of a knowledge domain. Knowledge maps are also known as topic maps and skill maps.

Knowledge Ontology: Common definitions established for captured knowledge, similar to keywords, used to capture and express a common context for search, retrieval, and use of knowledge.

Knowledge Taxonomy: The hierarchical organization of knowledge categories within a knowledge management system.

Technology and Transformation in Government

Vincent Homburg
Erasmus University Rotterdam, The Netherlands

INTRODUCTION

Information technology and public administration are an odd couple. Students of information technology have long neglected arduous issues of public sector reform and public policymaking (Borins, Kernaghan, Brown, Bontis, & Thompson, 2007; Orlikowkski & Barley, 2001). Likewise, public administration scholars have rarely paid attention to information technology beyond treating it pragmatically (Gruening, 2001), at the periphery of governments' core activities of policy making and policy implementation. This situation of disciplinary negligence, however, has changed since the advent of the admittedly voguish term electronic government ("e-government"). E-government refers to a practice in which governments throughout the world embrace information and communication technologies in order to transform the machinery of governance (Bekkers & Homburg, 2007; Borins et al., 2007; Chadwick & May, 2003; Dunleavy, Margetts, Bastow, & Tinkler, 2006; Heeks, 2006).

The relation between technology and transformation is not as straightforward as might appear at first sight (Williams & Edge, 1996), for at least two reasons. First, the clamor for transformation and reform was first heard in the beginning of the 1990s (Osborne & Gaebler, 1992) without technology playing a role. Rather, the focus was on organizational and managerial changes, in particular focusing on establishing customer orientation and use of market-type mechanisms (Guy Peters, 1996; Hood, 1991; Pollitt, van Thiel, & Homburg, 2007), that later blended with the emergence of new technologies. Second, e-government practices throughout the world display a huge variety of forms, shapes and effects that are not easily attributed to technology alone. In the national policies of the United Kingdom and the United States, for instance, the focus is on achieving one-stop service shops that enable transactions with citizens on the basis of clearly defined "service themes" (Chadwick & May, 2003). At municipal levels in Sweden, on the other hand, e-government takes the form of electronic interactions between municipal commissioners and citizens, in such a way that citizens can watch video broadcasts of city council meetings, and can submit questions to commissioners during the half-way break (Grönlund, 2003).

The above discussion makes clear that the use of ICTs in government has moved from being a peripheral concern, to a topic that concerns the core activities of government, policy making and policy implementation, and that e-government is intrinsically linked to transformation and reform of governments. It does not, however, make clear how to circumscribe and define "e-government," and what obstacles and dilemmas can be witnessed in practice. The remainder of this chapter addresses these issues.

BACKGROUND

Electronic government (or e-government) has emerged as a powerful catchphrase to indicate situations in which ICTs are associated with bureaucratic renewal and institutional innovation in general (Homburg & Bekkers, 2005). The term New Public Management appeared in the 1980s in Anglo-American discussions about how to reform rather traditional bureaucratic structures and practices. One of the dominant observations related to bureaucratic renewal and New Public Management was that it truly was management ideology: In talk, writing and discussions, there was a powerful and almost compelling rhetoric of administrative reform, yet in practice the clamor for reform suffered from a lack of useful and practical instruments with which actual change could be accomplished. Since the advent of Web technology, many reform adepts have embraced information and communication technology, and have used the concept of e-government as a "tool" to actually implement changes in and around governments. In *The Economist* of June 24, 2000, it is stated that the once fashionable idea of reinventing government, is now finally being made possible by the Internet (Symonds, 2000).

Central to the reform ideas at the corner stones of New Public Management and the emergence of communication technologies is the focus on client (or citizen) orientation. Not surprisingly, many definitions of e-government emphasize electronic service delivery as a main objective for e-government (for a review, see Yildiz, 2007), thus portraying e-government as "e-commerce for governments" (Wimmer, Traunmüller, & Lenk, 2001). There are, however, various arguments for declaring such a definition too narrow in focus (Bekkers & Homburg, 2005b).

First, e-commerce concerns itself with transactions between suppliers and customers. If we extrapolate that to ICTs

in relation to government, we see that the notion of "customer" is far more problematic. Citizens can be customers, in the sense that they are beneficiaries of public services, but at the same time they are co-creators of the policies (in the case of Bollnäs mentioned above), and, more importantly, they are sometimes involuntarily involved in transactions with governments (e.g., in the case of electronic tax services and electronically administered fines for speeding).

Second, the objectives of e-government applications address, in many cases, more values than efficiency of service delivery and customer orientation alone. E-government implementations can also serve other purposes like increasing transparency of the government apparatus (Homburg, 2008; LaPorte, de Jong, & Demchak, 2000), bridging the gap between citizens and administration (Bekkers & Homburg, 2005a), or addressing (and preferably decreasing) the democratic deficit.

Third, many public electronic one-shop facilities necessitate data sharing and standardization of practices among multiple, relative autonomous agencies in order to provide integrated services. From a technological point of view, it is understood that data sharing is severely hampered by lack of consistency of data and, in general, a lack of data standardization. In the information systems literature, various Strategic Information Systems Planning (SISP) methodologies have been proposed that can be put to use to alleviate this situation. In specific e-government initiatives, however, data sharing is not so much hampered by more or less operational inconsistencies, but rather by checks-and-balances (e.g., between executive and judicial branches in penal law enforcement) and disagreement over professional values (of social workers and medical professionals in cases of child protection services).

Fourth, it may be tempting to assume that e-government is a more or less direct translation of a global, unequivocal and consistent wave of administrative reform, New Public Management. A closer look at the phenomenon New Public Management reveals, on the other hand, that the trajectories of reform are different in various institutional contexts (Pollitt et al., 2007). New Public Management takes many forms and shapes in Singapore as opposed to Denmark, Spain, or Guatemala, to name a few institutional contexts, and so does e-government. This issue is furthermore addressed in the subsequent section.

In recognition of the arguments set out above, e-government is defined not as e-commerce for government, but rather as a redesign of information relations of a public agency with stakeholders in its environment (Bekkers & Homburg, 2005b; Homburg, 2008). Redesign, in this definition, can apply to front offices, that is, to relations between governments and citizens (in either of the roles of customer, voter, "citoyen" and subordinate of policy) but also to back offices, indicating a redesign of information relations between various agencies, or even branches of government. The various issues and obstacles of redesign are presented and discussed in the following section.

REDESIGN OF INFORMATION RELATIONSHIPS: RESULTS AND ISSUES

A first issue concerns the type of front office services (at the government-society interface) that are offered in the actual practice of e-government: information services, contact services, transaction services and participation services. Chadwick and May have convincingly argued that explaining the kinds of front office services offered (i.e., whether authorities offer information services, or electronic participation services, or several of these kinds of services at the same time), is not so much a technological issue of "maturity" but is the result of an underlying normative frame of reference (Chadwick & May, 2003). Hence, understanding e-government is not a question of understanding technology, but rather grasping the concept of democracy (Barber, 1997).

In practice of national e-government initiatives at the federal level in the United States (Chadwick & May, 2003) and national levels of policy making in the United Kingdom (Bekkers & Homburg, 2007; Chadwick & May, 2003), the Netherlands, Denmark and Australia (Bekkers & Homburg, 2007), e-government policies focus on information services and especially on transaction services, especially at the expense of participation services.

A second issue with the redesign of information relationships is if and how the *appearance* of service counters (i.e., the *front office*) relates to the back office organizational (departmental or interorganizational) structures. Alfred Tat-Kei Ho (2002) analyzed Web portals of 55 of the most populous cities in the United States. He concluded that most cities had, over time, transformed their Web presence from an administrative-oriented portal design (reflecting bureaucratic logic of a variety of functionally differentiated departments) to user-oriented portals. Furthermore, responses by city Web masters indicated that many city officials had abandoned a departmental mentality in Web management. Donald Norris, on the other hand, noticed that most municipal Web sites offer information services, but few transaction services. Moreover, Norris concluded on the basis of survey data of American local authorities that services that horizontally or vertically span various authorities, are notably lacking (Norris, 2005). Obviously, e-government is being used to break down departmental barriers, but collapsing interorganizational boundaries still results in many problems.

A third issue, which is related to the issue of collapsing interorganizational boundaries mentioned above, is the re-organization of information relations in the back office. Sharing information across organizational boundaries is far

from an operational, neutral issue, neither in the private sector (Webster, 1995) nor in the public sector (Homburg, 2000). The issue of back office interorganizational information exchange is addressed in the public management literature by using the term joined-up government (JUG). Joined-up government refers to the aspiration to achieve horizontal and vertical coordination ("cross-cutting approaches") in and among organizations (Ling, 2002; Pollitt, 2003). Both the information systems literature as well as the public management literature report formidable difficulties in actually achieving interorganizational information integration and joined-up government. It may be tempting to propose all-encompassing and unequivocal ontologies (which in fact takes place at numerous e-government conferences). A recent European study, however, has shown that there is in practice a large divergence in ways in which joined-up government and integration among agencies is actually achieved (Millard, Iversen, Kubicek, Westholm, & Cimander, 2004), and that JUG and integration are far more contextually bound than is apparent at first sight. The authors compared JUG implementations in several service clusters: income tax, car registration, citizen certificates, family allowances, student grants, social benefits, building permissions, enrolment in higher education, citizen portals, social contributions for employers, corporation taxes, customs declarations, business registration, environmental-related permits and business portals in Austria, the Benelux countries, Finland, France, the UK, Greece, Iceland, Ireland, Italy, Norway, Portugal, Spain and Sweden, and found a large variety of mechanisms with which interoperability and joined-up government was actually enforced (Millard et al., 2004, pp. 27-44):

- by means of digitization of organizationally unchanged back-offices;
- by means of fundamental redesign of back-offices;
- by means of centralization of back-offices;
- by means of simultaneous centralization and back-offices and decentralization of front-offices;
- by means of modularizing common back-office components over broad areas, while retaining flexibility and possibilities to adapt to specific requirements; and
- by means of clearing houses that enable the exchange of information from various sources without the need to necessarily integrate data sources.

The authors conclude that "One of the clearest conclusions emerging from the present study is that state structures, and institutional, legal, regulatory and cultural factors, can be extremely important in determining the nature, cost and success of eGovernment. (…) Different countries across Europe need to develop their own paths as each has unique identities, cultures, legal systems and institutional structures" (Millard et al., 2004, p. 61).

The importance of institutional context is exemplified in a study on integration and joined-up government in the back office of social security in the Netherlands and Belgium (Homburg, 2007). Although the Netherlands and Belgium are, seen from a distance, rather comparable nation states (in terms of size, geographic location, etc.) and the specific sector of social insurance has been confronted with comparable issues (fiscal crises since the 1970s, reforms of welfare state regimes, etc.), and hence, one would expect a certain amount of resemblance of technological solutions to integrate these sectors. In practice rather different solutions were implemented to allow for joined-up government. In Belgium, a relatively centralized initiative was taken which resulted in changes in legislation, the introduction of a new, powerful player in the form of the Cross Point Bank (a centralized clearing house), and large-scale standardization throughout organizations in the sector, enabled by missionary activities of the Cross Point Bank. In the Netherlands, on the other hand, executive agencies themselves initiated a decentralized clearing house, governed by representatives of executive agencies, thereby fostering decentralization and strengthening the power base of executive organizations (vis-à-vis policy making bodies like the Ministry of Social Affairs and Employment). The diversity of organizational form and organizational practice can be explained in terms of varying power bases of the executive in social security in Belgium and the Netherlands, but also in terms of technological competencies in policy making and policy implementation.

FUTURE TRENDS

Setting the difficulties of understanding e-government and explaining the diversity of form and impact aside, it is possible to discern a number of future trends.

A first trend—observable in the government-society interface—that can be observed in the realm of public service delivery is a trend toward further personalization. Increasingly, service delivery by a variety of authorities is organized around a limited number of *life events* and is presented to individual citizens and companies in a personalized manner: Citizens increasingly do not have to know anymore which agency exactly is responsible for specific services, and services are tailored as much as possible toward individual circumstances. In the Netherlands, for example, municipal electronic service counters increasingly become the *de facto* integrated service outlets for various governmental agencies.

A second trend—observable in the back-office of government—is the formation of information networks, implying a transformation of traditional bureaucracies into virtual public bureaucracies (Bekkers, 1998), called infocracies by Zuurmond (1998). Characteristic for the latter types of

organization is the disappearance of functionally defined organizational boundaries, and changes in ways in which accountability takes place. Whereas political, vertically-oriented accountability is a central value in traditional public bureaucracies, this type of accountability is blended with horizontal and public forms of accountability. Horizontal accountability is accountability targeted at peers (comparable organizations). Public accountability is focused at increasing legitimacy in the eyes of the general public.

CONCLUSION

E-government has been defined as redesign of information relations between government agencies and stakeholders in their environments. In this chapter, the focus was on understanding variety in forms and shapes that e-government initiatives take, both in the front office (the appearance of service counters and other manifestations of government-society interfaces) as well as in the back office (cooperative relations and information exchanges between governmental agencies). Although it is tempting to assume "maturity" models of growth here, understanding front office and back office developments in e-government initiatives requires in-depth understanding of values, norms, normative frames of reference and taken for granted assumptions (in short: institutions) of localized worlds of government and public administration. If we accept this view and its consequences, we see that developing e-government applications is by far a neutral exercise, and that design requirements are constituted in settings in which normative frames of reference may collide. Developing and implementing e-government initiatives, therefore, is a complex endeavor in which politicians, policymakers, public managers and developers face formidable challenges. Nevertheless, e-government progresses and has shown to be able to actually instrument government reform and desired institutional change.

KEY TERMS

E-Government: Redesign of information relations of a public agency with stakeholders in its environment.

NPM (New Public Management): Management ideology with which private-sector business management techniques (performance management systems, benchmarking, autonomization) are introduced in the public sector.

JUG (Joined Up Government): Aspiration to aspiration to achieve horizontal and vertical coordination ("cross-cutting approaches") in and among public sector organizations.

Institutions: Values, norms, normative frames of reference, taken for granted assumptions and practices.

Front Office: Part of the organization that is specialized in interaction with society (citizens, companies) and that is responsible for, among other things, managing the government-society interface.

Back Office: Part of the organization that is specialized in meeting information requirements of front office processes and is responsible for, among other things, registering and exchanging information between public, private and hybrid organizations.

Technology Discourses in Globalization Debates

Yasmin Ibrahim
University of Brighton, UK

INTRODUCTION

Globalization, a key concept in our modern and postmodern discourse, is a highly contentious term that continues to generate endless debates about its form and consequences on our societies. Anthony Giddens (1999) professes that while the term is "not particularly attractive or an elegant one, absolutely no one who wants to understand our prospects and possibilities can ignore it." While many agree that it denotes the occurrence of social change, there is, however, less agreement what these changes may be and whether they, in effect, represent the transition of one form of society to another (i.e., the industrial to the postindustrial or information society). Nevertheless, the increase in the volume of discourses surrounding the term is significant in illuminating that the increased interdependence of the world can lead to new forms of challenges, concerns, empowerment, and resistance with the symbolic and material exchanges of ideas, products, and services, as well as the formation of social networks (Castells, 1998). Castells (1996, 2000, 2001), in his numerous reflections on the network society, asserts that since the 1980s, a new economy has emerged that is global, information-based, and interconnected. This new form of economy remains capitalist in form but is situated on an informational rather than an industrial form of development; at the core of the informational mode of development are networks contributing to a network society.

The term globalization then captures a complex set of processes that involve political, social, economic, cultural, and technological factors, and these intersect with each other in crucial but unpredictable and uneven ways (Stammers & Eschle, 2005, p. 57). Crucial to the debates on globalization is the role of information and communication technologies (ICTs) in making the world a connected entity. ICTs are often seen as providing a new platform to enable the flows, exchanges, and networks in analysing globalization as a multidimensional process. According to Hamid Mowlana (1997), a useful way of viewing the "postindustrial age" or the "information age" is to look at it as a tangible or material infrastructure being built into contemporary societies (p. 176). In this sense, modern communication and information technologies, in the form of satellites, computers, and radar, comprise the new infrastructure. Characteristics of new media technologies, like the Internet and mobile phones, include digitization, convergence, and networking, which enables new ways to distribute, store, consume, and interact with information that facilitates a networked distribution on a global scale (Flew, 2007, p. 22).

BACKGROUND

While globalization is a relatively a new concept that has gained much currency and controversy in the last two to three decades, the idea of high-speed transport and communications in some ways altering our social reality in terms of the construction of the temporal or social space is not in itself a new idea. There is an abundance of references in literary texts and historical annals to human interaction and concepts of geography being negotiated through technological innovations. In literary fiction, specifically, the future is often imaged through the advances in technology that prophesy degrees of technological determinism on human society. There have been references to a global economy through industrialization and technological innovations dating back from 1870 to 1914 (See Kobrin). Marshall McLuhan's (1964) concept of the "global village" constructed the notion of a world community brought about by communication technologies and, consequently, technical biases, he argues, were intrinsic to our cognitive constructions of reality.

Similar ideas were propounded by Martin Heidegger (1971), who prophesied the "abolition of distance" as a distinctive feature of our modern condition where all "distances in time and space are shrinking" (p. 165). Addressing the ability of modern technology to premise on simultaneity and instantaneousness, Heidegger perceived technology as a levelling experience for individuals and in the process it produces a loss of meaning in defining what is far or near. Equally, Robertson (1992) alludes to the compression of time and space and an intensification of a consciousness of the world. Benedict Anderson (1991), in *Imagined Communities*, locates cultural artefacts and technological innovations, including books and press, as crucial in shaping our social imagination, political engagements, and our notions of community. Much of the rhetoric on globalization, as such, has revolved around the notion of "deterritorialization," where the material space is replaced with social activities that emphasise the connectedness of the world. However,

globalization, in our contemporary context, is deemed to be more expansive in terms of the nations involved and deeper in terms of the intensity of interactions and interdependence (Haleja, 2005, p. 7). In later debates, globalization has entailed the reconfiguration of material spaces where social space is no longer tightly defined by territoriality and, as such, the world becomes borderless. In a nutshell, globalization as advanced by ICTs is seen as both empowering as well as causing conflict and divisiveness within and between countries (Wilson, 1998, p.2).

The Implication of ICTs

Globalization has been discussed as a philosophy of ideas and as empirically (i.e., quantitatively and qualitatively) discernible processes that are occurring throughout the world. The process of change associated with globalization has been defined and viewed from various perspectives spanning the economic, social, political, legal, technological, and cultural, and has involved a range of viewpoints from the cynics to the ardent supporters of an open, borderless world of trade, commerce, and symbolic exchanges. Kaldor et al. (cf. Zanfei, 2005, p. 7) refer to the different perspectives of economic globalization ranging from the "supporters" who have championed the value of free international integration of economies since the early 1990s, to the "regressives" who have endorsed globalization when only deemed beneficial to an indigenous nation, and "rejectionists" who have clamoured for the greater protection of national economies.

These debates often implicate information and communication technologies (ICTs) as driving the change. ICTs encompass the full range of the "production, distribution and consumption of messages, across all media from radio and television, to satellite to Internet, and tangentially the 'information revolution' denotes the rapid advances in the power and speed of computers, the digitalization of information, and the convergence of once-separate industries to a new amalgam of production, distribution and consumption activities" (Wilson, 1998, pp. 6-7). According to Wilson (1998), this conveys both the "cross-border flow of information content as well as hardware used nationally and locally to produce, distribute and consume information" (pp. 6-7). Globalization has also been viewed as being primarily driven by the Internet and ICTs, which enable peoples, ideas, investments, goods, and services to come together through interconnected economies (Lang, 2001). Manuel Castells (2000) situates ICTs as fundamental in enabling the expansion of social and organizational networks in the information age, where information generation and processing are intrinsically entwined in the transformation of societies.

From this perspective, "globalization and technological advances in ICTs signify a fundamental transformation of the economy" (Alecke & Untiedt, 2000). Inevitably, the ICT revolution has been viewed as the primary catalyst for the process of globalization. It provides the tools for the postindustrial age and the foundations for a knowledge economy facilitating the rapid transfer and acquisition of knowledge (Ajayi, 2000; Morales-Gomez & Melesse, 1998). The wiring of the planet through ICTs has been seen as the "death of distance" (Caincross, 1997), where there is a shrinking of physical spaces and temporal distances. Anthony Giddens (1990, p. 64) similarly stresses the reframing of social geography due to globalization where there is "an intensification of worldwide social relations which link distant localities in such a way that local happenings are shaped by events occurring many miles away and vice versa." While the death of distance through the speed of communication presents opportunities for economies and polities, the increasing modernization and industrialization, as well as the attendant interconnectedness of the world, is also seen as giving rise to new forms of risk (Beck, 1992). Ulrich Beck (1992) argues that "a universalization of hazards accompanies industrial production, independent of the place where they are produced; food chains connect practically everyone on earth to everyone else" (p. 39). For example, terrorism in the age of globalization is seen as a global threat that can have consequences for both the global economy as well as individual governments, posing new forms of security threat which require both local and global governance.

In fact, reductionist models of globalization have limited their analyses to primarily economic and/or technological perspectives. These perspectives stress the "growing integration and liberalisation of worldwide markets, the development of communications and transport technologies and the rapid growth of global governance institutions above and beyond the state" (Stammers & Eschle, 2005, p. 55). Marxist and neo-Marxists view technological and institutional developments as indicative of a shift in the more fundamental structures of capitalism while being uncertain of whether these have constrained or empowered local spaces (Stammers & Eschle, 2005, p. 55).

Giddens (1990, 1999) defines globalization as not a singular process, but a complex set of processes that operate in a contradictory and dialectical manner. While nations lose a degree of economic power through these processes, Giddens reiterates that globalization has also been the reason for cultural revival of local identities in different parts of the world. In tandem with the resonant theme of deterritorialization, the discourses of globalization in its initial phases also mooted the withering of nation states and the inability of politicians to influence events. Hardt and Negri (2000) propound that in the age of globalization, a system of imperialism is created through a network of global and supranational entities that have forced nation states in some ways to compromise their jurisdiction and sovereignty. While postmodernity has not witnessed the demise of the nation state, it has nevertheless witnessed the emergence of global governance through intermediary and international institu-

tions such as the World Trade Organization, International Telecommunication Union, and the World Intellectual Property Organization (WIPO). The nation state is vulnerable to market pressures to liberalize and attract investments and equally, to preserve its sovereignty and jurisdictions despite these external and global pressures.

As such, globalization has also been equated with internationalization and liberalization denoting the increase in interdependence between nation states and the "removal of government-imposed restrictions on movements between countries in order to create an open and borderless world economy" (Scholte, 2000, p. 6). In tandem with the discourse of globalization and proliferation of ICTs is the use of the term "Information Society," which stresses the "rapid adoption and diffusion of new ICTs which has also precipitated the call for the liberalization of the telecommunications industry to reduce the barriers to the adoption of the new technologies and to ensure equal access to the global infrastructure" (Wolfe, 2000).

On the other hand, globalization has been associated with hegemonic discourses of cultural imperialism, where there is a flow of ideas and tangible and intangible cultural goods from the West to the East. Thus, globalization has been discussed as synonymous with modernization or westernization where the social structures of modernity, such as industrialization and rationalization, are spread over the world. Information and entertainment themselves have emerged as major industries and are presently the fastest growing segments of the global economy, characterised by the highest degrees of concentration and centralization compared to other sectors (Ghosh, 2004, p. 101). As Ghosh (p. 101) asserts, the "multimedia boom has spawned large multimedia companies that constitute the largest Multinational Corporations (MNCs). Cultural imperialism is then manifested in the bulk of the content, forms of expressions and structures of ownership and management reflect the domination of the core capitalist countries, especially the US." Nicholas Negroponte argues that in the information age, the mass media is both small and big, with global players, such as CNN, that reach a global audience. In comparison, new types of technology have also enabled narrowcasting, which caters to small demographic groups.

As Stammers and Eschle (2005, p. 57) point out, one main argument that has dominated discussions about globalization is the "tension between homogenising and fragmenting tendencies within globalizing processes and potential emergence of diverse innovative and hybrid cultural, political and even economic forms." In line with this, local responses to global processes become a major issue of scrutiny in globalization debates, where localization denotes both the tensions between the local spaces and global processes as well as cultural and social appropriation, negotiations, and hybridization that can happen in local spaces as a response to these global processes and influences. Robertson (1992), though acknowledging the time-space compression enabled by ICTs, contends that it also accentuates the tensions between global, societal, and communal attitudes and in this sense, while certain imported themes can be indigenized, others may be resisted or adapted in particular ways. In a similar vein, Appadurai (1997) negates the homogenization thesis through a recognition that the appropriation of ideas and practices in indigenous societies can be mediated through their cultural landscape (i.e., geographies, histories, or languages).

Thoman Friedman (2005) proposes that we are entering an accelerated phase, which he terms as Globalization 3.0, that captures the global changes facilitated by the semantic Web, where there is a fusion of people and lifestyles through a complex layering of economies and cultures. For Friedman, this entails ubiquitous computing, fibre optics, better bandwidth capacity, and software that connects nations, corporations, and people in an unrelenting manner. Friedman argues that the semantic Web, with English as its *lingua franca*, will homogenize through language and will accentuate the flattening of cultures. The recent discourses about the semantic Web argue for the need to pursue a "universal" imperative, viewing it more than a linguistic concept. Cho and Giustini propound that the semantic Web is actually a way to translate and merge languages, including computer languages, into something universal. This entails promoting standards for databases through the incoporation of artificial intelligence so that similar concepts are not confused within the Internet, enabling users to retrieve information without confusion between similar terms or concepts. While Web 2.0 is seen as a "disjoined space where everything is miscellaneous and governed by the dichotomy of the global-local dynamic" (Cho & Giustini), the semantic Web reinstates the need for a universal logic or language beyond the linguistic notions of language. While Web 2.0 conveyed the increased intractivity, customization, and social aspects of the Internet along with its viability as an advertising medium, the semantic Web emphasises the integration of data where there will be cross-referencing between countless data bases. This will affect the social and economic ways in which people, advertisers, and industries engage with technology and information in a global society.

From an economic perspective, globalization denotes a global economy in which capital markets are interconnected, and where investments and savings in indigenous economies can be affected by the behaviour of global financial markets (Castells, 1998). Undeniably, foreign direct investments and the activities of transnational companies are also seen as important, as well as contentious, components of the globalization process in the last few decades (Zanfei, 2005, p. 9). According to Greg Buckman (2004, p. 35), there are two groups of institutions that are relentless in their promotion and expansion of economic globalization. These include the world's transnational corporations (TNCs), which control most of the investment, trade, and employment decisions of

economic globalization. The other is the public international financial institutions created to oversee the management of economic globalization, which include organizations such as the World Bank and the International Monetary Fund (IMF).

In stressing the role of the MNCs, Bailey et al. (cf. Castells, 1998) point out that while in the early 1990s MNCs employed directly only about 70 million workers, producing one-third of the world's total private output, these, at times, outweighed the total value of world trade. Consequentially, MNCs in manufacturing, services, and finance constitute the core of the world economy, which creates dependence between local firms and global marketplaces, thus impacting the fate of workers and their life outcomes at local levels (Castells, 1998). This highlights the fact that the mode of production has been reconfigured in the information society, where knowledge-based activities have come to play a central role in the production process and the rise in the proportion of the labour force that deals with the production, distribution, and processing of information and knowledge, in contrast to the proportion which handles tangible goods (Wolfe, 2000, p. 2). Additionally, the globalization of technology is also linked to the increasing significance of research and design (R&D) in the new paradigm, while ICTs have been the main catalyst in stimulating new technical and social networks that can enable strategic planning for MNCs (Wolfe, 2000). This can include technology transfer and outsourcing, which can transform the structure of the global economy (Nelson, 2005). The transfer of technology across borders to different cultural environments is one way in which ICTs are involved in cross-cultural interaction (Walsham, 2001). Thus, in the context of rapid development and dissemination of new knowledge, innovation has become a critical element of competitiveness, which has led to global innovation networks enabling sharing and reciprocity of knowledge, as well as the exploitation and the reinstatement of national identity and ownership through patents and copyrights (Fruchterman, 2007; Rycroft, 2002).

The concept of globalization, Wolfe (2000) argues, implies that "individual economies are becoming more transnationalized or integrated into the international economy and this entails losing an important degree of national sovereignty and autonomy" (p.2). Globalization, Wolfe contends, can encompass the "growing integration of markets and production strategies which facilitates the design and production of goods for global, rather than simply national markets as well as the sourcing of components on a global basis." The reduction in transportation and communication costs, along with the digitalization of information, has resulted in the physical distintegration of production, as different components of a final product are now manufactured in several different countries (Fruchterman 2007). The growth, demand, and migration of highly-skilled labour is also indicative of a world economy. Castells (1998) reiterates that this global economy is a relatively new entity in terms of its history as the infrastructure (i.e., telecommunications, information systems, microelectronics-based manufacturing and processes, information-based air transportation, container cargo transport, etc.) required to facilitate it has only been available in the last two decades.

Castells (1998, p. 3) contends that since the 1990s, the entire planet has become organized around telecommunicated networks of computers at the heart of information systems and telecommunication networks, and categorises the availability of ICTs as a prerequisite for economic and social development in our world. Technological advances in microprocessors, fibre optics, memory chips, along with other complementary technologies, have dramatically increased the speed, storage, and processing capacity of computers and telecommunication networks. Kahin and Neeson (cf. Wilson, 1998, p. 8) are of the view that the present 'information revolution' will have a far greater and qualitatively different impact compared to any previous phenomenon. The role of ICTs has also been bound with development studies literature where the use and dissemination of media is seen crucial to both economic and political development (See Lerner 1958). In contrast others have argued that such media technologies are amenable to abuse by governments for political propaganda.

On the other hand, the adoption and proliferation of ICTs are seen as an enabling force not just for business and trade, but also for governments where innovations in information technology and policy, including data warehousing, civic networking, and the Internet, can provide new means to create public agencies that emphasise democratic participation and citizen access to information (Sunarno 2001, p. 64). ICTs have been framed as both enhancing and debilitating democracy. Theorists (See Talero, 1997; Toffler, 1980) have suggested that the information revolution will enable citizens to be connected to one another and to sources of power that will bring transparency to internal governmental processes and help liberate political debates and, in the process, deliver new ways of expressing and aggregating individual and communal expressions.

Globalization from this perspective has also been viewed as "bottom up," where globalization of ICTs can lower communication and coordination costs for NGOs and social movements to distribute their messages, mobilize support, and influence public discourse (Wilson, 1998, p. 34). As pointed out by Benjamin Barber (1996, p. 17), the information revolution unleashes both centrifugal and centripetal forces where homogenization tendencies will be counter-balanced by balkanization in terms of political and social expression. According to Bill Robinson (2004, p.184), the rise of a global justice movement is the clearest example that popular and transitional forces had begun to transnationalise in the 1990s,

moving to create alliances, networks, and organizations that transcend national and even regional borders.

Many nations around the world have recognised the role that ICTs can play in socioeconomic development (Ogunsola, 2005), whether they be developing or developed nations. Manuel Castells (1998) argues that though technology on its own does not resolve social problems, the availability and use of information and communication technologies are prerequisites for economic and social development in our world. For Castells (1998), ICTs can be a double-edged sword for, on the one hand, they have the ability to boost economies when complemented with the right policies of augmenting technical literacy and education in a country. On the other hand, countries that do not adapt to the changing technical landscape can be left behind, thus imposing an uneven spread of economic and social benefits that can then exacerbate the digital divide. Alan Freeman (2004, p. 47) supports the hypothesis that globalization has doubled the inequality between the advanced countries and the rest of the world. Freeman argues (2004) that in 20 years (assuming that the starting point of globalization is 1980), globalization has reasserted and sharpened the division of the world's nations into two fundamentally unequal blocs (p.47). As Buckman (2004, p. 68) points out, since the start of the Industrial Revolution rich countries have benefited more from economic globalization than poorer countries, and in recent decades some countries have become even poorer as a result of it.

FUTURE TRENDS

The processes of change that globalization have unleashed in developed and developing economies will inevitably be contradictory and uneven, warranting closer cooperation between countries and governments. In the process, they will increase the growing interdependence of countries, but also cement existing power structures in which the more economically powerful countries will increase their power to make decisions on many aspects of global governance, including poverty, environmental concerns, disease control, the digital divide, and global migration patterns, among others. The recent rhetoric on globalization has focused on issues of inequality, resistance to globalization, and the new forms of dependence that less developed countries are subjected to in a globalized world. The rise of global civil society organizations, and their use of ICTs to express and harness support locally and globally against international organisations such as the WTO and the IMF, exemplifies the present forms of concern that occupy globalization debates. In addition, since the events of 9/11, increased globalization is perceived to result in increased risks. Such risks transcend "national borders and bring into being supranational and non-class specific global hazards with a new type of social and political dynamism" (Beck 1992, p. 13). Due to an overwhelming recognition in the world community of environmental issues, exploring resources, services, and solutions within local contexts is also being put on the political agenda in different societies, and will continue to be a major concern in the coming years.

CONCLUSION

Globalization as a phenomenon has been analysed from various perspectives. The optimists, pessimists, rejectionists, and the anti-globalisation advocates have discussed issues ranging from the economic, political, social, and technological to the cultural, illuminating the diverse and dialectical processes that embody the term.

The interconnectedness of the world through ICTs has provided nations with opportunities and problems. It has allowed richer nations to profit from the ability to make strategic alliances, and to produce and source globally while creating global markets for their products and services. For less developed nations, it has created a siege mentality and a fear that they may be left far behind if they do not adapt to the changing nature of the world economy. This, in tandem, has produced varying degrees of media literacy, as well as digital and economic divides in various parts of the world. Globalization has also been discussed as a form of cultural imperialism, with the emergence of global media players and the rise in Western cultural imports to the rest of the world. Equally, local responses to global cultural flows and indigenous forms of production and consumption have also been argued as forms of resistance, as have localization and hybridization of global and local products and practices. Globalization and ICTs have also been bound with both political democratization and its opposite, where technologies present opportunities for abuse by governments through centralization of information, but also empowerment of citizens through information dissemination and aggregation of public opinion.

Despite the new forms of engagement and connectivity presented by ICTs, and the emergence of global governance as well as social networks, age-old problems, such as poverty and disease, still plague the globe. In addition, the new connectivities facilitated through communication and transport networks will constitute new forms of risks that will be borderless, global, and instantaneous, such as the threat of terrorism and disease (Beck 1993). Zygmunt Bauman (2006, p. 98) captures the zeitgeist of this postmodern condition by eloquently arguing that in a "planet tightly wrapped in the web of human interdependence, of nothing which the others do or can do we may be sure that it won't affect our prospects, chances and dreams."

KEY TERMS

Digital Divide: The separation between the information rich, or haves, and information poor, or have-nots.

Globalization: The integration of the world through a complex set of social, economic, political, technical and cultural processeses

ICTs: Information and communication technologies, seen as the driving force of globalization and new forms of connectivity.

Information Society: The transition from the modern and industrial age in which modes of production, exchange, and social capital are increasingly defined through information

MNCs or Multinational Corporations: In the age of globalization, MNCs have an increasing role in global economies, flow of capital, and in the formation of strategic economic and global alliances.

Network Society: The rise of information society will see the emergence of a network society in which information and technology will enable the formation of networks and strategic planning.

Postindustrial Society: The transition from the industrial society will lead to a postindustrial society characterised by increasing emphasis on global connectivity and capitalisation of information.

Technology Leapfrogging for Developing Countries

Michelle W. L. Fong
Victoria University, Australia

INTRODUCTION

Information and communication technologies (ICTs) have been acknowledged, in research works on developed and industrialized countries, for their potential in opening up development opportunities. At firm level, ICTs can facilitate communications and coordination of processes within a firm or between firms in a supply chain such as through e-collaboration (Fong, 2005; Hammant, 1995; Jin, 2006; Porter, 2001; Porter & Millar, 1985). These technologies can also improve management decision-making process through better and faster marshalling of information. Gains from these applications may be in the form of scale economies, cost-savings, increased productivity, and improved competitiveness (Bourlakis & Bourlakis, 2006; Farrell, 2003; Hammant, 1995; Howgego, 2002; Pilat, 2004; Porter & Millar, 1985). At industry level, ICTs can improve the functioning or governance of market (James, 2000; Malone, Yates, & Benjamin, 1989; Matsuda, 1994; OECD, 2005). From the social-economic perspective, ICTs can improve quality of life of communities, provide greater access to health and education services, and create economic opportunities for any underprivileged population groups (Mercer, 2001; Oberski, 2004; Reisman, Roger, & Edge, 2001; The World Bank, 2001; UNDP, 2001a; United Nations, 2006). All these improvements in efficiency and access are likely to be aggregated at the national level in the form of economic growth or sustainability, and welfare gains (Madden & Savage, 2000; OECD, 2005).

Developing countries are generally latecomers to the ICT revolution, but if they can emulate industrialized countries in their adoption of ICTs, they will be afforded the same technological opportunities. Successful exploitation of such opportunities by developing countries can significantly narrow the economic gap between them and developed countries as they catch up in economic development.

In ICT's advancement trajectory, the opportunities offered by a newly emerged ICT tend to be superior to those of prior versions of technology. If a developing country leapfrogged to a newly emerged ICT, it would then be exposed to unprecedented potential in alleviating poverty and securing economic growth, as well as the possibility of surpassing developed and industrialized countries in economic development. Thus, technology leapfrogging is an attractive notion to developing countries, but is it a realistic goal?

BACKGROUND

"Technology leapfrogging" refers to the adoption of advanced or state-of-the-art technology in an application area where immediate prior technology has not been adopted. Discussions of ICT leapfrogging have largely focused on developing countries, which generally lag behind on technology adoption, and unlike the developed countries, are not inhibited by entrenched intermediate technology. New and advanced technology provides developing countries with the opportunity to accelerate economic development (Hanna, Guy, & Arnold, 1995; Prayag, 2001; OECD, 2005; UNDP, 2001b). In addition, the advancement of ICTs has reduced costs and imposed lesser demands on the skill of the users due to user-friendly features (Ensley, 2005). The possibility of achieving significant economic growth through advanced and less costly technology thus seems exceptionally attractive to developing countries. It has also been suggested that developing countries do not have any alternative in technology adoption, except to leapfrog to new and advanced technologies (Choucri, 1998; Mansell & Wehn, 1998; Davison, Vogel, Harris, & Jones, 2000).

The concept of technology leapfrogging for ICTs first emerged in the early 1990s (Antonelli, 1991; Lamberton, 1994; Mody & Dahlman, 1992). However, research works in this area were still limited, hindered by a lack of clear empirical data from developing countries, measurement difficulties, the relatively short-time span of newly emerged and advanced ICTs, and the long time span involved in gathering reliable data to understand technology leapfrogging in developing countries (Alzouma, 2005; Ausubel, 1991; Prakash 2005; Sharif, 1989; UNESCO, 1996).

As a result, technology leapfrogging remains a controversial concept. For example, in the case of Africa, Chisenga (2000) believes that the implementation of this concept would facilitate global integration of businesses, and provide a better learning environment for African children, all to the benefit of the economy. Ochieng (2000), on the other hand, believes that investments in ICT compete with the provision of basic necessities for the poor. One of the general arguments against leapfrogging has been that it might turn out to be an expensive trajectory in the short run for developing countries, which tend to bear a high burden of debts (Chen, Farinelli, & Johansson, 2004). In addition, investment in a

new technology is likely to involve a long payback period for developing countries because of the nascent conditions of their market. It has been further argued that the worst possible outcome from this exercise would be when the new investment was displaced by a major breakthrough before these developing countries geared up in their capabilities to sufficiently harness their technology investment. Some commentators believe that the developmental effects of ICT applications have been greatly exaggerated and caution that advanced technology makes little difference and can even inflict harmful effects, such as creating a digital divide, in the lives of people in developing countries (Mansell, 1999; Sussman, 1997; United Nations Commission on Science for Technology and Development, 1997; Van Dijk, 1999; Wang, 1991).

Kojima (2003, p. 1), however, highlighted that the concept of technology leapfrogging requires selective and discerning application. She noted that technology leapfrogging is applicable to certain technologies such as ICTs but not to emission control technology, a field where developing countries should wait for developed countries to test out the emerging technology before adopting it.

LEAPFROG TO WIRELESS ICTs

It has been claimed that leapfrog technologies are largely those that do not rely on tangible grid. These include mobile phones, satellite communications, and decentralized power sources like solar power (Article 13, 2005). Wireless ICTs, such as mobile phones, have emerged as a leading leapfrog technology (BBC News, 2002; Nkwae, 2002; Cascio, 2004). Mobile phone communication technology has even substituted the traditional fixed networks in developing countries such as China and many African countries.

Leapfrog wireless communications technologies (ICTs) have often generated significant benefits for communities. For example, villages in Robib, Cambodia, were reported to have leapfrogged from an agricultural to an information economy through wireless network (oneworld radio, 2006). The villagers were able to access medical and health services, and a global marketplace for their cottage industry through wireless communications technology. In Africa, information available through mobile phones enabled farmers in Senegal to double the prices of their crops and herders in Angola to locate their cattle through GPS (global positioning system) technology (oneworld radio, 2006). In another study by Williams on "The relationship between mobile telecommunications infrastructure and FDI in Africa" (as cited in Vodafone, 2005), at least 50% of small businesses surveyed in South Africa and Egypt attributed profit increases to mobile phone usage. The same study also found that more than 75% of respondents in Tanzania and South Africa experienced improvement in contact and relationships with close ones because of mobile phone communications technology (Vodafone, 2005). In all these cases, however, the actual benefits from leapfrogging were yet to be ascertained at the aggregate level.

Technology by itself does not solve problems, but the availability and use of ICTs are a prerequisite for economic and social development in developing countries. In other words, ICTs are not a standalone solution to development problems. Developing countries characteristically lack many of the conditions needed to harness and sustain leapfrog-type development offered by new and advanced technology. Because the conditions in developing countries are usually weak or inadequate, cultivating, building, and deepening these conditions to support the mastery, applications, diffusion, and innovation of leapfrog technologies are unlikely to prove easy or straightforward. It is therefore anticipated that developing countries would not be able to fully utilize or exploit the potential of advanced technology at the early stage of leapfrogging due to their limited infrastructure. Despite this, there is no point for developing countries to go through the fiber optic building process for their telecommunication infrastructure when they could start out with wireless telecommunications. Leapfrogging to wireless communications technology is a valid strategy based on the promising technology's potential for economic advancement, and the lower costs and resources involved in setting up a telecommunication infrastructure. It has been estimated that wireless technologies cost about 20% of traditional wired installations (United Nations General Assembly and Economic & Social Council, 2000). Developing countries should develop and strengthen their infrastructure within the framework of advanced technology rather than time- and resources-consuming intermediate technology that is likely to prolong their subservient position in development. In capabilities development and learning processes for example, developing countries should be exposed to and educated in the skills required by higher-level technologies.

However, technology leapfrogging may pose very high risks to developing countries if immature or unproven technologies are involved. Despite this, the risks can be managed and minimized by careful planning and evaluation, to capitalize on the opportunities of leapfrog technology. Otherwise, they are likely to end up as expensive failures. In the planning and implementation of any technology leapfrogging process, developing countries need to take into consideration a number of factors (shown in Figure 1) which are likely to impact on the time span involved in the mastery, applications, diffusion and innovation of the technologies involved.

Figure 1 includes certain conditions such as literacy and education that cannot be immediately emulated or leapfrogged despite their undoubted importance in reaping the greatest advantages from advanced ICTs. The nurturing of human capabilities requires substantial investment in

Table 1. Factors relevant to conditions for technology leapfrogging

Factors	Example of issues	Source
Market condition: • Market demand • Market competition	• Market competition for rational pricing of ICT & access, • Development of locally relevant content and languages to promote advanced technology uptake, • Foreign participation through investment to break down monopoly structure.	Adzadi, 2001; Alzouma, 2005; Choucri, 1998; Davison et al., 2000; Ensley, 2005; Garcia & Gorenflo, 1999; Grace et al., 2001; Haddad & MacLeod, 1999; International Telecommunication Union, 2004; Mansell, 1999; Mbambo, 1996; Nkwae, B. (2002); OECD, 2005, 2006; Praskash, 2005; Pringle & David, 2002; Raji et al., 2006; Sehrt, 2003; Sinha, 2005; UNDP, 2001a, 2001b; United Nations General Assembly and Economic & Social Council, 2000; Vodafone, 2005; Wijkman & Afifi, 2002.
Institutional capacity	• Support for intellectual capital development, • Development of stable learning and attractive investment environment, • Ensuring security and stability in the environment, • Establishment of an enabling regulatory and legislative framework, • Economic, social, and political stability.	
Social	• Ensuring equity in digital access, • Narrowing or erasure of digital divide.	
Human capabilities	• Improvement of literacy and computer literacy levels, • Nurturing of requisite skills and expertise. • Continuous investment.	
Government	• Definitive guiding policies, • Strategic deployment of ICT, • Coordination and linkages among actors in the system.	
Stakeholders	• Interaction and strategic links among actors in the system, • Regional and international cooperation and collaboration, • Identification of e-champions and e-leaders to spearhead technology leapfrogging projects.	
Utility infrastructure	• Electricity, transportation networks, etc.	

education and skills transfer, and also government intervention to expedite the development and accumulation of human capabilities. Governments, besides being providers of national education, can use incentives to encourage private initiatives in the provision of training resources.

In regard to market conditions, telecommunication markets that are operated by a monopoly which charges high access fees represent a serious obstacle to advanced technology uptake and investment. The ITU (2004) observed that mobile markets of competitive structure have significantly higher rates of mobile penetration than monopoly markets, even where per-capita incomes are the same. Competition is important for making access cost affordable to users, and for developing products and services that meet users' requirements. This in turn would help to generate substantive market demand and confidence in future technology investment.

In addition to achieving competitive market conditions, strong legislative frameworks must be introduced to provide environmental stability and security, such that businesses are confident to invest and consumers are confident to uptake new technology and trial its sophisticated potentials. Governments in developing countries are likely to face the challenge of designing an appropriate regulatory environment to support and enable effective operation of a sophisticated telecommunication infrastructure. However, an appropriate regulatory environment could be achieved through goodwill assistance from experienced international aid agencies and developed countries. Such assistance should not be limited to regulatory or legislative environment; developing countries in fact require partnerships and long-term support at the local, national and international levels for their capabilities and other institutional capacity building, research and development, and innovation of leapfrog technologies.

It must also be noted that a new and advanced technology, which is capable of offering development opportunities to developing countries, may also be capable of creating a digital divide within these economies. Therefore, advanced technology adoption and diffusion must be user-focused rather than technology-focused, as social issues can turn out to be a formidable barrier to technology leapfrogging. To prevent the emergence of digital divide, government-donor-community-enterprise partnerships may be initiated to support ongoing projects of expanding wireless communication access to rural areas. To advance the goals of a country's leapfrogging strategy, commitments from a strong network of governmental and nongovernment participants including e-leaders and e-champions, are vital for its success.

FUTURE TRENDS

In communications technology adoption, wireless and mobile technologies offer a relatively quicker and less costly way to leapfrog the more expensive and time-consuming task of building fixed-line telephone networks. In addition, these technologies are built on an easily deployable infrastructure. As a result, wireless and mobile communication technologies will become a dominant medium in developing and transitional countries in the coming years.

The wireless mobile phone industry is in the early phase of deploying its third generation (3G) technologies, which are capable of sophisticated communication features. These technologies have the potential to integrate data communications and computing capabilities into handsets such as mobile Internet. The full deployment of 3G technologies will change industry value networks through their wide range of nonvoice services.

CONCLUSION

Technology leapfrogging is likely to be difficult and challenging for developing countries. Rather than start out with traditional fixed-line solutions, developing countries should leapfrog to wireless technologies which offer a relatively quicker and less costly way of building a telecommunication infrastructure. However, economic development benefits may not quickly accrue to developing countries in their leapfrogging efforts. These countries are likely to take a considerable period of time in building their capabilities to absorb, master, use, and innovate leapfrog technologies. Nevertheless, the process may be expedited by the deliberate policies and guidance of governments in these countries, with support from the international arena. At the same time, governments in these countries must constantly reassess the impact of policies and align them with the social objectives so as to remain user-focused in the need to harness the technology quickly.

KEY TERMS

Digital Divide: Refers to the disparity between two or more groups of people in their access to digital technology. Digital divide can occur at national level (between different groups within the economy) and/or global level (between different countries or regions).

E-Collaboration: A process by which internal and external individuals and/or groups work together on a practical endeavour through integrated electronic networks enabled by ICTs or coordination technologies.

GPS: A global positioning system that uses satellites, computers, and receivers. It can be used for navigation and tracking purposes, based on computer calculation of time difference between signals emitted from satellites and received by receivers.

ICT: Encompasses all the technology that facilitates the processing, transfer and exchange of information and communication services.

Productivity: In economic terms, is the value of output produced using one unit of input. Workplace productivity generally means output per worker. For a considerable period of time, economists failed to determine the relationship between investments in ICT and productivity. This phenomenon was known as "productivity paradox". Although evidence of this relationship has emerged from studies at the firm level in recent times, measures of it at the aggregate or industry level remain nebulous (Pilat, 2005).

Technology-Enhanced Progressive Inquiry in Higher Education

Hanni Muukkonen
University of Helsinki, Finland

Minna Lakkala
University of Helsinki, Finland

Kai Hakkarainen
University of Helsinki, Finland

INTRODUCTION

In higher education, students are often asked to demonstrate critical thinking, academic literacy (Geisler, 1994), expert-like use of knowledge, and creation of knowledge artifacts without ever having been guided or scaffolded in learning the relevant skills. Too frequently, universities teach the content, and it is assumed that the metaskills of taking part in expert-like activities are somehow acquired along the way. Several researchers have proposed that in order to facilitate higher-level processes of inquiry in education, cultures of education and schooling should more closely correspond to cultures of scientific inquiry (e.g., Carey & Smith, 1995; Perkins, Crismond, Simmons & Under, 1995). Points of correspondence include contributing to collaborative processes of asking questions, producing theories and explanations, and using information sources critically to deepen one's own conceptual understanding. In this way, students can adopt scientific ways of thinking and practices of producing new knowledge, not just exploit and assimilate given knowledge.

BACKGROUND

The best practices in the computer-supported collaborative learning (CSCL) paradigm have several features in common: consideration in an interrelated manner of the development of technological applications, use of timely pedagogical models, and attention to the social and cognitive aspects of learning. Emphasis is placed on creating a collaborative community that shares goals, tools, and practices for taking part in an inquiry process.

Synthesizing these demands, Hakkarainen and his colleagues at the University of Helsinki have developed a model of *progressive inquiry* as a pedagogical and epistemological framework. It is designed to facilitate expert-like working with knowledge in the context of computer-supported collaborative learning. It is primarily based on Scardamalia and Bereiter's (1994) theory of knowledge building, on the interrogative model of scientific inquiry (Hintikka, 1999; Hakkarainen & Sintonen, 2002), and on the idea of distributed expertise in a community of learners (Brown & Campione, 1994). The model has also been implemented and studied in various educational settings from elementary to higher education (see, e.g., Hakkarainen, Järvelä, Lipponen, & Lehtinen, 1998; Lipponen, 2000; Veermans & Järvelä, 2004; Muukkonen, Lakkala, & Hakkarainen, 2005; Lakkala, Lallimo, & Hakkarainen, 2005; Lakkala, Ilomäki, & Palonen, 2007).

The Progressive Inquiry Model

In progressive inquiry, students' own, genuine questions and their previous knowledge of the phenomena in question are a starting point for the process, and attention is drawn to the main concepts and deep principles of the domain. From a cognitive point of view, inquiry can be characterized as a question-driven process of understanding; without research questions, there cannot be a genuine process of inquiry, although in education, information is frequently conveyed or compiled without any guiding questions. The aim is to explain the phenomena in a deepening question-explanation process, in which students and teachers share their expertise and build new knowledge collaboratively with the support of information sources and technology.

The progressive inquiry model specifies certain epistemologically essential processes that a learning community needs to go through, although the relative importance of these elements, their order, and actual contents may involve a great deal of variation from one setting to another. As depicted in Figure 1, the following elements have been placed in a cyclic, but not step-wise succession to describe the progressive inquiry process (Hakkarainen, 2003; Muukkonen, Hakkarainen, & Lakkala, 1999, 2004):

a. *Distributed expertise* is a central concept in the model. Progressive inquiry intends to engage the community in a shared process of knowledge advancement, and to convey, simultaneously, the cognitive goals for collaboration. Diversity in expertise among participants, and interaction with expert cultures promotes knowledge advancement (Brown et al., 1993; Dunbar, 1995). Acting as a member in the community includes sharing cognitive responsibility for the success of its inquiry. This responsibility essentially involves not only completing tasks or delivering productions on time, but also learners taking responsibility for discovering what needs to be known, goal setting, planning, and monitoring the inquiry process (Scardamalia, 2002). There should be development of students' (and experts') social metacognition (Salomon & Perkins, 1998): students learning to understand the cognitive value of social collaboration and gaining the capacity to utilize socially distributed cognitive resources.
b. The process begins by *creating the context* to anchor the inquiry to central conceptual principles of the domain or complex real-world problems. The learning community is established by joint planning and setting up common goals. It is important to create a social culture that supports collaborative sharing of knowledge and ideas that are in the process of being formulated and improved.
c. An essential element of progressive inquiry is *setting up research questions* generated by students themselves to direct the inquiry. Explanation-seeking questions (Why? How? What?) are especially valuable. The learning community should be encouraged to focus on questions that are knowledge driven and based on results of students' own cognitive efforts and the need to understand (Bereiter, 2002; Scardamalia & Bereiter, 1994). It is crucial that students come to treat studying as a problem-solving process that includes addressing problems in understanding the theoretical constructs, methods, and practices of scientific culture.
d. It is also important that students explain phenomena under study with their own existing background knowledge by *constructing working theories* before using information sources. This serves a number of goals: First is to make visible the prior (intuitive) conceptions of the issues at hand. Second, in trying to explain to others, students effectively test the coherence of their own understanding, and make the gaps and contradictions in their own knowledge more apparent (e.g., Hatano & Inakagi, 1992; Perkins et al., 1995). Third, it serves to create a culture in which knowledge is treated as essentially evolving objects and artifacts (Bereiter, 2002). Thoughts and ideas presented are not final and unchangeable, but rather utterances in an ongoing discourse (Wells, 1999).
e. *Critical evaluation* addresses the need to assess strengths and weaknesses of theories and explanations that are produced, in order to direct and regulate the community's joint cognitive efforts. In part, it focuses on the inquiry process itself, placing the process as the center of evaluation and not only the end result. Rather than focusing on individual students' productions, it is more fruitful to evaluate the community's productions and efforts, and give the student participants a main role in this evaluation process. Critical evaluation is a way of helping the community to rise above its earlier achievements, creating a higher-level synthesis of the results of inquiry processes.
f. Students are also guided to engage in *searching deepening knowledge* in order to find answers to their questions. Looking for and working with explanatory scientific knowledge is necessary for deepening one's understanding (Chi, Bassok, Lewis, Reiman, & Glaser, 1989). A comparison between intuitive working theories produced and well-established scientific theories tends to show the weaknesses and limitations of the community's conceptions (Scardamalia & Bereiter, 1994). The teacher of a course must decide how many of the materials should be offered to the students and how much they should actually search out for themselves. Questions stemming from true wonderment on the part of the students can easily extend the scope of materials beyond what a teacher can foresee or provide suggestions for. Furthermore, searching for relevant materials provides an excellent opportunity for self-directed inquiry and hands-on practice in struggling to grasp the differences between various concepts and theories.
g. *Generating subordinate questions* is part of the process of advancing inquiry; learners transform the initial big and unspecified questions into subordinate and more specific questions, based on their evaluation of produced new knowledge. This transformation helps to refocus the inquiry (Hakkarainen & Sintonen, 2002; Hintikka 1999). Directing students to return to previously stated problems, to make more subordinate questions and answer them, are ways to scaffold the inquiry.
h. *Developing new working theories* arises out of the fresh questions and scientific knowledge that the participants attain. The process includes publication of the summaries and conclusions of the community's inquiry. If all productions to the shared database in a collaborative environment have been meaningfully organized, participants should have an easy access to prior productions and theories, making the development of conceptions and artifacts a visible process.

Cases of Progressive Inquiry in Higher Education

Progressive Inquiry in a Cognitive Psychology Course

In a study reported by Muukkonen, Lakkala, and Hakkarainen (2001), the progressive inquiry model was implemented in a cognitive psychology course with the use of the Future Learning Environment (FLE). The FLE is an open-source collaborative tool that has the progressive inquiry model embedded in its design and functionality (http://fle3.uiah.fi/; Muukkonen et al., 1999). All the students in the course were guided, during the first two lectures, to formulate research problems. In the beginning, they individually produced these formulations. They continued by discussing their research problems with a peer and, finally, within a small group, selected the most interesting questions to pursue. These questions were then presented to all the participants in the lecture. After this initial problem setting, the technology-mediated groups (three groups of 4-7 volunteers) were instructed to continue their inquiry processes between the weekly lectures in the FLE. The tutor-facilitators took part in the FLE, whereas the teacher conducted the weekly lectures without participating in the database discourse. The rest of the students also formed groups based on their questions, but continued their inquiry process by writing learning logs and commenting on the logs produced by other members of their group without collaborative technology.

A comparative analysis of the knowledge produced by the students in the two conditions provided evidence that the technology-mediated groups were more engaged in problem-setting and redefining practices. Further, they reflected on the process they had undertaken, in respect of the collaboration and their individual efforts. In the productions of the groups who had not used collaboration tools, the social and communal aspects of inquiry and knowledge building were not evident at all in their learning logs, although they were engaged in collaboration during the lectures. The type of comments they provided to two of the learning logs written by other members of their group were very general, and they concentrated mainly on evaluating the level of writing, not on advancement of ideas. However, many of the learning logs were conceptually well developed and integrated. Discourse interaction within the FLE was different in respect of

the participants sometimes engaging in extensive dialogues with ideas presented by the fellow students.

Progressive Inquiry in a Design Course

Two studies carried out by Seitamaa-Hakkarainen and her colleagues (Seitamaa-Hakkarainen, Lahti, Muukkonen, & Hakkarainen, 2000; Seitamaa-Hakkarainen, Raunio, Raami, Muukkonen, & Hakkarainen, 2001) analyzed a collaborative design process as it occurred in a complex and authentic design task of designing clothing for premature babies. The framework of the studies was based on evidence from cognitive research on expertise, which indicated that novices in design tend to generate problem solutions without engaging in extensive problem structuring; experts, by contrast, focus on structuring and restructuring the problem space before proposing solutions (Glaser & Chi, 1988). The studies described in this case were designed to examine whether an expert-like engagement in design process would be supported in the FLE-environment. Features of the environment were used to encourage the users to engage in expert-like designing, and to enable graphic presentation of the knowledge artifacts in the form of importing students' drafts and prototypes into the collaborative environment and developing multiple versions of the designs.

During the collaborative design course, the students were first guided to find out information about the constraints of their design task, such as the size of the babies, special needs for the usability of the clothing, and about the materials. Then they were asked to produce their own sketches and work in small groups to share design ideas and develop their designs. Following this development, each group produced a prototype, which was tested by actual end users in a hospital. Feedback and suggestions were then used to develop advanced design ideas.

In these studies of designing with the support of a networked collaborative environment, Seitamaa-Hakkarainen et al. (2001) found that a key aspect of these environments is the provision of tools for progressive discourse interaction between the designers and users of the future products. Further, the environments offer shared spaces and tools to elaborate conceptual knowledge related to the design problem. The collaborative technology made design thinking more explicit and accessible to the fellow designers, and enabled participants to share their ideas and construct a joint understanding of design problems and solutions.

Supporting and Guiding Students' Progressive Inquiry Processes

A special question in implementing progressive inquiry and knowledge-building practices in higher education is the teacher's or tutor's role in supporting and guiding students' collaborative inquiry. In progressive inquiry, the traditional role of a teacher as an expert, who delivers the essential information by lecturing, is radically changed. The important roles of the teacher and the facilitators of collaboration are:

1. to create the context for the collaborative inquiry practices by organizing the community's activities and establishing the underlying conditions of the educational setting (Lakkala et al., 2005), and;
2. to supervise and scaffold the process, keep it active and in focus during the progression of the course, and to help students gradually take on themselves the responsibility for the higher-level cognitive processes (Scardamalia, 2002).

Our recent studies indicate that, in order to successfully engage students' in progressive inquiry, the whole educational setting should be carefully planned and constructed to support the eligible activities, because expert-like inquiry practices do not emerge spontaneously. However, it does not mean pre-planning detailed tasks, but *indirectly* designing conditions for the community's activities (Jones, Dirckinck-Holmfeld, & Lindström, 2006). Building on previous studies (e.g., Bielaczyc, 2001; Guribye, 2005; Lakkala et al., 2005; Paavola, Lipponen, & Hakkarainen, 2002), we have started to use the notion *pedagogical infrastructures* to illustrate how the pedagogical design of collaborative inquiry practices resembles the construction of basic physical infrastructure to support smooth and effective functioning of people's daily activities. We have developed the *framework of pedagogical infrastructures* (Muukkonen, Lakkala, & Paavola, in press; Lakkala, Muukkonen, Paavola, & Hakkarainen 2008), consisting of *technical*, *social*, *epistemological*, and *cognitive infrastructure*, to be used to classify, design, and evaluate the elements of educational settings based on technology-enhanced collaborative inquiry. The separate infrastructures exist in parallel, and in a successful educational setting, all aspects are taken care of and designed to foster collaborative knowledge creation: appropriate technology is easily accessible and it is used meaningfully (technical infrastructure); there is deliberate collaboration built into the tasks (social infrastructure); students' activity is organized to be creative working with knowledge, not just internalizing certain content (epistemological infrastructure); and students' autonomy and the development of skills are supported by explicit cognitive modeling of expert-like practices (cognitive infrastructure).

In addition to appropriate and supportive overall design of the educational setting for progressive inquiry, timely guidance and tutor's participation throughout the process is important for further shaping and directing students' engagement in inquiry. In one study (Muukkonen et al., 2005) we compared students' technology-enhanced inquiry practices in

two conditions, either with or without tutor participation. As evidence for the tutors' role, the process analysis recovered a more focused problem-setting tendency in tutored groups: instead of opening up new lines of questions, the tutored groups were more likely to present subordinate questions to previous ones. The results of another study, comparing three tutors' scaffolding practices (Lakkala et al., 2007b), indicated that the kind of advice and expert model that the tutor offered had an effect on the style of the inquiry discourse in the group: either it concentrated more on theory reviewing, focusing of the inquiry, or generating of divergent ideas. The scaffolding that appears to have promoted deepening discourse may be characterized as explicitly built on the students' preceding discourse and, accordingly, as providing a content-specific and well-timed expert recommendation to refocus the inquiry.

FUTURE TRENDS

Productive changes in educational systems towards establishing inquiry-based approaches in studying and teaching call for an alignment of pedagogical and institutional goals and actions (Muukkonen et al., 2004). Learning technologies also need to be critically viewed for their role in fostering expert-like skills in advancing knowledge. For instance, availability of scaffolding, support for multiple forms of collaboration, and shared development of knowledge objects are challenges for designing learning technologies.

CONCLUSION

The progressive inquiry model may be utilized in a variety of educational settings to provide a heuristic framework for the key activities and epistemic goals of a knowledge-building community. The community may provide multiple levels of expertise and, equally importantly, social support for engaging in a strenuous quest for learning and advancing knowledge. Especially in higher education, a progressive inquiry approach may support the development of academic literacy, scientific thinking, and epistemic agency, particularly when integrated with the use of appropriate collaborative technology and supportive arrangements in curriculum design.

KEY TERMS

Distributed Expertise: Cognition and knowing are distributed over individuals, their tools, environments, and networks.

Epistemic Agency: Taking responsibility over one's own learning efforts and advancement of understanding.

Knowledge Building*:* A framework for collective knowledge advancement and development of knowledge artifacts.

Learning Community/Community of Learners: All participants in a learning process (students, teachers, tutors, and experts) have valuable expertise and skills, which benefit collective efforts.

Metaskills: Skills involved in academic literacy, as well as metacognitive skills related to planning, monitoring, and regulating comprehension-related activities.

Progressive Inquiry: A pedagogical model for structuring and supporting a group of learners in a deepening question-explanation process.

Pedagogical Infrastructures: In the present context, the concept is intended to refer to the elementary preconditions that should be designed to shape and support collaborative inquiry practices in educational settings.

Scaffolding: Providing support, which enables a learner to carry out a task that would not be possible without that support, and enabling the learner gradually to master that task without support.

Teens and Information and Communication Technologies

Leanne Bowler
McGill University, USA

INTRODUCTION

In the late 20th century, the digital revolution in information and communication technology (ICT) moved into the homes and private lives of ordinary people. Unsurprisingly, the early adopters of domesticated ICT have been youth, young people between the ages of 12 and 19, whose lives have become increasingly shaped and mediated by information and communication technologies. Called the "Net Generation" (Tabscott, 1998, p. 3), these young people are leading the charge toward what the United Nations has called "an unprecedented and global media culture" (United Nations, 2003. p. 311).

The focus of this article is on how young people, ages 12–19, in the early 21st century use information and communications technologies. The wide and diverse nature of the landscape, composed of multiple platforms and applications in continuous change, necessitates a broad approach. Information technologies are now bundled with communications capabilities and vice versa, making a focus on one and not the other virtually impossible. Furthermore, one of the difficulties in studying ICT use among children and teenagers is that statistics and studies are still limited, even within digitally privileged countries. Ironically, while research in this area has focused on the educational use of ICT, young people overwhelmingly use it for personal reasons. This article, therefore, looks at ICT through a wide angle and offers a snapshot of the role of ICT in the lives of young people in the early days of the 21st century, suggesting in broad terms where the emerging issues and trends may lie.

BACKGROUND

Youth have traditionally been the early adopters of digital ICT, forging new patterns of information and communication behavior. The next generation of ICT users, those born after 2000, will move with even greater ease among the emerging information and communications technologies. This generation will enter their teen years never having known a world without personal computers, the Internet, cellular telephones (more commonly called "cell phones" in North America and "mobile phones" in the UK), and personal digital assistants. While the Net Generation's first experiences on the Web, and with ICT in general, were typically asynchronous and tied to a physical location, namely the home or classroom, young people who are now entering their teens increasingly find that information and communication technologies are accessible anywhere, anytime, and anyplace. Cell phones are quickly becoming personal digital assistants, providing a broad range of information services beyond basic voice capabilities. Portable hardware such as MP3 players and the "podcasts" used to deliver content from the Internet to the device have helped move the Internet beyond the desktop and into the street. The onset of Web 2.0 — the social Web — has further enhanced the immediacy of the experience.

For many young people living in digitally privileged societies, ICT represents a world of entertainment, the most popular activities being communicating with friends, online gaming, and downloading music (United Nations, 2003). ICT now rivals home and school as a "space" for socialization and identity development. While opportunities await technology-savvy educators and marketers — reaching young people "where they live" and in a language they understand — these same opportunities can turn to manipulation and threat in a technology-rich, media-saturated world that is sometimes disconnected from the worlds of parents and other adults significant in the lives of teens. Whether young people will be at risk in this world, or will adapt to and even shape it, is a question to consider.

ACCESS TO ICT

How pervasive is ICT in the lives of youth? In the United States, 9 out of 10 teens are Internet users. The vast majority (84%) report owning one personal media device — a computer, a cell phone, or a personal digital assistant — and half of American families with teens have broadband connections to the Internet. Eighty-seven percent of American youth between 12 and 17 years old have used the Internet, and of that number, half (51%) report going online at least once a day (Lenhart, Madden, & Hitlin, 2005). Across the border in Canada, the situation is similar: 94% of young people in grades 4 to 11 (ages 9 to 17 years) report going online from home. Sixty-one percent of Canadian online youth have high-speed access and 23% have their own cell phone, 44% of which have Internet capability (Environics Research Group, 2005). Australian youth are among the world's leading users of computers, with 94% of Australian students reporting that they have access to a home computer for schoolwork and 100% reporting that they have access to a computer at school

(OECD, 2003). In the United Kingdom, 75% of youth between the ages 9–19 have accessed the Internet from a computer at home, and school access is nearly universal (92%). Young people in the UK use as diverse a range of platforms as those in the United States and Canada, with 71% living in a home with a computer and 38% owning a cell phone (Livingstone & Bober, 2005). Access to computers is almost universal for 15-year-olds living in countries of the Organization for Economic Cooperation and Development (OECD): 98% or more in 21 of the 25 OECD countries that participated in the 2003 PISA study have experience with computers, and the vast majority of these young people report confidence performing basic ICT skills, such as opening, deleting, and saving files, and using the Internet (OECD, 2003). Internet access is high, if not universal, in schools throughout much of Europe and large areas of Asia, specifically Australia, Singapore, Korea, Hong Kong, Taiwan, and New Zealand (Kirkman, Cornelius, Sachs, & Schwab, 2002).

Despite the seeming pervasiveness of ICT in the lives of youth, inequity of access exists. The OECD (2001) defines this as the digital divide — "the gap between individuals, households, businesses and geographic areas at different socio-economic levels with regard to both their opportunities to access information and communication technology (ICTs) and to their use of the Internet for a wide variety of activities."

Internationally, the lines between those with access and those without are clearly drawn between developed and developing nations. In developed countries, virtually every child has access to a telephone, a television, and a computer, either at home, school, or a public library. The same cannot be said for youth in developing countries (United Nations, 2003). Access to computers in developing countries is typically through the school, but not all children go to school because many countries do not have a universal, free education system. The Internet reaches little more than 10% of the world's population; while 331 per 1,000 people in Europe use the Internet, only 37 per 1,000 in the Middle East and Africa, 92 per 1,000 in Latin America and the Caribbean, and 15 per 1,000 in South Asia and sub-Saharan Africa use the Internet (United Nations, 2005). While these figures include all Internet users, and not just youth, young people are often the first adopters of ICT. Therefore these figures suggest a profound gap between the ICT experiences of youth in developed countries and developing countries.

Even within developed nations, the distribution of ICT access can be uneven. Physical access to a computer, a network connection, and increasingly a cell phone or personal digital assistant, is the starting point. Income, social class, and proximity to urban areas play a key role in determining the accessibility of such tools. While many schools provide computers for student use, the student-computer ratio may be so high, the quality of hardware and software so poor, and the network connection so slow, that access to technology is more theoretical than practical. Beyond the basic physical access, users of ICT must have intellectual access in the form of multiple literacies: the basic literacy skills of reading and writing, the language skills to understand and contribute to the discourse, and the critical thinking skills required to decode media messages and sift through a myriad of information sources.

HOW ARE YOUTH USING ICT?

This section looks at what young people are doing with ICT and studies this question within the framework of "purpose" rather than format, application, or specific technology. So, how are young people using ICT in their lives? Regardless of the mode of delivery, young people use ICT for three principle reasons: as a tool for learning, a channel for human interaction, and a form of entertainment. At times, these purposes are deeply intertwined, as in the case of networked learning environments or virtual reality games that teach.

ICT and Learning

ICT has become an essential educational tool in the 21st century, and for purposes of learning, young people most commonly use it to find information resources on the Web (OECD, 2003). Fifty-five percent of students in OECD countries report searching the Internet for information about people, things, or ideas, with the highest use of the Internet as a source for information resources in Canada (75%), the United States (74%), and Australia (74%) (OECD, 2003). For Canadian youth, searching the Internet for

information is as popular as playing games online, and they willingly choose the Internet over other information sources (Environics Research Group, 2004). American youth look for information about current events, politics, religion, careers and colleges, and increasingly, health. While its not clear whether American teens seek information on these topics for educational or personal reasons, the Internet is now a key source for information, especially for those who have access to broadband connections (Lenhart et al., 2005).

The shear volume of information on the Internet can be more frustrating than useful when it threatens to overwhelm young people. Young adults report feelings of being lost in a sea of information and say they have problems filtering the "good" information from the "bad" (Environics Research Group, 2004; McMillan & Morrison, 2006). A meta-analysis of research related to youth information-seeking behavior revealed that young people are not experiencing the richness of the Internet because of "poorly developed information-seeking skills or a propensity to take the easiest path possible" (Dresang, 2005, p. 181). For those teens who do happen to stumble upon information they feel is useful, the operative phrase "use with caution" still remains. In an environment

where the traditional filters of editor and publisher have been cast aside and anyone with Web publishing software can launch their own Web page, it is difficult to determine the reliability of information. The problem is more acute in the world of Web 2.0 — the second generation of the Internet, the social Web — where the Internet it is the facilitator of conversations and users *are* the content. In this new online world of wikis, blogs, and socially mediated knowledge bases such as *YahooAnswers*, the lines between author, publisher, and user have grown ever more fuzzy. Now, typing and clicking a mouse is all that is required to add content to the Internet. Given this profusion of information choices/sources and the corresponding decrease in their reliability, the ability to effectively find, choose, and use information has become a key educational outcome for schools — generally falling under the rubric of information literacy, the set of problem-solving skills needed to negotiate a complex world of information.

Information seeking on the Internet is the principle online learning activity of teens (OECD, 2003). Increasingly, young people have access to networked educational software, such as *Blackboard* or *WebCT*. As its name suggests, networked educational software is an ICT tool designed specifically for the purposes of teaching and learning in an online environment. It is actually a suite of applications and it operates in a closed, password-protected environment where teachers can moderate online discussions, share course materials, assess student learning, and communicate with students, parents, and other teachers. On a smaller scale, educational content can now be delivered directly into the hands of teens via their cell phones; class reminders can be e-mailed to mobile devices, Web-enabled browsers for small screens provide access to digital information resources, and podcasts — audio files distributed by subscriptions over the Internet — can be sent to MP3-enabled cell phones.

While the Internet plays an increasingly important role in education, its overall use by young people for school-related reasons remains surprisingly low in comparison to other functions such as communication with friends, downloading music, and online gaming (United Nations, 2003). However, as the size and cost of digital devices decreases and the number of broadband and wireless connections increases, it seems safe to say that the digital classroom, as yet more theory than practice, will move closer to the reality.

ICT and Human Interaction

One of the principle tasks of adolescence is to establish a personal identity within the social framework of family, friends, school, and community. Friendship and a sense of belonging are critical to the development of self- and social identity. It is no surprise, then, that young people increasingly take advantage of ICT tools that enable social networking. The communications possibilities offered through ICT — such as e-mail, chat and instant messaging, text messaging, multimedia messaging, blogs, and Web sites that leverage social networking capabilities — offer young people a forum for the expression of identity and a way to connect with others. Teens who live in a "wired world" can choose to communicate anytime, anywhere, and sometimes more worryingly, with anyone.

Social networking on the Internet is an essential component of Web 2.0, the next generation of the Web. The digital equivalent to "hanging out at the mall," social networking Web sites provide a popular platform for teen communication and personal expression. Web sites such as MySpace and Facebook allow users to post a profile and build a personal network, all within the context of the free and open Web. Teens with something more to say can begin a blog (a "Web-log"), which is essentially an online journal akin to the handwritten diaries and the personal homepages of earlier days. Blogs, however, are interactive and allow readers of the journal to post comments and contribute to the discourse.

More than half (55%) of all online American youths ages 12–17 use online social networking sites (Lenhart & Madden, 2007). In the UK, Bebo attracted more than 22 million members in its first 13 months, most of them school and college students (Ward, 2006). Social networking sites are about friendship: girls use them to reinforce pre-existing friendships, while boys use them for flirting and making new friends (Lenhart & Madden, 2007). Young people use Web sites' social networking sites to build community, to construct a social world that is distinct from their parents. Social networking is also about identity. Users in such environments can create false personas — an interesting experiment for a teenager exploring self-identity, but one that is more worrisome when created by an online predator. How to find a balance between the exploratory, identity-building behavior that is crucial for adolescent development and their online safety is a critical question for parents, educators, policymakers, and ICT developers in future decades.

E-mail and instant messaging (IM) are popular channels of communication via ICT, but a clear division between the two has arisen: E-mail is for communicating with adults and IM is for friends. E-mail is task-oriented; IM is for fun (Schiano et al., 2002; Lenhart et al., 2005). Young people in the early 21st century are indeed the "IM Generation," instant messaging being the most popular of Internet communication modalities (Greenfield, Subrahmanyam, Suzuki, & Tynes, 2006, p. 198). IM allows young people to have private real-time conversations with a friend while "hanging out" with a group of friends — two important functions built into one application. While there are concerns regarding who teens let into their "buddy" group when communicating via IM, they tend not to stray beyond their in-person network of friends, most typically other teens they have met at school or who live nearby (Boneva, Quinn, Kraut, Kiesler, & Shklovski, 2006). But interestingly, IM can be

used to maintain ties with family; in the United States, almost one in three American teens (29%) say they use IM to communicate with their parents (Lenhart et al., 2005). As a space for personal expression, IM offers users many options beyond text-based communication. IM-using teens also share photos, music and video files, and links to Web sites or articles (Lenhart et al., 2005). The medium of IM opens up possibilities for information seeking on topics that teens may be too embarrassed to ask in person. That information is, of course, only as reliable as the person who answers the question. In a move to fill this "reliability gap," libraries have begun to offer synchronous, online reference services using IM technology. Called "virtual reference," these services are aimed squarely at the young adult clientele.

As IM spreads to new, smaller platforms, such as cell phones and handheld digital assistants, teens are taking their text-based conversations to the street, with the subsequent blurring between the distinction of "home" and "not home" (Minoura, 2001). While this means that teens are no longer "land locked" by their desktop computers, they are also "placeless" and often "faceless," a development that threatens to break the social bonds that are built through face-to-face communication. But teens still prefer face-to-face time spent with friends and seem to use IM as a supplement to, and not a replacement for, in-person communication (Lenhart et al., 2005; Boneva et al., 2006).

The cell phone has become a part of the everyday lives of youth living in affluent countries. Portable, easy to use, and inconspicuous, cell phones are a basic tool for young people growing up in the information age. For example, in North America at least 45% of American teens and 46% of Canadian youth in grade 11 own cell phones (Lenhart et al., 2005; Media Awareness Network, 2005). Approximately 80% of young people in the European Union use a cell phone at least once a week (United Nations, 2005). The growth of cell phone use among young people has been phenomenal and continues to expand. In 1999, only 15% of Finnish 15-year-olds owned a cell phone. Three years later, in 2001, that number had climbed to 66% (United Nations, 2003).

The functionality of cell phones has moved beyond the traditional voice capabilities to include text messaging, multimedia messaging, wireless e-mail, MP3 players, Internet browsers, and digital cameras, and young people are taking full advantage of this array of options. For many young people, cell phones are the e-mail terminal of choice, some even accessing a scaled-down Web built for small screens, slower speeds, and keypunching. "Texting" (or SMS) — short text messages sent between cell phones — is growing in use, with at least 33% of American youth reporting that they text, rather than talk by cell phone. Interestingly, almost one in three (29%) of teens who use text messaging or IM use it to communicate with their parents, indicating the emergence of a new channel of communication between parent and child (Lenhart et al., 2005).

ICT and Entertainment

Teens and technology go hand in hand when it comes to leisure and recreation, and for many young people, ICT is synonymous with entertainment (United Nations, 2003, p. 321). Most large-scale studies that have looked at teens and ICT have focused on its use in educational settings and as a tool for communication. Reports from the PEW/American Life series and the Kaiser Family Foundation, which both looked at youth in the United States, provide a snapshot of how online teens use ICT to interact with media in the service of fun and entertainment (Lenhart et al., 2005; Lenhart & Madden, 2007; Rideout, Roberts, & Foehr, 2005). While these reports do not represent the global picture, they illustrate how the separate worlds of teens, entertainment, and ICT are converging in the 21st century. Calling today's young people "Generation M" — for media — the Kaiser Foundation reports that youth, ages 8–18, in the United States spend an average of up to six-and-a-half hours each day with media (Rideoute et al., 2005). While this statistic includes both analog and digital media, such as television, movies, magazines, music, and video games, it nevertheless represents an enormous chunk of time in the lives of youth; and given that the "amount of media a person used to consume in a month can be downloaded in minutes and carried in a device the size of a lipstick tube" (Rideout et al., 2005), media is now rooted in all aspects of the lives of teens who have access to ICTs. The following section discusses briefly two uses of ICT for entertainment — music downloading and online gaming.

Music is a vital part of many teens' lives: on a typical day, 68% of young people in the United States listen to music, either by CD, tape, or MP3 player (Rideout et al., 2005), so it is no surprise that the Internet, embedded as it is in the lives of many, has been appropriated by young people as a tool for retrieving and sharing music. Using peer-to-peer networks, online music services such as iTunes or BuyMusic.com, instant messaging, or e-mail, music can be downloaded and then listened to using a computer or an MP3 player. In the United States, just over half (51%) of online teens in the United States say they have downloaded music, and nearly one-third (31%) have downloaded video files (Lenhart & Madden, 2005). While these teens are at ease downloading content, many have little concern for the actual source of music, with the majority (55%) of downloading teens saying they do not care whether the music is copyrighted or not (Lenhart & Madden, 2005, p. 14). But over half of online teens are creating content too, for their own amusement and to entertain other teens (Lenhart & Madden, 2005).

Eight in ten teens in the United States (81%) who use the Internet play online games (Lenhart & Madden, 2007), interacting with other players in virtual worlds via multiplayer online games. Some games are limited to a few players; others have worldwide subscriptions in the millions. One example

is the game "Second Life," a 3D virtual world inhabited by 1.3 million people/players. A teen version, called "Teen Second Life" exists as well. Players in "Second Life" occupy a digital continent, where they meet new people, buy property and build homes, learn new skills, and create businesses. In this virtual world, entertainment, communication, and education have merged, and educators have taken note. Already one public library in the United States, aware that gaming, multimedia, and ICTs play a huge role in the lives of many of their teen patrons, has launched a pilot project exploring the creation of teen library services in a virtual world (PLCMC, 2006). McMaster University in Canada has opened a library facility in "Second Life." Students can visit it and even speak to a librarian, represented of course by an avatar (McMaster University, 2006). The use of online gaming as a platform for information seeking and learning is still in its infancy, but opportunities for such experiences can be expected to expand in the 21rst century.

FUTURE TRENDS

There is little doubt that teens will increasingly live in a wired world. Computers and cell phones will in time converge into mobile personal digital assistants — the digital "Swiss Army knives" of the 21st century (Rainie, 2006) — and the Internet will continue to spread worldwide. And yet little is known about teen patterns of behavior in relation to ICT and, more importantly, its impact on their lives. Many profound questions regarding the effect of ICT on the lives of teens remain, suggesting fruitful areas for research:

- How do we bring ICT to those who as yet have no access to it?
- For those who do have access to ICT, how are they using it? As ICT becomes more ever-present in the lives of teens worldwide, we might begin asking if the patterns of use are universal or if local culture makes a difference in the way young people use ICT.
- Given the ubiquitous nature of ICT in the lives of many teens, it seems critical to ask whether it has an effect on the intellectual, emotional, and physical development of young people.
- Do teens have the intellectual skills needed to safely and effectively use ICT? If not, what should be the focus of intervention?
- Should ICT-related applications and interfaces be designed specifically for teens, and if so, how? To what extent do teens adapt to existing technology? To what extent do they shape it?
- We know that teens use ICT as a channel for socializing and interacting with their peers. What, then, is the nature of teen online culture? Does it affect family relationships? Does participation in social groups mediated by ICT differ from traditional participation? Are traditional modes of socializing and participating falling to the wayside, or does ICT simply supplement them?
- The Internet is a primary source of information for online teens and yet we are only just beginning to understand how they use it to look for information. How do teens use ICTs to fulfill their information needs?
- For teens who use ICTs, the lines between learning, socializing, and entertainment are merging. How close can the lines be drawn? Are there aspects of these activities that should remain distinct? If not, what is the best way to leverage one, without sacrificing the other two?
- Computers and cell phones will in time converge into mobile personal digital assistants. How are teens using these portable tools, and what is the impact on their lives? A natural extension of this question should be asked by educators: Can personal digital assistants be used in service to teaching and learning, and if so, how?
- And finally, does ICT function within a policy framework that meets the needs of young people?

CONCLUSION

Despite its phenomenal growth, information and communication technology remains a tool for the privileged, and access to it is not the norm throughout the world. It is still the case that on a global scale, very few teens actually have access to ICTs. This digital divide is an inequity so fundamental that one could compare it to the effects of being illiterate in a world of people who read. Even so, experience has shown that when they do have access to ICT, it is young people who lead the charge in adopting it into their everyday lives.

KEY TERMS

Information and Communication Technology (ICT): Technology that enables the handling of information and facilitates different forms of communication.

Instant Messaging (IM): A text-based method for communicating one to one or in groups in real time over the Internet using standard IP protocol.

OECD Countries: The member countries of the Organization for Economic Cooperation and Development (OEDC) include: Australia, Austria, Belgium, Canada, the Czech Republic, Denmark, Finland, France, Germany, Greece, Hungary, Iceland, Ireland, Italy, Japan, Korea, Luxembourg, Mexico, The Netherlands, New Zealand, Norway, Poland, Portugal, the Slovak Republic, Spain, Sweden, Switzerland, Turkey, the United Kingdom, and the United States.

Personal Digital Assistant (PDA): A handheld digital device that combines the functionality of the telephone with computing and networking. It can operate as a cell phone, a Web browser, an e-mail terminal, digital camera, and personal assistant.

Podcast: A method of publishing audio files to the Internet. The term is a combination of the word "iPod" and "broadcasting." Podcasts are often distributed through RSS feeds.

Social Networking Web Sites: Web sites that facilitate the development of online social networks and collaborative knowledge building through the use of social software.

Social Software: Software tools for computer-mediated communication. Includes instant messaging, text chat, blogs, wikis, and Internet forums. From these have arisen new areas of collaborative knowledge building such as folksonomies, social bookmarking, social citations, and knowledge bases.

Text Messaging: Short text messages received by and sent to a mobile, handheld communication device such as a cellular phone, a personal digital assistant, or a pager. Text messages can be also sent from the Web, either through the Web page of the cellular service provider or through some Web sites that offer to send text messages free of charge. Also called *texting, short message service,* or *SMS.*

Virtual Reference: An online information service that uses computer-mediated communication to answer questions. The service can be asynchronous (e-mail) or synchronous (instant messaging). Also called *digital reference.*

Web 2.0: The so-called second generation of the Web. A suite of Web-based services where users control the content by contributing, collaborating, and sharing. Sometimes called the *social Web,* Web 2.0 architecture is dependant on the participation of its users.

Telemedicine Applications and Challenges

Lakshmi S. Iyer
The University of North Carolina at Greensboro, USA

INTRODUCTION

Telemedicine is a function of information and communication technologies (ICT) that facilitates exchange of medical data to assist the health care industry in providing services to the society more competently. Its applications range from diagnosis, treatment, and prevention of disease, to continuing education of medical professionals, research and evaluation. Telemedicine is not a process aimed to replace traditional practices of medicine. It simply acts as a partner of the industry to reduce inadequacies in time and resources. ICT should not be viewed only as a competitive advantage of health care organizations, but rather a fundamental commodity intrinsic to the delivery of global health care (Iyer & Dey, 2005; Nash & Gremmillion, 2004).

Pedigo (1997) illustrates the essence of telemedicine with the follow example: In April 1995, a student at Peking University sent an e-mail requesting medical assistance for a fellow student, Zhu Ling. Zhu Ling was experiencing rapid hair loss and paralysis. An extensive online network of physicians, toxicologists and other experts collaborated with Ling's physician in Beijing to respond to the SOS e-mail. With the assistance and suggestions from over 2,000 responses, the Beijing physician was able to treat Ling in the best possible way and prevent death. The Zhu Ling case was the first recorded use of the Internet to seek diagnosis and patient care from a distance.

Telemedicine has the potential to help bridge the time and distance gaps that can mean life or death for some patients. It can provide live video conferencing between local, rural doctors and clinics to the necessary specialists at a major hospital or research center. These conferences can provide quick and accurate diagnosis and save both the patient and the doctor time and money.

This article presents a background on telemedicine including components, applications and benefits of telemedicine, challenges and trends in telemedicine, and conclusion with some direction for future research in telemedicine.

BACKGROUND

Telemedicine removes geographic barriers and is anticipated to save money by treating patients on-site rather than in an expensive hospital setting, improve patient care by giving health care providers access to teaching medicine resources, and target services to populations that have been hard to reach (remote rural areas), expensive to serve (prisons, mental institutions), and historically neglected (urban poor). The most important benefit of telemedicine is its ability to access patient data from any remote location (Demiris, 2004). It is impossible to have specialists in all areas available at all times to any given hospital or emergency care service. There are people worldwide that live in rural and remote areas who are not able to receive the type of care they need due to their distance from the nearest facility that specializes in their illness. Moreover, in most developing countries, there is a severe scarcity of medical specialists. Lack of capital, facilities, and systems are some of the common problems faced by developing countries. Telemedicine coupled with telecommunications can provide a solution to some of the above problems.

The U.S. Department of Defense has been using telemedicine technologies to support their operations in Saudi Arabia, Kuwait, Somalia, Haiti, Cuba, Panama, Croatia, and Macedonia (Garshnek, Logan, & Hassell, 1997). The telemedicine project in the Persian Gulf in 1993 had computerized tomography (CT) scanners installed in transportable modular military hospital units and deployed in the Saudi desert just south of the Iraqi and Kuwaiti borders. During Operation Restore Hope, physicians in Somalia were able to communication and share medical data with specialists in Washington DC.

Telemedicine has always played an important role in astro medicine as well. From the 1960s, astronauts have been monitored by groups of medical specialists through telemetry during the space operations. Currently, NASA is making efforts to hold conferences in the micro-gravity environment between astronauts on the orbiting space-crafts and the medical specialists on earth (Garshnek et al., 1997). These one-way video and two-way audio conferences would make a phenomenal difference in the safety and security of the astronauts on board.

Treatment of inmates in the prison (Cooper, 1997) is another application of telemedicine. It helps to maintain a secure prison system by minimizing movement of the prisoners in case of a medical problem. The state of Iowa has implemented a telemedicine project via which medical staff of the prison can consult with doctors at the University of Iowa through a two-way video conference. This system transmits captured images letting physicians located at a remote place view a patient's ears, throat, or skin. It also

enables sharing of x-rays and other information to help with diagnosis and follow-up care.

Telemedicine and telehealth also eliminates travel cost as well as travel delay (Jossi, 2005). Moreover, immediate real-time access to patient data gets rid of time lag and accelerates early detection of diseases that can improve overall performance of the health care industry (Jossi, 2005).

Medical information shared over a network can support research collaboration by allowing researchers to exchange findings over the networks at no additional cost. Informational networks online also provide a means to establish official and unofficial educational programs over a wide area across the globe.

Components of Telemedicine

The success of telemedicine depends on how effectively the capabilities of technology have been exploited to benefit the health care industry. Health care industry requirements should be analyzed carefully before considering technology as a solution. Telemedicine systems may be developed using two key dimensions: internal and external integrations (Raghupathi & Tany, 2002). Internal integration refers to technologies that are applied to integrate systems with one another within an organization. External integration refers to systems and technologies interfacing with outside organizations and agency computer systems.

The fundamental telemedicine integration should be planned to allow a scope for future expansion if necessary. Scalability should be used as a valuable measuring rod for every telemedicine project. The basic components of a telemedicine project infrastructure are discussed in the following sections.

Telecommunication

The first step is to ensure a network connecting all remote facilities in order to communicate with each as desired. This could vary from a basic telephone service to broadband Internet. Considering complex operations requiring huge amounts of data being interchanged across the globe in seconds between systems, telemedicine networks often require a high bandwidth. Asynchronous transfer mode (ATM) coupled with resilient synchronous optical network (SONET) has been one of the most popular configurations from the early 2000s. It offers high-quality and low-delay conditions. These systems are supported by fiber optic cables that allow data to be transferred up to 40 gigabytes per second.

Mobile communication systems are also critical to telemedicine industry. This includes cordless, cellular, satellite, paging, and private mobile radio systems (Ackerman, et al., 2002). Wireless technology is the next big step for telemedicine. Wireless end users within a physician's office, hospital building, or even medical campus can be connected with a wireless local area network (WLAN).

Interoperable Systems

Interoperability adds value to the system by ensuring flexibility and cost-effectiveness (Ackerman et al., 2002). The system design should allow stations developed by independent vendors to interact with each other. Medical devices and other peripherals connected to one vendor's station should be able to interact with that of another station created by another vendor. Systems should be further designed to allow creation of individual stations in a plug-and-play

Table 1. Telemedicine interactions and technical requirements (Adapted from Garshnek et al., 1997)

Applications	Interaction Processes	Data Transferred	Min. Bandwidth Reqd.
* Telepsychiatry * Remote Surgery * Interactive Exams	Real time, one-way or two-way interactive motion video	Voice, sound, motion video, images, text	Moderate to High
* Dermatology * Cardiology * Otolaryngology * Orthopedics	Still images or video clips with real-time telephone voice interaction, 'store and forward' with data acquired and sent for later review	Voice, sound, still video images, text	Low to Moderate
* Distance Education * Training	One-way or two-way real-time or delayed video	Voice, sound, motion video, images, text	Full Spectrum: Low to High
* Health Info. Networks * Medical Records	Transfer of electronic text, image, or other data	Text, images, documents, related data	Low to High

fashion from components developed by multiple vendors. Middleware is a possible solution to ensure interoperability with systems.

Computing Processes

Store-and-Forward: It is usually used for sending digital data between hosts in a telemedicine network. Images taken on digital cameras or still videos are sent as simple e-mail attachments. Depending on the data range, computing power and speed requirements may vary from two desktops connected to the Internet to a whole grid-enabled network.

Real-Time Video Linking: Typically higher bandwidth communication channels (ISDN lines) are required to enable real-time processing (Biomedical Informatics Ltd., 2003). It is the basis for "face-to-face" consultation between patients and specialists located at two different parts of the world. Specialized video conferencing equipments at both locations are used to facilitate "real-time" consultation.

Computing power and speed are determined based on the combination of processes involved in the particular telemedicine application. Table 1 illustrates the differences in the technical requirements of telemedicine in respect to its application.

Telemedicine Equipment

There are a huge range of devices that are used in telemedicine for acquisition, presentation, storage and delivery of medical data (Mirza 2004). In this article, a few typical equipments are discussed as follows:

- **Electric Phone Stethoscope** is used to pass high quality auscultation sounds over low bit rate with switches at receiving units picking diaphragm frequency sounds. An e-steth produces phonocardiogram by digitalizing heart and lung sounds using a sound card. The relevant data is then attached to an email for transmission. Physicians opening the email attachments receive the pertinent diaphragm frequency with the phonocardiogram and sound playing in the background automatically.

- **Telemedicine Video Imaging System** assists diagnosis of patient data. Special cameras with specific features to power zoom, auto focus, frame capture, and electronic image polarization together are used for video imaging.
- **Vital Signs Devices** is typically used for homebound patients. It helps in the constant monitoring of heart rate, respiratory rate, blood pressure, and temperature of patients located in remote areas. Patient data can be transmitted to the hospital through this machine while the patient remains at their home or any other remote location.

APPLICATIONS OF TELEMEDICINE

Telemedicine enables health care providers to deliver efficient and cost effective quality care to persons at some distance from the provider. Organizations such as the European Space Agency (ESA) are providing funding for projects to support the provision of health care services in rural and remote areas (see Figure 1).

The most common applications of telemedicine are telecardiology, teledentistry, teledermatology, telepathology, telepsychiatry, and telesurgery.

Telecardiology

Telecardiology, along with ECG interpretation service, aids physicians by providing them with instant access to cardiac assessment. Besides direct telephone access to cardiologists, general practitioners are prepared with hand-held, automatic standard 12-lead electrocardiogram ECG transmitters. These 12- ECG transmitters allow for online cardiac consultations and ECG interpretation. A full medical report including ECG signals are sent out by the general practitioners to the cardiologists. In turn, the respective cardiologists respond to the report with their consultation to the general practitioners.

Teledentistry

Teledentistry benefits patients in remote locations by allowing them to get specialized dental consultation over a network. Their dental information is electronically sent and reviewed

Figure 1. Visiting patients in their homes through telemedicine (Source: ESA, http://www.esa.int/esaCP/SEMMT0M26WD_index_0.html)

by dental specialists. Teledentistry encompasses real time and offline dental care which includes diagnosis, treatment planning, consulting and follow-up.

Teledermatology

Teledermatology is the process of providing patients situated at remote locations with dermatology consultations using information technology mechanisms. Telemedicine is exceptionally valuable to teledermatology since it is visual in nature, and health practitioners other than dermatologists are poor at diagnosing skin diseases. Studies have shown that 20% of general practitioners are not able to diagnose twenty of the most common dermatological problems.

Telepathology

Telepathology is the transmission of digitalized histological or macroscopic images between remote locations. It is used for diagnostic, prognostic, quality control, research, and educational purposes. An example of a typical telepathological structure would consist of a CCD or digital camera connected to a microscope with a computer having a good graphics card and software to control the images over a network. Telepathology is an important contribution to the health care industry as it allows for faster diagnosis and consultations by pathologists located at remote places.

Telepsychiatry

Telepsychiatry provides specialized psychiatry care or support from remote settings. Patients, physicians, and specialists communicate with each other by phone, fax, e-mail, the Internet, still imaging, and live interactive two-way audio-video conferences. Video conferencing is primarily used for clinical consultative sessions. Telepsychiatry services include assessments, diagnosis, treatment, psychological testing, medico legal assessment, case conferencing and management, education, supervision, support, administration, and research. However, patient's privacy and confidentiality of communication are vital concerns in telepsychiatry. Telepsychiatry sessions are making sincere efforts to maintain the same standards as those followed by face-to-face consultations to protect patient information.

Telesurgery

Telesurgery is the most interesting application of telemedicine. Surgeons perform micro-surgery by manipulating the hands of a robot (Angood, 2001). Over 2,000 brain surgeries performed by telesurgery have been successful. Currently, the main problem is that the robotic tools do not let surgeons feel patients' tissues. Researchers at the Biorobotics Laboratory at Harvard are conducting further research to enhance this issue. Sensors enabled to send three-dimensional information to tiny pins on the surgeon's fingertips are being designed to let the doctors feel changes in texture or the strength of his or her grip. This technology is being developed to be used as a medium to detect lung tumors or to insert needles into delicate tissues.

Telecardiology, teledentistry, teledermatology, telepathology, telepsychiatry, and telesurgery are only a few of the extensive list of applications of telemedicine. However, there are several challenges of telemedicine that it needs to overcome before being utilized to its full potential.

TELEMEDICINE CHALLENGES

There are many issues involved with telemedicine that must be addressed before it can be utilized or applied to its full potential. Some of these issues include: licensure of those that provide the service over state/country lines, insurance payment issues, privacy and security, cost and accessibility, and industry-wide standards, especially relating to safety and liability (Kantor, 1997). Organizations such as the Sandia National Laboratories (www.sandia.gov) are developing secure online telemedicine techniques. Figure 2 shows Sandia's Linda Gallagher checking her blood oxygenation and pressure with sensors connected to a state-of-the-art unit from TelAssist Corp.

In general the challenges of telemedicine can be broadly categorized into the two following sections.

Figure 2. Use of online techniques at Sandia National Lab for checking blood oxygenation and pressure (Source: http://www.sandia.gov/media/NewsRel/NR1999/telemed.htm)

Telecommunications Challenges

In rural and underdeveloped areas, where telemedicine is most needed, telecommunication technology is not up-to-date. Standard telephone lines do not provide the bandwidth necessary for many telemedicine projects.

In addition, setting up telecommunication channels is an expensive mission. Proponents of telemedicine are still not sure whether they can afford such a huge investment solely because cost of telemedicine projects is not yet accurately justified (Huston & Huston, 2000). Even though a large number of prison-based teleconsultations cases have been able to show cost savings, this data could not be used for reimbursement purposes considering its exclusive security and transportation expenses.

Socioeconomic Challenges

Legal issues regarding physician licensing, liability, and patient confidentiality exist. As physicians are licensed by states, there is a legal problem when a physician consults across state lines. It is necessary for states to engage in interstate provisions of service in order to fully benefit from telemedicine. Currently, interstate agreements vary greatly. Several states maintain that physicians must be licensed in both the sending and receiving states. Other states have entered reciprocity agreements with neighbors.

Liability is an obstacle in providing telemedicine. There is a debate related to which physician would be liable for a poor patient outcome: the primary care or the consulting physician. In the case of a poor outcome, it is not clear if the patient should file suit in the residing state or in the state the practitioner is located.

Medicaid covers telemedicine consultation in only 10 states. Medicare will reimburse for telemedicine services provided in rural counties that are designated as health professional shortage areas. This Medicare provision, authored by North Dakota Senator Kent Conrad, was part of the Balanced Budget Act of 1997 (Moreno 1998). Most commercial payers do not cover routine telemedicine consultation. Physician reluctance and patient apprehension are also obstacles. Some rural physicians fear the loss of patients to urban facilities.

The public and physicians worry about the impersonality of telemedicine as well. Differences in resources available, language, and literacy together with cultural differences in acceptability of telemedicine are other serious obstacles telemedicine needs to overcome.

TELEMEDICINE TRENDS

The full scope of telemedicine is currently being defined, but its future will be driven primarily by the new economic imperatives which are dramatically changing health care delivery. Telemedicine will not only allow physicians and other health care workers to take better care of patients, but will provide patients with tools to allow them to take a much more active and effective role in taking care of themselves. There have been several measures taken to solve the issues discussed. In the United States, the Telecommunications Act of 1996 established supplements to the cost of providing the necessary structure to support the technology in some rural areas. In addition, telecommunication companies are working on projects to connect the government with education, health care and business (Brown, 2002). There are scientific advancements such as "intelligent clothing," which monitors the condition of a patient's health then relays that information to medical specialist. Nevertheless, these measures are still at their development stages. The full potential of telemedicine can only be understood when all or most of the barriers of telemedicine are eliminated.

CONCLUSION

Developing a reliable delivery system has been slow, which contributed to the cautious pace of telemedicine in the early 90s. Reliability is an issue for some aspects partly due to a lack of industry standards. Although the technology appears as simple and as familiar as turning on a TV set, in fact multiple technical elements are involved, and users must be trained to operate the equipment. Telemedicine projects require broad-based planning, installation, and operational support. Legal and jurisdiction issues are also a concern for some types of telemedicine. If the diagnosis is incorrect, who is liable: the consulting doctors or the one that is present with the patient? Which state or country is responsible? Who gets paid by the insurance company and how much? These are questions that are still being considered for the future of telemedicine.

KEY TERMS

ICT (Information and Communication Technologies): Includes computers, software, peripherals, and connections that are intended to fulfill information processing and communications functions.

Internet: A computer network consisting of a worldwide network of computer networks that use the network protocols to facilitate data transmission and exchange.

ISDN (Integrated Services Digital Network): A system of digital phone connections that allows voice and data to be transmitted simultaneously across the world using end-to-end digital connectivity.

SONET (Synchronous Optical NETwork): The standard for synchronous data transmission on optical media.

Telehealth: The use of ICTs to deliver health and health care services and information over large and small distances.

Telemedicine: Derived from the Greek 'tele' meaning "at a distance" and the present word "medicine" which itself derives from the Latin "mederi" meaning"healing".

Teleradiology: A means of transmitting radiographic patient images and consultative text from one location to another with the use of ICTs.

Telesurgery: The use of medical technology such as robotics, sensory devices and imaging video that allows a surgeon to operate long distance. This technology provides doctors the full sensory experience of hands-on surgery.

Telescopic Ads on Interactive Digital Television

Verolien Cauberghe
University of Antwerp, Belgium

Patrick De Pelsmacker
University of Antwerp, Belgium

INTRODUCTION

The adoption of interactive digital television (IDTV) and related technologies such as the personal video recorder (PVR) make IDTV attractive for advertisers in terms of reach. Although IDTV leads to an increase in advertising avoidance behaviour, it also offers new advertising opportunities (Cauberghe & De Pelsmacker, 2006). One of them is the telescopic advertisement. This format consists of a "30-second TV ad with a call-to-action button with clickable content or micro sites featuring individual still screens providing additional product information" (Bellman & Varan, 2004, p. 2). When the viewer clicks on the call-to-action button, he or she leaves the linear broadcast stream to enter a dedicated advertising location (DAL). There, the viewer can navigate through the additional information, which can be structured in different layers. The purpose of this study is to investigate the impact of two aspects of the complexity of a telescopic ad by experimentally manipulating the amount of information and the level of interactivity in the DAL. Additionally, the role of time spent in the DAL is explored.

BACKGROUND

Advertising Complexity and Information Load

To keep the consumer's interest focused on a persuasive message, an appropriate level of complexity is recommended (Putrevu, Tan, & Lord, 2004). Complexity has been identified as one of the major dimensions of information load. An increase in information load generates a positive effect on information processing until a certain threshold is reached, at which the consumer will be overloaded with information. At this point the consumer will no longer consider additional information and will become confused, and it is harder to recall previous information (Lang, 2000). The effects of complexity and information load follow an inverted *U* shape, by which a moderate level of complexity leads to the most optimal advertising results (e.g., Geissler, Zinkhan, & Watson, 2006; Martin, Sherrard, & Wentzel, 2005; Wang, Chou, Su, & Tsai, 2007).

Amount of Information

The effect of the amount of information follows an inverted *U* shape (e.g., Meyer, 1998), leading to negative effects in decision quality when too much information is provided. Although an increase in the quality of the additional information decreases message complexity, increases the credibility of product information, and leads to a positive effect on decision making (Keller & Staelin, 1987), increasing the quantity of information leads to an increase in complexity and can, due to limited cognitive capacity and information overload, lead to confusion and negative evaluative effects after a certain threshold is reached (Lang, 2000). In the present study, the quantity of information in the DAL is manipulated, keeping the quality constant. Therefore, the following can be expected.

H1: A high amount of information in the DAL leads to lower brand recall and a less positive brand attitude than a low amount of information.

Level of Interactivity

Interactivity has the capability to develop feelings of flow, "an intrinsically motivated optimal enjoyable mental state" (Csikszentmihalyi & Lefevre, 1989). This mental state increases the cognitive involvement with the interactive content due to focused attention and the possibility for consumers to take control over the time, structure, and order in which they want to be exposed to the information (Liu & Shrum, 2002); it also increases the processing of the information presented in the interactive context (e.g., Chung & Zhao, 2004; Macias, 2003; Sicilia, Ruiz, & Munera, 2005). The intrinsically motivated joy evoked by flow may be transferred to the persuasive message and brand, leading to a positive effect on the attitude toward the ad, brand attitude, and pur-

chase intention (Chung & Zhao; Ko, Cho, & Roberts, 2005; Macias, 2003). Therefore, we expect the following.

H2: A high level of interactivity in the DAL leads to higher brand recall and a more positive brand attitude than a low level of interactivity.

Mediating Role of Time Spent in the DAL

Longer ads have more opportunities to provide extra product arguments and to repeat key points of the message compared to their shorter equivalents. The longer a consumer is exposed to an advertisement, the more opportunity the consumer has to process it, and the more he or she will remember of it. Longer commercials lead to more positive brand attitudes (e.g., Danaher & Mullarkey, 2003). Since both the amount of information and interactivity increase the level of complexity, we can expect that more complexity will lead to more time spent in the DAL and that, next to a direct effect of the amount of information and the level of interactivity on brand responses, part of this effect is mediated by the time spent in the DAL.

H3: Time spent in the DAL mediates the effects of the amount of information and the level of interactivity on brand recall and brand attitude.

EMPIRICAL STUDY

Research Method

The hypotheses were tested using a 2x2 (information x interactivity) between-participant factorial design. A telescopic ad was developed, consisting of a 30" television ad, a call-to-action button ("click on the red button for more information"), and an interactive DAL. To avoid confounding effects, a traditional 30" advertisement for a travel agency originating in The Netherlands was used, unknown to Dutch-speaking Belgians. The attitude toward the 30" advertisement was controlled to be positive to avoid negative affective reactions. The ad contained a feel-good conversation between two men on an airplane.

In the DAL, the amount of information was manipulated at two levels. Information about different kinds of holiday formulas and hotels was provided for different countries. The information in the high-level condition was more of the same compared to the low information level (e.g., information about 29 hotels vs. 106 hotels). Interactivity was manipulated at two levels by means of the amount of links in the DAL (12 vs. 92), the availability of a navigation bar (yes or no), and the possibility of two-way communication (e.g., "search an address," yes or no). The layout of the DAL was kept stable over conditions.

Out of a database of a Belgian market research agency, a gross sample of 521 individuals was randomly selected based on age, gender, and education quota. A net sample of 282 participants cooperated in the study. The average age of respondents in the sample was 38 (range 21-56); 61.8% were males, and 55.3% finished higher education. The respondents were randomly assigned to one of the four experimental conditions. The respondents were individually invited to an experimental living-room setting. After the briefing, they watched a 6-minute neutral-mood excerpt of a TV programme followed by the advertisement. At the end of the 30" television ad, a call-to-action button appeared on the screen in combination with a voice-over that invited the respondent to press the button for more product information. After viewing the DAL, the respondents entered a computer-assisted questionnaire. The experiment lasted 40 minutes in total. Each respondent received €25.

The questionnaire contained a brand attitude (Ab) measurement (which did not contain the brand name; seven-point four-item scale, α =.87) and a measure of the attitude toward the 30" ad (used as a covariate in the analysis; seven-point four-item scale, α =.95). After questions about the age, gender, and education level of the participants, unaided brand recall was measured using an open-ended question.

Results

Manipulation Check

The perceived amount of information (two-item five-point semantic differential scale, α =.93) and the perceived level of interactivity were measured by three-item five-point Likert scales (α =.93 and .74). The t-tests indicate that both manipulations were successful ($M_{low\ information}$=3.281 vs. $M_{high\ information}$=4.022, t=5.885, p<.001; $M_{low\ interactivity}$= 3.286 vs. $M_{high\ interactivity}$=3.644, t=6.024, p<.001).

Main Effect of Amount of Information

The amount of information in the DAL had no effect on brand recall (low amount of information=52.1% vs. high amount of information=47.9%, chi^2=.845, p=.358). To measure the effect of the amount of information on brand attitude, an ANCOVA (analysis of covariance) was conducted in which the attitude toward the 30" television ad was used as a covariate. The attitude toward the 30" television ad had a significant positive effect on Ab (F (1, 240)=65.128, p<.001). However, there was no significant main effect of the amount of information on Ab (F (1, 240)=.039, p=.843; $M_{low\ information}$=4.28 vs. $M_{high\ information}$=4.37). H1 is not supported.

Main Effect of Level of Interactivity

The level of interactivity had a positive effect on brand recall and attitude. As compared to a low level of interactivity, a high level of interactivity increased brand recall from 43.6% to 56.4% (chi^2=5.371, p=.020). This positive effect of interactivity was also found for Ab (F (1, 240)=9.502, p=.002; $M_{low\ interactivity}$=4.19 vs. $M_{high\ interactivity}$= 4.46). H2 is supported.

Mediating Role of Time Spent in the DAL

We chose not to constrain the time in our study to keep the external validity high. In real life, the viewer also has the freedom to choose how much time he or she spends to process the additional information. To investigate the mediating effect of time spent in the DAL on the relation between the amount of information, the level of interactivity, and the attitude toward the brand, we used the three-step procedure of Baron and Kenny (1986).

Brand Recall

The amount of information has no significant direct effect on brand recall (see above main effect of the amount of information; chi^2=.845, p=.358). However, to detect a mediation effect, significance in this first step is not required. The effect of the amount of information on the time spent in the DAL is positive and significant (Step 2; low amount of information: M_{time}=4.768; high amount of information: M_{time}=5.745, t=2.514, p=.013). In Step 3, both the amount of information (dichotomous variable) and the time spent in the DAL were inserted as independent variables in a logistic regression with brand recall as a dichotomous dependent variable. The results show that the time spent (p=.007) fully mediates the effect of the amount of information (p=.224) on brand recall. The main effect of the level of interactivity on brand recall is positively significant (Step 1; see above main effect of the level of interactivity; chi^2=5.371, p=.020). The level of interactivity also significantly increases the time spent in the DAL ($M_{low\ interactivity}$=4.373 vs. $M_{high\ interactivity}$=6.148, t=4.710, p<.001). The logistic regression indicates that the effect of the level of interactivity on brand recall is only partially mediated by the time spent in the DAL (p=.047). Interactivity is still (marginally) significant (p=.08).

Brand Attitude

The amount of information has no significant effect on brand attitude (Step 1; see effect of the amount of information, $M_{low\ information}$=4.279 vs. $M_{high\ information}$=4.366, t=.698, p=.486). The amount of information has a positively significant effect on time spent in the DAL (Step 2; $M_{low\ information}$=4.767 vs. $M_{high\ information}$=5.745, t=2.514, p=.013). ANCOVA was used to investigate the combined effect of the amount of information (dichotomous variable) and the time spent in the DAL (Step 3). The effect of the amount of information on brand attitude stays insignificant (F(1, 2.13), p=.645), and time spent had a positive, significant effect (F(1, 4.612), p=.033). These results indicate that the effect of the amount of information on brand attitude is fully mediated by the time spent in the DAL. The level of interactivity has a positive, significant effect on brand attitude (Step 1; see above main effect of the amount of information, $M_{low\ interactivity}$= 4.187 vs. $M_{high\ interactivity}$=4.457, t=2.188, p=.030). Next, the level of interactivity significantly increases the time spent in the DAL ($M_{low\ information}$=4.373 vs. $M_{high\ information}$=6.148, t=4.710, p<.001). The ANCOVA (Step 3) illustrates that the effect of interactivity on brand attitude is no longer significant (F(1, 2.093), p=.149) when integrating the time spent in the DAL (F(1, 2.769), p=.097) as a covariate. However, the significance levels of the effects of both variables (interactivity and time) on brand attitude are rather weak. This indicates that time spent in the DAL fully but weakly mediates the effect of interactivity on brand attitude.

H3 is supported. Both the effects of the level of interactivity and the amount of information on brand recall and brand attitude are at least partly mediated by the time spent in the DAL.

FUTURE TRENDS

The main conclusion of this study is that the positive effect of interactivity in the DAL is remarkably noticeable on both brand recall and attitude. Since the amount of information did not have a negative effect in any way, advertisers may be advised to provide their DAL with enough information. High amounts of information will increase the time spent in the DAL, and will therefore indirectly have a positive effect on brand attitude and recall.

A telescopic ad fits into a number of new advertising and marketing trends (see also Rappaport, 2007). A telescopic ad can be used on demand given the technical possibility to store the DAL on the television. This allows the viewer to ask for product information whenever convenient for him or her and fits into the trend of consumer-controlled two-way communication. A telescopic ad can also be the starting point to increase engagement with the brand. All consumer data (clicking behaviour, time spent, e-mail, etc.) can be stored and used to develop long-lasting relationships between the customer and the company. In this way, it fits into the trend of shifting the focus from transaction-oriented marketing (push) to relationship marketing. The telescopic ad can also be used as an extra service for the consumer. This is particularly relevant for product categories that are at least moderately involving, such as banking, insurances,

and durables. In mature and saturated markets, brands will have to be full-scale solution providers rather than merely offering functional product benefits. Telescopic ads can also tap into the experiential marketing trend: Brands should be experienced, not merely communicated. Telescopic ads can offer the extra experiential context that a modern brand needs.

Our study provides some directions for research that would provide guidance with respect to what successful telescopic ads should look like in the future. First, our results are only pertinent when the respondent reacts to the call for action and uses the interactive possibilities. A real-life study is necessary to explore the actual click-through behaviour more validly. Further research could investigate under which circumstances a viewer will react to the call to action that appears in the 30" ad. Further research could examine the role of the product message or offer in the ad, the creative style of the ad, the impact of the congruency between the ad message and the information provided in the DAL (in terms of expectancy, relevance, humour, etc.), and so on. Only the amount of information and the level of interactivity were manipulated in this study. Other aspects of the DAL, such as the quality of the information, the vividness (color, animation, graphics), or the occurrence of a simultaneous media context, could also be investigated.

CONCLUSION

The cognitive involvement and the intrinsic enjoyable experience evoked by the interactivity may explain these results, which are in line with earlier Internet studies (e.g., Sicilia et al., 2005). A higher level of interactivity presumably makes the DAL moderately complex without demanding too much cognitive resources to process it, and therefore leads to positive results. The amount of information had no negative effect on brand recall or on brand attitude. The level of interactivity had a positive effect on both brand recall and attitude. Therefore, this study could not confirm the expectations based on the complexity theory and the cognitive-load theory, which states that too much information causes the respondents to feel lost or overwhelmed, leading them to lose focus and interest rapidly.

There are several possible explanations for not finding the information overload effect. The effect of the amount of information appears to be fully mediated by the time spent in the DAL. Also, the effect of the level of interactivity is partially mediated by the time spent in the DAL. Consequently, if the amount of information and the level of interactivity increase, the respondent will also spend more time processing that interactive information. This may offer an explanation as to why the overload phenomenon did not occur. A second explanation can be offered based on the information processing insight that a consumer can experience information overload in decision making processing, but will not necessarily do so. Maybe in this study the information overload, and thus the negative advertising results, did not occur because the individuals did not allow it to happen, only processing the amount of information that they desired. A third possible explanation is based on the premise that when individuals get familiar and experienced with interactivity, the cognitive load induced by it may be reduced. As such, experienced Web users have less difficulty with processing interactive content than less experienced ones. The participants in our study, like many people nowadays, were probably used to frequently engaging in interactive information processing (e.g., on the Internet, third-generation mobile phones, ATMs, etc.), and therefore did not experience overload.

In conclusion, the study illustrates that the negative impact on brand responses of information overload induced by a complex advertising stimulus (manipulated by the amount of information and level of interactivity) is not likely to occur in a real-life interactive context. The interactivity does increase user control, and the user can decide on the sequence and how much time he or she spends processing the information, therefore managing the information load him- or herself. Our results show that interactivity can increase advertising effectiveness regardless of the amount of information provided. Moreover, the longer the viewer stays in the DAL (as a result of interaction possibilities and/or extra information), the more positive the advertising effects become.

KEY TERMS

Cognitive Overload: Cognitive overload occurs when the volume of information supply exceeds the information processing capacity of the individual.

Dedicated Advertising Location (DAL): A DAL contains clickable content featuring individual still screens providing additional product information.

Flow: Flow is an intrinsically motivated, optimal enjoyable mental state leading to increased attention, cognitive involvement, and a feeling of fun and escapism.

Interactive Digital Television (IDTV): IDTV is the merging of the Internet and television.

Interactivity: It is human-to-human interaction that places the emphasis on two-way communication, mutual discourse, feedback, and so forth, and message-to-human interaction, which is related to aspects of content such as user choice, user (information) control, structure, and so on.

Stimulus Complexity: This refers to the amount of variety and diversity in a stimulus pattern.

Telescopic Ad: It is a 30-second TV ad with a call-to-action button and clickable content or microsites featuring individual still screens providing additional product information.

Testing Graphical User Interfaces

Jaymie Strecker
University of Maryland, USA

Atif M Memon
University of Maryland, USA

INTRODUCTION

In recent years, an emerging trend in software products has been toward the use of graphical user interfaces (GUIs). More user-friendly than traditional, text-based interfaces, GUIs serve as the front-end for a large portion of today's software applications. Technologies like Ajax are helping to spread familiar GUI interaction styles to Web applications. With the rise of ubiquitous computing, users are interacting with GUIs in a widening range of situations—not just with their PCs, but with their dishwashers and cars. Critical applications, such as banking systems, are moving to GUIs as well. Thus, quality assurance for GUI-based software is growing more important every day.

With GUIs, users enjoy many degrees of freedom in the way they interact with the software. While this benefits users, it challenges testers. Because users may interact with a GUI in a variety of unexpected ways, it is difficult to insure that the software meets its functional requirements (correctness) and non-functional requirements (e.g., usability) for all possible interactions. The difficulties are compounded by the frequent intersection of GUIs with other emerging technologies, including component-based and service-oriented architectures. New trends in software development, such as rapid development cycles, globally distributed developers, and open-source projects, make the quality assurance process ever more challenging.

This chapter describes the state of the art in testing GUI-based software. Traditionally, GUI testing has been performed manually or semimanually, with the aid of capture-replay tools. Since this process may be too slow and ineffective to meet the demands of today's developers and users, recent research in GUI testing has pushed toward automation. Model-based approaches are being used to generate and execute test cases, implement test oracles, and perform regression testing of GUIs automatically. This chapter shows how research to date has addressed the difficulties of testing GUIs in today's rapidly evolving technological world, and it points to the many challenges that lie ahead.

BACKGROUND

A GUI provides a visual front-end through which a user can interact with a software application. Although there are various models for GUI design, the most commonly used in practice and in software-testing research—and hence the model assumed in this chapter—is the WIMP model with *w*indows, *i*cons, *m*enus, and *p*ointing devices (Nielsen, 1993). The GUI is made up of *widgets*—such as buttons, text boxes, and labels—that the user can manipulate to send input to the underlying software and the software can, in turn, manipulate to send output to the user. Each widget has a set of *properties*—for example, "font", "width", "enabled"—each of which has some *value*—for example, "Helvetica", "100", "true" (Yuan & Memon, 2007).

Widgets are contained in *windows*, which may either be *modal* or *modeless*. A modal window blocks the user's interaction with other windows while it is active, whereas a modeless window imposes no such restrictions. A *window's state* at any particular time is the set of all triples (*w*,*p*,*v*) such that *w* is a widget in the window, *p* is a property of *w*, and *v* is the value of *p*. The *GUI state* then consists of the state of all windows in the GUI (Yuan & Memon, 2007).

As the user interacts with the GUI, the state of both the GUI and the underlying software can change. When the user performs an *event* on the GUI—such as clicking a button or typing in a text box—a piece of application code called an *event handler* is executed. The event is the basic unit of interaction with a GUI. To accomplish a task, a user typically must perform multiple events in sequence. Hence, a *GUI test case* consists of a sequence of events (Yuan & Memon, 2007).

Several tools and techniques are available to aid testing of GUI-based applications, varying greatly in the level of automation they provide. Ignoring the GUI altogether, test harnesses like JUnit can interact directly with the underlying software much like the GUI would. However, this may require major changes to the GUI's architecture, and, at any rate, it leaves an important part of the end-user software untested.

JUnit has been extended in tools such as JFCUnit, Pounder, and Jemmy Module to interact with the application under test through its GUI. With these tools, test cases must be written manually. Alternatively, a tester can generate test cases by recording sequences of events, which the tester manually performs on the GUI, using a capture-replay tool. Some capture-replay tools—for example, CAPBAK and TestWorks—record events in terms of mouse coordinates, while others—for example, WinRunner, Abbot, and Rational Robot—record the GUI widgets associated with events. The latter are more robust in the face of superficial changes to the GUI layout (Memon & Xie, 2005).

All of the tools and techniques mentioned so far automate the execution of test cases but still require substantial effort on the part of the tester to generate test cases, define the test oracle, and modify the test suite as the application under test evolves. Tools like the visual test-development environment created by Ostrand, Anodide, Foster, and Goradia (1998) streamline the testing process but do not depart from the conceptualization of GUI testing as a fundamentally manual process. Similarly, while Kasik and George (1996) have shown how genetic algorithms can be used to augment a test suite, they leave much work to the tester. Fortunately, new techniques based on various types of models of the GUI are shifting much of the burden of the testing process from humans to machines.

The most popular type of GUI model, the state-machine model, makes it possible to generate test cases—or perform model-checking, a related activity—automatically (Belli, 2001; Berstel, Reghizzi, Roussel, & Pietro, 2005; Dwyer, Carr, & Hines, 1997; Holzmann & Smith, 1999; Shehady & Siewiorek, 1997; White & Almezen, 2000). But techniques based on state-machine models have serious drawbacks. These techniques require that the model be created manually, that a formal specification be written, or that the source code be annotated—in any case, a potentially laborious task susceptible to human error. Further, since the effectiveness of the test cases generated from the state-machine model depends on the model creator's definition of "state", two testers testing the same application may get quite different results (Yuan & Memon, 2007). Techniques for generating test cases from UML diagrams suffer from similar weaknesses (Vieira, Leduc, Hasling, Subramanyan, & Kazmeier, 2006).

Rather than modeling a GUI in terms of states, others have modeled it in terms of events. Memon, Pollack, and Soffa (2001) have used automated planning to generate test cases that consist of sequences of events chosen to accomplish tasks specified by the tester. In this approach, model creation requires substantial human effort: although the events in the model are identified automatically, their preconditions and effects must be defined manually. More recently, techniques have used event-based models to further reduce the amount of effort required in the testing process while improving its effectiveness. These are described in the next section.

GUI TESTING WITH EVENT-FLOW MODELS

Events are central to the dynamic structure of a GUI-based application. A user accomplishes tasks via the GUI by performing sequences of events. Thus, the execution of the application occurs as the execution of a sequence of event handlers, each of which may depend on and may also affect the state of the application. Users may interact with the application in unexpected ways, so the event handlers may be executed in unexpected orderings. In these respects, GUI-based applications differ from traditional, batch-style software (e.g., compilers), which receives some input, processes it, produces some output, and terminates. Traditional testing techniques like code-based coverage criteria that were designed for such software may not work as well for much differently-structured GUI-based applications, so new techniques have been developed to address GUIs' event-driven nature (Memon, 2002).

The previous section showed how GUI-testing tools and techniques have evolved to be faster and more effective. Notable advances have been achieved through model-based testing, using various types of models. In recent years, one type of model has proved particularly successful: the *event-flow graph*.

Event-Flow Graph

In an event-flow graph, a GUI is represented by a graph whose vertices represent events and whose edges represent the *follows* relationship. Event e_1 is said to *follow* event e_2 if e_1 can be executed immediately after e_2, with no events intervening. Test cases can be generated rapidly and automatically by traversing the EFG, and coverage criteria can be defined in terms of the EFG. Variations of the EFG have been used to further improve the cost-effectiveness of GUI testing. Each of these topics will be elaborated upon after the process of creating an EFG is explained (Xie & Memon, 2006).

An EFG can be reverse engineered semi-automatically from a GUI in a process called *GUI ripping*. A single GUI window is ripped by identifying and recording properties of all of the widgets it contains, then executing any events available in the window that open new windows. This can be accomplished by running the GUI with reflection to access the currently open windows and inspect their widgets. Widgets likely to open new windows can be identified based on conventions in GUI design: clicking on a widget whose caption ends in "..." typically opens a window. As

new windows are discovered, each is ripped until no more new windows are found. Since the GUI may not be ripped perfectly—indeed, the GUI itself may contain defects that show up in the resulting GUI model—the tester must examine and possibly edit the model. The GUI model provides the information necessary to determine the *follows* relationships for all of the events and, hence, to construct the EFG (Memon, Banerjee & Nagarajan, 2003).

Any path through the EFG starting at an event that is available when the application under test is launched can serve as a test case. However, the number of possible test cases grows exponentially with the length of the path. Short test cases can find some faults, but many faults can only be detected with longer event sequences (Yuan & Memon, 2007). Thus, one challenge of GUI testing is to identify which of the longer sequences are most likely to add value to testing. Several variations of the EFG have been created to address this challenge.

Variations of the Event-Flow Graph

An important observation about the EFG is that it contains many events that are unlikely to be defective. The handler for an event that opens a menu, for example, is almost always located in library code and does not interact with the application code in any way. This observation leads to a variation of the EFG called the *event interaction graph (EIG)* that achieves marked size reduction without sacrificing fault-detection potential by omitting events that need not be tested as rigorously as the rest. The vertices in the EIG represent *system-interaction events*—events that either close windows or perform actions without opening or closing any windows or menus. Examples of system-interaction events include clicking the "OK" button in a preferences window and using the "copy" event to copy objects to the clipboard. Edges in the EIG represent the *interacts-with* relationship. A system-interaction event e_1 is said to *interact with* a system-interaction event e_2 if there is a path from e_1 to e_2 in the EFG that contains no system-interaction events other than e_1 and e_2. Test cases can be generated by traversing the EIG to get sequences of system-interaction events. To make the test cases executable on the GUI, they must be mapped onto the EFG to fill in the necessary nonsystem-interaction events before and between system-interaction events (Memon & Xie, 2005).

Even with its substantial size reduction compared to the EFG, the EIG can be unwieldy for large applications. Testing all length-*n* event sequences in the EIG is only feasible for the smallest values of *n*, often just 2. But many of the longer event sequences can safely be skipped during testing—namely, sequences in which the event handlers do not affect each other. If the handlers of events e_1 and e_2 do not interact, then executing e_1 and e_2 in sequence will not reveal any faults that could not be revealed by executing each of e_1 and e_2 by itself. The *event semantic interaction graph (ESIG)* is a subgraph of the EIG that omits edges between unrelated events. In the ESIG, an edge from event e_1 to e_2 means that there is an *event semantic interaction* relationship between e_1 and e_2, or, in other words, executing e_1 followed by e_2 results in a GUI state that is in some sense different from the state that would have resulted if e_1 and e_2 had been executed in isolation. An example of an event semantic interaction in a word processor occurs between the events "select all" and "delete": performing delete just after select all modifies the text on the screen differently than executing either select all or delete does. But select all would not be expected to semantically interact with, say, "change page orientation". The event semantic interaction relationship is defined in terms of dynamic GUI state, rather than static source-code properties such as variables shared by event handlers, because pervasive design elements in GUI software—such as multiple languages, callbacks for event handlers, multi-threading, and the use of libraries—limit the applicability of static analysis. The ESIG is constructed automatically by running an initial test suite that covers all edges in the EIG and analyzing the states into which each test case drives the GUI. As with the EIG, test cases can be generated from the ESIG by traversing the graph and filling in any necessary nonsystem-interaction events (Yuan & Memon, 2007).

Another variation of the EFG, the *probabilistic event flow graph (PEFG)*, has been used to focus testing on the event sequences that users are most likely to perform. The PEFG consists of an EFG in which paths are annotated with probabilities indicating the likelihood that a user would follow that path. These probabilities come from *usage profiles* (also called *operational profiles* or *session data*), which are event sequences captured automatically as users interact with the program. Although the usage profiles could simply be replayed on the application (as in capture-replay tools), test cases generated by traversing high-probability paths in the PEFG offer some advantages. First, because the PEFG represents a composite of different usage patterns, some high-probability paths, while not executed by any individual user during usage-profile collection, are likely to be executed by future users. Testing these paths, then, can reveal faults that future users would be likely to encounter. Second, generating test cases from the PEFG is more flexible in the face of changes to the GUI than replaying users' interactions verbatim (Brooks & Memon, 2007).

Running Test Cases

Test cases generated from any of these models—the EFG, the EIG, the ESIG, or the PEFG—can be executed automatically. Much like in GUI ripping, the application under test is run under reflection, enabling the widgets specified in the test cases to be identified and manipulated to perform

events. The resulting output can be recorded and checked (run through the oracle procedure) automatically (Xie & Memon, 2007).

As mentioned previously, the way GUIs communicate information to users departs from the traditional batch style. GUI output is complex: rather than a number or text string, it consists of the property values of all of the widgets the user can see, including their structure and position relative to one another. Each event the user performs can drive the GUI into a new state, producing new output in the form of changes to the GUI. Even if the final GUI state resulting from an event sequence is correct, those at intermediate steps may not be. Recording and checking the entire GUI state after each intermediate event, while effective at detecting faults, costs time and space. The cost of applying the test oracle can be reduced by collecting less *oracle information* or relaxing the *oracle procedure*, at the price of reduced fault detection. The amount of oracle information—property values of widgets in the GUI—that must be collected and checked each time the GUI state is captured can be reduced by omitting widgets outside the currently active window or even outside the most recently manipulated widget. The oracle procedure—which compares the actual oracle information to the expected behavior—may be called less frequently—for example, only after the last event in the test case. Although less stringent oracles may be cheaper, thorough oracles can be more cost-effective. Moreover, stricter oracles can make up for a shortage of longer test cases (Xie & Memon, 2007).

Another factor that affects the cost-effectiveness of GUI testing is the coverage criterion (or test-adequacy criterion) that defines when the GUI has been tested enough. Coverage criteria have been defined in terms of the event-flow models described above—for example, "all events", "all EIG edges", or "all length-*n* event sequences in the EFG". Event-based coverage criteria are more closely tied than code-based coverage criteria to the way the application is used and the way its components interact. Model-based approaches to GUI testing not only provide a way to define coverage criteria, but, by enabling many testing tasks to be automated, also make it feasible to satisfy those criteria (Memon, 2002; Memon, Soffa & Pollack, 2001).

Regression Testing

Of course, a testing technique does not just need to be successful the first time around—it must be cost-effective throughout the life-cycle of the software, across many iterations of regression testing. This is especially critical given the rise of rapid development cycles and multiple, geographically-distributed developers and maintainers. Enabling testers to rapidly construct a GUI model and generate test cases from it, event-flow models support the creation of a new, disposable test suite for each revision of the software. In addition, testers may want to create a more permanent set of test cases for regression testing. Although minor changes to the GUI tend to break test cases generated from the EFG, test cases generated from the EIG have proved to be more robust, withstanding changes like moving events from one window to another and changing the structure of menus (Memon & Xie, 2005; Xie & Memon, 2006).

FUTURE TRENDS

As GUI testing is integrated into development processes, we expect that different styles of GUI testing will be adapted to different parts of the processes. Xie and Memon (2006) have proposed three concentric loops of testing that vary in speed and thoroughness. For rapid, fully automated testing, which may be performed each time a code revision is committed, a few EIG edges are covered and the oracle procedure simply checks for crashes; this technique is called *crash testing*. Over multiple iterations of crash testing, different EIG edges are covered, so that eventually all are tested. In *smoke testing*—a slower, more comprehensive form of testing that may be performed in conjunction with a nightly build—test cases covering all EFG vertices or edges are generated and used to reference test the current version of the software against an earlier version. The most labor-intensive forms of GUI validation—such as manually-created test cases and state-model-based techniques—may be reserved for release testing.

GUIs belong to the larger class of event-driven (or reactive) software—a class of software that challenges testers in many ways. The GUI-testing techniques described here may in the future be generalized to other kinds of event-driven software. This may include component-based applications, object- and service-oriented applications, network protocols, and Web applications, as well as nonWIMP GUIs. The event-flow models of GUI usage will have to be extended to handle complications like event timing, multiple users or input streams, and relaxed assumptions about turn-taking between users and computers (Memon, 2004; Nielsen, 1993).

CONCLUSION

As GUIs become more pervasive and more is demanded of them, the importance of their quality assurance is growing. The need to incorporate GUI testing into testing processes throughout the software life-cycle is becoming apparent. Over the past several years, advances in model-based GUI testing have made this more cost-effective by providing test-adequacy criteria and by automating test-case generation, test execution, test oracles, and regression testing. In the future, GUI testing may commonly be woven into the testing process, with different levels of testing designed to

meet goals at different time scales. Lessons learned from GUI testing will likely be applied to the testing of other kinds of event-driven software.

Yuan, X. & Memon, A. M. (2007). Using GUI run-time state as feedback to generate test cases. In *Proceedings of the 29th International Conference on Software Engineering* (pp. 396-405).

KEY TERMS

Graphical User Interface (GUI): A visual front-end through which a user can interact with a software application.

GUI State: The collection of states of all windows in the GUI, where a window's state is the set of all triples (w,p,v) such that w is a widget in the window, p is a property of w, and v is the value of p.

Event: The basic unit of input to a GUI, triggered by such user actions as clicking a button or typing in a text box.

GUI Test Case: A sequence of events to be performed on the GUI.

Event Handler: A piece of application code that executes in response to an event.

System-Interaction Event: An event that either closes a window or performs some action without opening or closing any windows or menus.

Event-Flow Graph (EFG): A graph representation of a GUI in which vertices represent events and an edge from event e_1 to event e_2 signifies that e_2 can be performed immediately after e_1.

Event-Interaction Graph (EIG): A graph representation of a GUI in which vertices represent system-interaction events and an edge from event e_1 to event e_2 signifies that there is a path from e_1 to e_2 in the EFG that contains no system-interaction events other than e_1 and e_2.

Event Semantic Interaction Graph (ESIG): A graph representation of a GUI in which vertices represent system-interaction events and an edge from event e_1 to event e_2 signifies that performing e_1 followed by e_2 results in a GUI state that is qualitatively different from the state that would have resulted had e_1 and e_2 been performed in isolation.

Probabilistic Event-Flow Graph (PEFG): A graph representation of a GUI that consists of an EFG whose paths are annotated with probabilities of traversal by users.

Third Places in the Blackosphere

C. Frank Igwe
The Pennsylvania State University, USA

INTRODUCTION

Although times change, there are certain human elements that survive through the ages. These elements include the need for expression, companionship, involvement, connection, and information. The avenues by which humans engage in these social practices have evolved, and with the dawn of the Information Age we are seeing the emergence of new forms of computer mediated communication (CMC), with Weblogs (or blogs) being a manifestation of this transformation. This chapter deals with these Information and Communicative Technologies (ICT), and more specifically, how blogs are being used by African Americans on the positive side of the digital divide to create virtual "third places", to rebuild aspects of community dialogue that have been lost in the physical "real-world". These "third places" arise out of a need for individuals to find a dependable, neutral place of refuge to gather and interact, away from first places (home) and second places (work), often conferring or dealing with issues that may considered too taboo for public discussion by the community at large.

With this in mind the researcher identified an issue within the African American community that was of consequence, and yet was not being addressed due to individual or social pressures. The problem that presented itself was the lack of discussion and social support pertaining to the Human Immunodeficiency Virus (HIV), and Acquired Immune Deficiency Syndrome (AIDS).

BACKGROUND

African American HIV/AIDS Statistics

HIV/AIDS statistics paint a particularly disturbing picture for African American females, due to the fact that they account for a disproportionate number of infections relative to other social groups (Phillips 2005), and 75% of new HIV/AIDS cases within the larger African American population. The Center for Disease Control (CDC), states that HIV/AIDS is among the top 4 causes of death for African American women aged 25–54 years, and the number 1 cause of death for African American women aged 25–34 years (CDC 2006). In 2001, HIV/AIDS was among the top three causes of death for African American men 25-54 years of age, and of persons diagnosed with AIDS since 1995, a smaller percentage of African Americans (60%) were alive after 9 years compared with Whites (70%) (due in part to late diagnosis) (National Institute of Health 2007). Despite these figures, there is still a deafening silence associated with the discussion of the disease, because contraction of the HIV virus is seen as a consequence of behaviors that are stigmatized within the largely religious and conservative African American community (i.e., promiscuity, homosexuality, or drug use), framed within the context of sin and immorality (Baker 1999).

Communities and Expression

An interesting element of any functional community is that it is self-sustaining. In order to be self-sustaining a community has to possess the ability to address issues that affect members' wellbeing, in either a direct or indirect fashion, to ensure that what members are getting out of the association exceeds the cost. Every healthy community discusses issues that threaten its survival. However, the number of African Americans infected and dying from HIV/AIDS is staggering, and the silence associated with the epidemic is akin to having "an elephant in the room" that nobody wants to talk about. This conflict, and the fear of violating group discussion norms, has created a prevalent silence on the subject, and degraded certain aspects of community, namely: emotional safety, sense of belonging, and positive reinforcement when members of the community engage the problem through dialogue.

It is believed that in an effort to "heal" itself of this silence, and restore aforementioned communicative elements of community that have been diminished, African Americans have resorted to finding other outlets to discuss the epidemic; one outlet is online third places. Blogs were chosen because they represent a single place, outside of large social gatherings, where people can engage in real time conversations on a grand scale, and unlike their physical counterparts, users are empowered by the relative cloak of anonymity afforded by the Internet. Never before has a medium such as ICT existed that can connect and enable conversations from members representing all classes of the community, with potentially everyone able to contribute to the discussion and be heard. By technology being an enabler for rebuilding aspects of community, it adds impetus to the drive towards eliminating the "digital-divide" through tangible benefits, such as improved health outcomes through preventative, rather than reactive, practices.

VIRTUAL COMMUNITIES

With the advent of the Internet, we are seeing a movement away from the traditional depiction of communities built around geographic lines, and are seeing the emergence of "communities of interest", or self-organizing virtual communities[a] that are born of individuals who share similar interests on a topic, or topics, that is independent of their geographic location. As stated by Weinberger, "what holds the Web together isn't a carpet of rocks [i.e., the physical Earth], but the worlds collective passion" (Weinberger 2002). With this statement in mind, Milne (2004) provided a germane and useful working "technological" definition of community that suits the needs of this paper. According to Milne, "Community is a social technology for bonding people together through shared characteristics that leads to a sense of belonging". Milne goes on to say that "community" also encompasses the people who are so bonded [technologically], and forming a community is a way to foster a sense of belonging, which serves a wide range of human needs and is the basic survival strategy for individuals and groups (Milne 2004).

Weblogs and Community

Weblogs are defined as "frequently modified Web pages in which dated entries are listed in reverse chronological sequence" (Herring, Scheidt et al. 2005). These Weblogs have also been characterized as having a "community-like" nature to them, due to the inherent interactiveness of the posts, which allow readers to respond to individual entries, which fosters "conversational" exchanges on the blog site itself. Marlow (2004) states that "The weblog medium, while fundamentally an innovation in personal publishing, has also come to engender a new form of social interaction on the Web: a massively distributed but completely connected conversation covering every imaginable topic of interest" (Herring, Kouper et al., 2005; Marlow 2004). Graham (1999) describes blogs as "a community, of sorts, a small town sharing gossip and news, recreation and sport, laughter and tears, all for the commonwealth." The power of real social bonds of virtual communities was captured by one blog participant when he stated that "Weblogs are the first example I've encountered where people are meeting each other in masses, and forming real social bonds, the type of relation you'd call your friend…There's a real sense of solidarity in the relationships we're forming."[b] (Bausch, Haughey et al., 2002). These virtual relationships may prove handy when individuals are faced with a myriad of pressures that may go unabated, with no source of social support systems upon which to lean, as evidenced by the HIV/AIDS epidemic, and its minimal discussion by African American's in "the real world".

THE DIGITAL DIVIDE

Past research has shown that there exists a chasm between individuals who have access to information via computers and the Internet, and those that do not. This chasm has resulted in a corresponding gap between the information rich and the information poor, the haves and the have-nots. This phenomenon has been described in literature as the "digital divide". The digital divide was first observed as distinct group clusters most likely to use the Internet, namely: white, men, residents of urban areas, greater access to education, income and other resources necessary to get ahead (Kvasny & Keil, forthcoming; Mossberger, Tolbert et al., 2003; Norris 2000).

Noting the effects of the digital divide, and the increased likelihood that poorer African Americans will not have access to computers, and thus access to virtual third place sites, one may be tempted to believe that this research is germane only to middle and upper-middle class African Americans. However, this assumption would be false, because research has shown that interactions between African Americans spans class, with upper and middle income members of the community in frequent contact with poorer friends and family. The socioeconomic Web of African Americans transcends the nuclear family that they themselves create, and reaches back to the families to which they were born, their siblings, extended family and friends (Pattillo, 2006). Therefore, the ensuing conversations on the site serve as a means to enrich personal networks via the accessing of new information by means of weak ties (or casual acquaintances), and sharing this newfound information with those with strong ties (or family and friends).

Oldenburg's "Third Places"

The silence associated with HIV/AIDS by traditional African American institutions created a need to form social bonds in other arenas. This need provided fertile conditions for the rise of an alternate place to gather and discuss transcendent issues; such places are typically born out of a need, and can be labeled as "third places". Every stable community is comprised of a first place (home), a second place (work), and a third place (informal gathering location). If one of these components is missing, it affects the stability of the community (Baker-Eveleth, Eveleth et al. 2005). The third place (bars, cafes, barbershops, etc.) provides a context for sociability, spontaneity, community building and emotional expressiveness" (Oldenburg & Brissett, 1982). Within the framework of computer mediated communication there has been a realization that cyberspace (such as blogs, chatrooms, etc.) resemble traditional types of physical social settings described by Oldenburg, providing an informal place where individuals gather to rebuild communicative aspects of community that may be lost (Soukup, 2006).

Oldenburg (1999) describes and elaborates the essential characteristics of third places as:

1. Being on neutral ground
2. Being levelers
3. Conversation being the main activity, with the mood being playful
4. Accessible
5. Are a home away from home, and have "regulars"

NEUTRAL GROUND

Neutrality is not used in a political or position-taking sense, rather it is used to denote that within third places nobody is burdened with the role of being a host or a visitor. This freedom gives individuals in these settings the ability to come and go as they please, easing the task of association, essential to community life. Neutral ground allows for more informal and intimate relationships among people, which cannot necessarily be found in the home.

Levelers

Places that are considered "levelers" are inclusive places that do not have any formal rules for membership and exclusion, and are accessible to the public at large. In locations that are levelers, worldly status claims do not carry as much weight, and there is a realization that there is more to a person than status may indicate. The nature of online environments make physical attributes or material wealth moot in regards to the ability to interact with other members of the community (Baker-Eveleth, Eveleth et al., 2005).

Conversation/Fun

Third places provide a fun atmosphere, due in part to the fact that friends gathered in numbers create a festive mood, and the burden to contribute to the conversation is spread out over many people, making individual interaction easy. This "fun" is created by the members of the community themselves, with the sustaining activity being conversation, which covers the entire range of being passionate and lighthearted, serious and witty, informative, and silly. Everyone who is part of these communities is expected to understand that it is in good fun, and also expected to give-and-take with civility and humor, with the style of conversation emphasized over vocabulary.

Accessible

Third places are places where individuals can go to at almost anytime of the day or night and be reasonably sure that acquaintances will be there to relieve loneliness, boredom or frustrations of the day. Accessibility should be qualified more specifically as "easy accessibility" in order for the third place to survive and serve. The nature of online conversations make it available to anybody who has access to a Web browser and an Internet connection, making it accessible 24 hours a day, seven days a week (Baker-Eveleth, Eveleth et al., 2005).

The Regulars

Third places are often considered more homelike than home, with the definition of a "home" conforming to the notion that it provides a "congenial environment". However, third places will remain simply a "space" without the right people who can transform it into a "place" (Harrison & Dourish, 1996). The people who make this transformation possible are the "regulars", who assure that on most visits a member of the core "gang" is there. It is the approval of the regulars that is critical for welcome and acceptance. Regulars are formed by reappearances and fairly decent game play, with the person able to give and take according to the group norms.

African American Virtual Third Places

Research has found that there is indeed a vibrant community of Black bloggers (Poole, 2005) that is known as the "Blackosphere", as described by Francis Hollander (2007):

These blogs are by and principally for Black people, focusing not only upon Black people but upon people and issues deemed relevant to the Black people who write these blogs and post comments. At Black blogs, we comment on the issues of the day raised in white newspapers and blogs, but we also highlight issues that whites mostly ignore, such as the unfair criminal prosecution of individual humble and unknown Blacks. Our commentary and the relative importance that we give news are informed by our unique historical perspective on and position in America. From our vantage point, we share with each other a distinct perspective and critique that white people, including white progressives, cannot have and generally do not want.

Empirical findings from research of this "Blackosphere" reveals that there are indeed a significant number of individuals within the African American community that utilize blog sites to discuss the crisis of HIV/AIDS, as opposed to the lack of discussion or communal support found in traditional African American "real world" communities (Igwe, forthcoming). This use of technology, specifically blogs, to discuss HIV/AIDS served as a means to circumvent and release frustration directed towards the inactivity of established institutions. This medium was also used to try to make sense of the HIV/AIDS dilemma while discussing

practical protective measures. The blog was a place where rich conversations took place, which helped increase community cohesiveness and emotional wellbeing as participants realized that they were not alone in dealing with the ramifications of the disease running rampant in the community (Igwe, forthcoming).

FUTURE TRENDS

Although information does not guarantee better health practices, it is an important step in health behavior change (Freimuth, Stein et al., 1989). Future research should investigate how conversations in virtual third places manifest themselves in real world action. For example, how do virtual third place HIV/AIDS conversations correspond to health information seeking from physical institutions? It should be said that in order for individuals to engage in health information seeking, uncertainty must be experienced, whether through physical symptoms, or external sources such as television, posters, friends, or information technology (Freimuth, Stein et al., 1989). Further research should explore whether technology (via virtual third places), stimulates this uncertainty, and is this uncertainty enough to stimulate further health information seeking among online African Americans?

CONCLUSION

Findings from researching the "Blackosphere" reveal that they do indeed exhibit characteristics of Oldenburg's third place communities, in virtual world environments (Igwe, forthcoming). The first level of inquiry finds that there is support for Oldenburg's characterization of conversations being the major activity found in third places, and these conversations tend to have a witty or playful nature and are on neutral ground. The second level of inquiry shows that there is support for Oldenburg's characterization of third places being accessible and having regulars. A third level of inquiry showed that there was support for Oldenburg's characterization of leveling found on the Website. The Websites found in the Blackosphere were places where rich conversations took place, and the anonymity afforded by the Internet allowed individuals to establish themselves based more on the content of their textual discourse, rather than real world physical characteristics.

The chapter makes a significant and novel contribution to the existing body of literature and knowledge within the Information Science domain through the utilization of an existing framework to build a strong foundation for future studies of blogs, virtual third places, and HIV/AIDS. This is a foundation that the author hopes will be built upon. This foundation further serves to aid in the understanding of factors that contribute to the utilization of technology by African Americans to rebuild communicative aspects of community. Finally, it aids in the understanding of how blogs serve as virtual third place for those in need of a place to discuss, vent, or cope emotionally with the HIV/AIDS epidemic, and circumvent the silence and inaction from traditional institutional forces within the community.

KEY TERMS

Virtual Communities of Interest: Self-organizing virtual communities that are born of individuals who share similar interests on a topic, or topics, that is independent of their geographic location.

Information Age: The period beginning in the last quarter of the 20th century marked by the increased production, transmission, consumption of, and reliance on information.

Third Places: a location that has a role intermediate between the home and the workplace and that allows people to be around other people without being in a structured setting. Examples include coffee shops, pubs, libraries, and public plazas. The essential characteristics of third places are: (1) being on neutral ground, (2) being levelers, (3) conversation being the main activity, with the mood being playful, (4) accessible, (5) are a home away from home, and have "regulars"

Weblogs: Frequently modified Web pages in which dated entries are listed in reverse chronological sequence.

Digital Divide: Chasm between individuals who have access to information via computers and the Internet, and those that do not.

Blackosphere: Blogs that are by, and principally for, Black people, focusing not only upon Black people but upon people and issues deemed relevant to the Black people who write these blogs and post comments.

Health Information Seeking: The search and retrieval of messages that help to reduce uncertainty regarding health status and construct a social and personal (cognitive) sense of health.

3-D Digitization Methodologies for Cultural Artifacts

K. Lee
The University of Auckland, New Zealand

X.W. Xu
The University of Auckland, New Zealand

INTRODUCTION

Historic cultural artifacts are objects of high importance and value. They give evidence of a civilization's culture, heritage, and development over time, and often date back thousands of years and are irreplaceable. Thus, the preservation and protection of artifacts against damage or theft is an issue of importance to museums and other conservation organizations.

Developments made in the fields of computer vision and technology have allowed information about artifacts to be archived digitally. These developments have facilitated the use of electronic models and replicas, and have led to numerous organizations, worldwide, increasing research into methods of artifact digitization . (Surendran, Xu, & Stead, 2007)

The three main methods of digitization can be broadly defined as contact digitization, image-based digitization (photogrammetry), and geometry-based digitization (laser scanning). With the development of the latter two digitization methods, and advanced rendering technologies, virtual displays and museums can now be used widely. (Hung, 2007) Furthermore, recent developments in interactive 3-D computer graphics technology have seen an increased interest in, and use of, 3-D digitization for cultural heritage objects. (Muller-Wittig, Zhu, & Voss, 2007) Technologies for reconstructing or remodeling physical components in 3-D formats are not new in the engineering field, in particular within manufacturing engineering. However, 3-D digitization used for the preservation and archiving of cultural artifacts is relatively recent.

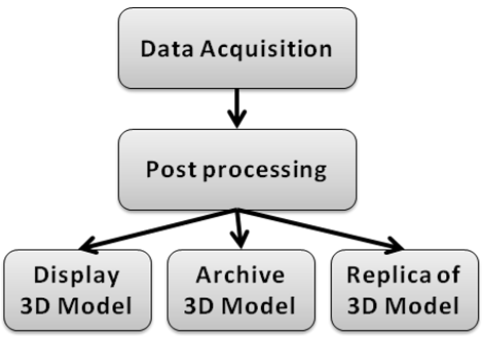
BACKGROUND

Digitization of artifacts is the process of converting spatial and color information into digital formats. 3-D digitization refers specifically to creating a digital representation of an object in three spatial dimensions, that is, Cartesian x, y, and z coordinates. During 3-D digitization, depth, size, proportion, and textural information about the artifact are recorded and stored in electronic form.

There are a wide range of techniques available in the field of 3-D digitization. The specific approach to digitization differs depending on the artifact and the final intended application of the data. The overall process of 3-D digitization involves three broad steps, as shown in Figure 1. Data are acquired using a method of determining and recording the spatial details of the artifact. The raw data are then processed to form complete rendered 3-D models, and then the data are applied to its intended purpose.

3-D digitization of artifacts is an effective method of archiving historic information. It is currently used within museums and other organizations for documentation and security purposes. Furthermore, electronic models give museums the ability to display digital models on the Internet, increasing public awareness and accessibility to the cultural artifacts. The models also facilitate the use of digital interactive displays within museums, allowing viewers to explore objects without risk of damaging the original artifact. Digital information can also be supplied to computer numerical control (CNC) machines to manufacture accurate replicas or

Figure 1. Overall digitization process



support pieces for artifacts. A further application of digitized data is in analysis of artifacts for historical restoration.

CURRENT DIGITIZATION PRACTICES

A number of organizations, worldwide, are promoting research into the digitization of cultural artifacts. These include the Canadian Heritage Information Network (CHIN), the Virtual Heritage Acquisition and Presentation (ViHAP3D) project in Europe, and the Salzburg Research Institute (SRI) in Austria. Some museums are working in collaboration with universities to further research in digitization; in 2004, approximately 35% of museums, worldwide, had initiated developments in some form of 3-D digitization of objects (White, Mourkoussis, Darcy, Petridis, Liarokapis, Lister, et al., 2004). These include the Museum of New York, the Royal Ontario Museum, the Museum of Science Boston, and the American Museum of Natural History. Efforts to establish entire "virtual museums" include The Canadian Museum of Civilization and the National Research Council of Canada collaborating on the production of the Inuit3D Virtual museum, launched in April 2001, and the Computer Science Department of Zhejiang University developing a 3-D Dunhuang cultural relic exhibition system in 2004. (Zhang, Pan, Ren, & Wang, 2007)

The field of 3-D artifact digitization also extends to independent projects, and in several cases, organizations have been assigned specifically to digitize iconic monuments. A project led by Gabriele Guidi, in 2005, involved digitizing the "Plastico di Roma antica," a model of ancient Rome created in the last century. A modulated light scanner was used to provide the accuracy needed to capture the detail of the model's features. The scanner was supplemented by a triangulation scanner to capture the more intricate parts of the model (Guidi, Micoli, Russo, Frischer, De Simone, Spinetti, & Carosso, 2005).

In 2004, the spiral motif at England's Castlerigg stone circle in Cumbria was digitized using the noncontact techniques of laser scanning (using a Minolta 910 scanner) and ground-based remote sensing. No motif was identified through the digitization process, despite the fact that in previous years, the motif image had been observed. This indicated that the spiral was probably painted or had faded due to natural events, and was a novel application of the highly objective methods of 3-D digitization to record the presence of an artifact feature (Diaz-Andreu, Brooke, Rainsbury, & Rosser, 2006).

In 2003, Subodh Kumar, and a team of students from the Johns Hopkins University in Baltimore, undertook the 3-D scanning of ancient cuneiform tablets. Cuneiform documents exhibit writing on three-dimensional surfaces. The team aimed to provide accurate, high-resolution 3-D models of these tablets for scholars' use in their research and for digital preservation of the unique historical artifacts. A laser triangulation scanner was used, using a regular grid pattern at a resolution of 0.025 mm. It was found that conclusive scanning was a challenge using current technologies (Kumar, Snyder, Duncan, Cohen, & Cooper, 2003).

In 2002, David Luebke, and a team from the University of Virginia's Computer Science Department, scanned Thomas Jefferson's Virginia home using a commercial time-of-flight laser scanner, the DeltaSphere 3000. The resultant data from the process was later combined with color data from digital photographs to create the Virtual Monticello, and the Jefferson's Cabinet exhibits, displayed in the New Orleans Art Museum in 2003 (Wang & Luebke, 2003).

The examples described are just a selection of projects that indicate the diversity of applications of 3-D digitization to cultural heritage artifacts.

DATA ACQUISITION TECHNIQUES

The past 15 years have seen the development of different 3-D data acquisition technologies. These include acoustic position trackers, close range photogrammetry, coordinate measurement machines (CMM), holography, laser scanners, magnetic position trackers, and touch probes. The methods of digitization available can be broadly classified as contact or noncontact (mechanical or optical) techniques. (Surendran et al., 2007)

Contact Digitization

Contact digitizing systems work by manually recording points, on the surface of the object, to be digitized. To acquire each data point a probe is activated and runs over the target object. Contact digitizers are commonly used in reverse engineering and manufacturing applications, and are inexpensive and efficient methods for obtaining digital models of objects with low geometric detail. Though these methods could be extended to artifact digitization, in some cases, the process is slower and does not capture as much geometric information as optical techniques. Furthermore, the process of physically touching the object has the potential to damage the artifact itself. For this reason, the two techniques that are predominantly used for artifact digitization are noncontact techniques of laser scanning and photogrammetry (Granero, Sánchez, Micó, Esteve, Hervás, Simón, & Perez, 2007).

Laser Scanning

Laser scanning is a method whereby surface information is captured using laser technology. A 3-D laser scanner is an active system that uses laser light to explore the surface of an object with a process called triangulation, as shown in

Figure 2. Laser triangulation diagram

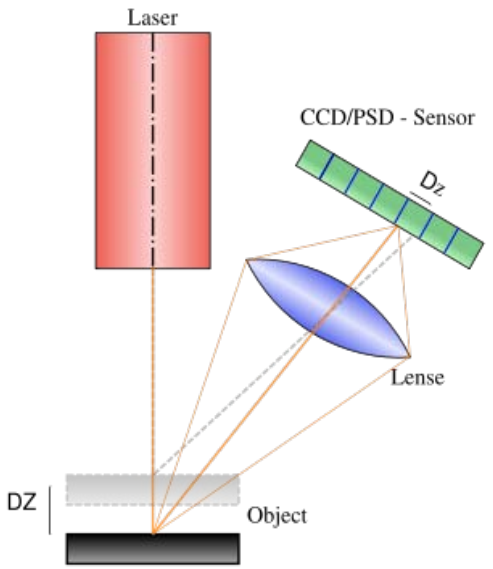


Figure 3. White Light digitisation process

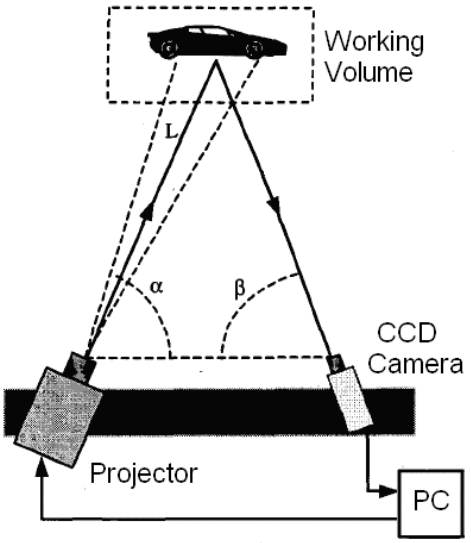

Figure 2 (Wiora, 2006). During the triangulation process, the scanner projects a laser point to the surface, and an angled camera is used to locate the position of the point in its frame of reference. The information from the location of the laser in the camera's field of view is used to determine how far away the object is. The process is called triangulation because the laser emitter, laser point, and camera form a triangle. The distance between the camera and laser emitter, and the angle of the laser emitter, are known. The angle of the camera corner can thus be determined by looking at the location of the laser point in the camera's field of view. This information is sufficient to determine the size and shape of the triangle giving the location of the laser point (Beraldin, 2004). In most scanners, a laser beam, rather than a point, is used to aid faster data acquisition.

Photogrammetry

Photogrammetry, also known as optical digitization, is a common technique used for the acquisition of 3-D data from cultural heritage artifacts. It is a remote sensing technique that uses photographic images to form geometrical information about objects. Photogrammetry systems can be roughly divided into passive or active digitization systems (Petrov, Talapov, Robertson, Lebedev, Zhilyaev, & Polonskiy, 1998).

Passive systems construct a 3-D model of an object's surface using stereoscopic images. Most stereoscopic digitisers are not truly passive, as they interact with the subject by projecting a grid onto its surface to aid image correlation (Petrov et al., 1998). An example of a stereoscopic system is the stereoSCAN produced by Breuckmann (Figure 3). This system comprises two 1.4mega pixel CCD digital cameras and a central halogen projector for projecting a grid onto the object. The camera angle can be adjusted to cater to different artifacts. Different lenses can also be used to alter the range of measurement (Breuckmann, 2006).

Active photogrammetry systems operate using a triangulation technique similar to that used in laser scanning. The difference is that white light, rather than laser light, is projected and reflected into a CCD camera to collect the geometric information (Petrov et al., 1998).

For this reason, they are also known as white light digitisers. White light digitisers are able to project light over a larger angle than laser scanners. Because of this, systems are able to project light from the same location as the sensors, and the size of the system can be reduced. This technique is able to capture color data, which makes it even more suitable for cultural artifact applications. A disadvantage is that white light digitisers are generally less accurate than laser digitisers (Petrov, et al., 1998).

POSTPROCESSING OF DATA

The data from scanning systems is in the form of a dense set of surface points, and is often referred to as "point cloud data." Each point has a distinct position in space dictated by Cartesian coordinates. In the case of color scanners, each vertex will have color information attached to its position data. (Chambard & Chalvidan, 2007)

Postprocessing is the stage responsible for the conversion of this point cloud data into complete and realistic 3-D models. There are several steps that can be implemented to form a final surface model. These include cleaning of irregularities, and the joining of points to form surfaces, filling holes and correcting data, and applying textural or color information.

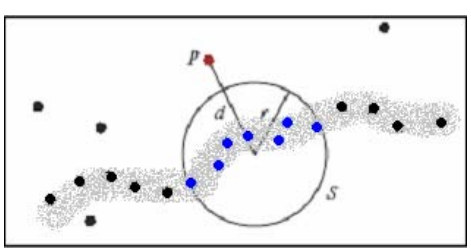
Postprocessing tasks are generally accomplished by using specifically designed software packages. These software packages not only render scan data into 3-D models, but can also provide an efficient means of reverse engineering. The models created through such software can be further used to generate highly accurate engineering drawings. Two of the most popular postprocessing software packages used in industry are Geomagic Studio and RapidForm.

Point Sampling

Point sampling is the first step to be implemented in postprocessing. In this step, data is selectively removed, which also helps to reduce the size of the data files that are being processed. Noisy data is the data that is captured in the process of scanning, but which is not part of the artifact itself. Noisy data can be removed by sampling large sections of data manually, or by allowing the software package to identify noisy points.

Outliers are erroneous data points that do not fall into the threshold of describing the object surface. This concept is illustrated in Figure 4 (Weyrich, Pauly, Keiser, Heinzle, & Gross, 2004). The thick grey line shows the form of the raw point cloud data, while the threshold P dictates the distance from the bulk of the data at which the point will be recognized as noise.

Figure 4. Outliers in scanned point cloud



Often the distribution of points within a scan is inconsistent. Some areas may have densely populated points while other areas may have sparse point data. Point relaxation is the step that aims to create a point cloud with evenly distributed data. By sampling areas according to a uniform density, redundant data can be removed, and the size of the file can be reduced.

Surface Creation

Once the points have been sampled they are able to be formed into surface data. The surface creation step joins adjacent points, in a process called triangulation, to form triangular faces. Each small face plane is built using three neighboring points. Every data point in the scan data is used to model the surface, and so, depending on the scanner accuracy, surface texture detail can be captured. There is a trade-off between model surface accuracy and data size, as a model generated with a larger number of triangular faces will be more representative of the real object, but requires more data.

Missing data or holes can be filled using software tools within postprocessing packages. Software packages consider surrounding face location to generate a best estimate fit for missing data. This step should be considered carefully in the field of artifact archiving, to preserve the integrity of digital models. Improvement of data accuracy to density ratios (higher accuracy for lower file size) and improved methods of interpolating missing data are likely to continue developing, and present a major research challenge in 3-D digitization.

Color and Texture Mapping

Once a surface model has been created, color data can be applied to the model to create realistic color and texture effects. If the scan data included color information, this data may have remained with the spatial data throughout the cleaning and surface generation stages, in which case, color mapping does not need to take place.

In the case where scan data does not include color information, this can be added through application of photographic images to the surface. Distinct geometric features on the model should be matched with their corresponding location on a photograph to position the image. This step can be difficult to accomplish accurately if surfaces have no distinctive features.

Model Validation

Once a model is produced, there must be a method to determine its accuracy. The simplest method is to compare the

original artifact, or images of the original artifact, with the generated model for consistency of features. Dimensions of the final model can be measured on screen and compared to actual dimensions.

A comparison of initial scan data to subsequent surface models can be made within postprocessing software, to form a quantitative test of the deviation of the surface model from its original data. Another method to ensure accuracy is if the textural details of the model surface and color information align. These methods are useful in ensuring that methods used within postprocessing were successful, but do not indicate whether the scan itself contained error. Research is ongoing to improve both the accuracy of scan data itself, as well as model validation methods.

MODEL VISUALIZATION

On completion, models can be displayed in a variety of formats. Exhibiting digitized models online can provide an effective avenue for increasing public awareness and knowledge surrounding historic artifacts.

The original data needs to be exported into a Web-compatible format to enable user viewing. Postprocessing software packages often come with the ability to export model files into publishable formats, for example, RapidForm's ICF format. Other more generic formats can be used for publication, for example, extensible 3-D (X3D), the ISO standard for real-time computer graphics from Web 3-D Consortium (Web 3-D, 2007) and Adobe Flash. Generic formats can be more easily accessible to users than proprietary display formats.

"Virtual museum" environments can be created to display a collection of artifacts models. Virtual digital museums carry out exhibition, preservation, education, and research through a variety of multimedia avenues, such as Web pages, animation, and video clips. These digital museums play an important role in the fields of information management, sharing, preservation, education, and scientific research (Zhu, Zhou, Sean, Tian, & Yan, 2007).

Security and Cultural Issues

Models that are used for Web site display should be protected against theft and plagiarism. Access to high quality 3-D data online presents the risk that information will be misused, for example, in creating unregistered replicas. Further research needs to be conducted to establish clear formats for protecting electronic information in these formats.

The publication of historic and cultural information online should be handled sensitively. Certain artifacts are culturally sensitive, and the parties concerned may not wish to have 3-D models of the artifacts available online. Consideration of these factors should be made in all digitization and display projects.

FUTURE TRENDS

3-D digitization of cultural artifacts is increasing worldwide. Currently, a large proportion of the projects undertaken use specialized equipment and processes developed for each specific project. As methods become standardized and futher research occurs, optimal digitization strategies may be developed and applied across a wider range of projects.

There are a number of research challenges including improving accuracy of data collection, developing data validation techniques, improving accuracy vs. economic viability of digitization, as well as providing secure Internet data structures for models.

As the standardization of digitization process occurs, methods of 3-D digitization for preservation of cultural artifacts will become more commonplace and accessible to museums. The increased development of "virtual museum" gallery environments will facilitate greater user interaction with artifacts online and across other digital media.

CONCLUSIONS

This chapter discussed the technical aspects of the digitization process, as well as applications in archiving, artifact preservation, and display and replica creation.

The digitization of artifacts offers an attractive alternative solution to preserving the historical information embodied in the spatial and textural qualities of artifacts. An accurate digital form of this information can be stored in multiple locations and safeguarded for future use. 3-D digitization also allows the application of 3-D model data to other purposes outside of digital archiving, for example, the 3-D geometric models give museums the ability to display artifacts on the Internet, increasing public awareness and accessibility to the cultural artifacts. The models may also facilitate the use of interactive digital displays within museums, allowing viewers to explore objects without risk of damaging the original artifact. 3-D geometric models can also be used to produce accurate replicas or support pieces for artifacts. A further application of digitized data is in analysis of artifacts and historical restoration.

It is believed that the field of 3-D digitization will continue to grow in scope as methods of digitization become progressively standardized and accessible. It provides an effective tool in the field of cultural heritage artifact preservation.

KEY TERMS

CHIN: Canadian Heritage Information Network – a network of professionals and volunteers whose objective is to promote the development, the presentation, and preservation of Canada's digital heritage content for current and future generations.

ICF: INUS compression format file for publication

Point cloud: The collection of points in 3-D space resulting from scanning an object

RapidForm: A comprehensive suite of software designed to convert real-world data from 3-D scanning devices into high quality, accurate, and useful data for a variety of applications.

SRI (Salzburg Research Institute): An institute fully owned by the Province of Salzburg, specializing in digital media

Stereoscopic: Two 2-D images that, when combined, give depth perception.

Triangulation: Within postprocessing of digitized spatial information, the creation of faces or surfaces by

joining vertices according to spatial distribution to create triangular planes.

ViHAP3D: Virtual heritage high quality 3-D acquisition and presentation – a project founded by the European Union deigned to increase public awareness of Europe's most precious artefacts and documents.

3D Graphics Standardization in MPEG-4

Françoise Preteux
Institut Telecom/Telecom & Management Sudparis, France

INTRODUCTION

Computer graphics is currently the spine of several industries of information technology. From computer aided design of almost all objects surrounding us, through virtualization of 3D environments such as Google Earth, to video games, 3D graphics becomes a valuable media with a similar impact as the one of video, image and audio. Such digital assets should be exchanged between producers, service providers, network providers and device manufacturers. Supporting large-scale interoperability needs the development and deployment of open standards. ISO[a], as a major international standardization organization, anticipated this issue and proposed in the last decade several standards addressing 3D graphics assets exchange. VRML (ISO, 1997) (Virtual Reality Modeling Language), published in 1997, provides basic geometry primitives, appearance models and animation mechanisms for representing 3D objects and scenes. Built on top of VRML, the first version of MPEG-4 (ISO, 1998) supports tools for the compression and streaming of graphics assets. Since then, MPEG improved the 3D graphics compression technologies and published the MPEG-4 Part 16 (ISO, 2004) in order to address theses issues within a unified and generic framework.

This chapter is dedicated to professionals of 3D graphics industry, solution providers for on-line systems involving 3D content (games, persistent universes, virtual spaces with graphical representation), students and professors in digital sciences.

The first section aims at presenting the background of the compression for multimedia signals. The second section presents the latest developments in MPEG-4 with respect to the compression and streaming of 3D graphics objects and scenes. The MPEG-4 tools, categorized into geometry, appearance and animation, are introduced. While MPEG standards specify only the bit-stream syntax and the architecture of the decoder, scheme for encoders' implementation are presented in this section.

In the third section we describe a recently adopted MPEG model for 3D graphics consisting in opening the representation of graphics primitives to any XML-based format and completing it with binarization and compression layers. This shift in the manner of using MPEG-4 for 3D graphics is concretized in Part 25 of MPEG-4 (Preda, Jovanova, Arsov& Prêteux, 2007).

BACKGROUND

A generic compression schema aims at eliminating redundancy in the data representation. Additionally when dealing with lossy compression, it makes also possible to identify

Figure 1. Generic signal compression schema

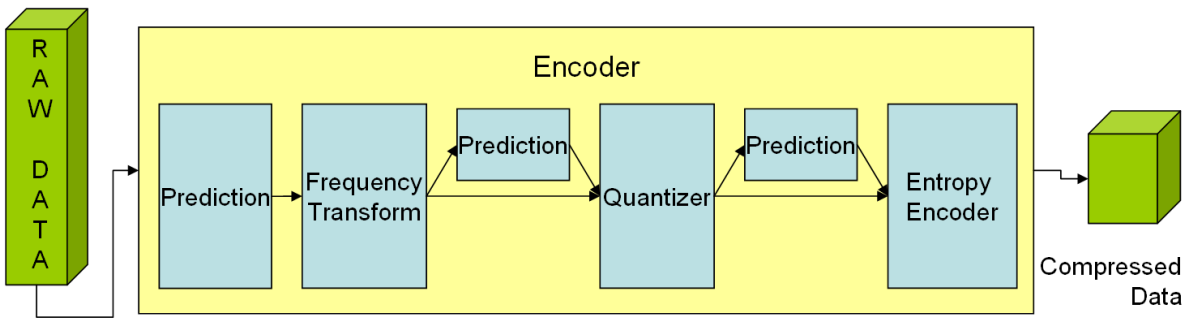

Table 1. MPEG-4 tools for 3D graphics compression

Compression Tool	Type
3D Mesh Compression	Geometry
Wavelet Subdivision Surface	Geometry
Coordinate, Orientation and Position Interpolator	Animation
Bone-based Animation	Animation
Frame-based Animated Mesh Compression	Animation
Octree Compression for Depth Image-based Representation	Appearance
Point Texture	Appearance

the attributes for which a less precise reconstruction results in an acceptable signal distortion for human observers. As example, image and video encoders exploits the way that humans perceive the colors. In general, a compression schema is based on prediction, frequency transform, quantization, and entropy encoder as illustrated in Figure 1.

Compression is necessary when data should be transmitted over the networks or to optimize the data storage. Nowadays, it is used in many applications of the real life: photo cameras, digital television, DVDs, video servers on the Internet (like Youtube) and so forth. Forecasting the importance of the compression for the development of multimedia applications, the MPEG consortium initiated in 1998 an international standardization project for specifying bit-stream syntax for audio and visual information. The first product, called MPEG-1 was designed for compressing video and audio at low bit-rates. A world-wide recognized part of MPEG-1 is the MP3format, used for compressing music data. The second product, MPEG-2 was designed for compressing video and audio in high-quality. The technical performances of MPEG-2 explain the success of applications such as DVD[b] (used by the movie industry) and DVB[c] (used in television). MPEG-4 completes the compression solutions provided by the MPEG consortium and is the main focus of the current chapter.

MAIN FOCUS OF THE CHAPTER: MPEG-4 TOOLS FOR 3D GRAPHICS COMPRESSION

A major advancement of MPEG-4 over its predecessors, MPEG-1 and MPEG-2, is the extension of data types to rich media, offering the possibility to handle, in a unique format, pixel-based image representation, 2D scalable vector graphics and 3D graphics. On top of these representations, the MPEG consortium developed generic and data-specific compression tools. In order to handle the composition and presentation of various media elements in the scene as well as the user interactivity, MPEG-4 introduced the concept of scene graph by adopting the VRML specifications and adapting it to specific requirements of streaming. A first tool responding to such adaptation is BIFS[d] (ISO, 2005), a binary encoded version of an extended set of VRML. Designed as a generic tool, BIFS attempts to balance the compression performances with the extensibility, ease of parsing and simple bit-stream syntax. It includes the traditional modules such as prediction, quantization and entropy coding, without pushing them to extreme complexity. With respect to the textual description of the same data, BIFS may compress by a factor up to 15:1, depending on quantization step. However, for 3D graphics primitives and for animation, BIFS does not fully exploit the spatial and respectively, temporal correlation of (animated) 3D objects. To overcome this limitation, MPEG defined specific tools in Part 16 of the MPEG-4 standard.

For compressing 3D graphics assets, MPEG-4 offers a rich set of tools classified with respect to the data type, namely geometry, appearance and animation (Table 1).

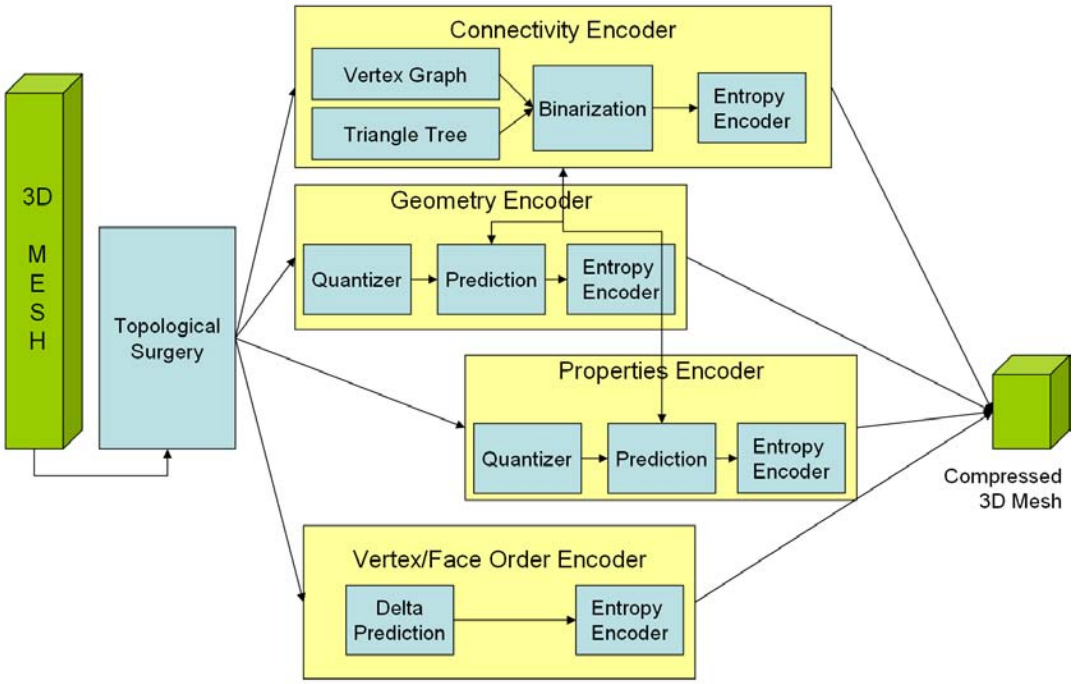
The following sections describe the key elements for geometry and animation compression tools.

3D Mesh Compression (3DMC)

3DMC, initially published in 1999 (ISO, 1999) and extended in 2007 (ISO, 2007) is based on the Topological Surgery (TS) representation (Taubin & Rossignac, 1998). It applies to 3D meshes defined as an indexed list of polygons and consists of geometry, topology and properties (e.g., color, normal, texture coordinate, and other attributes).

The connectivity information is encoded loss-less, whereas the other information could be quantized before compression. In order to maintain the congruence of the system, geometry and properties information are encoded in a similar fashion. 3DMC supports three modes of compressing the mesh: single resolution, when the entire mesh is encoded as indivisible data, incremental representation, when data is interleaved such as each triangle may be rendered immediately after decoding, and the hierarchical mode, when an initial approximation of the mesh is improved by additional decoding of the details. 3DMC supports error resilience and computational graceful degradation. The extension published

Figure 2. General block diagram of an MPEG-4 3D mesh encoder



in 2006 allows preserving vertex and/or triangle order and improves compression of the texture mapping information. When using 3DMC or its extension, the compression gain is up to 40:1 with respect to textual representation. Figure 2 shows the encoder scheme highlighting the main components.

Wavelet Subdivision Surface Streams (WSS)

Wavelet methods for geometry encoding are a superset of multi-resolution analysis which has proven to be very efficient in terms of compression and adaptive transmission of three-dimensional (3D) data. The decorrelating power and space/scale localization of wavelets enable efficient compression of arbitrary meshes as well as progressive and local reconstruction. Especially for signal transmission purposes, subband decomposition is a very important concept. Not only does it permit to send a coarse version of the signal first and progressively refine it afterwards, but it also enables a more compact coding of the information carried by signals whose energy is mostly concentrated in their low-frequency part.

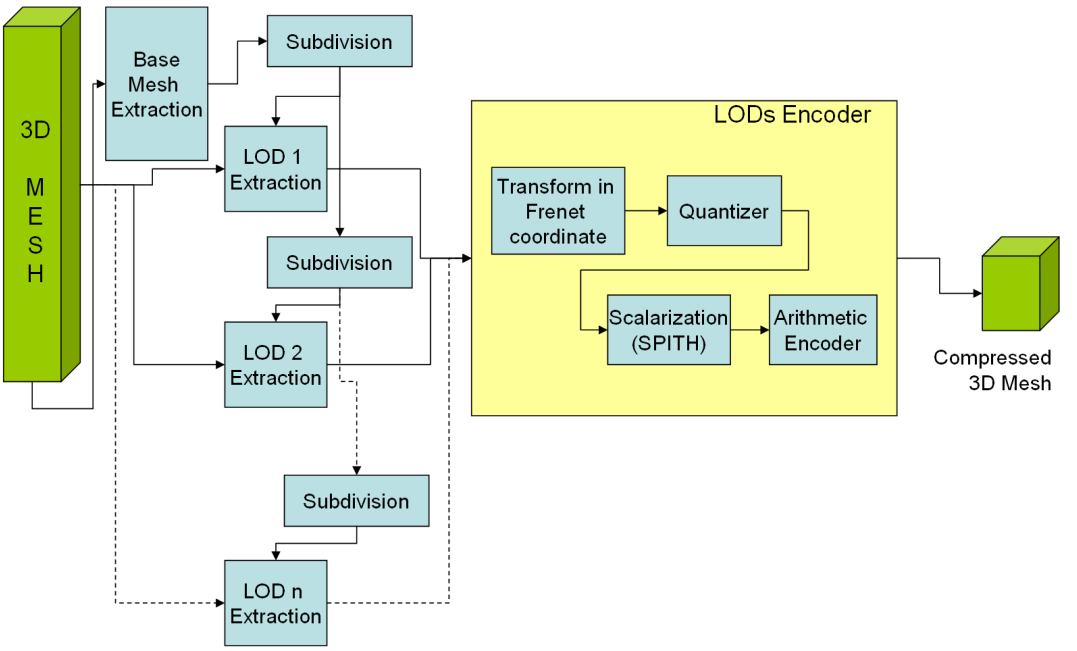
WSS of MPEG-4 is a hierarchical compression tool that uses a list of indexed triangles as a base mesh and encodes the vertex positions at different resolution levels based on subdivision surface predictors. The WSS contains only corrections of vertex position prediction encoded by using SPIHT (Set Partitioning In Hierarchical Trees) technique (Said & Pearlman, 1996); for all the other attributes defined per vertex (normals, colors, texture coordinates, etc.) linear interpolation schemes are used. WSS is well suited for applications such as terrain navigation. Optimal systems using WSS (Gioia, Aubault & Bouville, 2004) combines algorithms for local updates, cache management and server/client dialog and reports compression gain of up to 40:1. The schema of a WSS encoder is illustrated in Figure 3.

Coordinate Interpolator, Orientation Interpolator and Position Interpolator Streams (CI, OI and PI)

Interpolator representation in key-frame animation is currently the most popular method for computer animation. The interpolator data consist of key and key value pairs, where a key is a time stamp and a key value is the corresponding value to the key. Depending on the data type (coordinate, orientation, or position) the key value may have different dimension. The key value for coordinate and position is the set of X, Y and Z (dimension 3), while for the orientation it is represented as an axis and an angle (dimension 4).

The structure of the Interpolator Compression (IC) is illustrated in Figure 4. First, the original interpolator data may be reduced through an analyzer with the role of removing the redundant or less meaningful keys from the original set. A redundant key is defined as a key that can obtained from its neighbors by interpolation and a less meaningful

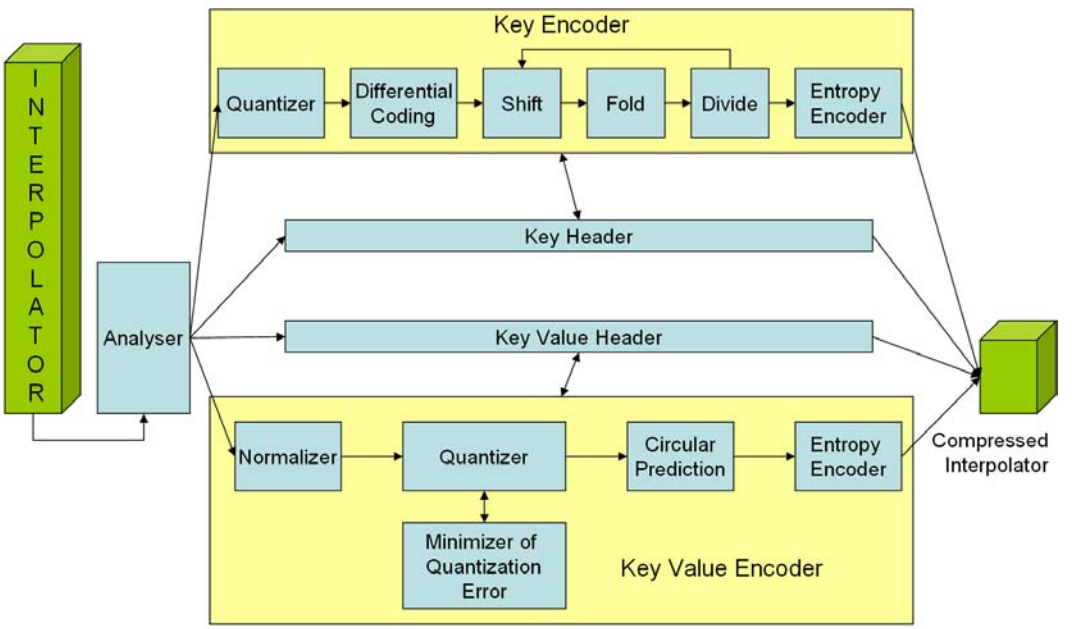
Figure 3. General block diagram of an MPEG-4 WSS Encoder. (LOD means Level of Details)



key is one for which the distortion between the original signal and the one reconstructed by interpolation is below a given threshold.

Once the significant keys are selected, each component of a pair (key, key value) is processed by a dedicated encoder. The key data, an array with monotonically non-decreasing values and usually unbounded, is first quantized and a delta prediction is applied. The result is further processed by a set of shift, fold, and divide operations with the goal of reducing the signal range (Jang, 2004).

Figure 4. Interpolators encoder



Data such as number of keys and quantization parameters are encoded by a header encoder using dictionaries. For the key values, the data is first normalized within a bounding box and then uniformly quantized. The quantized values are predicted from their one or two already transmitted key-values and the prediction errors are arithmetically encoded.

By using this method for representing interpolators, the compression performances are up to 30:1 with respect to textual representation of the same data.

Bone-Based Animation Stream (BBA)

In order to represent compactly the animation data (varying different vertex attributes, mainly spatial coordinates, but also normals or texture coordinates), some kind of redundancy in the animation is exploited: either temporal or spatial. In the first case, linear or higher order interpolation is used to compute the value of an attribute based on key values. In the second, vertices are clustered and a unique value or geometric transform is assigned to each cluster. For avatar animation, MPEG published BBA (Preda, Salomie, Prêteux & Lafruit, 2004) which is a compression tool for geometric transforms of bones (used in skinning-based animation) and weights (used in morphing animation). These elements are defined in the scene graph and should be uniquely identified. The BBA stream refers to these identifiers and contains, at each frame, the new transforms of bones (expressed as Euler angles or quaternion) and the new weights of the morph targets.

A key point for ensuring a compact representation of the BBA animation parameters consists in decomposing the geometric transformations into elementary motions. For example, when using only the rotation component of the bone geometric transformation, a binary mask indicates that the other components are not involved. The compactness of the animation stream can still be improved when dealing with rotations by expressing them in local coordinates system. The rotation can be represented either as a quaternion (4 fields to be encoded) or as Euler angles (3 fields to be encoded).

BBA follows traditional signal compression schema by including two encoding methods as illustrated in Figure 5. Optimized implementation (Preda et al., 2007) of the BBA encoder obtains up to 70:1 compression factor with respect to a textual representation.

Frame-Based Animated Mesh Compression Stream (FAMC)

FAMC is a tool to compress an animated mesh by encoding on a time basis the attributes (position, normals, etc.) of vertices composing a mesh. FAMC is independent on the manner how animation is obtained (deformation or rigid motion). The data in a FAMC stream is structured into segments of several frames that can be decoded individually. Within a segment, a temporal prediction model, used for motion compensation, is represented.

Each decoded animation frame updates the geometry and possibly the attributes of the 3D graphic object that FAMC is referred to. Once the mesh is segmented with respect to motion of each cluster, three kinds of data are obtained and encoded as illustrated in Figure 6. First, the mesh partitioning

Figure 5. BBA Encoder. (DC means Discreet Coefficient, AC means Alternative Coefficients).

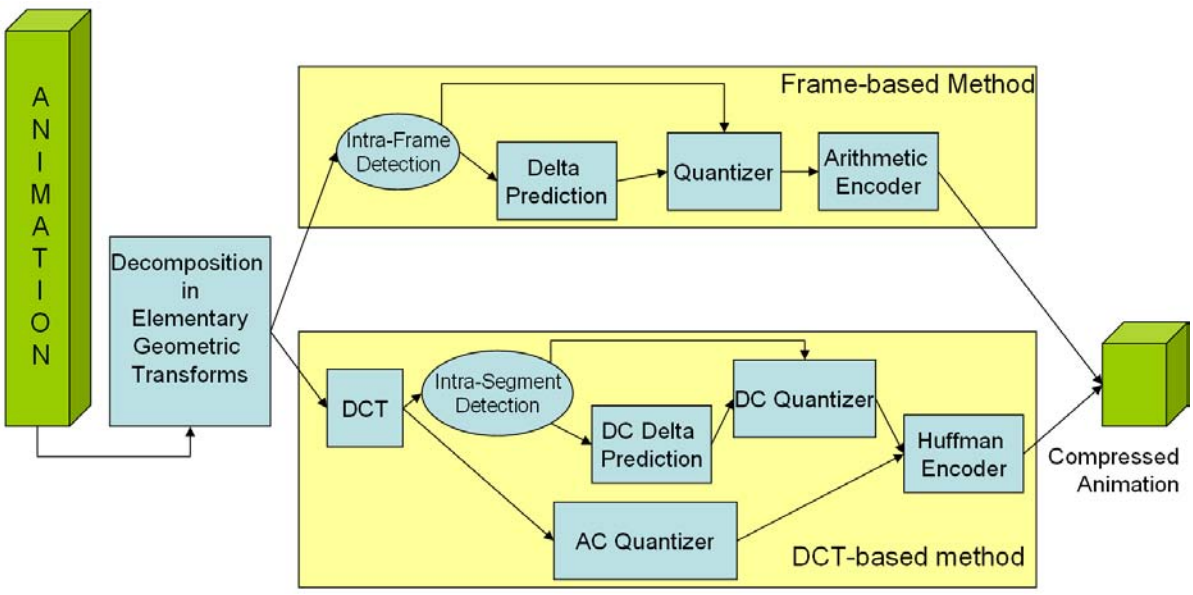


Figure 6. FAMC encoder

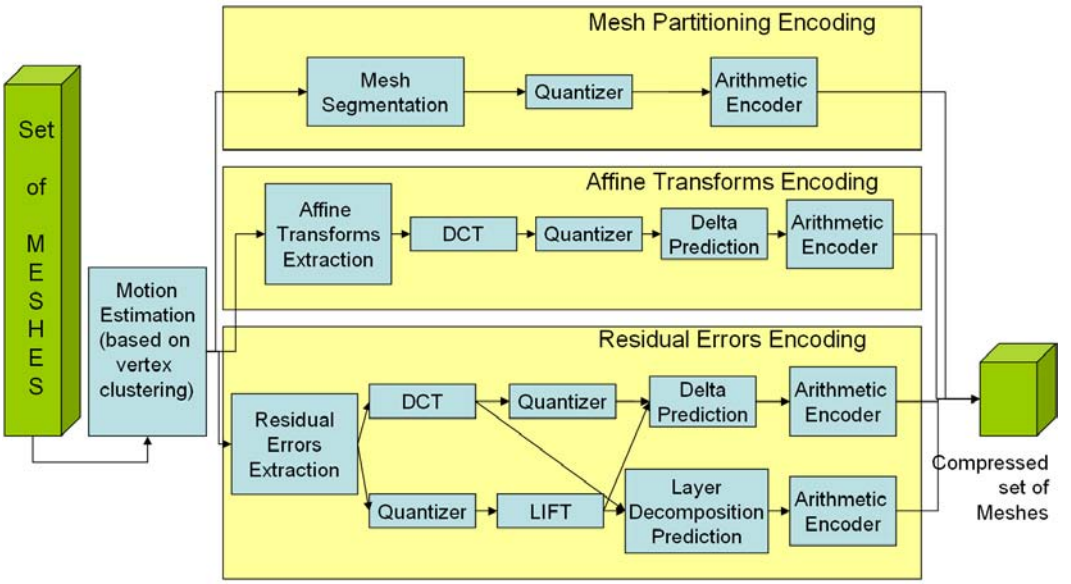


indicates for each vertex the attachment to one or several clusters. Secondly, for each cluster an affine transform is encoded by following a traditional approach (frequency transform, quantization, prediction of a subset of the spectral coefficients, and arithmetic encoder). Last, for each vertex a residual error is encoded. The frequency transform may be chosen between DCT and Wavelet (LIFT) and the prediction may be delta prediction or one based on multi-layer decomposition of the mesh. Current implementation (Mamou, 2007) of the FAMC encoders reports up to 45:1 compression factor with respect to a textual representation.

FUTURE TRENDS: MPEG-4 PART25, A NEW MANNER TO ACCESS MPEG COMPRESSION

Initially, all the 3D graphics compression tools developed by MPEG were designed to be applied on top of graphics primitives specified by BIFS. Each compression tool corresponds to one or several nodes in the scene graph, being able to efficiently encode the information of the node (as in the case of geometry tools) or to update some fields of the node (as in the case of animation tools).

Recent developments in the space of 3D graphics formats show a large diversity for definition of scene graph and graphics primitives, several standards being available today. The most known are COLLADA by Khronos Group[e], X3D by Web3D Consortium and XMT by MPEG. Other proprietary formats are defined, in general each authoring tool having a proprietary format. Some of them include rich sets of primitives; others are specialized for specific data (e.g. avatars for H-Anim). The majority of them use XML (XML, 2006). However, beside MPEG-4, none of them provide tools for compression, in general an entropy encoder (usually gzip) satisfying this need.

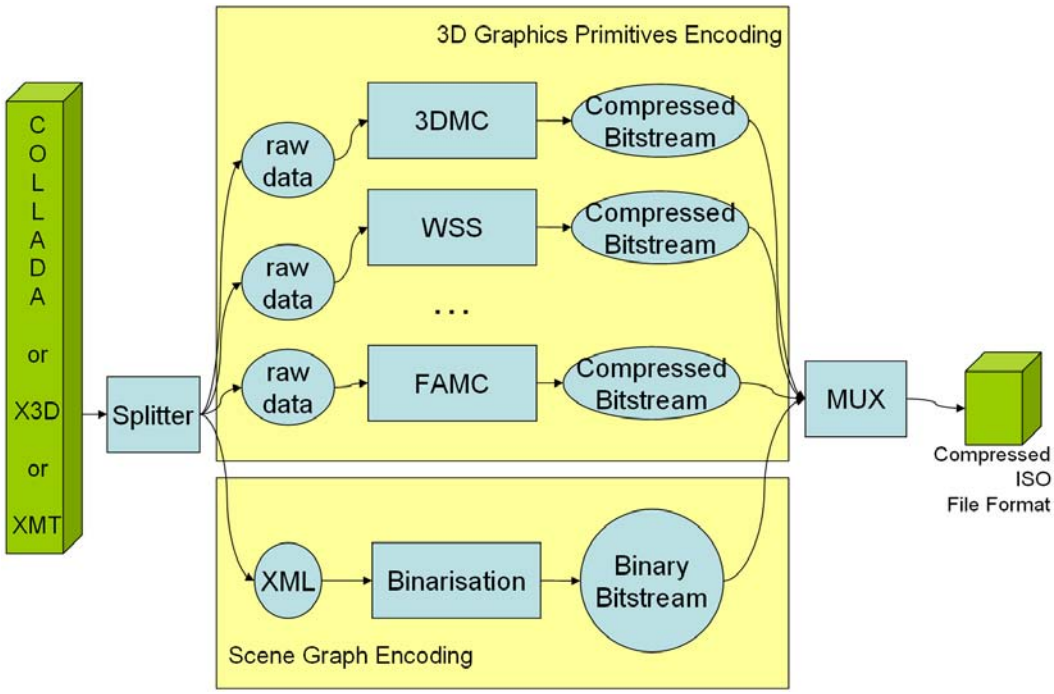
The goal of P25 of the MPEG-4 standard, also called 3D Graphics Compression Model, is to specify an architectural model able to accommodate third-party XML based description of scene graph and graphics primitives with binarisation tools and with MPEG-4 3D Graphics compression tools.

The advantages of such approach are on one side the use of powerful MPEG-4 compression tools for graphics and, one another side, the support of a large set of graphics primitives formats. Hence the compression tools described in previous section would not be applied only to the scene graph defined by MPEG but to any scene graph definition. The bit-streams obtained when using the P25 model are MP4 formatted and contain XML (or binarized XML) data for scene graph and binary elementary streams for graphics primitives (geometry, texture and animation).

Architecture Model

The architectural model has three layers: Textual Data Representation, Binarisation and Compression. In the Textual Data Representation layer, the model can accommodate any scene graph and graphics primitives' representation formalism. The only requirement on this representation is that it should be expressed in XML. Any XML Schema (specified by MPEG or by external bodies) may be used. Currently P25 supports the following XML Schemas: XMT, COLLADA, X3D, for each one the standard indicating the connection between the XML elements and the compression tool.

Figure 7. Encoding path in Part 25



The Binarisation layer provides a generic binarisation tool of the XML Schema. The XML data is represented in a "meta" atom of an MP4 file and can be textual or binary (gzip).

Finally, the compression layer includes the elementary streams listed in Table 1 and encoded as specified in the previous sections. A usual implementation of an MPEG-4 encoder generating bit-streams compliant with P25 is indicated in Figure 7. The MUX is used for multiplexing the elementary streams and formats the MP4 file.

CONCLUSION

This overview is purposed to the standardization of compression for different graphics primitives as specified in MPEG-4. This standard addresses a complete set of such primitives, ensuring efficient representation and streaming capabilities and allowing for reduction of the data size up to 70 times. Initially designed as a complete solution for 3D graphics (by specifying a formalism for textual representation usable for production purposes together with the compression tools), MPEG-4 recently opened the door to third-party solutions for graphics primitive formalisms, building a generic architectural model, called P25. The model is able to accommodate the MPEG compression tools on top of XML representation. Therefore, with P25, MPEG-4 for 3D graphics becomes a transparent layer for storage and transmission, without imposing a format for content production or/and consumption.

KEY TERMS

MPEG: "Motion Picture Expert Group", marketing name of the "ISOIEC SC29 WG11" standardization committee, affiliated to ISO (International Standardization Office) and creator of the multimedia standards: MPEG-1, MPEG-2, MPEG-4, MPEG-7 and MPEG-21.

3DGC: "3D Graphics Compression" – an MPEG working group dealing with specifications of 3D Graphics tools and integration of synthetic and natural media in hybrid scenes.

3DMC: "3D Mesh Compression" – a part of MPEG-4 specifications dealing with the specification of the bit-stream syntax for compressed meshes.

BIFS: "Binary Format for Scene" – a binary formalism defined by MPEG in the standard ISO/IEC 14496-11 for compressing the scene graph.

XMT: "eXtensible MPEG 4 Textual Format" – a XML formalism defined by MPEG in the standard ISO/IEC 14496-11 for representing the scene graph.

WSS: "Wavelet Subdivision Surfaces" – a part of MPEG-4 specifications dealing with the specification of the bit-stream syntax for compressed meshes described in a hierarchical manner.

IC: "Interpolator Compression" – a part of MPEG-4 specifications dealing with the specification of the bit-stream syntax for compressed animation interpolators.

BBA: "Bone-based Animation" – a part of MPEG-4 specifications dealing with the definition and the animation at very low bit-rate of a generic articulated model based on a seamless representation of the skin and a hierarchical structure of bones and muscles.

FAMC: "Frame-based Animation Compression" – a part of MPEG-4 specifications dealing with the specification of the bit-stream syntax for a set of meshes with consistent connectivity and temporal updates of vertex attributes.

COLLADA: An XML based formalism standardized by the Khronos consortium for representing 3D graphics assets.

INTRODUCTION

Television (TV) is a ubiquitous consumer electronics device representing the traditional information and entertainment medium for the majority of the people.

Following the rapidly growing technology, TV started to switch-off from the analogue world to the modern digital technologies of broadcasting. Digital technology has the potential to offer the audience a variety of services apart from the common audiovisual stream. Many of the new services are inherited from the Personal Computers (PC) world, including on-demand features, games, transactions, and other interactive options.

Television has had a long history of performing an educational function for the mass audience, typically by broadcasting culturally-relevant movies, documentaries and news, as well as educational programmes. The idea of Distance Learning through a TV blossomed extensively in particular as a complementary educational option besides PC-based e-learning and traditional analogue TV educational programs. In particular, TV-based interactive education promises a huge potential due to its ability to support interactivity while compensating for the low penetration of Internet-enabled computers in comparison with the penetration of a TV in a household.

"T-learning" was the new term, which prevailed for the definition of TV-based interactive learning (Aarreniemi-Jokipelto, 2005).

BACKGROUND

The first forms of learning with interactive Digital TV (iDTV) have been little more than modified or enhanced videoconferencing. Today, iDTV platforms for learning provide a big amount of audiovisual and educational contents to the viewer through interactive and content personalization. iDTV is considered as the convergence of television and computer technologies by encompassing three important features typical of computer-based technologies (Lytras Lougos, Chozos, & Pouloudi, 2002):

- **Interactivity:** The control of the whole activity and of the elements of a single activity can be placed into the hands of the potential consumer (Watheieu & Zoglio, 2002);
- **Personalization:** Use of technology and viewer information, to tailor interactive content to each individual viewer profile (Lekakos & Giaglis, 2001); and
- **Digitization:** Technological advancements that allow better quality of sound and picture (Kenyon, Miles, & Rose, 2000).

In particular, considering the use of the media by its audience, TV has some features that make it different from PCs. First of all, TV is usually watched by more than one person (co-viewing), and usually triggers social interactions that are very useful for a more effective experience and interiorization of the contents. Secondly, the logic of broadcasting to a wide population enables social mass mechanisms that typically enhance the impact of the broadcast program.

Nowadays, there are signs that the TV providers are moving to interactive education by broadcasting educational programs that exploit the interactivity of iDTV. A characteristic example is the BBC channel, which offers a learning portal (BBC learning) that provides interactive learning services and covers all the most widespread media, such as radio, TV, iDTV, Web and broadband. Some of the Web interactive services of BBC are also available in BBCi Interactive TV as the ones devoted to preschool children (BBC CBeebies) and support "Learning through play"[1]. Although t-learning as a rather new concept has not been applied so widely in interactive TV, there is a number of projects that support and investigate the future penetration of t-learning as the Enhanced Learning Unlimited (ELU) project which is currently dealing with the iDTV technologies for the design and the implementation of an integrated t-learning system[2].

The article is organized as follows: the pedagogical aspect of t-learning is presented in the next section while the part "Technologies Involved in T-learning" is dedicated to a description of the available technologies and standards of iDTV which are exploited in an education-effective way by t-learning.

PEDAGOGICAL ASPECTS OF T-LEARNING

In defining a t-learning pedagogy it is crucial to deal with an active learning model, the constraints imposed by the actual development of the technology and the nature of the allowed interactions. Related research acknowledges active learning as an exceptionally effective teaching technique (Clark, Nguyen, & Sweller, 2006). More specifically, active learning strongly relies on the learners' interactions with their environment that lead to mental actions through which they construct ideas about what they are encountering.

In this context, the challenge is to exploit the added value of providing an interactive learning environment and the potential of allowing people to access learning activities and contents directly in their house, at distance, through media easy to access and simply to use.

This reflection produces a twofold vision that aims at balancing learning and teaching strategies:

1. Leave the control to the learner.
2. Guide the learner.

Thus, to draw a pedagogy for t-learning experiences, two dimensions have to be explored and taken into account as the drivers of the design process:

- The context where learning happens and the behaviour of learners in this environment;
- The specific features of the medium.

The interactivity, audio/video-based experiences, narrative learning environment and informal learning/edutainment are the key points that emerged from this exploration.

TECHNOLOGIES INVOLVED IN T-LEARNING

T-learning exploits in an educational manner the available technologies and standards for iDTV such as the broadcast technology, the supported middleware for applications and the variety of related tools.

Interactive Digital TV

iDTV has been pushed into the marketplace by the broadcast industry and the network operators in the last decade, introducing two major features, which will be presented in this section: the digitization of the broadcasting and the availability of interactive programs (Baker, Pulles, & Sasno, 2004).

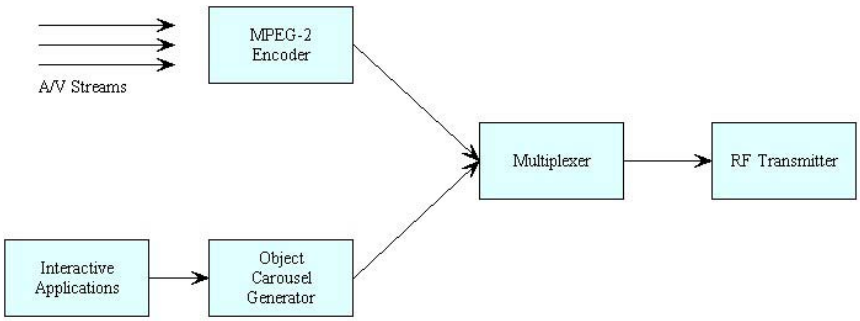
Audio Visual and Data Broadcast Technology

Digital television mostly relies on the Digital Video Broadcasting (DVB) standard, characterized as DVB-T for terrestrial, DVB-S for Satellite and DVB-C for Cable transmissions. DVB has been defined by a consortium of public and private organizations in the iDTV sector[3].

In the DVB schema, the digital TV signal is transmitted as a stream of MPEG-2 data known as a transport stream. This stream consists of a set of substreams (elementary streams), where each substream can contain MPEG-2 encoded audio, MPEG-2 encoded video or data encapsulated in MPEG-2 stream. The elementary stream which carries the application data is constructed using a Digital Storage Media-command and Control (DSM-CC) Object Carousel. Subsequently, the transport stream is passed to the multiplexer and then to a Radio Frequency (RF) transmitter in order to be broadcast. The overall broadcasting system for digital TV is illustrated in Figure 1.

The received signal is demodulated and afterward it has to be decoded appropriately. The common TV sets are manufactured to deal with analogue signals. Hence, a device called Set Top Box (STB) is used to transform the digital signal. Moreover, it also provides a middleware, based on an embedded Operating System (OS), which is an execution environment for running the interactive applications that are broadcast in a channel together with the main audiovisual stream. Execution environments are standard and the most common are: the European Multimedia Home Platform

Figure 1. Schema of the broadcast system



(MHP), the American Open Cable Application Platform (OCAP) and DTV Application Software Environment (DASE), the Japanese STD-B23/STD-B24. Because MHP is the standard in Europe and a subset of it, the Globally Executable MHP (GEM), is becoming the common reference worldwide, in this section we focus on MHP.

MHP

MHP is the middleware system for interactive TV development designed by the DVB Project[4]. The first draft of MHP was released in August 1999 and the first version of MHP 1.0 was approved by DVB in February 2000. MHP offers a standard platform for application developers. Applications are written in Java and HTML, so they don't depend on any single hardware platform or operating system. Due to the iDTV's special context, MHP-Java applications are slightly different from normal Java applications. However, due to the similarities with Java applets, MHP-Java applications are called Xlets.

On the one hand, MHP Java limitations are mainly related to the constraints given by the STB's hardware and OS in terms of computational power, memory size, storage, communication facilities, screen resolution, font and colour availability and their size is severely constrained by the limited bandwidth available. On the other hand, MHP provides support for those special features which are essential in the digital TV world such as low-level access to the transport stream, service information access, and support for the specialized graphics model of the digital TV. MHP can be extensively exploited by t-learning as it offers the proper middleware for learning interactive applications.

Tools for T-Learning

Based on the aforementioned technologies, a number of tools are appearing to support t-learning, such as authoring tools, games, personalization techniques and virtual tutor avatar.

Authoring Tools for T-Learning Courses

Authoring tools are software environments that support content providers in the creation of applications. There is a large number of authoring tools for the editing of e-learning courses in the market and in the last years, authoring tools for the creation of MHP applications appropriate for iDTV were developed.

On the e-learning side, authoring tools provide an environment that allows the insertion of learning resources (video, text, games, etc.) for creating the course. The structure of the course is organized usually with the definition of a sequence that relates these resources and allows different paths based on rules set by the author. The output of such kind of tools is appropriate to be used for learning purposes on a computer, but it is cannot be used for iDTV.

On the other hand, MHP authoring tools typically allow the creation of MHP-Java applications, suitable for iDTV but they are not learning-oriented. Up to now there are not any authoring tools dedicated specifically to the creation of t-learning courses. The tools that are used nowadays for t-learning purposes are the MHP authoring tools, which have to support the implementation of learning strategies suitable to TV-based education through the realization of MHP Java Xlets .

Games

Games in iDTV could play an important role to t-learning, although today they are used mostly for entertainment. Nowadays, there is a number of games for iDTV, covering various categories, such as arcade, adventure, puzzle and educational games. Quizzes, multiple-choice and memory games could increase the interest of the viewer-learner supporting the concept of relaxed-learning that seems suited to TV.

iDTV games are typically broadcast as applications resided inside the object carousel of a transport stream. Most of current games are stand-alone: they are not related with the A/V stream which is broadcast in parallel. This is because it is difficult to design and develop meaningful applications with a live, simultaneous interaction of games synchronized with the A/V stream. Even more important, synchronization drastically limits the use-timeframe of a game that can be played only at a given moment in time.

T-learning has the ambition of creating educational games for a wide range of users, in particular those with limited attitude to computers. The games are considered as an integral part of a t-learning course as they could support the learning procedure involving a wide audience through challenges and engaging activities that are anyway able to meet the typical user need for relax and sympathy.

Personalization

In general, the final goal of personalized learning is to provide a learning path that is matched to the learner's needs and abilities, resulting in a more efficient and high quality learning process. In order to obtain this matching of learner's profile and objectives, current learning context and available pedagogical resources, a well-defined description of each component involved in the process is needed, with specific focus on the user model. An additional interesting aspect of the personalization process is that, once the user model has been identified, the accuracy of the personalization can be iteratively improved with time, as more dynamic data are collected and stored regarding the ongoing interactions of the user with the system and the continuous monitoring and re-assessment of the user's satisfaction. This also allows for a classification and "clustering" of learners (Blanco-Fernández et al., 2004).

Personalization in terms of t-learning implies that a potential iDTV learner can easily be offered on his/her TV equipment a selection of available pedagogical contents and services according to his/her interests, skills and preferences.

From the conceptual and technological perspective, supporting personalization implies designing and developing suitable *services* to be integrated in the final t-learning application and able to provide contents and learning processes adapted to the user profile. The minimum set of such services includes:

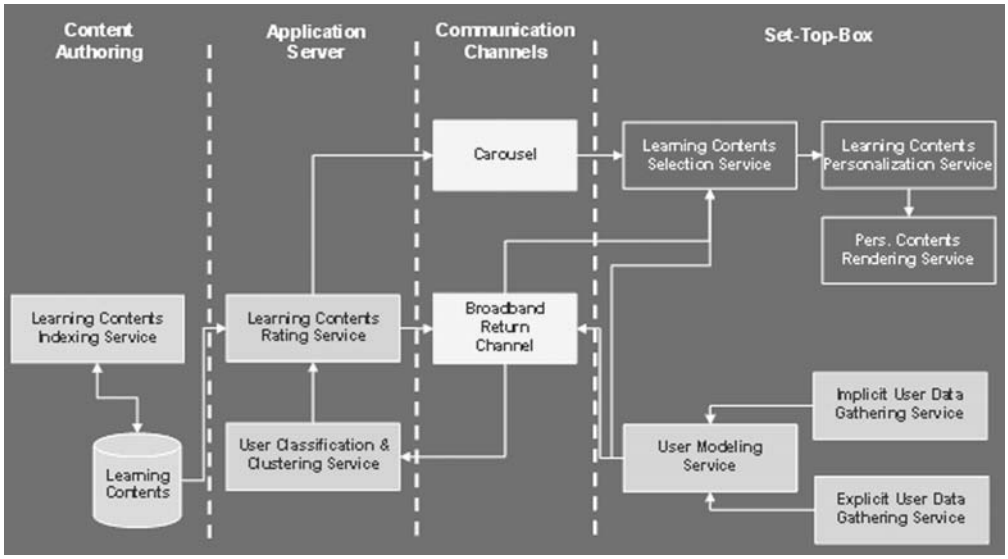
- **Implicit User Data Gathering Service:** Transparent acquisition of learner-related information through the automatic analysis of his/her behaviour while selecting/navigating learning contents.
- **Explicit User Data Gathering Service:** This service should offer to the user the possibility of providing personal information through an easy-to-use interactive interface.
- **User Modeling Service:** The information acquired by the two previous services need to be processed by the user modeling module, in order to produce a user profile that can be given as an input to other services in charge of automatically select and adapt available learning contents.
- **Users Classification and Clustering Service:** This service receives as input a set of user profiles, which are then classified and clustered. This would allow for the definition of "group" or "category profiles."
- **Learning Contents Rating Service:** The content rating engine is in charge of matching the existing available contents with the current user or category profile. The output is a list of relevant contents, among which the user is allowed to select interactively.
- **Learning Content Selection Service:** It allows for a selection of a subset of relevant contents coming from the carousel. This can be used to offer a limited degree of personalization on the Set-To-Box.
- **Learning Content Personalization Service:** When a specific learning object has been selected, a further personalization step is performed at the single content level, again according to the user or category profile.
- **Personalized Learning Content Rendering Service:** This service would be in charge of properly rendering the personalized content, for a better fruition by the user.

In Figure 2, a complex technological framework suitable to integrate, personalization services for iDTV-based knowledge management and t-learning/t-training applications is presented.

Besides the constraints coming from computational power and local storage features on the Set-Top-Box, the offered degree of interactivity in terms of available return channel has a strong influence on the personalization level. Having this in mind, three main profiles can be identified:

- STB without return channel (*basic profile*): includes local user profile processing, selection of relevant contents from the carousel and local processing of the selected content;

Figure 2. The personalization framework in t-learning



- STB with narrowband return channel (*advanced profile*): it offers the same features as the basic profile plus server side user profiles processing, dynamic adaptation of broadcast contents, server side synchronization of user behaviour, limited on-demand access to contents; and
- STB with broadband return channel (*full interaction profile*): same as advanced profile plus full on-demand access to contents through the return channel.

Virtual Teacher

A success factor in the distance courses is the simulation of an interaction between teacher and student. This can be achieved by using the figure of a tutor. It is generally accepted that the presence of the tutor is important for better understanding and motivating students. In particular, it was identified that a virtual teacher avatar could be a good means to achieve better audiovisual communication with the learner. An avatar is an intelligent agent with graphical representation, often humanoid and with speech capabilities (Ortiz, Aizpurua, Oyarzun, Arizkuren, & Posada, 2003).

Nowadays, avatars are used in the iDTV world mainly in online games in order to represent the viewer. However, they can also play the role of a virtual teacher (VT) in a t-learning course. The implementation of a virtual teacher for t-learning courses has to carefully react to the user behaviour and performance. Events can be generated from the AV stream and from other applications, and the VT may react to them on the basis of specific rules defined by the educational designer. In such a case, an events manager is needed by the system architecture to manage the incoming events and dispatch them to the VT.

User Interface and Synchronization Issues in T-Learning

During a t-learning course, the viewer-learner would be able to watch rich multimedia content accompanied by MHP applications. These applications can be either synchronized or not with the broadcast video. The screen can be divided in parts where every part could visualize different content as the video, the application or a virtual teacher including control instructions and help. Additionally, an application could overlay the A/V stream, also exploiting transparencies and semitransparencies. These display modalities can be supported in both synchronized and not synchronized courses. Synchronization of the video with the MHP application can be achieved with the insertion of triggers in the A/V stream that launch events to the listening application. In the case of a synchronized application, the viewer would have a specific amount of time to interact with the application. In a nonsynchronized application, the course would allow a more relaxed learning, but it would not benefit from synergies with the underlying A/V stream.

The user can provide inputs to an application through the remote control buttons. The arrows play an important role in the choice of preferences or the navigation, while the "OK" button would be usually used for confirmation purposes. The color buttons are typically used to provide access to

options. Text insertion is possible, in particular by using virtual keyboards on the screen, but its use is not encouraged as it is rather time-consuming and awkward because it is not directly supported by the remote control.

Architecture of an Integrated T-Learning System

The proposed architecture which is illustrated in Figure 3 is split in two parts: the production side where the content is prepared and the receiver side where the course is presented to the viewer through the appropriate terminal.

The production side is the area where the content and the applications are prepared. The educative A/V stream for the t-learning course is built by a TV producer, while the applications are developed in the authoring tool by the educators. The content including games, images, VT characters and text is used for the development of personalized courses and can be retrieved from a server where learning resources are stored. Eventual A/V-application synchronization is achieved with the aid of an authoring tool as well, where the content created is matched on specific time stamps inserted in the A/V stream. Subsequently, the A/V stream is fed into the MPEG2 encoder, while the content and the Xlet produced by the authoring tool are inserted into the object carousel. In this way the substreams are constructed and then multiplexed the final transport stream, which is broadcast.

The signal is received at the receiver side and processed by the STB where the A/V stream and the applications are restored from the transport stream. The Xlet that contains the t-learning course runs on the STB MHP middleware presenting the content of the course. The existence of an Internet IP return channel on the STB allows the use of on-demand features. Through this return channel it is possible to send requests regarding the retrieval of additional learning resources as well as information about the viewer in order to support more advanced personalization features.

FUTURE TRENDS

T-learning is based on modern technologies employed in Digital TV. Despite the fact that the world policies are supporting the switch-off from analogue TV to digital, there are still many analogue TVs in many homes and the people are not yet familiar with the new technologies and the interactive services introduced by iDTV. However, it is likely that the evolution of digital TV in the future years, accompanied by an increasing familiarity of users with its interactive services, will augment the penetration of t-learning into the households.

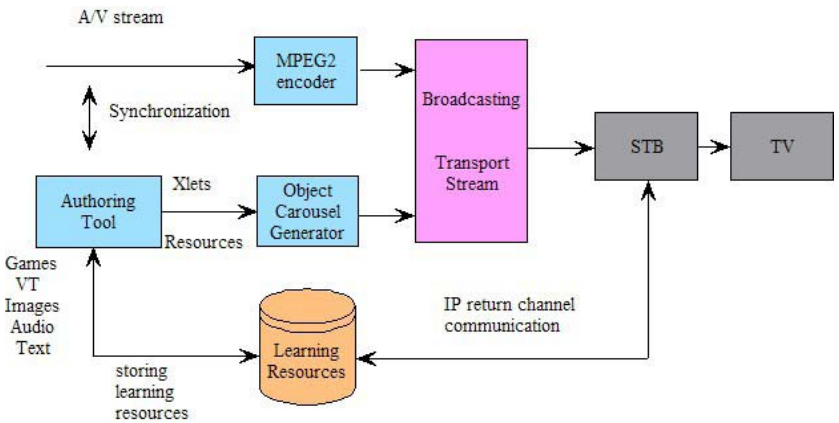
The spreading of the new technologies will further speed up the evolution of t-learning, as they will increase the recording, playing and computational capabilities of the TV-sets, increasing the scope and the quality of the offered services.

CONCLUSION

The most important technologies involved in t-learning were discussed and described in this article. These technologies are still evolving in order to support more efficiently t-learning and other interactive services for TV.

T-learning is a relatively new concept. It is a challenge for the world of interactive TV and distance learning with a potential to concretely complement e-learning, in particular given its potential to reach a much wider audience, and in

Figure 3. T-learning architecture system



different contexts (e.g., in relaxed situations). The ambition of more opportunities for learning in home may be fulfilled by t-learning as TV is still the medium that is present in every household. T-learning exploits the available technologies of iDTV and it can also spur them by introducing new needs and requirements.

The real potential of t-learning is promising, but the best ways to offer it to a wide audience and different target groups has still to be carefully investigated, in particular through extensive field experiments.

KEY TERMS

Authoring Tool: Environment for applications creation without the need of programming and technical skills.

E-Learning: Distance learning with the aid of a personal computer.

iDTV: Interactive Digital TV is the evolution of the traditional TV set based on digital transmission and has the capability of running interactive applications.

MHP: Multimedia Home Platform is the common middleware for running applications for iDTV.

Personalization: The customization and categorization procedure of a viewer-learner.

Return Channel: Port that allows IP connectivity of the STB to support on demand features.

STB: Set Top Box is the device that decodes and processes the digital received signal.

Synchronization: This term is used to specify the time-matching between the t-learning content and the respective video.

T-Learning: Term that defines the TV-based interactive learning.

Virtual Teacher: Avatar that plays the role of a teacher during a t-learning course by providing instructions and help.

Toward a Framework of Programming Pedagogy

Wilfred W. F. Lau
The University of Hong Kong, Hong Kong

Allan H. K. Yuen
The University of Hong Kong, Hong Kong

INTRODUCTION

As a major topic in information technology education, computer programming has been taught to both major and non-major students in universities. While there has been ongoing debate on whether students should be taught programming (Soloway, 1993), the literature shows that learning to program poses a lot of difficulties to novices (Bonar & Soloway, 1989). Dijkstra (1989) describes programming as "radical novelty" in which our usual strategy of metaphors and analogies simply does not apply. Pea (1986) identifies three types of conceptual bugs which are rooted in a superbug where "there is a hidden mind somewhere in the programming language that has intelligent interpretive powers".

Why is learning to program so difficult? One difficulty is that learning to program needs the acquisition of a multitude of inter-related skills. Jenkins (2002) argues that programming is a complicated task, which requires the mastery of a number of skills such as problem solving, abstraction, mathematical logic and testing, debugging and so forth. A novice programmer simply lacks these skills. More importantly, success in learning to program demands knowledge of computer itself. Ben-Ari (1998) points out that students lack a viable mental model to learn programming. On the other hand, undue emphasis is placed on the learning of programming syntax (Deek, 1999). In this article, we will focus on approaches of teaching computer programing. Winslow (1996) introduced the term "programming pedagogy" in his paper. Although programming pedagogy is not explicitly defined in the paper, the term here refers to any instructional methods and strategies which are used to teach students introductory programming. Due to these reasons, programming pedagogy calls for special attention.

BACKGROUND

Over the years, pedagogical innovations have been proposed to cope with these difficulties. These include a variety of programming tools (Smith & Webb, 2000). These tools help novice programmers to develop programs through program visualisation and algorithm animation. Deek and McHugh (1998) evaluate programming tools used to teach programming. One common problem among these tools is that they fail to integrate into the curriculum. This suggests that there is a need to investigate what programming pedagogy should be adopted together with tools to bring about innovations in programming instruction. This article intends to review on programming pedagogy reported in the literature. A theoretical framework on programming pedagogy grounded on literature review is proposed which attempts to conceptualise pedagogy in terms of the cognitive and technological dimensions. For researchers, this review not only provides a summary of pedagogy adopted to date, but also theoretical underpinning for future research on programming pedagogy. For practitioners, the proposed framework can help them to evaluate and reflect on their own pedagogy with an aim to improve the quality of teaching and learning computer programming.

APPROACHES OF TEACHING PROGRAMMING

We identified seven pedagogical approaches of teaching computer programming arising from the review of appropriate literature. The following sections provide a brief description of each of these approaches.

Structured Programming Approach

In the 1970s, one catchword in programming is structured programming. It is an approach, which intends to "support the production of correct, understandable programs which are easy to modify and maintain" (Freiburghouse & Liskov, 1973). The approach allows control structures of sequence, selection, and repetition only. The GOTO statement is considered detrimental to structured programming (Dijkstra, 1968). To facilitate the development of a structured program, a top-down design, which decomposes a large program into a manageable smaller program, is used. Programs are improved successively through stepwise refinement. In this

manner, it is hoped that quality program can be produced. Although it was advocated in the 1970s, it is still one of the prevalent programming approaches today.

Problem Solving Approach

Barnes, Fincher, and Thompson (1997) describe a programming methodology consisting of four steps, namely, Understanding, Designing, Writing and Reviewing. Following the same line of thinking, Thompson (1997) proposes a problem solving approach in teaching functional programming. He claims that using the approach, "a novice can make substantial progress in completing a programming task before beginning to write any program code." Gries (1974) emphasizes the importance of problem solving in programming. He argues that usual assumption that students should have learned programming after giving tools and examples is not pedagogically sound. To address this problem, he suggests the four-phase process of problem solving by Polya (1957).

Software Development Approach

It is equally important that students should know how to translate algorithms into syntactically and semantically correct solution of the problem that form the program. In this regard, Deek (1999) develops a methodology which incorporates both the problem solving skills and the programming skills into a single process that provides a framework for beginning students. As noted by Deek (1999), there are three kinds of difficulties faced by students when learning to program: (1) deficiencies in problem solving strategies and tactical knowledge; (2) ineffective pedagogy of programming instruction; and (3) misconceptions about syntax, semantics, and pragmatics. The new approach, which incorporates both the problem solving skills and the programming skills, can help address all the three kinds of difficulties.

Small Programming Approach

If programming creates a large cognitive load on novices, it is reasonable to reduce such load by programming in a "small" scale. In this sense, we distinguish between the terms Programming-in-the-small and Programming Language-in-the-small.

Glaser, Hartel, and Garratt (2000) introduce the idea Programming by Number in teaching ML and Java. Programming by Number is intended to get students started in writing program by providing a step-by-step guidance to students while allowing flexibility in the design of the solution to a problem. When writing functions, they suggest the following steps: (1) name the function; (2) write down its type; (3) enumerate all cases; (4) deal with any simple case(s); (5) list the ingredients in preparation for the complex case(s); (6) deal with the complex case(s), where some inspiration is required; and (7) think about the result.

Brusilovsky, Kouchnirenko, Miller, and Tomek (1994) review on three approaches of teaching introductory programming, namely, the incremental approach, the mini-language approach, and the sub-language approach. In the incremental approach, new language subsets, which introduce new programming language constructs while retaining all the constructs of preceding subsets, are introduced successively to novices. In the mini-language approach, a small and simple language is used to support the first steps in learning to program. In most cases, a student learns how to program by controlling an actor, which can be a turtle, a robot, or any other active entity, in a microworld. The sub-language approach uses a special starting subset of the full language which contains easily visualizable operations to introduce programming to novices. In short, these three approaches provide a simple and small language subsets and a visually appealing metaphor embedded in a context-rich environment to help novices start programming.

Language Teaching Approach

Robertson and Lee (1995) give a research manifesto for the application of a second natural language acquisition pedagogy to the teaching of programming languages. They argue that programming has traditionally taught with little reference to natural language pedagogy. To conclude, they provide some areas for further research such as the value of reading programs before writing, the use of authentic programs, the study of the cultural milieu of programs, and so forth. Baldwin and Macredie (1999) argue that research in the learner strategies in second language pedagogy may provide insight into programming pegadogy. Based on the call for a more learner-centred environment, they believe that learner strategies are one of the issues in teaching programming that can help address difficulties in learning to program. Deek and Friedman (2001) describe their ideas of how programming and writing are learned in parallel. They argue that the common element that exists in both domains, problem solving and program development, provides "new ways for students to transfer skills between domains".

Learning Theory Approach

Lister and Leaney (2003) argue that traditional norm-referencing approach to grading tends to target at average students. As a result, weaker students cannot program well and stronger students are not challenged. They suggest a criterion-referencing approach to grading so that explicit and clear criteria are set for each grade. In deciding the criteria, reference is made to the Bloom's Taxonomy of Educational Objectives (Bloom, 1956). Macfarlane and Mynatt (1988) examine the effectiveness of advance organizer in teaching

the syntax of arrays. The tasks of the subjects were to enter syntactically and semantically correct Pascal statements to manipulate arrays in a training program. The study used a metaphorical advance organizer–a one-story apartment building. Results revealed that the groups did not differ on syntactic knowledge (near transfer). Yet the advance organizer group outperformed the other two groups in semantic knowledge (far transfer).

Other Approaches

There are other innovative attempts in programming pedagogy. Astrachan and Reed (1995) propose an apprenticeship model of learning in which students begin by reading, studying, and extending programs written by expert programmers. Through this approach, students learn from real-world examples, practice code, and concept reuse. Jenkins (1998) attempts to get students actively participate in learning to program. His participative approach aims to make the learning of some abstract programming concepts such as procedures, parameters, pointers, and linked lists more accessible to students. Proulx (2000) introduces the use of programming patterns in learning to program. The idea is to organize the common used methods like reading data in programming as patterns for reuse.

DISCUSSION

In this section, pedagogical remarks are made on these approaches. Then, it is followed by the discussion of a proposed theoretical framework which attempts to conceptualise programming pedagogy in terms of two dimensions.

Empirical Evaluation

It is common that many approaches lack classroom evaluation of their effectiveness. In many cases, they are simply ideas based on the experience of the practioners in teaching. While some studies show empirical evaluations of their approaches (Glaser et al., 2000; Macfarlane & Mynatt, 1988), many simply do not provide sufficient evidence to support their claims. For instance, Proulx (2000) reports that, "Overall, we felt the course was a success. Students performed better on the midterm exam and seemed more confident than in the past". Yet, no information on the students' background or even results of the mid-term examination are provided. Nevertheless, it is of paramount importance that any claims on the effectiveness of an approach should be grounded on empirically tested evidence (Deek & McHugh, 1998) in pedagogical practices.

Support from Learning Theory

If approaches are not grounded on empirical data, an established theory may serve as the foundation for the approaches. However, not many approaches have explicitly mentioned the use of any learning theory in its design. The risk of not basing the approach on established theory can be detrimental since the approach remains ad hoc and may not be generalized to other settings. As pointed out by Berglund (2002), the problem is, "Although valuable as a mean of sharing experiences between computer science educators, the results are…often hard to generalise, since they are not based on pedagogically sound theories of learning or carried out with sound methodological principles".

Individualization

One of the foci of our curricula in the school education today is learner-centerness. It is our responsibility to provide such an environment for the needs of individuals. In terms of pedagogy, the usual strategy adopted is "one size fits all". This results in weaker students learn well while stronger students are unchallenged (Lister & Leaney, 2003). It is argued that learning styles provide a vehicle through which individual differences are addressed. The literature has shown that learning styles do affect programming performance (Ross, Drysdale, & Schulz, 2001). It is thus possible to make use of learning style data to individualize pedagogy to bring about innovation in teaching.

Towards a Conceptual Framework

Learning to program is recognized as a cognitively demanding process in the literature. It involves expressing solutions to problems in terms of programming language syntax as well as understanding of how programs work in the computer. In the former case, Linn and Dalbey (1985) propose a chain of cognitive accomplishments for computer programming instruction consisting of three main stages: (1) single language features, (2) design skills, and (3) general problem-solving skills. Besides, Bayman and Mayer (1988) propose three interrelated types of programming knowledge necessary to understand the underlying complex processes involved in programming: syntactic, conceptual, and strategic. Such discussion indicates a developmental change from learning programming syntax to learning programming concepts in terms of programming knowledge. Recently, technology advancement has made computer programming more visually than before. This is achieved in one way by visual programming (Green, 1995). It points to a dimension in programming pedagogy in terms of programming representation.

In this article, an initial framework on programming pedagogy is suggested which attempts to conceptualise

pedagogy along the two dimensions, namely, programming knowledge and programming representation. For the dimension of programming knowledge, the two poles are programming syntax and programming concept, which correspond to the developmental change in learning programming. For the dimension of programming representation, the two poles are textual representation and visual representation, which reflects the advancement of technology in programming presentation. Figure 1 shows a classification of aforementioned programming approaches under this framework. Structured programming is traditionally learned with focus on programming syntax in textual representation. As a result, it is considered as a more syntax-oriented and textual-based (i.e., syntax-textual pedagogy). Problem Solving, Software Development, Language Learning, and Learning Theory approaches are regarded as more concept-oriented and textual-based (i.e., concept-textual pedagogy) since they emphasise the mastery of problem solving skills. Mini-language and Sub-language approaches usually make use of visual metaphor to help beginners to start programming. In this sense, they focus more on concepts building through a visual programming representation (i.e., concept-visual pedagogy). However, we could not find any approach which is under syntax-visual pedagogy. With a trend towards user-friendliness and technology development, it is anticipated that there will be a gradual shift from the concept-textual pedagogy to concept-visual pedagogy in the future.

FUTURE TRENDS

Guzdial and Soloway (2002) advocate the use of authentic multimedia construction to engage students to learn programming. Jimenez-Peris, Pareja-Flores, Patino-Martinez and Velazquez-Iturbide (2000) foretell a day in a 2020 university, saying that, "current lab programming environments are truly educational, and they are highly visual and intuitive. They detect and accurately diagnose most errors…" From these observations, in the future, learning to program will be probably dominated by a visual and media-rich environment, and this is in agreement with our guess.

CONCLUSION

The fact that programming is difficult to novices is reported enormously in the literature. Pedagogical innovations have been suggested to address the issue. In this article, programming pedagogy is reviewed. Approaches of teaching programming are discussed and grouped under seven categories. Problems associated with these approaches are discussed. To conceptualise pedagogy, a theoretical framework consisting of the programming knowledge and programming representation dimensions is proposed. An attempt has been made to classify the approaches under this framework. While the approaches discussed are not meant to be exhaustive, it is hoped that this article may shed light on the discussion of programming pedagogy and arouse further exploration and research in programming education.

KEY TERMS

Computer Programming: Mainly consists of designing the underlying algorithm and representing that algorithm as a program.

Curriculum: Consists of four interacting components, namely, teaching objective, teaching material, teaching method, and assessment.

Novice Programmer: A computer programmer who is not experienced at programming.

Problem Solving: To solve, problem is to find a way where no way is known off-hand, to find a way out of a difficulty, to find a way around an obstacle, to attain a desired end that is not immediately attainable by appropriate means. The emphasis of problem solving in programming instruction focuses on the expression of solutions in terms of mathematical functions.

Programming Pedagogy: The study and theory of the methods and principles of teaching and learning computer programming. It refers to any instructional methods and strategies which are used to teach students introductory programming.

Textual Programming: The representation of programming processes is based on written texts.

Visual programming: The representation of programming processes is based on graphics and images. It allows the manipulation of visual information and provides support for visual interaction.

Toward Societal Acceptance of Artificial Beings

Daniel I. Thomas
Technology One Corp,, Australia

Ljubo B. Vlacic
Griffith University, Australia

INTRODUCTION

Modern organizations are faced with many challenges with the trend toward distribution of their workforce across the planet. With this situation becoming more common, it is important for organizations to find ways of encouraging effective leadership and strong teamwork. Training and evaluation of the effectiveness of those employed can be an expensive exercise due to geographic separation of the parties involved. To this end, we propose a collaborative play scenario, using humans and artificial beings as *fully equal partners* (FEPs), to facilitate training and evaluation of a dispersed workforce.

While this scenario is a simple example of collaboration among human and artificial entities, moving this concept forward in other application areas creates questions about how artificial entities influence outcomes in the context of group decision making. The idea of social influence and acceptance of artificial beings as equal decision makers is explored, and how they may integrate into larger societies.

In this article, we present a simple training exercise designed to test a candidate's leadership ability to negotiate with other members of the organization, using their influence to achieve (partially or fully) their goals. While in practice, the play scenario would consist of combinations of human and artificial beings, the training scenario presented shall consist solely of artificial FEPs in order to demonstrate how influence can affect a result in a collaborative process.

BACKGROUND

Artificial Beings as Fully Equal Partners

When the average person is confronted with the term "Artificial Intelligence" it is more likely to conjure images of science fiction than science fact (Khan, 1998). Yet throughout our daily lives, we experience various degrees of artificial intelligence in such mundane devices as washing machines and refrigerators. Beyond this, organisations have been using intelligent systems in a myriad of endeavours. Beyond today however, "We may hope that machines will eventually compete with men in all purely intellectual fields" (Turing, 1950, p 460). Turing's remarks may not be fully realized today; however, the integration of artificial beings into human organizations and society evoke powerful images of both positive and negative possibility.

One possibility is artificial beings emerging as partners rather than tools in various collaborative situations. Unlike past revolutions of mechanical automation, the presence of artificial beings should not imply a redundancy for human partners, but rather a complimentary relationship. Group decision making, including both humans and artificial beings as equals, increases the diversity of the knowledge pool (Dunbar 1995), improving the likelihood of positive outcomes.

In order for artificial beings to be realized as collaborative partners, as opposed to an intelligent tool, they must be able to articulate their perspectives and opinions, while taking onboard the knowledge and opinions of others. For this to occur, artificial beings require a degree of social influence. For this influence to occur, the artificial being needs to become acceptable within the social system: Society, organization or group (Kelman, Fiske, Kazdin, & Schacter, 2006). In making the transition to societal acceptance of artificial beings, there are great challenges, both technical and social. To better study artificial beings as collaborative partners, it is possible to focus on a smaller, group social setting, with an assumption of social acceptance (and therefore the capability to influence) collaborative group decision making. For this reason, computer games provide an excellent environment for understanding how humans and artificial beings can positively influence outcomes in a collaborative group situation.

Much of our work into collaboration has been influenced by the use of intelligent autonomous agents in computer games. Jennings and Wooldrige (1995) describe an intelligent agent as one that enjoys the attributes of autonomy, situatedness, social ability, reactivity and proactiveness.

Basing intelligent entities around this core concept of agency has led researchers such as Laird (2001) and Kaminka et al. (2002) to create intelligent opponents for human players.

Taking this a step further, we see future applications for intelligent artificial beings as more than just opponents or nonplayer characters (called NPCs) in computer games, but rather we see artificial beings being utilised as *fully equal partners*.

Extending these concepts of humans and artificial entities interacting collaboratively in computer games, it is necessary to define a type of entity that:

- Does not treat human and artificial players differently during interaction;
- Can work cooperatively with other fully equal partners (including humans);
- "Plays" the game as a human would;
- Does not work to a defined script or take direction from an agent "director" such as those described by Magerko et al. (2004) and Riedl, Saretto, and Young (2003) and;
- Is not necessarily aware of the nature of other FEP beings (human or artificial in nature).

Simply, a *Fully Equal Partner* (or *FEP*) is an intelligent entity that performs tasks cooperatively with other FEPs (human or artificial), but is also capable of being replaced one with another. These beings are not necessarily aware of the nature of their fellow partners.

A Collaborative Architecture

In order to facilitate the collaboration among fully equal partners, the involved computer games must support a number of key features (Thomas & Vlacic, 2003), including:

i) A clean and well-defined interface or separation between the beings and the game (Vincent et al., 1999);
ii) A concept of time and causality; and
iii) Support for experimentation (Cohen, Hanks, & Pollack, 1993).

To create a computer game that enjoys many of these features, Thomas and Vlacic (2005) developed a layered architectural approach to collaborative games. Collaborative computer games that involve FEPs have three architectural layers: A communications, a physical and a cognitive layer.

The communications layer is essentially the protocols and low-level software that facilitate interaction and communication. The physical layer describes items and entities within the game world and how they may be manipulated. The cognitive layer describes the processes required to facilitate intelligent collaboration.

Collaborative process

If considered at a high level, the collaborative process *c* involves taking a set of fully equal partners *P* with a set of goals *G* and producing a set of outcomes *O*. An outcome may not necessarily satisfy the set of goals (e.g., a failure outcome).

$O = c(P,G)$

In order to obtain these outcomes to the collaborative process, FEPs engage in conversations. The result of these conversations are pieces of group collective knowledge *K*; that is, knowledge that is known to the group. Outcomes of the collaborative group are a result of the collaborative process between the group of FEPs and the goals of the collaborative process.

$$O = c(P,G)$$
$$O = c(P,G)$$
$$O = \{o_1,..,o_n\}$$
$$o_n = s(P,n(G,K^P))$$

where *s* is a function of all partners *P* applied to an interpretation function *n* of the set of goals *G*, the set of group collective knowledge across the entire set of partners K^P, resulting in an outcome o_n.

INFLUENCE IN THE COLLABORATIVE PROCESS

In human to human interactions, we see many forces at play that influence one person to agree or take the side of another in a discussion. These influences need to be taken into account when collaborative work is undertaken. Even the size of a group (Fay, Garrod, & Carletta, 2000) can change the way in which partners are influenced, and by whom.

Collaborative FEPs may create an affinity with one or more entities and are more likely to accept their position during negotiation. Possible methods for obtaining an affinity with one or more FEPs include:

1. The degree to which one FEP's responses convey a perception/opinion that matches that of another FEP. The more that one partner's position matches that of another partner, it becomes more likely that the partner will "trust" the statements of that partner.
2. Some arbitrary/authoritative influence factor that has the partner tending toward the position of one or more

other partners. An example in a business sense might be seniority or position within an organization.

3. Trade: changing a given position in order to influence another partner's position on another item in the collaborative process.
4. A pre-existing relationship (e.g., a friendship) that exists beyond the scope of the collaborative process.

The scope of the play scenario discussed shall focus on two forms of influence, that of arbitrary/authoritative influence and common interest.

During the collaborative process, any partner p_l, where $l \neq k$, may ask a question q_m of any other partner p_k in order to receive a response r_m, where $m = j+i$

$$r_m = f(p_k, q_m)$$

The set of Group Collective Knowledge K obtained by the group through the collaborative process is a subset of the responses obtained during the collaborative process.

$$K \subseteq R$$
$$K \subseteq \{r_1,..,r_m\}$$
$$\{k_1,..k_q\} \subseteq \{r_1,..,r_m\}$$

To influence group collective knowledge, resulting responses r_m that contribute to K must be changed in some way. Assuming that all responses contribute to collective knowledge:

$$K = R$$
$$\{k_1,..,k_q\} = \{r_1,..,r_m\}$$
i.e., $q = m$

During the negotiation phase, an influence function changes the response for a given partner's initial decision based on the degree of influence the other partners have with the first partner. The influence function that is used here is simply the sum of the proportion difference between one partner's response (obtained during the conversation process) and that of another partner:

$$i(r_{pk}) = \sum_{1-n,n\neq i} p_{nf} * (r_{pn} - r_{pk})$$

Where $i(r_{pk})$ is the influenced response which is the sum of all influence factors p_{nf} multiplied by the response difference partner p_n and the partner under influence p_k. FEPs using this influence function cannot influence themselves.

PLAY SCENARIO: PROJECT PLANNING

In order to investigate influence in the collaborative process, a play scenario was devised based upon a documented real-world project planning process from industry. The scenario is used as a training exercise for management candidates to investigate their negotiation skills in representing their business group's interests in a collaborative situation.

The scenario involves a particular enterprise software developer that utilises a common infrastructure upon which all its enterprise solutions are based. When a new version of the infrastructure is to be developed, the managers and architects of this business unit formulate a list of potential projects that can be pursued within the next version's development timeframe. Each project has an estimated development time budget.

Unfortunately, the list of potential projects greatly exceeds the number of development days available within the new version development period.

In order to satisfy the needs of the enterprise product business groups, the manager responsible for infrastructure therefore contacts the managers of the various enterprise products to obtain their feedback on what projects are most desirable in their respective areas.

Because there are timeframe limitations, and the enterprise products address different business needs, a significant amount of time is involved in negotiating a "best fit" for all parties. As such, each of the business group managers wants to influence the decisions of the others in order to influence the inclusion in the development plan of their highest priority requirements.

Table 1 documents the business units involved.

The Experiment

The play scenario is calibrated against the original business data that was collected prior to the meetings. Each business group was requested to review the list of potential projects (88 in total) and place a numbered priority next to each item until the development days from the items totaled approximately 400 days.

When a candidate undertakes the training scenario, they must represent their business group's interests, maximising the number of inclusions within the project.

Unlike a regular play scenario, the following exercises have been undertaken with artificial FEPs only, in order to investigate their effectiveness in influencing the final outcomes. The following influence methods were undertaken:

1. No Influence (baseline);
2. Arbitrary Influence; and
3. Common Interest.

The participating FEPs utilize a collaborative fuzzy logic process (Thomas & Vlacic, 2007) to determine the responses given during the collaborative process.

Determining Influence

In order to determine influence between the FEPs involved, the following methods were used.

An arbitrary percentage influence from 0% to 10% was allocated to each business unit representative. As the collaborative process progressed, the responses by each representative were influenced by the other 10 member's influence. The breakdown of the allocated influence was:

Common interest influence was determined by informing each FEP of the other member's "Top 5" projects. If a project matched one of the other's in the top five, an influence percentage was awarded between 1% and 5%. This influence was allowed to compound if more than one project was in common. A 5% influence was awarded when there was a total match (i.e., Partner *A*'s first project choice is the same as Partner *B*), reducing to 0% the further away a project was in terms of order (i.e., Partner *A*'s project is ranked 3, and partner *B*'s project is ranked 5; therefore, the influence is 3%). Table 2 documents the common influence factors across the business units.

Results

After completing each run of the play scenario, the results were compared to the actual results collected during the industry process.

Across the 88 projects identified, approximately 70% of projects were common to all results. It can also be seen from the captured results that influence does impact the final makeup of the projects to be included within the allowable project budget timeframe.

While the percentage of match with the industry results is fairly high, of more interest are the reasons of difference between the industry and the play scenarios. As stated earlier, factors such as trade and pre-existing relationships were beyond the scope of this experiment. In addition, given the business unit group size of 11, they may also be factors of influence such as the group size (Fay et al., 2000). Subsequent play scenarios will require the incorporation of these additional factors. Closing this "collaborative gap" between a human social group and an artificial social group with the same goals and objectives is a compelling area of research, and a large step along the road to achieving social acceptance of artificial beings as FEPs.

Actual Results

As noted earlier, the data collected for this play scenario is sourced from real-world business data. As such, the collected data does not have the rigour true experimental collection. For example, the business groups involved in the real process interpreted the ranking instructions sent out by the infrastructure team in different ways. While the scenario itself was a compelling real-world case, further work on industry scenarios will require more explicit information to ensure the resulting data collection is of experimental quality.

FUTURE TRENDS

As artificial entities become more widely used in collaborative cognitive applications, negotiation skills become more important. There are many applications where the use of collaborative human and artificial FEPs may be utilised. Broadly speaking, to apply these concepts can be applied to any collaborative decision making scenario, as long as the following criteria are well-defined: The scenario's objectives and goals must be established; the communication, physical and cognitive layers are clearly defined; and the collaborative process is applied as a framework to facilitate the collection and application of group collective knowledge in order to achieve the defined objectives/goals.

In the enterprise, collaborative FEPs can be applied in training scenarios such as the project planning exercise. Beyond this, FEPs can also play an effective role in collaborative business intelligence and strategic planning. Stepping out of the enterprise, the nature of FEPs being human or artificial, allows artificial FEPs to find application in automated transport systems that can "collaborate" with other human and artificial road users. In addition, there are compelling reasons for artificial FEPs to be used in pure entertainment applications, by allowing computer game developers to create richer, more interactive experiences. Interestingly, collaborative FEPs could facilitate the study of human behaviour and interaction, through the creation of safe environments for behavioural studies and clinical psychology (we strongly believe that it may be used for the purpose of assisting patients in overcoming difficulties of expression and engaging in collaborative play scenarios).

For artificial beings emerging as equal partners in society, the future becomes more speculative. As stated earlier, artificial beings need to move from the position of an intelligent tool to some form of acceptance of equality, in order to become "collaboratively equal" to their human counterparts. For this kind of acceptance to occur, FEP applications such as business analysis, transportation and entertainment need to form the groundwork for basic acceptance.

Beyond overcoming the technical challenges of integrating artificial beings into collaborative partnerships

with humans, there are also the challenges of acceptance. Preconceived notions of science fiction (Khan, 1998) and cultural perceptions between different cultures (Kaplan, 2004) are some of these challenges. The positive benefits of collaborative artificial FEPs also faces challenges of negative perceptions within different social groups and societies. Addressing these issues effectively shall ensure that collaboration among human and artificial beings is an effective method of group decision making.

CONCLUSION

Human and artificial beings as Fully Equal Partners (FEPs) offer compelling applications in industry. There are many challenges faced in the integration and acceptance of artificial FEPs into the social groups of humans. One challenge described was the capability of artificial FEPs to influence group decision making outcomes. FEPs and the collaborative process were described, showing how these are applied in a simple training play scenario. The negotiation processes of the artificial FEPs were presented and how different forms of influence may be used to affect a collaborative outcome. The outcome of the play scenarios indicates a "collaborative gap" between humans and artificial beings. Further work on reducing the size of this gap will contribute to the acceptance of artificial beings as collaborative entities within the group decision making process.

Beyond this play scenario and its application in training, FEPs offer a wide variety of applications across varied business sectors including training, business analysis, transportation, entertainment and behavioural studies. By understanding the scenario objectives, architectural layers and collaborative process framework, it is possible to apply this concept to any collaborative process. As humans work more closely with artificial entities in the future, collaborative FEPs offer a mechanism to ensure that work is mutually productive to all entities involved, regardless of their physical nature.

KEY TERMS

Fully Equal Partner (FEP): An intelligent entity that performs tasks cooperatively with other FEPs (biological or artificial), but is also capable of being replaced one with another. These beings are not necessarily aware of the nature of their fellow partners.

Group Collective Knowledge: Information that is presented to a group of FEPs collaboration.

Collaborative Process: Involves the interaction of FEPs to achieve defined outcomes. The process involves questions, responses, actions and negotiation.

Influence: Among FEPs is the ability of a FEP, during collaborative negotiation, to align another FEPs response with their own.

Collaborative Gap: The difference between the outcomes of groups of human and artificial entities in a collaborative decision-making scenario, where both sets of entities have the same beliefs and objectives.

Intelligent Tools: Intelligent artificial entities that are utilised by humans but do not impact any collaborative decision-making process via social influences.

Social Acceptance: Social acceptance of artificial FEPs is the ability of human FEPs to accept Artificial FEPs into the collaborative process and influence, and be influenced, by these entities.

Transforming Recursion to Iteration in Programming

Athanasios Tsadiras
Technological Educational Institute of Thessaloniki, Greece

INTRODUCTION

The main advantage of a Recursive Algorithm (an algorithm defined in terms of itself) is that it can be easily described and easily implemented in a programming language (van Breughel, 1997). On the other hand, the efficiency of such an algorithm is relatively low because for every recursive call not yet terminated, a number of data should be maintained in a stack, causing time delays and requiring higher memory space (Rohl, 1984). Solving the same problem iteratively instead of recursively can improve time and space efficiency. For example, to solve a problem that involves N recursive procedure calls, it will require stack space linear to N. On the contrary, using iteration, the program will need a constant amount of space, independent of the number of iterations. There are **programming languages**, such as **Prolog**, that do not possess built-in iterative structures and so recursion should be used instead. Nevertheless, there are ways to write recursive programs that have similar behaviour with that of the corresponding iterative programs.

BACKGROUND

The transformation of **recursion** to **iteration** is not a new problem and it has been studied by various scientists, for example, De Moor and Sittampalam (2001) and Clinger (1998). This competition between recursion and iteration is interesting because they represent two different schools of thought in Computer Science. Various programming languages use **recursion** extensively, especially high-level programming languages that cope with Artificial Intelligence problems (Luger, 2002) such as Prolog (Bratko, 2000; Ramachandran, 1986), LISP (Lamkins, 2004; Seibel, 2005) or Scheme (Dybvig, 2004; Watson, 1996). The Prolog language will be used to exhibit the transformation of recursion to iteration (Clocksin & Mellish, 2003; Shoham, 1994). **Prolog** is a **Logic Programming Language** (Bramer, 2005) that uses heavily recursion. This happens because Prolog lacks iterative structures such as "for," "while-do" or "repeat-until" (Holmes, 2001; Langfield, 2003). In Prolog, a clause can be iterative even if it contains a recursive call. That is, a Prolog clause is iterative if it has zero or more calls to Prolog system predicates before the recursive call (Sterling & Shapiro, 1986). Furthermore, a Prolog procedure is iterative if it contains only unit clauses (facts) and iterative clauses. Having these in mind, we will try to transform **recursion** to **iteration** in Prolog, but that can apply to all other languages that use recursion.

TRANSFORMING RECURSION TO ITERATION

The fact is that there is no easy or general way to transform a recursive algorithm to an iterative algorithm. What a programmer can do to increase the efficiency of a recursive algorithm is to implement the recursive algorithm in an iterative manner. This can be done by using special variables called accumulators that will be used to keep intermediate results and facilitate acceleration.

To demonstrate the technique, the calculation of the sum of all integers from 1 to N will be used. The recursive relation that can be used to calculate the sum S of all positive integers from 1 to N is S(N)=S(N-1)+N. A Prolog predicate sum(N,S) that evaluates sum S of all integer numbers from 1 to N, is the following:

```
sum(1,1).
sum(N,S):-N1 is N-1,
          sum(N1,S1),
          S is S1+N.
```

This is a recursive implementation because the second clause involves the call of the same predicate and after it, there is a Prolog system call (S is S1+N). To illustrate the computational effort of the above implementation, the trace of the call to find the sum of all integers from 1 to 4 is shown below (Figure 1).

In Figure 1, we see that after a series of recursive calls the call sum(1,S3) stops the recursion and initiates a series of value returns, until the initial call sum(4,S) is reached. The common process of recursion is now apparent where first the problem is getting smaller and smaller, until it meets the limit case. After that, values of intermediate call are returned until the initial call is answered. If we call the same predicate for an integer that is above a certain limit, the computer will

Figure 1. The trace of the recursive implementation

```
?-sum(4,S).
   → sum(3,S1)
     → sum(2,S2)
       → sum(1,S3)
       ← sum(1,1)
     ← sum(2,3)
   ←sum(3,6)
 sum(4,10)
S=10
```

Figure 2. Trace of the iterative implementation, involving two additional parameters, one accumulator and one counter

```
?-sum_iterative1(4,S).
  → sum1(1,4,1,S)
    → sum1(2,4,3,S)
      → sum1(3,4,6,S)
        → sum1(4,4,10,S)
S=10
```

reach stack overflow because it cannot afford to provide memory space for all the recursive calls.

We will try to implement the same algorithm in an iterative manner using predicate sum_iterative1(N,S). This will require the introduction of two new parameters. The first one will play the role of the **counter** of the iteration and the second will play the role of the **accumulator**. That is, the predicate sum_iterative1(N,S) will call an augmented predicate sum1(I,N,T,S) that has the two additional parameters. Counter "I" represents the I-th iteration and accumulator "T" the temporal sum until iteration I. Both the counter and the accumulator should be initiated with value 1. For this reason, the call of sum_iterative1(N,S) lead to the call of predicate sum1(1,N,1,S) that has the first and the third argument equal to 1. The complete code is given below.

```
sum_iterative1(N,S):-
sum1(1,N,1,S).

sum1(I,N,T,S):-
      I<N,
      I1 is I+1,
      T1 is T+I1,
      sum1(I1,N,T1,S).
sum1(N,N,S,S).
```

Predicate sum1 is iterative because, as it is mentioned in the "Background" section, after the pseudo-"recursive" call at sum1(I1,N,T1,S), there is no other call. This kind of **iteration** is also called **Tail Recursion**. The introduction of the 2 parameters leads to the evaluation of the partial result of the sum at each step of the iteration and cause the termination of the iteration when counter I becomes equal to N. It is apparent that the recursion is transformed into an iteration of N steps. The iterative nature of the above implementation is illustrated in Figure 2, which shows the trace of the call to find the sum of all integers from 1 to 4.

Comparing this trace with that of Figure 1, we see that now the solution is found as soon as the call reaches the limit case at sum1(4,4,10,S). This means that the second stage of returning values and making calculations that is present in the trace of Figure 1 is now avoided, shortening the whole process.

The same problem can be solved iteratively even without having the counter I described above. In this case only one additional parameter, that of the accumulator, will be needed. The accumulator will store the partial result up to the current step of iteration. The accumulator should be initiated with value 0; this is why the second argument of the call of predicate sum2(N,0,S)is zero. The code is given below:

```
sum_iterative2(N,S):-
sum2(N,0,S).

sum2(N,T,S):-
      N>0,
      T1 is T+N,
      N1 is N-1,
      sum2(N1,T1,S).
sum2(0,S,S).
```

In this second implementation variable N also plays the role of the counter, because at every iteration step, its value decreases by one, terminating when its value becomes zero. Once again, the recursion is transformed into an iteration of N steps. This can be shown with the following trace of the call sum_iterative2(4,S).

The trace of Figure 3 is similar of that of Figure 2, that is, the second stage of returning values found in Figure 1, is omitted, and additionally, needs less memory space than the implementation traced at Figure 2, because only one additional parameter is added instead of two.

Figure 3. Trace of the second iterative implementation, involving only one additional parameter, that of an accumulator

```
?-sum_iterative2(4,S).
  → sum2(4,0,S)
   →sum2(3,4,S)
    → sum2(2,7,S)
      → sum2(1,9,S)
        → sum2(0,10,S)
S=10
```

Figure 4. Trace of the recursive implementation

```
?-sumlist([3,5,7,8],S).
   → sumlist([5,7,8],S1)
    → sumlist([7,8],S2)
     → sumlist([8],S3)
        → sumlist([],S4)
        ← sumlist([],0)
     ← sumlist([8],8)
    ← sumlist([7,8],15)
  ←sumlist([5,7,8],20)
 sumlist([3,5,7,8],23)
S=23
```

We conclude that both above implementations demonstrate the technique of the transformation of the recursion to iteration. This transformation leads to more efficient use of computer resources, something especially useful in cases of time or space critical applications.

The same technique can be applied also to programs that involve lists. The data structure of list is recursive in nature, because it can be defined as a structure that has a single element at its head and all other elements at its tail (Clocksin, 2003). Because the tail is also a list, we conclude that a list is an element and a list. This recursive nature is the reason why most of the problems concerning lists are solved in a recursive way. For example, the following predicate calculates recursively in Prolog, the sum of a list of integers.

```
sumlist([],0).
sumlist([H|Tail],Sum):-
        sumlist(Tail,Sum1),
        Sum is Sum1+H.
```

Because the second clause has a recursive call to the same predicate and this call is followed by a Prolog system call (Sum is Sum1+H), this is a recursive implementation. To illustrate this recursion, the trace of a Prolog call that asks for the sum of the numbers in the list [3,5,7,8], is shown below.

As it is shown in Figure 4, after a series of recursive calls that gradually shorten the length of the list of numbers, the call sumlist([],S4) is reached. According to the first clause of the predicate sumlist([],0), S4 should equal zero. This result is returned to the parent recursive call. This process of returning the result to the parent recursive call is continued until the final result S=23 is returned.

To increase the efficiency of the program above, an iterative version of the same predicate must be implemented. Once again, an additional argument should be introduced, playing the role of the accumulator. The accumulator will keep the partial sum of numbers that have been added until that point. It should be initiated with value 0, which is why the second argument of the call of predicate sumlist1 is zero.

```
sumlist_interative(L,S):-
        sumlist1(L,0,S).
sumlist1([],S,S).
sumlist1([H|Tail],T,Sum):-
        T1 is T+H,
        sumlist1(Tail,T1,Sum).
```

We see that predicate sumlist1 is iterative because, as it is mentioned in the "Background" section, after the pseudo-"recursive" call at sumlist1(Tail,T1,Sum), there is no other call. The second argument T plays that role of an accumulator. This accumulator has the complete solution as soon as the whole list is processed.

To illustrate this version of sumlist, the trace of the same Prolog call with that of Figure 4 is shown below.

It is clear that the sum of the numbers in the list [3,5,7,8] is gradually calculated at the accumulator, that is the second argument of sumlist1. When the list reaches its limit state, that is, when it becomes empty, the value of the accumulator is the solution. In Figure 5, the iterative nature of the implementation is apparent, especially if we compare it with that of Figure 4. In Figure 4, where recursion is used, there is a

Figure 5. Trace of the iterative implementation, involving the use of an accumulator

```
?-sumlist_iterative([3,5,7,8],S).
  → sumlist1([3,5,7,8],0,S)
   → sumlist1([5,7,8],3,S)
    → sumlist1([7,8],8,S)
      → sumlist1([8],15,S)
        → sumlist1([],23,S)
S=23
```

second phase in which the return of values is happening. In Figure 5, this second phase is completely omitted.

FUTURE TRENDS

The "competition" between the use of recursion or iteration is not new. Both techniques have advantages and disadvantages. The programmer should be aware of these advantages and disadvantages and use the right technique to the right problem.

As soon as Artificial Intelligence Applications and other applications start to incorporate time critical subprograms, the recursion should to be avoided because it can cause unnecessary time delays. In such cases, the transformation of recursion to iteration is a valid solution. The same applies when memory space is limited and recursion is a luxury that we cannot afford.

Furthermore, the technique that transforms recursion to iteration can be useful from an educational point of view. Students that learn how to program both recursively and iteratively should know about the technique presented above, in order to understand how recursion and iteration are achieved internally in a computer and choose the more suitable implementation. Because time and space efficiency is a requirement in modern programming, the transformation of recursion to iteration as presented above will become more and more popular.

CONCLUSION

Transforming recursion to iteration/tail recursion can provide many advantages, especially from a time or a memory space point of view. The current article has presented a technique to achieve such a transformation. This technique incorporates the introduction of one or two internal parameters that play the role of the accumulator and the counter. These two additional parameters are used in order:

a. the accumulator to keep partial results that are evaluated during the execution of the program and
b. the counter to keep the number of iterations that are made until that point of execution.

KEY TERMS

Accumulator: A variable used for the accumulation of arithmetic sums, usually evaluated in the form Sum:=Sum+X. Usually, it is initialized with the value zero.

Counter: A variable that stores a single natural number and usually represents the number of iterations that have to be done so far or the number of iterations that are needed from that point on. In the first case, its value is usually evaluated by the form N:=N+1 and its initial value is zero. In the second case, its value is usually evaluated by the form N:=N-1 and its final value is zero.

Iteration: The repeated execution of the same process a given number of times or until a specified result is obtained.

Predicate: A predicate is an operator or function which returns a Boolean value (e.g., true or false).

Recursion: The definition of a program in terms of itself. This gives the program the ability to call itself.

Stack Overflow: The condition that occurs when a computer program makes too many calls to subprograms, leading the memory stack to run out of space.

Trace: A report showing the detailed step-by-step execution of a computer program

Transmission of Scalable Video in Computer Networks

INTRODUCTION

The Internet as a video distribution medium has seen a tremendous growth in recent years with the advent of new broadband access networks and the widespread adoption of media terminals supporting video reception and storage. This growth of Internet video transmission resulted from the advances in video encoding solutions and the increase in the bandwidth of terminals. However, it has also placed new challenges in the developments of video standards, due to the heterogeneous characteristics of current terminals and of the wired and wireless distribution networks.

As the terminal capabilities increase in terms of display definition, processing power, and bandwidth, users tend to expect higher qualities from the received video streams. Additionally, as different types of terminals will likely coexist in the same network, it will be necessary to adapt the content transmitted according to the receiving terminal. Instead of re-encoding (or transcoding) the bitstream, which requires a high computational power on intermediate nodes, rate adaptation would preferably be done by extracting parts of the original bitstream.

In terms of network scalability, encoding and transmitting the same video sequence in a large-scale live video distribution system is a challenge, which may only rely on point-to-multipoint transmissions like IP multicast or broadcast. The traditional solution for point-to-multipoint video transmission in heterogeneous networks and with terminals with very different capabilities relies on a process usually called simulcast or replicated streams transmission. In this process, a discrete number of independent video streams are encoded and distributed through the multicast or broadcast path. Terminals request and decode the video stream that better fits their characteristics and communication rate, switching between video streams according to bandwidth variations. However, the major drawback of *simulcast* is that much of the information carried in one stream is also carried in adjacent streams, and therefore the total rate required for a video transmission is much higher than the rate of a single stream. In these scenarios it would be preferable to encode different levels of quality—one base layer quality and one or more enhancement layers—which could be used to increase the quality of the base layer. Accordingly, terminals with lower bandwidth or computational power could request the reception of lower layers, and terminals with higher capabilities could request additional enhancement layers.

In this article we analyze scalable video transmission, from the perspective of video coding standards and the necessary developments in protocols that support media distribution in current and future network architectures. In the next section we start by describing the first contributions to this topic and following developments in related video coding standards. We then describe the structure of a scalable video bitstream, taking the novel H.264/SVC standard as reference, and we further proceed with an analysis of the protocols that can be used for the description, signaling, and transport of scalable video. We describe different network scenarios and examples where scalable video offers significant advantages, before moving on to some remarks on future trends in this area, discussing those mechanisms that must be associated with SVC techniques to achieve an efficient and robust transmission system, and concluding the article.

BACKGROUND

The use of layered video transmission in IP multicast was originally proposed by Deering (1993), who suggested the transport of different video layers in different multicast groups. With this solution the encoder would produce a set of interdependent layers (one base layer and one or more enhancement layers), and the receiver, starting with a base layer, could adapt his quality by joining and leaving multicast trees, each one carrying a different quality layer.

Deering's proposal was followed by several protocols like: receiver driven layered multicast (RLM) protocol (Mc-

Canne, Jacobson, & Vetterli, 1996), layered video multicast with retransmission (LVMR) protocol (Li, Paul, Pancha, & Ammar, 1997; Li, Paul, & Ammar, 1998), and ThinStreams (Wu, Sharma, & Smith, 1997).

The advantages of layered video multicast were confirmed by Kim and Ammar (2001) for scenarios where receivers are distributed in the same domain, with multiple streams sharing the same bottleneck link, as occurs in many video distribution scenarios.

In terms of video coding, layered video transmission requires a layered encoding of video, a process usually referred to as scalable video coding (SVC). Video coding standards like *ITU-T Recommendation H.263* from the International Telecommunication Union-Telecommunication (ITU-T, 2000) and *MPEG-2 Video* from the ITU-T and the International Organization for Standardization/International Electrotechnical Commission (ITU-T & ISO/IEC, 1994) included several tools that supported the most important scalability options. However, none of these scalable extensions was broadly implemented since they imply a loss in coding efficiency and also a significant increase in terms of decoder complexity.

In January 2005, the Joint Video Team (JVT) from ISO/IEC Moving Picture Experts Group (MPEG) and the ITU-T Video Coding Experts Group (VCEG) started developing a scalable video coding extension for the H.264 Advanced Video Coding standard (ITU-T & ISO/IEC, 2003), known as H.264 Scalable Video Coding (ITU-T & ISO/IEC, 2007). The H.264 SVC augments the original encoder's functionality to generate several layers of quality. Enhancement layers may enhance the content represented by lower layers in terms of temporal resolution (i.e., the frame rate), spatial resolution (i.e., image size), and the quality—specified as signal-to-noise ratio resolution (i.e., SNR).

By using the H.264 SVC, different levels of quality could be transmitted efficiently over both wired and wireless networks, allowing seamless adaptation to available bandwidth and to the characteristics of the terminal. However, the transport of SVC presents many challenges which must be considered in order to take full advantage of its potential.

CODING AND TRANSMISSION OF SCALABLE VIDEO

The most adequate technique for efficiently transmitting scalable video is highly dependent on the video encoding technology itself. Hence, for this article we have used the scalable video extensions to the H.264 standard as reference since these represent the most advanced technology currently available in this area.

The H.264 Advanced Video Coding (AVC) standard is currently emerging as the preferred solution for video services in third-generation (3G) mobile networks, which include packet-switched streaming services, messaging services, conversational services, and multimedia broadcast/multicast services (MBMS) (3GPP TS 26.346, 2005). It will also be used for mobile TV distribution to handheld devices (DVB-H) (ETSI TR 102 377, 2005).

SVC Bitstream Structure

The scalable extension of H.264/AVC includes several layers of quality. Relative to the base layer of an SVC bitstream, and for compatibility purposes, the JVT decided to make it compatible with the H.264/AVC profile.

The SVC bitstream may be composed of multiple spatial, temporal, and SNR layers of combined scalability. Temporal scalability is a technique that allows supporting multiple frame rates. In SVC, temporal scalability is usually implemented by using hierarchical B-pictures.

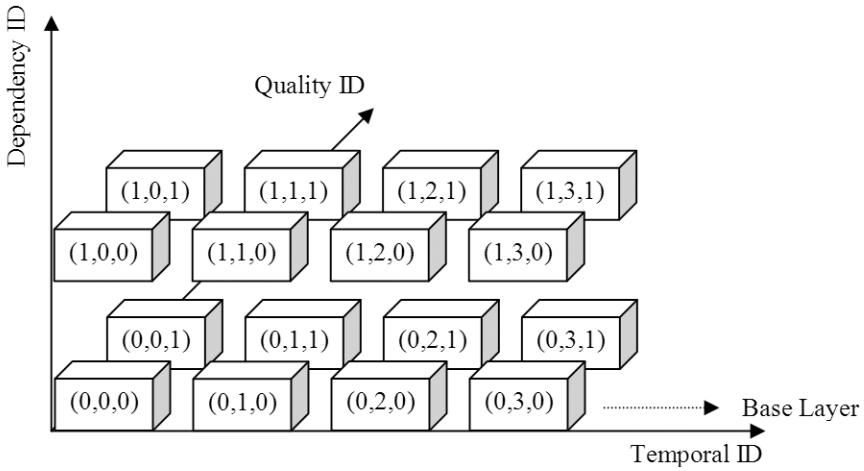
Quality (or SNR) scalability relies on both *coarse-grain quality scalable* (CGS) and *medium-grain quality scalable* (MGS) coding. While CGS encodes the transform coefficients in a nonscalable way, in MGS, which is a variation of CGS, fragments of transform coefficients are split into several network adaptation layer (NAL) units, enabling a more graceful degradation of quality when these units are discarded for rate adaptation purposes. The JVT also considered the possibility of including another form of scalability named *fine-grain scalability* (FGS), which was proposed in MPEG-4 Visual. FGS arranges the transform coefficients as an embedded bitstream, enabling truncation of these NAL units at any arbitrary point. However, in the first specification of SVC (Phase I) (ITU-T & ISO/IEC, 2007), FGS layers were not supported.

Spatial scalability provides support for several display resolutions (e.g., 4CIF, CIF, or QCIF) and is implemented by decomposing the original video into a spatial pyramid.

These spatial, temporal, and SNR layers are identified using a triple identification (ID), consisting of the *dependency ID* identifying the spatial definition, the *temporal ID*, and the *quality* (i.e., SNR) *ID*, which is referred as tuple (D,T,Q). For instance, a base layer NAL unit of the lowest temporal resolution and SNR scalability should be identified as (D,T,Q)=(0,0,0). Accordingly the network adaptation layer structure of H.264/AVC has been extended to include these three IDs. These three layers may be represented using a three-dimensional graph, such as the one in Figure 1.

SVC layers can be highly interdependent from each other, which means that the loss of an NAL unit of a certain layer may cause a severe reduction of quality or even prevent the correct decoding of other layers. This implies that lower layers should be protected from bit errors or packet losses.

Figure 1. Example of a coded video sequence with four temporal layers, two image definitions, and two quality layers per image definition



Protocols for Scalable Video Description, Signaling, and Transport

Scalable transmission of H.264 SVC is based on the Internet Engineering Task Force (IETF)-defined architecture and suit of protocols. SVC NAL units are encapsulated in real-time transport protocol (RTP) (Schulzrinne, Casner, Frederick, & Jacobson, 2003) packets, which are usually carried over user datagram protocol (UDP) (Postel, 1980) and Internet protocol (IP) (Postel, 1981) datagrams.

Concerning the RTP payload format definition, the IETF is currently working on such a draft (Wenger, Wang, & Schierl, 2007). Special attention is being taken in order to make the SVC payload format an extension of the original H.264 payload format defined in RFC 3984 (Wenger, Hannuksela, Stockhammer, Westerlund, & Singer, 2005), so that SVC servers can distribute data to legacy receiver equipment. The main mechanisms for fragmentation and aggregation defined in RFC 3984 are being maintained in Wenger et al. (2007).

In terms of session signaling, two main protocols are used to initiate and control streaming sessions, namely the session initiation protocol (SIP) (Rosenberg et al., 2002) and the real-time streaming protocol (RTSP) (Schulzrinne, Rao, & Lanphier, 1998). Both of these protocols use the session description protocol (SDP) (Handley, Jacobson, & Perkins, 2006) to describe terminals' capabilities. Thus SVC information must be conveyed using SDP, and this protocol must be updated to include the description of interlayer dependencies.

The communication topology defined for SVC transmission considers the possibility of including one or more intermediate nodes, named Media Aware Network Element (MANE) (Wenger et al., 2005), which could adapt unicast and multicast transmission modes, aggregate several streams, or perform rate-adaptation tasks adapting a bitstream according to the capabilities of a particular receiver. These elements also constitute session signaling endpoints between servers and clients.

Scenarios Where Scalable Video Offers Significant Advantages

Layered video transmission was initially intended for IP multicast networks. However, IP multicast is not being largely used on the Internet. Instead, it is currently considered as an important solution for edge IP networks, like those of service providers. Nevertheless, even in these networks, IP multicast constitutes a good solution for scalable transmission of video with the advantage that it is easier to associate it with quality of service (QoS) solutions that guarantee a higher priority to video or other sensitive data.

Two basic video distribution scenarios for SVC can be considered. In a first scenario IP multicast is used between a server and clients. As previously explained, this may be the case for a large private IP network of a service provider, as

for example MBMS (3GPP TS 26.346, 2005) in mobile 3G networks. In this scenario receivers request the SVC layers according to their capacity, dynamically joining or leaving multicast groups. The signaling for session establishment is also performed on an end-to-end basis. In this architecture, it is important to specify a protocol or mechanism that guarantees equality between receivers, since a greedy or naive user could request a rate far beyond the network capacity, thus leading the network to a persistent congested state.

One of the problems pointed out to this solution is the number of firewall ports opened in receivers, which may constitute a security problem.

In a second scenario, one or more MANEs could be placed between a server and clients. MANEs constitute a signaling and RTP endpoint. They can perform rate adaptation tasks, removing packets from an incoming RTP stream and rewriting RTP headers, or even aggregate several video layers in one unique RTP flow of video in case an endpoint does not have the processing power or display size to decode all layers. Using the example of a mobile 3G network, the MANE should be placed close to a base station, with access to both signaling and media traffic. This element can also be associated with other modules or functions which, for instance, perform adaptation between unicast and multicast transmission modes, QoS broking, adaptation between QoS-capable and best-effort networks, or even admission control tasks. This scenario could constitute part of an overlay network that manages the distribution of media at the application layer.

FUTURE TRENDS

The integration of scalable video transmission techniques in current and emerging network architectures still presents some challenges that must be considered prior to being able of taking the most of it.

QoS solutions should be considered for giving higher priority to video data when compared with less sensitive data. QoS solutions for wireless networks, like for instance the IEEE Standard 802.11e (2005), usually include several mechanisms like queue management and automatic repeat request (ARQ) solutions. Link layer ARQ solutions can be associated with QoS provisioning, quickly recovering from packet losses in more important layers.

Concerning large-scale multicast and broadcast networks, the retransmission of lost packets could constitute a scalability problem, and therefore the protection of lower layers may be performed by applying forward error correcting (FEC) codes. In such scenarios the use of raptor codes (Shokrollahi, 2006) is gaining popularity due to their high flexibility and effectiveness. As an example, the use of raptor codes was proposed for H.264/AVC video transmission in mobile MBMS networks (3GPP TS 26.346, 2005).

Finally, in terms of coding, current H.264/SVC encoding and decoding processes present additional complexity when compared with the AVC standard. In particular, decoding time must be minimized in order to encourage the widespread adoption of this novel technology.

CONCLUSION

In this article we describe the main issues associated the transmission of scalable video coding. Although the basic mechanisms of scalable video transmission were defined more than a decade ago, there is still a lack of encoding and transmission mechanisms to support it. In terms of video coding, the flexibility offered by the scalable extension of the H.264/AVC provides considerable opportunities to extend current video distribution networks without the penalty of having to change or upgrade H.264/AVC terminals: its base layer and signaling mechanisms are designed to guarantee the compatibility with legacy equipments.

In terms of network support, several challenges remain that must be considered. However, the advent of mobile and wireless networks with very different terminal capabilities, combined with wired access networks capable of delivering high-quality videos, will require a flexible technology that supports easier rate-adaptation mechanisms with graceful degradation when facing bandwidth reduction.

KEY TERMS

Automatic Repeat Request (ARQ): A method for error control in packets or frames that uses redundant bits, acknowledgment packets, and timeouts to detect and retransmit data affected by errors.

Broadcast: Process of transmitting a flow of data from a source to all receivers of the broadcast domain or of the network where the terminal operates.

Forward Error Correction (FEC): A method for error correction that uses redundant bits to detect and correct errors in data without the need for retransmission.

IP Multicast: The transmission of Internet protocol (IP) datagrams from a source to all the receivers that belong to a certain IP multicast group. In IP multicast, terminals that wish to receive data must register with that multicast group. IP multicast routing protocols are used to create distribution trees.

Network Adaptation Layer (NAL): An H.264 syntax structure that represents a frame or part of it, integrating information about its encoding parameters. NAL structures are appropriate for the transport of H.264 over several types of networks.

Quality of Service (QoS): Process of providing different priorities to different flows of data or to guarantee a certain level of quality to a data flow. Examples of quality parameters are transmission rate, delay, delay variation (jitter), and packet loss.

Simulcast: Also referred to as replicated streaming, the process of simultaneously encoding and transmitting a same video sequence through a discrete number of quality video streams to several receivers.

Transcoding: The process of partially or totally decoding and re-encoding a certain video stream in order to change its characteristics in terms of definition, frame rate, or transmission rate.

Unicast: Process of transmitting a flow of data from a source to a particular receiver.

The Trends and Problems of Virtual Schools

Glenn Russell
Monash University, Australia

INTRODUCTION: THE EMERGENCE OF THE VIRTUAL SCHOOL

Until recent times, schools have been characterized by the physical presence of teachers and students together. Usually, a building is used for instruction, and teaching materials such as books or blackboards are often in evidence. In the 20th century, alternatives to what may be called "bricks-and-mortar" schools emerged. These were forms of distance education, where children could learn without attending classes on a regular basis. The technologies used included mail, for correspondence schools, and the 20th century technologies of radio and television.

Virtual schools can be seen as a variant of distance education. Russell (2004) argued that they emerged in the closing years of the 20th century and can be understood as a form of schooling that uses online computers to provide some or all of a student's education. Typically, spatial and temporal distancing is employed, and this results in students being able to use their computers at convenient times in their homes or elsewhere, rather than being subject to meeting at an agreed upon time in a school building.

The concept of a virtual school is agreed upon only in broad terms, as there are a number of variants. Some virtual schools insist on an agreed upon minimum of face-to-face contact, while others are so organized that a student might never set foot in a classroom. It is possible for a virtual school to have no physical presence for students to visit, and an office building in one state or country can be used to deliver virtual school services to interstate or international students.

One way of categorizing virtual schools is by imagining where they might be placed on a scale of face-to-face contact between students and teachers. At the conservative end of this scale, there would be conventional schools, where students use online computers in classrooms or labs for some of their lessons. A trained teacher in the same subject area might be available to help students, or other teachers, volunteers, or parents could supervise them.

Toward the middle of such a scale would be mixed-mode examples, where some subjects are offered in virtual mode, but students are asked to visit the school on a regular basis to monitor their progress or to participate in other face-to-face subjects, such as sport, drama, or art. At the other end of the scale are virtual schools, where the student and teacher never meet, and there is no requirement for the student to enter a school building for the duration of the course. One example of such a virtual school is Florida High School, where there is no Florida High School building, and students and teachers can be anywhere in the world (Florida High School Evaluation, 2000, 2002).

FACTORS PROMOTING THE RISE OF VIRTUAL SCHOOLS

Russell (2005) has argued that the principal factors that account for the growth of virtual schools include globalization, technological change, availability of information technology (IT), economic rationalism, the model provided by higher education, perceptions about traditional schools, and the vested interests of those involved in them.

The first of these factors, globalization, refers to a process in which traditional geographic boundaries are bypassed by international businesses that use IT for globally oriented companies. It is now possible for curriculum to be delivered remotely from across state and national borders. Educational administrators can purchase online units of work for their school, and parents in developed countries can sometimes choose between a traditional school and its virtual counterpart.

As IT continues to develop, there is a correspondingly increased capacity to deliver relevant curricula online. As broadband connections become more common, students will be less likely to encounter prolonged delays while Web pages load or other information is downloaded. Advances in computers and software design have led to developments such as full-motion video clips, animations, desktop videoconferencing, and online music. Collectively, what is referred to as the Internet is already very different from the simple slow-loading Web pages of the early 1990s.

Economic rationalism also drives the spread of virtual schools, because the application of economic rationalism is associated with productivity. For education, as Rutherford (1993) suggested, the collective or government provision of goods and services is a disincentive to private provision, and that deregulation and commercialization should be encouraged. Consistent with this understanding is the idea that schools, as we know them, are inefficient and should be radically changed. Perelman (1992) argued that schools are remnants of an earlier industrial era that ought to be replaced with technology.

The ways in which higher education has adopted online teaching provide an example of how online education can be accepted as an alternative. The online courses provided by universities in recent years have proliferated (Russell & Russell, 2001). As increasing numbers of parents complete an online tertiary course, there is a corresponding growth in the conceptual understanding that virtual schooling may also be a viable alternative.

Those convinced that existing schools are unsatisfactory can see virtual schools as one alternative. Criticism of schools for not adequately meeting student needs, for providing inadequate skills required for employment, or not preparing students for examinations and entrance tests, are continuing themes that can be identified in a number of educational systems. Discussions related to school reform can include funding, resourcing, teacher supply, curriculum change, and pedagogy, but they can also include more radical alternatives, such as virtual schooling.

PROBLEMS OF VIRTUAL SCHOOLS AND THEIR SOLUTIONS

Virtual schools face a number of challenges related to the way that teaching and learning are implemented in online environments. While similar problems can also be identified in conventional schools, the different natures of virtual schools serve to highlight these concerns. These problems include authenticity, interactivity, socialization, experiential learning, responsibility and accountability, teacher training, certification, class sizes, accreditation, student suitability, and equity.

The first of these problems, authenticity, relates to the verification of the student as the person who has completed the corresponding assignments and tests from a virtual school. Virtual schools may assign students a secure password to use over the Internet, but this procedure would not preclude students from giving their passwords to a parent or tutor who completed the work on their behalf. A possible solution that may have to be considered is to test students independently to confirm that they have the understanding, knowledge, and skills suggested by their submitted work. Some virtual schools, such as Louisiana Virtual School (2006), ask students and parents to sign an honesty policy in an effort to maintain the authenticity of students' work.

Interactivity describes the relationship between the learner and the educational environment. For virtual school students, there is an interactive relationship involving the multimedia, the online materials used, and the teacher. Students would typically access materials on the World Wide Web, respond to them, and send completed work electronically to their teachers. The preferred way for students to become involved in online learning is to have an active engagement involving a response. If a student is directed to a static Web page containing a teacher's lecture notes, learning may be less effective, unless other teaching methods are used to supplement it. The solution to this problem will be found in both the increased capability of students' online computers to operate in a rich multimedia environment, and the recognition by course designers that virtual schools should take advantage of advances in learning theory and technological capability. In the U.S., the National Education Association's *Guide to Online High School Courses* (NEA, 2006) has maintained that online courses should reflect current research on learning theory and recognize the opportunities provided by online learning environments.

Socialization continues to be a problem with virtual schools, because there is an expectation in conventional schooling that students will learn how to work cooperatively with others and will internalize the norms and values necessary for living in a civilized community. Moll (1998) is concerned with disruption to the tradition of public education as the primary vehicle for the transference of national narratives and humanistic and democratic values. Clearly, socialization will still occur if students use online learning supplemented by some contact with teachers and opportunities for organized sports. However, students' ability to relate to others in society is likely to change. Despite this concern, a type of virtual school that routinely insists on organized face-to-face learning and social situations, with peers, teachers, and other adults, will reduce the problems that otherwise are likely to arise.

A related concern to that of socialization is the belief that Web culture is inherently isolating, and that by encouraging students to pursue their education with a virtual school, an existing trend toward loss of community may be exacerbated. Kraut et al. (1998) originally suggested that Internet use could be associated with declines in participants' communication with family members in the household, declines in the size of their social circles, and increases in depression and loneliness. However, more recent research (Kraut et al., 2002) found that negative effects had largely dissipated.

There are some teaching activities in conventional schools referred to as experiential. These usually involve some form of hands-on activity or physical interaction with others. Typically, a teacher will provide a demonstration, explanation, or modeling of what is to be learned, and activities that follow provide opportunity to correct errors. While virtual schools commonly offer subjects such as mathematics and social studies, the study of physical education, drama, art, and the laboratory component of science is more problematic. Sometimes the problem does not arise, because students will enroll only for subjects that they missed or that they need for credit toward a qualification.

A common solution to these problems is for the virtual school to provide online or print-based teaching materials, as with other subjects in the range to be offered. Students complete the activities and send evidence of the completed

work to the school. The Open School (2002) in British Columbia, Canada, offers art in both elementary and secondary school levels. At the Fraser Valley Distance Education Centre (2006), students are invited to participate in a science fair by sending in digital pictures and a digital video clip of their project to the supervising teacher.

Changing notions of responsibility, accountability, and student discipline are also likely to arise in virtual school environments (Russell, 2002). In a traditional school, teachers accept responsibility for the students in their charge, including the prevention of physical injury, and accountability for using appropriate teaching techniques. When there is a spatial and temporal distance between teacher and student, teachers are unable to exercise some of their accustomed responsibilities. While there is still a requirement to act ethically, and to ensure that appropriate teaching materials and methods are used, much of the responsibility shifts to parents, students, and to the suppliers of the online materials.

Teacher training is also emerging as an area of concern. Virtual teachers will find that some new skills are required, while others are less important. Class management skills in a face-to-face environment will differ from their online equivalents, as will many of the teaching practices. Salmon (2000) identified a number of skills that will be required by online teachers in the future. It is clear that there will be an ongoing need to use technological skills and to apply these skills to an appropriate educational context. However, it is unlikely that many teachers' colleges and other providers of trained teachers have modified their courses to reflect these changes, as mainstream teacher education is still focused on conventional school education. There are, nevertheless, some hopeful signs. The California Virtual School Report (2000) provided evidence of the use of online modules for teachers at Durham Virtual High School, in Canada, and a 15-week teacher-training program in Fairfax County School District.

Parents would normally expect that the virtual teacher working with their child would be a competent online teacher and be certified or registered with the corresponding school system. Where a student is working from home, and the principal contact with the teacher is by e-mail, the anonymity of the communication mode could conceivably cover the use of unqualified teachers. The necessity for demonstrating that a high-quality educational experience is being supplied is, however, likely to reduce this possibility. Florida Virtual High School uses only certified classroom teachers (Schnitz & Young, 2002). As the online environment becomes more competitive, it is likely that virtual schools will provide evidence of their teachers' certifications.

With conventional schools, the issue of class sizes is a perennial problem. The diversity of virtual schools means that it is not easy to determine corresponding workloads. The evaluation of Virtual High School (VHS) (Kozma et al., 2000) revealed that some of the teachers involved in the case study had to complete their VHS work at home in addition to their normal teaching load during the day. When teachers are asked to take responsibility for large groups of students, the time available for individual attention is likely to be reduced, and the quality of the educational service provided may be less satisfactory. There are indications that some virtual schools have recognized this problem. Louisiana Virtual School (2002), for example, is limited to 20 students per course.

Accreditation of courses across geographic regions will also become an increasing problem. Palloff and Pratt (2001) noted concerns with the quality of online high school programs as early as 2001. Varying standards can mean that a course in one area is not recognized in another. Students will increasingly be able to choose programs across state and even national borders and complete their schoolwork by sitting at home with their computers.

An important item relating to the quality of a student's educational experience in a virtual school is the recognition that not all students are suited to online learning. Already, some virtual schools try to determine whether the prospective student is suited to online learning by using questionnaires. Typically, these questionnaires ask students about their independent learning skills, motivation, time management abilities, and comfort with technology.

If virtual schools are perceived to be advantageous for those enrolled in them, there are also concerns as to when the access to them is seen as inequitable. Bikson and Paris (1999) found that there were "highly significant differences in household computer access based on income" (p. 9), in the United States. It is reasonable to assume that households with children will have less access to computers to use in a virtual school if they are part of a disadvantaged group. Unless there is careful planning, the use of technology-mediated education is likely, in the short term, to further entrench those inequalities that exist in society.

FUTURE TRENDS IN VIRTUAL SCHOOLS

Three broad trends can be identified in the growth of virtual schools. These are the continued expansion in the number of virtual schools, the trend from virtual high schools to virtual K-12 schools in North America, and the growth of virtual schools in other parts of the world. Research by Clark (2001) indicated that more virtual schools began their operations in the United States during the period 2000-2001 (43%) than in the previous four years combined. Fifty-one percent of virtual schools surveyed offered junior high and middle school courses as well as high school courses, and about one in four schools offered courses across the whole K-12 spectrum (Clark, 2001). In Canada, there is also evidence of growing demand for virtual schools. The two-year

cumulative growth rate for Alberta virtual schools was 125% (SAEE, 2002).

Collectively, the implication of the trends from North America toward an increased number of virtual schools and the extension of virtual schooling to K-12 is that there will be increased attention devoted to solving problems associated with virtual schooling. When virtual schools made their first appearance, it would have been possible for some educators to dismiss them because they were experimental, or ignore their existence because they catered only to a niche market of high school students. In some cases, this suggestion may still be valid, but support for virtual schooling is increasing, rather than decreasing, and the nature of what is offered is becoming more comprehensive and established.

Virtual schools have also continued to develop in other parts of the world. Russell (2006) has also observed a new trend in the evolution of virtual schools in Europe. The *conventional school* is likely to be the most common way in which online learning is used in European schools. In this schooling mode, students physically meet with their teachers in a dedicated building or classroom where online facilities are available, although some additional work may be completed at home. *Resources* are often available online from a provider, vendor, or umbrella organization. In Europe, one of the key providers is *European Schoolnet*, an international association of ministries of education from Europe and elsewhere. European Schoolnet provides a portal for members that includes a number of innovative projects for schools, in addition to policy information and online services. The European Schoolnet (EUN) describe their operations as follows:

The European Schoolnet is a unique international partnership of 26 Ministries of Education developing learning for schools, teachers and pupils across Europe and beyond. We provide insight into the use of ICT (information and communications technology) in Europe for policy-makers and education professionals. This goal is achieved through communication and information exchange at all levels of school education using innovative technologies, and by acting as a gateway to national and regional school networks. (European Schoolnet, 2005)

In the UK, a type of virtual school is being trialed that aims to re-engage school-age students into learning who have previously been out of more traditional educational systems. The project (Notschool, 2006) aims to establish a virtual community and develop students' self-esteem using new technology and community support.

In China, Hung, Chen, and Wong (2006) cite evidence that there are now more than 600,000 students enrolled in virtual schools, with more than 30 online virtual schools having been established in Beijing alone. Typically, many of these virtual schools are sponsored by enterprises. An example of one of these virtual schools is the 101 Distance Learning Center (2006) in Beijing.

In Australia, virtual schools have been established in Qld (VSS, 2006) and Tasmania (Distance Education Tasmania, 2006) by the relevant educational authorities. These virtual schools use conventional schools. Schools elect to receive or provide instruction in designated subject areas, but there are important differences in the way that these approaches to virtual schooling have evolved.

CONCLUSION

Virtual schools continue the tradition whereby students learn at a distance from their teachers. The availability of online courses through the Internet has simultaneously reduced the emphasis given to older forms of distance education and increased the opportunities for students to explore alternatives to traditional school education. It is likely that there will be an increase in the number of virtual schools and that they will continue to attract students. The expected increase in the number and type of virtual schools is likely to provide both exciting possibilities and daunting challenges.

KEY TERMS

Bricks-and-Mortar Schools: Traditional schools, where students attend at a physical school building.

Distance Education: A generic term referring to education where teachers and students are geographically separate. Modes employed include print and non-print technologies.

Experiential Learning: Learning based on direct and unmediated instruction or on physical interaction with people and materials.

Globalization: The bypassing of traditional geographic borders using information technology to enable global orientation of business and remote curriculum delivery.

Interactivity: The relationship between the learner and the educational environment.

Socialization: The process by which students internalize the norms and values necessary for living in a civilized community.

Virtual School: A form of schooling that uses online computers for part or all of a student's education.

Trends in Information Technology Governance

Ryan R. Peterson
Information Management Research Center, Spain

INTRODUCTION

Information technology (IT) *governance* has been a perennial item on the corporate agenda of many organizations. Ever since IT proved to be more than an administrative tool, researchers and practitioners have pondered its governance. Defined as the locus of IT decision-making authority (Brown & Magill, 1994; Sambamurthy & Zmud, 1999), discussions concerning IT governance have flourished for more than four decades across research communities and boardrooms. Posed as a question of *centralization* during the 70s, IT governance drifted towards *decentralization* in the 80s, and the recentralization of IT decision-making was a 90s trend.

Today, IT governance is experiencing yet another transformation, and persists as a complex and evolving phenomenon (Grembergen, 2003). As business environments continuously change and new technologies evolve rapidly, how to govern IT effectively remains an enduring and challenging question. This chapter discusses past developments and the present status quo of IT governance, and outlines several critical questions, which are pending future investigation.

BACKGROUND

Traditionally, three IT governance models have been distinguished (Brown & Magill, 1998; Sambamurthy & Zmud, 1999). In each model, stakeholder constituencies take different lead roles and responsibilities for IT decision-making across the *IT portfolio*. In the centralized model, corporate IT management has decision-making authority concerning *IT infrastructure* and *IT applications*. In the decentralized model, division IT management and business management have authority for IT infrastructure and IT applications. In the *federal* model, corporate IT has authority over IT infrastructure, and (either or both) division IT and business-units have authority over IT applications.

In general, it is argued that centralization provides greater efficiency, control, and standardization, while decentralization improves business ownership, flexibility, and responsiveness (Brown, 1997; Rockart, Earl, & Ross, 1996). Literature suggests that the federal model provides the benefits of both centralization and decentralization (see Table 1). Research indicates that organizations adopt a federal model when pursuing multiple competing objectives involving a simultaneous focus on cost-efficiency and business-flexibility

Table 1. Drivers and design of IT governance (Adapted from Hodgkinson, 1996; Peterson, O'Callaghan, & Ribbers, 2000; Sambamurthy & Zmud, 1999)

Model / Drivers	Centralized IT Governance	Decentralized IT Governance	Federal IT Governance
Synergy	+	-	+
Standardization	+	-	+
Specialization	+	-	+
Customer responsiveness	-	+	+
Business ownership	-	+	+
Flexibility	-	+	+

1.

(Peterson, O'Callaghan, & Ribbers, 2000; Sambamurthy & Zmud, 1999).

MAIN THRUST

While the federal model seems to be the dominant configuration in contemporary firms (Peterson, O'Callaghan, & Ribbers, 2000; Sambamurthy & Zmud, 1999), empirical studies regarding the complexity of this configuration are sparse. Specifically, *allocation of IT decision-making authority does not resolve the need for effective coordination between corporate IT, division IT and business-unit management*. Continuous differentiation leads to fragmentation, unless a corresponding process of integration complements it. The problems reported in practice and research regarding the lack of, for example, IT prioritization, top management IT commitment, IT management business understanding, business management IT responsibility, and IT value generation, are symptomatic of this fragmentation and are typically encountered in the federal IT governance model (Peterson, 2001; Weill & Broadbent, 1998).

In order to provide direction and achieve organizational effectiveness, differentiation begets integration (Daft, 1998; Galbraith, 1994; Lawrence & Lorsch, 1967). Designing effective IT governance is dependent on both the *differentiation* and *integration* of decision-making for IT across the portfolio of business IT investments and processes (see Figure 1).

Whereas differentiation focuses on the distribution of IT decision-making rights and responsibilities among different stakeholders in the organization (i.e., the locus of IT decision-making), integration focuses on the coordination of IT decision-making/-monitoring processes and structures across stakeholder constituencies. Organizations thus need to consider and implement integration mechanisms for the effective governance of IT.

FUTURE TRENDS

Integration mechanisms for IT governance can be classified according to two dimensions (Peterson, 2003). Vertically, integration mechanisms focus either on integration structures or integration processes; whereas horizontally, a division is made between formal positions and processes, and relational networks and capabilities. Collectively, this provides four types of generic integration mechanisms for IT governance (see Figure 2).

Formal integration structures involve appointing IT executives (e.g., CIO) and IT functions (e.g., client-account and user relationship managers), and institutionalizing special and standing IT committees and councils. Committees and/or

Figure 1. Differentiation and integration IT decision-making (Adapted from Weill & Broadbent, 1998)

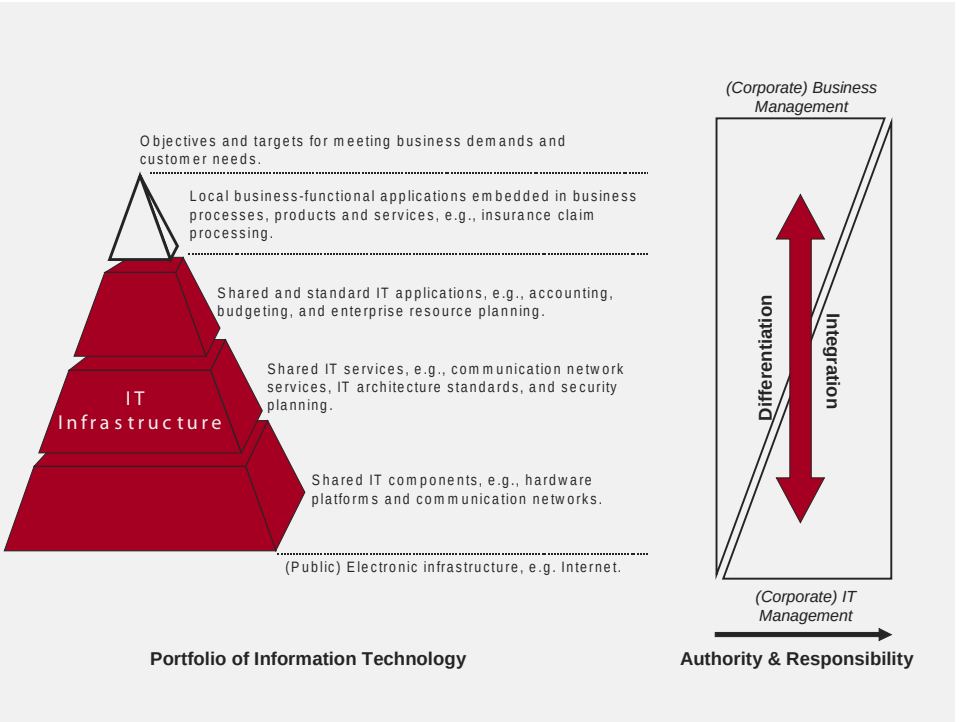

Figure 2. Generic integration mechanisms for IT governance (Adapted from Peterson, 2003)

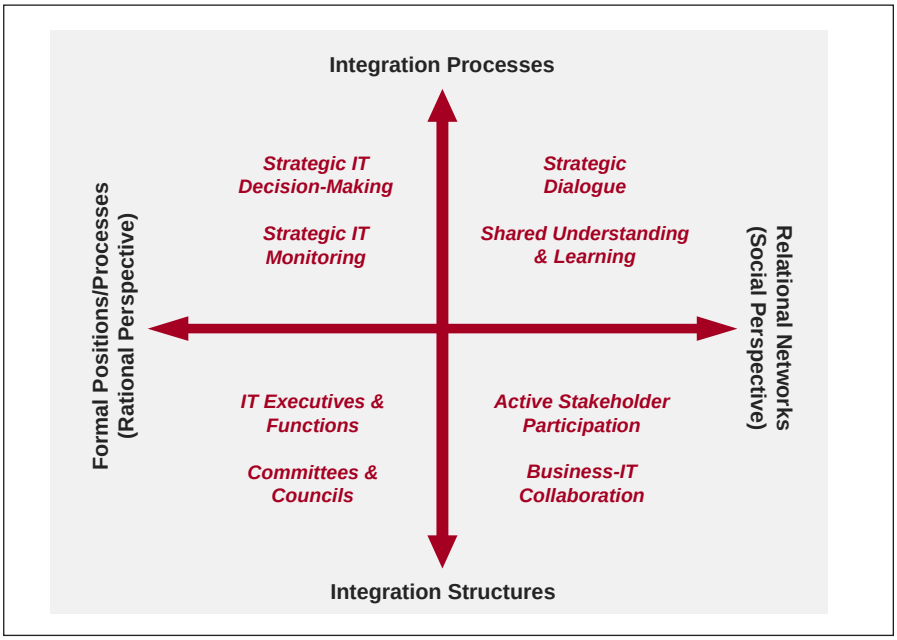

executive teams can take the form of temporary task forces (e.g., project steering committees), or can alternatively be institutionalized as an overlay structure in the organization in the form executive and/or IT management councils. Formal integration processes describe the formalization and institutionalization of IT decision-making-/monitoring procedures and performance. Formal integration processes vary with levels of IT governance *comprehensiveness*, *formalization*, and *integration*.

Whereas the foregoing formal integration mechanisms tend to be mandatory and tangible, relational integration mechanisms are "voluntary" and "tacit" actions, which cannot be programmed and/or formalized. While formal integration mechanisms are necessary, they are insufficient for designing effective IT governance in competitive environments (Peterson, O'Callaghan, & Ribbers, 2000).

Relational integration structures involve the active *participation* and *collaboration* between corporate executives, IT management, and business management. Central to relational integration is the participative behavior of different stakeholders to clarify differences and solve problems in order to find integrative solutions. The ability to integrate relationally allows an organization to find broader solutions, and unleashes the creativity involved in joint exploration of solutions that transcend functional boundaries and define future possibilities. Relational integration processes describe strategic dialogue and *shared learning* between principle business and IT stakeholders. Strategic IT dialogue incorporates a wide range of initially unstructured business perspectives and IT views, and involves rich conversation to resolve diverging perspectives and stakeholder conflicts. Shared learning describes the co-creation of mutual understanding by members of organizational sub-units of each other's goals and objectives.

In summation, formal and relational structures and processes collectively constitute and determine the integration capability of IT governance, and underscore the importance of flexible management systems in complex and uncertain environments. The organizing logic is characterized by a collaborative network, where communication is more likely to be lateral, task definitions are more fluid and flexible (i.e., related to competencies and skills, rather than being a function of position in the organization), and where influencing of business-IT decisions is based on expertise, rather than an individual's (or group's) position (Peterson, 2003).

CONCLUSION

Amidst the challenges and changes of the 21st century, involving hyper-competitive market spaces, electronically-enabled global network businesses, and corporate governance reform, IT governance has become a fundamental business imperative. IT governance is a top management priority, and

Table 2. Future research

Suggested Research Questions	Suggested Research Design and Methodology
What types of integration mechanisms are used in conjunction with different IT governance models? Do certain IT governance *gestalts* exist that combine IT governance differentiation and integration mechanisms?	A quantitative approach (large scale survey) to identify and validate patterns of IT governance differentiation and integration. Multiple case studies can also be used to explore and discover new patterns.
What are the most effective integration mechanisms under different IT governance models?	A quantitative approach (large scale survey) to identify effective integration mechanisms for IT governance. Multiple case studies can be of value when considering the business and industry context.
How do integration mechanisms moderate the relationship between IT governance and IT business value?	A quantitative approach (large scale survey) to measure and validate the moderating impact of integration mechanisms on IT business value realization
How do organizations design and implement integration mechanisms for IT governance?	A longitudinal research design involving field-research and multiple case studies. A single in-depth case study can also provide rich (theoretical) insights.
What are the (inter-) dependencies between integration mechanisms? Do companies follow a specific path when developing and implementing integration mechanisms (e.g., do they start with positions, the processes and finally relationships?)	A longitudinal or retrospective field-study on the development and evolution of integration mechanisms in certain companies
Are certain drivers (e.g., standardization, responsiveness, flexibility) related to the use (or non-use) of specific integration mechanisms? How do the competing drivers of efficiency and flexibility impact the adoption and usage of integration mechanisms?	Both surveys and/or case studies can be used. A (quantitative) survey would identify empirically significant relationships amongst certain drivers and integration mechanisms. Multiple case studies would help explain why and how these (competing) drivers lead to the adoption and usage of integration mechanisms

rightfully so, because it is the single most important determinant of IT value realization (Mata, Fuerst, & Barney, 1995; Peterson, 2001; Rockart, Earl, & Ross, 1996; Sambamurthy & Zmud, 1999; Weill & Broadbent, 1998).

More than simply assigning and allocating IT decision-making authority, IT governance is the system by which an organization's IT portfolio is directed, and describes the distribution of IT decision-making rights and responsibilities among different stakeholders in the organization, and the rules and procedures for making and monitoring decisions on strategic IT concerns. These rules and procedures address the integration mechanisms, which are fundamental to effective IT governance.

Nevertheless, research has only recently focused on the use and effectiveness of integration mechanisms for IT governance. More research is definitely and urgently required in this area (Table 2). It is only through empirical investigation of these and other related research questions that we will be able to advance the current body of knowledge and understanding in the area of IT governance.

KEY TERMS

Centralized Model: The concentration of decision-making in a single point in the organization, in which a single decision applies.

Collaboration: A close, functionally interdependent relationship, in which organizational units strive to create mutually beneficial outcomes. Collaboration involves mutual trust, the sharing of information and knowledge at multiple levels, and includes a process of sharing benefits and risks. Effective collaboration cannot be mandated.

Decentralized Model: The dispersion of decision-making, in which different independent decisions are made simultaneously.

Differentiation: The state of segmentation or division of an organizational system into subsystems, each of which tends to develop particular attributes in relation to the requirements posed by the relevant environment. This includes both the formal division, as well as, behavioral attributes of the members of organizational subsystems.

Federal Model: A hybrid configuration of centralization and decentralization, in which decision-making is differentiated across divisional and corporate units.

Integration: 1) The process of achieving unity of effort among various subsystems in the accomplishment of the organizational task (*process focus*). 2) The quality of the state of collaboration that exists among departments, which is required to achieve unity of effort by the demands of the environment (*outcome focus*).

IT Applications: Local business-functional applications embedded in business processes, activities, products and/or services.

IT Governance: 1) Locus of IT decision-making authority *(narrow definition).* 2) The distribution of IT decision-making rights and responsibilities among different stakeholders in the organization, and the rules and procedures for making and monitoring decisions on strategic IT concerns *(comprehensive definition).*

IT Governance Comprehensiveness: Degree to which IT decision-making/-monitoring activities are systematically and exhaustively addressed.

IT Governance Formalization: Degree to which IT decision-making/-monitoring follows specified rules and standard procedures.

IT Infrastructure: The base foundation of the IT portfolio, delivered as reliable shared services throughout the organization, and centrally directed, usually by corporate IT management.

IT Governance Integration: Degree to which business and IT decisions are integrated administratively, sequentially, or reciprocally.

IT Portfolio: Portfolio of investments and activities regarding IT operations and IT developments spanning IT infrastructure (technical and organizational components) and IT applications.

Participation: Process in which influence is exercised and shared among stakeholders, regardless of their formal position or hierarchical level in the organization.

Shared Learning: The co-creation of mutual understanding by members of organizational sub-units of each other's goals and objectives.

Trends in the Higher Education E-Learning Markets

John J. Regazzi
Long Island University, USA

Nicole Caliguiri
Long Island University, USA

INTRODUCTION

This article describes research undertaken at the Scholarly Communications Lab of the College of Information and Computer Science at Long Island University in the area of higher education e-learning market in the United States. It is organized around three topics: a definition of e-learning and distance education; a description of the size, growth, and future outlook for this market; and the identification of some of the key growth drivers both historically and for the future.

The distant education market is now a mature market and has been around for a long while, with its antecedents established decades ago. The market has grown substantially in the last 10 years, and will continue to grow significantly, with an estimated market size of over $17 billion in 2010, representing a penetration rate of over 30% of the total higher education market in the United States. Many institutions of higher education have embraced some type of online programs, with 96% of universities with enrollments of 15,000 students having some e-learning programs. Major new entrants from the for-profit sector are now active in this marketplace. With the combination of new entrants and new technology advancements, the opportunities for value creation have increased while the nature of competition has intensified substantially.

BACKGROUND

According to Western Governors University (USA), distance learning and e-learning is simply:

Education that takes place when the instructor and student are separated by space and/or time. The gap between the two can be bridged through the use of technology—audio tapes, videoconferencing, satellite broadcasts and online technology, just to name a few—and/or more traditional delivery methods, such as the postal service. (WGU, 2004)

As communications and computer technology evolve, the definition of distance learning continues to develop. Asynchronous or time-delayed computer conferencing has given institutions the capability to network groups of learners over a period of time, allowing students in distance learning programs to be taught in groups rather than as individuals (Gunawardena & McIsaac, 2003).

Distance learning, before it evolved into primarily e-learning, has been around for a long period of time. It began in the second half of the 19th century with the exchange of print materials, assignments, and feedback by mail. Over the course of the 20th century, the development of radio and television made the delivery of additional materials (lectures and demonstrations) by electronic means possible. The 1950s saw the growth of a number of video projects that sought to identify expert science, math, and language teachers who could spread their expertise to students across a region or across the whole country. In 1989, Congress enacted the Star Schools legislation, intended to deliver quality instruction to largely rural or underserved areas. Among the Star School projects were three courses designed for adult learners, two of which used a studio teacher providing regular classes on topics ranging from job-seeking skills to skill-building needed to qualify for the GED. (www.ed.gov/prog_info/StarSchools/).

CURRENTLY CHANGING DEVELOPMENTS

More recent technologies have expanded the number of communication channels available to distant educators. E-mail and computer conferencing began in the early 1970s as part of the government sponsored ARPANET (Advanced Research Projects Agency Network) (Harasim, Hiltz, Teles, & Turoff, 1995). Although scientific work groups quickly adopted these communicative tools to advance collaborative activity at a distance, they were not available to educators and off-campus students for another decade. In education, these tools could permit learners to exchange and debate

ideas. But only in recent years have educators recognized the potential of these tools to support a different model of distance education, a model built on more constructivist principles of learning. Over the 20th century, the technological possibilities have changed, although the pedagogical model has not (Tolmie & Boyle, 2000). Most distance courses that use the modern information handling technologies are still built on a transmission model in which instructors create material to be consumed by learners, and learners are given exercises and tests that they submit to the instructor demonstrating their mastery of the material; that they understand it, remember it, and can apply this knowledge in testing situations (Askov, 2003).

In the 1990s, new tools became available to the scientific community: the Internet and the Web. By the mid 1990s, these were made available to the broader public. Educators recognized the potential of these technologies immediately, and a few distance educators began to recommend a new model of education that emphasized the qualitative improvements in learning itself, if learners had ready access to a variety of electronic materials and were supported in examining and discussing these materials with other learners. These educators sought to distinguish this form of distance learning from more traditional forms by using new terms: distributed or flexible learning. (Bates, 2000) It is estimated that by the year 2012, schools and colleges will routinely use "computerized teaching programs and interactive television lectures and seminars, as well as traditional methods" ("Emerging," 2003, p. 8). Videoconferencing and other technologies will also help enrich media and provide many benefits of face to face instruction (Wonacott, 2002).

In 2003, the first in a series of annual reports by The Sloan Consortium on the state of online learning in U.S. higher education, "Sizing the Opportunity: The Quality and Extent of Online Education in the United States, 2002 and 2003" was released. The initiation of this annual study emerged from a search for an authoritative answer to the question: "How many students are learning online?"

Market Size estimates. The answer determined by that first study was that for the fall 2002 term, slightly more than 1.6 million students took at least one online course at U.S. degree granting institutions. This same study asked institutions to predict the rate of growth (or decline) in their online enrollments for the following year, and respondents projected an average annual growth rate of 19.8%. This number was substantially above the annual rate of increase in the overall population of higher education students, whose annual growth has been estimated as between 0.8 and 1.3% (Allen & Seaman, 2006). It is evident that higher education administrators have been both optimistic and aggressive in their views of the growth of online learning in the U.S. This view of the marketplace has been validated, and significant investments into this market for e-learning courses have followed consistently. For example, the second annual study, "Entering the Mainstream, The Quality and Extent of Online Education in the United States, 2003 and 2004," found that the overall growth in the number of online learners actually exceeded the optimistic projections of the previous year, increasing at a 22.9% rate, to reach 1.9 million online students for fall 2003 (Allen & Seaman, 2006).

The strength of this market in terms on new students, new courses, and new entrants continue unabated. In 2003, the yearly increase of about 360,000 new online learning students was matched by the results of the 2005 study, Growing by Degrees, Online Education in the United States, 2005, with more than 2.3 million students taking at least one online course during the 2004 fall term. Despite a lower percentage increase reported in 2005 of 18.2%, as there is an increasing larger base population, there are more and more students taking online courses and further there are increasingly more students taking online courses for the first time. This trend was further illustrated in the results the fourth annual Sloan Consortium study showing there has been no leveling in the growth rate and strength of this market. During the 2005 term higher education institutions taught nearly 3.2 million online students, an increase of about 850,000 students and a growth rate of 35%. 2005 marks both the largest increase in the number of online students and the largest percentage increase since these tracking surveys have begun. In 2005,

Table 1. Students taking at least one online course—Fall 2005 (Source: Allen & Seaman, 2006)

Undergraduate	2,621,713
First Professional	39,350
Graduate	443,827
Other for-credit	75,159
Total	3,180,050

the overall size of the higher education student population is sized at approximately 17 million with the number of students taking online courses at approximately 3 million or now representing nearly 17% of all higher education students (Allen & Seaman, 2006) (Table 1).

Using our current estimates of growth, the current 2007 market size is estimated between 4.5 to 5.0 million students enrolled in e-learning courses or 25% to 30% of the overall higher education market. The demand for this form of education is continuing steadily and strongly.

In meeting this strong and increasing demand for online education, it appears that the large universities have responded first and most strongly. The size of an institution has a clear impact on the average number of online students at institutions. The largest institutions (defined as institutions with enrollments of 15,000 or more), for example, are each teaching an average of more than 3,200 online students at the undergraduate level alone. This compares to about half that amount (1,500 online students) for the next smaller-sized institution type (those with overall enrollments between 7,500 and 14,999). It is estimated that currently the average number of online students enrolled is proportional to the size of the institution (Kariya, 2003). In 2005, for each institutional size type, the average number of students is around 20% of the lower range of each size type, except for the smallest of the institutions (those with less than 1,500 total students) which is below this level, while the largest institutions are slightly above this average. However it is estimated, the proportion of the student population that is taking at least one online course has begun to reach a level that institutions of all sizes must address this as an important educational issue (Table 2).

The Doctoral/Research and Master's institutions have the largest average online total enrollments since they are more likely on average to be the largest schools. Associates institutions offering 2 year only Associate Degree programs also have a sizable average online enrollment (nearly 800 undergraduate students per institution), but the large number of Associates institutions is what accounts for the large number of online students at such schools (Allen & Seaman, 2006) (Table 3).

Course offerings and institutional profiles. Evidence has shown in the past a very uneven distribution of online course and program offerings by type of institution. Public institutions and the largest institutions of all types have consistently been at the forefront of online offerings. Those that are the least likely to offer online courses, and typically have the most concern about online education in general, have been the small, private, 4-year institutions. It must be taken into account that not all schools offer online courses, and not all schools that have online courses offer fully online programs (Hickman, 2003). Examining the pattern of online offerings

Table 2. Mean undergraduate online enrollment by size of institution—Fall 2005 (Source: Allen & Seaman, 2006)

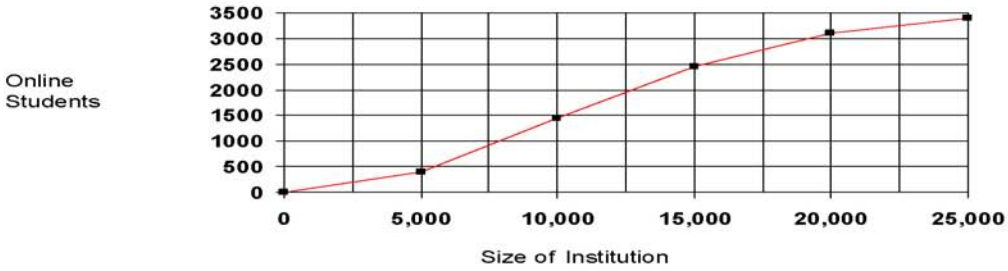

Table 3. Mean number of online students per institution—Fall 2005 (Source: Allen & Seaman, 2006)

	Doctoral/Research	Masters	Baccalaureate	Associates	Specialized
Undergraduate	1017.1	988.3	148.7	797.5	84.2
Professional	21.7	1.1	0.8	2.6	10.3
Graduate	520.6	365.5	14.1	0.3	47.1
Other for credit	16.9	9.7	0.6	23.3	1.8

does show some interesting patterns when the results are compared to the distribution of online students. For example, Doctoral/Research institutions, which enroll 13% of all online students, have the greatest penetration of offering online programs as well as the highest overall rate (more than 80%) of having some form of online offering (either courses or full programs). Although Associates schools have by far the largest contingent of online students, they trail both Doctoral/Research and Master institutions in the proportion with online programs or any type of online offering.

More than 96% of the very largest institutions have some online offerings, which is more than double the rate observed for the smallest institutions. The proportion of institutions with fully online programs rises steadily as institutional size increases, and about two-thirds of the very largest institutions have fully online programs, compared to only about one-sixth of the smallest institutions. Doctoral/Research institutions have the greatest penetration of offering online programs as well as the highest overall rate (more than 80%) of having some form of online offering. The proportion of institutions with fully online programs rises steadily as institutional size increases, and about two-thirds of the very largest institutions have fully online programs, compared to only about one-sixth of the smallest institutions. Additionally, Doctoral/Research institutions are far more likely to have online programs than are Baccalaureate institutions (Table 4).

Market competitive issues. With markets no longer defined by geography and as the quality and quantity of online courses increases, the trend toward electronic learning is perhaps entering a new era of growth and competition in higher education.

According to a 2004 report by Eduventures, while enrollment in fully online distance education programs is growing at 30% (Gallagher, 2004), the average tuition per student is approximately $5,500 and represents a total market of about $5 billion in tuition revenue for 2004. Our estimates suggest that the fully online distance education will represent a market of $17 billion by 2010. The overall revenue market size for fully online education is expected to grow approximately 38% in 2004. The estimated growth rates for the number of students enrolled in online education programs will remain above 20% for at least the next 3 to 5 years, slowing as the market matures further (Table 5).

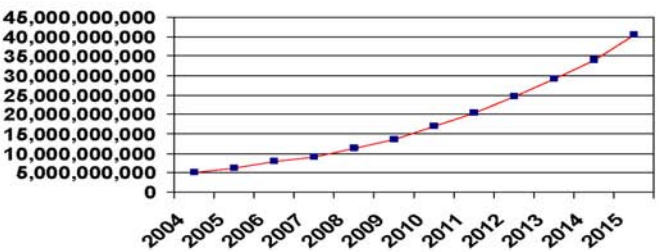
It is estimated that undergraduate student enrollment programs will drive approximately 73% of revenues in the online education market in 2004. The majority of students in online education programs are undergraduate students. However, the share of the online market regarding graduate level education is greater than its share of campus-based education, mostly due to the disproportionate number of working adults in graduate programs. It is expected that the undergraduate market will continue to grow, while the graduate-level programs will experience a surge in the coming years due to the current undergraduates continuing their education after obtaining their undergraduate degree.

For-profit institutions have taken a significant market share of the online education market, clearly disproportionate to their share of higher education overall market. For-profit institutions were early entrants and aggressive investors in this market and these factors coupled with their programs typically priced higher than nonprofit institutions, have permitted the for-profits a command of nearly 44% of the

Table 4. Online offerings—Fall 2005 (Source: Allen & Seaman, 2006)

	Doctoral/Research	Masters	Baccalaureate	Associates	Specialized	Total
Online Programs	55.7%	43.6%	17.2%	31.2%	26.0%	31.4%
Courses Only	24.9%	33.9%	24.0%	39.8%	22.7%	31.5%
No Online	19.4%	22.5%	58.8%	29.0%	51.3%	37.0%

Table 5. Fully online distance education enrollment (Source: Gallagher, 2004)



online market revenues in 2004, up from 30% in 2000. In fact, online education revenues in the for-profit section of the market have grown by more than 50% per year for several years and have grown at an estimated 25 to 30% per year through 2006. The for-profit sector represents significant and sustained competition in the online higher education market. As the overall higher education market moves to a more online offering, for-profit institutions will become a more significant player in the overall market.

FUTURE TRENDS

In reviewing the development of the last 20 years of the online higher education market, we see the growth of this market in three distinct phases. Each phase is characterized by a different competitive advantage. These are: Phase1. Technology Superiority; Phase 2. Breath of Content Offerings; and Phase 3. Brand equity.

1. Technology Superiority 1980-1997

The 1980s and early1990s represented the pioneering days of online distance education. With the emergence and availability of the World Wide Web, this set the stage for colleges and universities with a history of distance programs to then expand and tap into a broader market. During this phase, student enrollment grew exponentially as leading colleges launched and marketed new and innovative programs.

- University of Phoenix launches online division via Compuserve
- Institutions with histories of distance education and outreach development Web-based courses
- Early course management system software emerges

This phase of development is characterized by a competitive landscape where the leaders made significant investments in the technology platforms and software systems that allow for the production and distribution of online education courses. In this initial phase, those institutions that held the technology to develop these courses held a significant competitive advantage. The cost of technology was a significant barrier to entry, and those organizations that had access to capital and a taste for risk represented the early leaders. With this profile it is not surprising that the for-profit institution gained early and significant market share from the onset.

2. Building the Inventory of Course Offerings 1998-2003

The promise of online education as a market was enhanced by the Internet "Gold Rush" of the late 1990s. Private investors began to invest aggressively in for-profit universities and software providers in the higher education market with more than $1.2 billion in capital in 1999 and 2000 alone, the majority of which was devoted to e-learning. This capital provided not only marketing dollars and infrastructure to enable distance education to take off, but during this phase most importantly much of this capital was used to develop a strong and robust portfolio of course offerings. These course offerings were developed by for-profits both on their own and in partnership with other higher education institutions. Nonprofit educational institutions built this inventory of courses by offering incentives to their faculty for the production of courses, while developing training programs for faculty to learn this new form of distance education.

With technologies and a robust inventory of courses in place, these years also triggered the initial boom in consumer awareness of online education. Marketing and organizational development became the pivotal factor in defining competitive winners and losers in this phase. For example,

- University of Phoenix spins out an its online subsidiary in an initial public offering (IPO), the first of its kind in this area
- Nonprofit universities such as NYU, Columbia, and the University of Maryland University College create for-profit spin offs to tap Internet course opportunities and have the access to capital available in this sector
- In order to leverage their investments in technology and content, collective advertising and marketing expenditures for online education top $200 million at for-profit institutions
- The number of colleges offering online education programs balloons into the thousands
- U.S. News and World Report launches an annual e-learning section evaluating online education programs.

Course development still continues today. Online courses now can be made available, but the faculty training and incentives needed to develop these programs are significant, particularly for those institutions that have not embraced online programs. We estimate that this development of content is still a barrier of entry for institutions without substantial programs now in place and will represent increasingly substantial investments for these institutions to "catch up" and try to level the competitive landscape for themselves.

3. Market Development and Brand Equity 2004 and Forward

Colleges and universities at all levels have utilized online education to tap new markets of working adults for whom participation in traditional postsecondary education was inconvenient or impossible. Institutions recognizing the potential of online education have made important investments not only in infrastructure, but also in faculty training, student services, and marketing to participate in the growth of the online education market.

Recognizing the growth opportunity, institutions are investing more heavily than they have in the past. Effective marketing is becoming more targeted and segmented as distinct value propositions, areas of focus and brands emerge. Additionally, many of the students of the early boom years are graduating, creating a powerful new word of mouth and viral marketing channel. For instance,

- Majority of degree-granting institutions, particularly large institutions over 15,000 students (at 96% for this group), are offering online education programs
- Capella University was selected by Wal-Mart as a preferred education provider
- University of Phoenix Online enrollments approach 100,000, nearly 50% of all enrollment at the nation's largest private university
- Nonprofit institutions partner with for-profit education experts such as UNext, Capella and Collegis in order to launch best-of-breed online offerings.

Many of these trends in higher education will influence the future of distance learning. Student enrollments are growing and with this learner profiles are changing, and students are becoming more demanding in the quality, breath and convenience of offerings, and as a result are shopping for educational programs that can be easily tailored to their needs (Brodsky, 2003). The Internet and other information technology devices are becoming more ubiquitous while technological fluency is becoming a common expectation. As these expectations are common and as the technology is broadly available, we see the competitive landscape moving beyond technology and content, and residing much more around the reputations of the online programs themselves. Though innovation will always be a factor, as will the breath of content offering, the key emerging competitive differentiate is likely to be the perceived quality of the offering and the support services around those programs. Customers will expect, demand, and evaluate the value of these online offerings based upon their complete experience, including the market positioning, the program support, and administrative functions, as well as the technology and quality of the faculty and content (Bates, 2003).

CONCLUSION

Technological advances and increased fluency will continue to open opportunities for distance education. Although higher education institutions are changing to favor distance education, the complexities of major transformations will require substantial investment and planning. As Bates (2000) suggests, perhaps "the biggest challenge [in distance education] is the lack of vision and the failure to use technology strategically" (p. 7). Though this challenge is understandable, given the complexity of the issues involved, institutions which now wish to enter this market will find the barriers to be substantial. Universities without e-learning programs may easily find the distribution technologies that will launch their programs, but their challenges will be in building an inventory of courses, faculty competent in this new educational media, the creation of adequate administrative and support services, and most importantly the need to market and build brand equity in their new e-learning programs. Further, institutions currently active will strengthen their distance-learning strategic plans by identifying and understanding distance-education trends for new student enrollments, faculty support, and larger academic, technological and economic issues (Howell, Williams, & Lindsay, 2003). The gap will increase between the current players and new aspiring entrants, who will need to be willing to make significant financial investments with a clear development plan, if they hope to catch up.

KEY TERMS

Collaborative Learning Online: Technologies that link together people in several locations so that they can interact with one another.

Computer-Based Learning: Refers to the use of computers as a key component of the educational environment. Broadly refers to a structured environment in which computers are used for teaching purposes.

Distance Education: The process of extending learning, or delivering instructional resource-sharing opportunities, to locations away from a classroom, building or site, to another classroom, building or site by using video, audio, computer, multimedia communications, or some combination of these with other traditional delivery methods.

Distance Learning: Courses in home: education for students working at home, with little or no face-to-face contact with teachers and with material provided remotely, for example, by e-mail, television, or correspondence.

E-Learning: Learning using electronic means: the acquisition of knowledge and skill using electronic technologies such as computer- and Internet-based courseware and local and wide area networks.

Higher Education: Education provided by universities, vocational universities and other collegial institutions that award academic degrees.

Online Learning: Learning via educational material that is presented on a computer via an intranet or the Internet.

Web-Based Training: Also referred to as "online courses" or "Web-based instruction," a form of learning in which the training material is contained on Web pages on the Internet or an intranet.

Triangular Strategic Analysis for Hybrid E-Retailers

In Lee
Western Illinois University, USA

INTRODUCTION

For traditional retailers, the success of an e-channel lies largely in formulating and implementing a sound e-channel strategy that leverages their resource base. Numerous evidences show that poorly developed e-channels have added little value to retailers (Huang, 2003; Prencipe & McCarthy, 2002). Some of the poorly developed e-channels have had a negative impact on business performance due to an excessive investment, disappointing sales, and low margin (Nataraj & Lee, 2002). The poor performance arose from focusing on the Internet as a separate channel not affected by the activities in other existing channels (Kannan, 2001). For many traditional retailers, their costly and frequent e-channel reorganizations could have been avoided if they had adequately analyzed the strategic fit between their external environment and e-channel organization.

There has been no universally applicable business strategy for e-channels. For many retailers, the right mix of the traditional channels and e-channel is critical to their business success (Gulati & Garino, 2000). Despite the strategic value of the e-channel, there have been only a paucity of frameworks that help managers initiate and formulate the e-commerce strategy (Allen & Fjermestad, 2001; Lee, 2001). A number of strategic analysis models such as SWOT analysis, five forces model, resource-based view, and critical success factors have been applied to the e-commerce strategy development. These models attempted to formulate a business strategy from different perspectives of a business organization, but have not been fully integrated with each other. Formulating a business strategy based on the analysis and integration of multiple perspectives will result in a more competitive strategy than those of a single perspective.

Based on a number of e-channel case studies and strategic management theories, this short article presents (1) an overview of a triangular strategic analysis and (2) an example application of the triangular strategic analysis with an Office Depot case study. Data on the Office Depot's e-channel strategy and implementation were collected through secondary sources such as trade journals and Office Depot's official publications. The triangular strategic analysis consists of (1) competitive forces analysis, (2) resource base analysis, and (3) critical success factor analysis

BACKGROUND

To capture the ever-increasing B2C population, retailers have experimented with a variety of B2C business models (Gulati & Garino, 2000). Some of the widely used e-commerce models include auction models (e.g., eBay.com), reverse auction models (e.g., Priceline.com), portal models (e.g., Yahoo.com), stand-alone e-retailer models (e.g., Amazon.com), and hybrid e-retailer models (e.g., Walmart.com). While B2B e-commerce applications such as e-procurement systems and the Internet-based supply chain management have brought significant benefits to business organizations, many B2C business models have failed to generate sustainable long-term profits.

In the late 1990s, most stand-alone e-retailers of commodity type products suffered the hardest hits due to low margin, rising customer acquisition cost, and the lack of financial support of investors (Stockport, Kunnath, & Sedick, 2001). Numerous stand-alone e-retailers such as Garden.com, Boo.com, and Petopia.com were consolidated with traditional retailers or liquidated (Kujubu & Martin, 2001). These failures were attributed to the poor business plan, weak complementary resources in distribution network and customer services, lack of brand name recognition, and low entry barriers.

Evidence shows that a misdirected e-channel development leads to costly and frequent revisions of e-commerce strategies. Kmart and Wal-Mart experienced a costly revision of their e-channel strategies. Kmart initially created a spin-off entity, BlueLight.com, in December 1999 as a joint venture between Kmart and Softbank Venture Capital. After Kmart withdrew from a planned initial public offering (IPO) for BlueLight.com in 2000, it acquired all of the interests of BlueLight.com in 2001. Walmart.com is another example of the costly revision of an e-channel strategy. Walmart.com was established in January 2000 as an independent company operating as a joint venture between Wal-Mart and Accel Partners. In 2001, Wal-Mart acquired all the minority interest in Walmart.com in order to establish the tight integration between its e-channel and physical stores.

Since each organization is uniquely positioned in a market with a different set of competitive forces, critical success factors, and capabilities, no single e-channel strategy would be suitable for all organizations. The successful deployment

of an e-channel requires a thorough review and analysis of all major business activities, including business strategies, processes, functions, and vendor/customer relationships. For traditional retailers, poorly deployed e-channels without cross-channel coordination and integration mechanisms in place cannot create competitive advantages. These e-channels may also have a negative impact on other channels by losing customers who value a seamless cross-channel experience. The triangular strategic analysis will provides managers with a unified view of a business organization by combining and presenting multiple organizational perspectives.

TRIANGULAR STRATEGIC ANALYSIS FOR HYBRID E-RETAILERS

The purposes of strategic analysis are to examine the current and future business environments, to identify new business opportunities and threats, and to develop strategies to counter competition and achieve strategic goals. A number of strategic analysis models have been developed with the emphasis on different perspectives of a business strategy development. Table 1 summarizes major strategic theories/models, their purposes, advantages, and disadvantages. Based on the complementarities of these models, we utilize three analysis models in an e-channel development framework. The triangular strategic analysis consists of (1) competitive forces analysis, (2) resource base analysis; and (3) critical success factor analysis. While each of these strategic analysis methods was developed in isolation of the others, they contribute unique yet complementary perspectives on the development of the business strategy. The integration of three analyses implicitly subsumes the essence of the core competence analysis. The balanced scorecard model can be used in parallel with the triangular strategic analysis or in the subsequent planning stage, and later in evaluating the organizational performance.

Table 1. Summary of major strategic management theories/models

Major Theories/Models	Proponents	Characteristics
Five Forces Model of Industry Competition	Porter (1980)	His basic theory was that dynamics of five competitive forces determine the nature of competitiveness in an industry and influence the strategies available to firms in the industry. The competitive forces are: (1) threat of new entry into an industry; (2) intensity of rivalry among existing competitors; (3) pressure from substitute products; (4) bargaining power of buyers; and (5) bargaining power of suppliers.
Resource Based View (RBV)	Wernerfelt (1984)	RBV suggests that firms compete not just in terms of final products, but more fundamentally in terms of the underlying "resources" which make production and product diversification possible. From a resource-based view every firm has a unique set of resources that the firm can leverage to exploit opportunities and counter threats.
Core Competence	Prahalad and Hamel (1990)	Core competencies are the collective learning in the organization that gives the company a unique advantage over its competitors. Core competence can manifest itself in many ways. Core competence is communication, involvement, and a deep commitment to working across organizational boundaries. It is the skills of individuals who can blend their expertise with that of others in new and interesting ways.
Balanced Scorecard (BSC)	Kaplan and Norton (1996)	The Balanced Scorecard is a method for turning a company's vision and strategy into a coherent set of performance measures distributed among four perspectives: Financial, Customer, Internal Business Processes, and Learning and Growth. The framework provides a balance between short- and long-term objectives, financial and nonfinancial measures, and external and internal performance indicators.
Critical Success Factor (CSF) Analysis	Rockart (1979)	CSF analysis is a method developed to guide businesses in creating and measuring success. CSFs are key areas where satisfactory performance is required for the organization to achieve its goals. Rockart provided the following as an example of the CSFs: new product development, good distribution, and effective advertising - factors that remain relevant today for many firms.

Table 2. Impacts of e-commerce on competitive forces' threats and firm's opportunities from retailers' perspective

Competitive Forces	Threats	Opportunities
Suppliers	Disintermediation Sell-Side Forward Auction	E-Procurement Group Purchasing Reverse Auction Internet-based EDI
Traditional Competitors	E-Channel E-Services Intranet Extranet E-Procurement	E-Channel Strategic Alliances Third-Party E-Marketplaces
New Market Entrants	E-Commerce Strategic Alliances	E-Channel Strategic Alliances, Merger/Acquisition
Customers (Corporate)	E-Procurement Third-Party Order Aggregation Price Comparison	E-Channel One-to-One Marketing Internet-based EDI Extranet
Customers (Consumers)	Price Comparison Third-Party Order Aggregation	E-Channel Web Personalization E-Services User Profiling
Substitute Products/Services	Digitized Products/Services On-Demand Delivery Services Portals	E-Channel Digitized Products/Services On-Demand Delivery Services New Services

Competitive Forces Analysis

Porter's Five Forces Model (1980) has been widely used in analyzing competitive forces that would shift an organization's strategic position in the industry. The components of the model include: (1) the traditional competitors, (2) the bargaining power of the customers, (3) the bargaining power of the suppliers, (4) the potential threat of new entrants, and (5) the threat of substitute products/services. The competitive forces analysis presents a picture of where the company's current strategy stands against competitive forces and a road map of where it should go for the success in the competitive environment. The emergence of e-commerce has changed the ways all competitive forces perform businesses in the industry. E-commerce provides customers with opportunities to comparison-shop and thereby raises the bargaining power of customers. E-commerce also provides suppliers with opportunities to disintermediate retailers. Traditional competitors establish e-commerce Web sites to enter into the e-marketplaces.

The competitive forces analysis provides managers with vital information on the opportunities and threats arising in the e-commerce market. Table 2 summarizes the opportunities and threats introduced by the e-commerce from the retailers' perspective. While the competitive forces analysis is effective in understanding external environment, some researchers have pointed out its limitations (Luffman, Lea, Sanderson, & Kenny, 1996). The analysis has not explicitly addressed what the critical factors are and what resources are needed for a successful execution of a business strategy. The following resource base analysis utilizes the results obtained from the competitive forces analysis and determines what resources are needed and how they are used in the execution of an e-channel strategy.

Resource Base Analysis

Many researchers have indicated that the resource-based view of a firm is the most important theory of sustainable competitive advantage (Conner, 1991). The fundamental logic of the resource-based view is that the desirable outcome of a business strategy is a sustainable competitive advantage. Since not all resources are equal in creating sustainable competitive advantage, many researchers focused on identifying advantage-creating resources. Barney (1986, 1991) suggested that the advantage-creating resources must be firm-specific, rare, and difficult to imitate. The resource-based view of a firm was applied to understand how the superior IT resources of organizations render the cost and value of IT innovations different from competitors (Bharadwaj,

2002). In a changing environment, firms must continuously invent and upgrade their resources and capabilities if they are to maintain a competitive advantage and growth. The sequential development of resources and capabilities can make a firm's advantage inimitable (Barney, 1991; Lado, Boyd, & Hanlon, 1997).

Each retailer has a different set of firm-specific resources to utilize, and an addition of an e-channel can be viewed as a unique resource utilization and development process in achieving sustainable growth. The mapping between the competitive forces and the resource base provides answers to two important questions: (1) what kinds of existing resources a retail organization can leverage and (2) what resources it needs to differentiate itself from the competitors. While strong resources are leveraged to survive, weak or non-existent resources need to be critically examined for the future resource development and sustainable competitive advantage. Traditional retailers' resources include physical stores, distribution centers, patent, trademark, brand, reputation, enterprise-wide database, integrated

Table 3. E-commerce analysis matrix of competitive forces and resource base: Office Depot's case

Competitive Forces	Suppliers		Traditional Competitors		New Market Entrants		Customers		Substitute Products/ Services	
Resource Base	Threats	Opportunities	Threats	Opportunities	Threats	Opportunities	Threats	Opportunities	Threats	Opportunities
Physical Stores							●			
Distribution Centers							●			
Database				●				●		
Integrated Information Systems	●							●		
Skills and Knowledge of Employees			●					●	●	
Organizational Culture and Trust								●		

Table 4. E-commerce analysis matrix of critical success factors and resource base: Office Depot's case

Competitive Forces	Suppliers		Traditional Competitors		New Market Entrants		Customers		Substitute Products/ Services	
Resource Base	Threats	Opportunities	Threats	Opportunities	Threats	Opportunities	Threats	Opportunities	Threats	Opportunities
Physical Stores							●			
Distribution Centers							●			
Database				●				●		
Integrated Information Systems	●							●		
Skills and Knowledge of Employees			●					●	●	
Organizational Culture and Trust								●		

information systems, skills and knowledge of employees, and organizational culture and trust. Some of these resources are more difficult to imitate and more valuable as a source of competitive advantage than others. In general, intangible resources would be more difficult to transfer and imitate than tangible resources.

Table 3 shows the e-commerce strategy matrix of the competitive forces and the resource bases of Office Depot. The rows list two types of resources: strong resources (sustaining resources) and weak/non-existent resources (developmental resources). Certain weights can be assigned to the competitive forces based on their importance to prioritize the resource allocation and development activities. The analysis of Office Depot suggests that the existing integrated information systems can be leveraged to counter the threat of the suppliers' e-commerce and to benefit from the growth of the customers' online purchases.

The matrix needs filling of e-commerce strategies and projects in relation to resources, threats and opportunities. Threats posed by new market entrants may force a retailer to choose the e-channel introduction as a strategic option. If a retailer has a strong resource base in support of an e-channel, then an immediate introduction of an e-channel may be feasible with little developmental resources. Overall, the e-commerce strategy matrix of the competitive forces and the resource base provides a conceptually grounded framework for assessing sustainable and developmental resources, and enables these resources to be examined in terms of the opportunities and threats for establishing sustainable competitive advantages.

Critical Success Factors Analysis

Once the previous analyses lead to an e-commerce strategy, critical success factors (CSFs) analysis decides what the most important determinants are in achieving strategic goals (Rockart, 1979). The successful execution of CSFs requires resources. Identifying a match between the firm's resources and the critical success factors in the industry is a demanding task, and the success of the match is a function of the accuracy of managerial expectations about the value of the strategy (Barney, 1986).

The e-commerce success factors for retailers include efficient business process, integrated distribution systems, multi-channel coordination and integration, customers' trust, strong brand recognition, superior customer service operations, financial stability, effective online technologies, and strategic alliances. Table 4 shows a matrix that develops matches between the Office Depot's resources and the critical success factors. For example, the business process redesign requires the integrated information systems, skills and knowledge of employees, and organizational culture and trust as critical resource bases.

The matrix helps managers determine what existing resources can be leveraged or what new resources are needed to achieve the CSFs and ultimately the business strategies. To successfully achieve e-channel strategic goals and sustain competitive advantages, retailers need to monitor the performance of these CSFs with a measurable objectives and metrics. Once CSFs and metrics are defined, a detailed e-channel plan should be developed to achieve these critical success factors and business strategies.

FUTURE TRENDS AND CONCLUSION

The rapid penetration of the World Wide Web and the explosion of e-commerce startups have changed the dynamics of the competitive forces across all industries. Due to the explosion in e-commerce competition, the e-channel has become a critical factor in the strategy development by the hybrid e-retailers. While managing the e-channel is one of the most important tasks for marketing managers, many managers are still unclear about e-channel strategies and lack core e-channel knowledge needed to analyze business environments, to develop strategies, and to evaluate alternative e-channel solutions. Empirical evidence shows that experimenting with different types of e-channels is very costly. Some retailers such as Kmart, Wal-Mart, CVS, and Staples experimented with spin-offs. These retailers later struggled to retrofit the spin-offs into their parent companies.

A number of strategic analysis models such as SWOT analysis, five forces model, resource-based view, and critical success factors have been applied to e-commerce strategy development. However, there has been little effort to integrate these models for e-channel strategy development. These models attempted to formulate a business strategy from different perspectives of a business organization, but have not been fully integrated with each other. The analysis and integration of multiple dimensions will result in a more comprehensive strategy than those of a single dimension. To develop a comprehensive e-channel strategy, the triangular strategic analysis attempted to integrate three well-known analysis models: competitive forces analysis, resource base analysis, and critical success factor analysis.

The triangular strategic analysis provides managers with a unified view of a business organization by combining and presenting multiple perspectives of an organization. The unified view will enhance managers' ability to effectively identify their present strategic position, internal resources, and critical success factors, and decide upon the most appropriate e-channel strategy. As important, the unified view will allow managers to utilize the emerging opportunities of e-commerce and to prevent threats that would be posed by carelessly developed e-channel strategies.

The triangular strategic analysis was applied to analyze Office Depot's e-channel development strategy. The evalua-

tion of Office Depot's e-channel development strategy suggests a number of its success factors that may be useful for other retailers' e-channel development: (1) Office Depot was an early adopter of an e-commerce technology, and continued to explore different e-commerce business models over time; (2) its e-channel was not only another distribution channel but also a service channel; (3) it also leveraged its own e-channel expertise and resources in office supplies in expanding to other markets; and (4) it treated an e-channel not as an independent entity but as an internal business unit in an integrated business organization; (5) its senior management supported an e-commerce project from a strategic point of view; and (6) it pursued a resource-based e-channel IT development.

KEY TERMS

Channel Conflict: Situation in which an e-channel creates a conflict with existing channels because of real or perceived damage from inter-channel competition.

Complementarities: Products or services that provide more value together than individually. For example, hybrid e-retailers can leverage complementarities by providing offline services to online shoppers.

E-Channel: An online marketing channel where companies and customers conduct business, no matter where they are. Since the e-commerce revolution, many brick-and-mortar businesses have expanded their marketing channel to include e-channel.

Hybrid E-Retailer: A click and mortar company which conducts retailing through e-channel as well as physical stores and other distribution channels. Compared to its pure e-commerce competitors, a hybrid e-retailer can leverage existing physical stores, brand recognition, distribution network, existing customer base, and so forth.

On-Demand Delivery Services: Express delivery of products made with highly efficient transportation systems after an online order is received.

Order Aggregation: A group purchase designed to achieve a volume discount by aggregating orders placed by individual buyers.

Reverse Auction: A fixed-duration auction hosted by a single buyer in which multiple sellers compete for business.

Sell-Side Forward Auction: An auction where a seller announces the items for quick sale and buyers bid on them.

Triune Continuum Paradigm

Andrey Naumenko
Triune Continuum Enterprise, Switzerland

INTRODUCTION

This article reviews the Triune Continuum Paradigm—a logically rigorous theoretical base for organization of conceptual frameworks that are used for system modeling in different contexts (e.g., in software development, in enterprise architecture, in the architecture of financial services, in jurisprudence, etc.). This paradigm is an important contribution to the system modeling domain, because currently none of the prevailing system modeling frameworks has a satisfactory formal theoretical foundation.

The absence of a theoretical foundation for modeling frameworks leads to the practical application experiences where modelers are constrained to be guided by chance and not by a founded reason. This often leads to the inadequate choices of modeling frameworks, that is, to the situations where a chosen modeling framework is not designed to deal with the targeted modeling problems. Possible consequences of such choices include incorrect (e.g., inadequate with regard to the requirements) information systems specifications, contradictory data architectures, incomplete service specifications, and so forth—all of these being the decisive contributions to failures of many projects. The paradigm, which we review in this article, fixes this problem providing missing theoretical foundations for frameworks positioned in the domain of general system modeling.

Many of the existing system modeling frameworks appeared as an integration of the best modeling practices. The reviewed paradigm does not repudiate the practical experience that was gathered by these different frameworks, but fixes its inconsistencies and complements it supporting with logically rigorous theoretical foundations. Therefore the paradigm brings a significant constructive potential to the evolution of modern system modeling frameworks. This potential could be realized if people responsible for the design of modeling frameworks and tools would heed the proposed paradigm.

BACKGROUND

The Cambridge Dictionary of Philosophy (Audi, 1999, p. 641) provides the following definition of the term "paradigm": "Paradigm, as used by Thomas Kuhn (The Structure of Scientific Revolutions, 1962), a set of scientific and metaphysical beliefs that make up a theoretical framework within which scientific theories can be tested, evaluated and if necessary revised."

In practice, a paradigm is usually defined for a collection of sciences. In this context a paradigm introduces and justifies a set of basic assumptions and principles on which any of sciences from the collection can rely as on their foundations. Then, starting from the principles provided by a paradigm, different sciences build their specific frameworks of knowledge. And if some sciences share the same paradigm, then they can bind and synchronize their specific frameworks of knowledge. By doing so they can mutually enrich each other with the knowledge obtained from the different (but consistent with regard to the basic principles) points of view.

The Triune Continuum Paradigm (Naumenko, 2002) is a paradigm for general system modeling. Thus the Triune Continuum Paradigm serves the sciences that have diverse interests in system modeling. As any paradigm, it introduces and justifies a set of principles that provide the sciences with the necessary starting points for building their diverse conceptual frameworks of scientific knowledge, in our case the principles that are necessary for building modeling frameworks.

THREE PRINCIPLES OF THE TRIUNE CONTINUUM PARADIGM

The Triune Continuum Paradigm is composed of three principles.

The first principle is the result of application of Tarski's Theory of Truth (Tarski, 1956) for the case of general system modeling. This application allows defining coherent semantics for the concepts of a modeling framework. This is done by constructing formal descriptions for the relations between the subjects that are interesting to be modeled on one side, and the concepts that have to represent these subjects in the models on the other side. This principle is necessary to assure the *coherency* and *unambiguity* within modeling interpretations performed using a single system modeling framework.

An application of the first principle provided by the Triune Continuum Paradigm results in a system modeling framework that features modeling terms with a coherently defined semantics in the form of Tarski's declarative semantics. The justifications of importance of this principle for the information systems modeling were presented and analyzed

in details (Naumenko, Wegmann, & Atkinson, 2003). In particular, it was demonstrated that Tarski's declarative semantics are:

- formally *sufficient* for the definition of the application scope of a modeling language;
- formally *sufficient* for unambiguity in coherency of interpretations within modeling representations; and
- formally *necessary and sufficient* for unambiguity in adequateness of modeling representations.

The second principle of the Triune Continuum Paradigm is the result of application of Russell's theory of types (Russell, 1908) for the case of general system modeling. This application defines the way to categorize concepts of a modeling framework so that in applications of this framework the concepts make up *internally consistent* structures of propositions. Thus this principle is necessary to assure the consistency of descriptions and specifications, which are constructed with the aid of the modeling frameworks.

The importance of this principle is justified by the fact that Russell's theory of types was formulated to resolve Russell's paradox, "the most famous of the logical or set-theoretical paradoxes" (Irvine, 2003). Thus with an application of the second principle of the Triune Continuum Paradigm, the resulting modeling framework in its own applications will produce internally consistent system specifications (i.e., system specifications that are devoid of self-contradictions).

The name of Triune Continuum Paradigm originates from the third theory that was employed for the paradigm definition, from the Theory of Triune Continuum. This theory was defined by Naumenko (2002). This theory allows for the introduction of the abstract ontologies that are formally *necessary and sufficient* to cover the modeling scope of different modeling contexts on the most abstract level.

In particular, the Theory of Triune Continuum was applied in the context of general system modeling (Naumenko, 2002), and this application contributed to the definition of the Triune Continuum Paradigm. The application is the third paradigm principle that allowed introducing and justifying a minimal set of modeling concepts that are necessary and sufficient to cover the representation scope of the general system modeling domain on the most abstract level. This principle is necessary for different system modeling frameworks to justify the existence of their basic modeling concepts.

The Theory of Triune Continuum introduces three continuums that represent in models the scope of general system modeling. The first two continuums are:

- **Spatiotemporal Continuum:** Where subjective space-time metrics are defined to be used in the subjective representations.
- **Constitution Continuum:** Where subjective constitutional metrics are defined to be used in the subjective representations, for example, objects defined in relation with their environments.

These two continuums are introduced in relation with each other as complements within the universal general system modeling scope. In other words, everything in the scope that is not space-time is constitution; and everything in the scope that is not constitution is space-time.

The third continuum is:

- **Information Continuum:** Which emerges from the mutual relations of the first two continuums and contains the corresponding information about these relations, for example, information about objects and their environments being related to the spatiotemporal intervals or to the points in space-time).

Thus the three continuums are *triune*: none of them exist without the others; either the three exist altogether, or they do not exist at all. Indeed, as soon as the first (spatiotemporal) continuum is introduced, everything in the universal scope that does not belong to the first continuum immediately shapes the second (constitution) continuum; and the third (information) continuum immediately emerges as the information about the mutual relations of the first two continuums (e.g., as spatiotemporal information about the constitution).

The third principle of Triune Continuum Paradigm is important for various system modeling frameworks, which are used in diversified domains of human activity (e.g., the frameworks used to analyze, design, and develop coherent structures providing useful functionalities in domains spread from jurisprudence and health care to software engineering and machine-building industries). Using the notion of Triune Continuum it is possible to introduce and justify minimal sets of modeling concepts that are necessary and sufficient for those diversified frameworks to cover their respective representation scopes.

APPLICATIONS OF THE TRIUNE CONTINUUM PARADIGM

The Triune Continuum Paradigm can be applied in practice either to improve an existing system modeling framework or to design a new system modeling framework for a given purpose. Let us mention here three of the existing applications of the paradigm:

- case of the Unified Modeling Language (UML);
- case of the reference model of open distributed processing (RM-ODP); and
- case of the systemic enterprise architecture methodology (SEAM).

The first two of the three cases illustrate the paradigm applications targeting improvements of the existing system modeling frameworks. The third case illustrates the paradigm application contributing to the design of a new system modeling framework.

Case 1: Triune Continuum Paradigm Application for UML

"The Unified Modeling Language (UML) is a language for specifying, visualizing, constructing, and documenting the artifacts of software systems, as well as for business modeling and other non-software systems" (OMG, 2003, section 1.1). UML is a proposition of the Object Management Group (OMG) that emerged from the integration of different industrial practical experiences and became an influential phenomenon in the system modeling. As a matter of fact, due to the multiple efforts of different interested parties, UML has gained a relative domination over the other modeling techniques in the current industrial practices. This is why it was interesting to apply the Triune Continuum Paradigm for the case of UML conceptual framework. Results of this application were presented to the UML research community (Naumenko & Wegmann, 2002). With the aid of the Triune Continuum Paradigm it was shown that the metamodel of UML features a number of undesirable properties, in particular:

- absence of an explicit structural organization defined for the UML metamodel;
- absence of Tarski's declarative semantics in the UML metamodel; and
- absence of theoretical justifications for the UML metamodel to represent the modeling scope that is targeted by UML.

The paradigm-based solutions were presented for each of the three identified problems (Naumenko & Wegmann, 2002) providing designers of UML with the benefits of the paradigm's logical rigor, of its formal presentation, and of its solid theoretical foundations.

Case 2: Triune Continuum Paradigm Application for RM-ODP

The RM-ODP is an ISO and ITU standard for system modeling, designed to model ODP-systems (ISO & ITU, 1998). The result of Triune Continuum Paradigm application for the RM-ODP case is especially interesting because it allowed accomplishing a single consistent formalization of the RM-ODP conceptual framework, providing the denotational semantics for the basic modeling and specification concepts of RM-ODP. Such formalization was officially declared as a goal of the ISO and ITU activities in the scope of RM-ODP standardization (ISO & ITU, 1998). But this goal was not achieved by the standard; and so far the paradigm-based formalization remains the only solution achieving the defined objective.

The formalization was expressed in a computer interpretable form using Alloy formal description technique (Jackson, 2002). Alloy was chosen because of the public availability of the corresponding software tool, "Alloy Constraint Analyzer," that allows simulating the instances of conceptual structures formalized with Alloy and representing these instances in a graphical form. However, due to the nature of denotational semantics (Naumenko et al., 2003), any choice of the formal description technique does not change semantic interrelations within the formalization. So, another formal description technique could also be used to express the paradigm-based formalization of the RM-ODP conceptual framework in a computer interpretable form.

The paradigm-based formalization of RM-ODP presents a concrete example of formal ontology for general system modeling. Thanks to the Triune Continuum Paradigm, the metamodel that is realized by the formal ontology is internally consistent, introduces logical coherency of interpretation of a subject of modeling, defines formal semantics for the modeling concepts, and its models are verifiable with the aid of computer tools. These results were presented to the RM-ODP research community (Naumenko & Wegmann, 2001, 2005; Naumenko, Wegmann, Genilloud, & Frank, 2001), and they attracted interest of the ISO/ITU committee that is responsible for the RM-ODP standardization. This provides the Triune Continuum Paradigm with a chance to influence future evolution of the ISO/ITU standard.

Case 3: Triune Continuum Paradigm Application for SEAM

The systemic enterprise architecture methodology (SEAM) is a methodology proposed by LAMS-EPFL (Wegmann, 2003) for system modeling in the domain of enterprise architecture, which is the domain that considers integration of IT systems and business systems in the context of an enterprise.

Applying the Triune Continuum Paradigm, a logically rigorous framework of concepts covering the representation scope of SEAM was designed and implemented as a specialization of the RM-ODP standard conceptual framework (ISO & ITU, 1998). Thus in this case the paradigm application provided a formal ontology for SEAM. The corresponding research results were reported to the Enterprise Architecture community (Wegmann & Naumenko, 2001) and provided the necessary basis for ongoing evolution of SEAM.

FUTURE TRENDS

The Triune Continuum Paradigm provides a set of theoretical foundations for different frameworks of knowledge belonging to the general system modeling domain. In most of the cases currently existing industrial and academic frameworks for system modeling do not feature such theoretical foundations, because these frameworks are developed using the so-called "best practices" approach (when results of different practical experiences of system modeling within a given domain are integrated to build a modeling framework for the domain). And if the "best practices" approach is not accompanied by theoretical foundations, then it is impossible to justify a number of important properties for the resulting system modeling frameworks (e.g., to guarantee the necessity and sufficiency of a framework for its domain representation, to assure internal consistency within different pieces of practical experience integrated in a single framework, etc.).

So, the Triune Continuum Paradigm provides an indispensable contribution to the general system modeling. And the future trends should assure practical realization of the significant constructive potential that the paradigm features for those numerous system modeling frameworks that currently do not have satisfactory theoretical foundations. This potential will be realized through the paradigm applications to these concrete system modeling frameworks. Some of the examples of such applications were presented in this article.

CONCLUSION

The Triune Continuum Paradigm provides system modelers (in particular, IS modelers) with a set of principles that are essential to build adequate system modeling frameworks. These principles are based on the solid theoretical foundations discovered in the last century: Tarski's Theory of Truth was presented in 1935, while Russell's Theory of Types was formulated in 1908. The authors of these two theories, Alfred Tarski and Bertrand Russell, are recognized to be among the greatest logicians throughout the history of humankind. Thus the Triune Continuum Paradigm, through its applications used in the computer-aided environment, promotes the use of fundamental logical theories to the practices of regular modelers, information system designers, and architects. The paradigm-based theoretically founded approaches to the information systems development make a constructive difference in the IS development projects where the usual "best practices methodologies" do not perform well enough due to a number of reasons (e.g., lack of flexibility, lack of representation possibilities, lack of internal consistency, etc.).

KEY TERMS

Reference Model of Open Distributed Processing (RM-ODP): An ISO and ITU standard for system modeling designed to model open distributed systems.

Russell's Theory of Types: A theory proposed by British logician Bertrand Russell to resolve Russell's paradox, which appears when the set of all sets that are not members of themselves is considered in naive set theory. The paradox is that such a set appears to be a member of itself if and only if it is not a member of itself.

Systemic Enterprise Architecture Methodology (SEAM): A methodology proposed by LAMS-EPFL for system modeling in the domain of enterprise architecture (the domain that considers integration of IT systems and business systems in the context of an enterprise).

Tarski's Theory of Truth: A theory proposed by Polish logician Alfred Tarski. The theory defines the criteria for a formal definition of a true sentence; the theory allows deriving the notion of Tarski's declarative semantics for a modeling language where the modeling language terms are put in the unambiguous correspondence with the subjects of modeling interest that they represent in applications of the language.

Theory of Triune Continuum: A modeling theory proposed by Andrey Naumenko. The theory introduces three continuums (spatiotemporal, constitution, and information continuums) to justify a minimal set of modeling concepts that are formally necessary and sufficient to cover the representation scope of different modeling contexts on the most abstract level.

Triune Continuum Paradigm: A paradigm for general system modeling. The paradigm introduces and justifies a set of principles that provide designers and architects of system modeling methodologies with the necessary theoretical support for building their modeling frameworks. The principles are derived from the Tarski's Theory of Truth, from the Russell's theory of types, and from the Theory of Triune Continuum.

Unified Modeling Language (UML): Proposed by the Object Management Group (OMG) for system modeling in the domains of software systems, of business systems, and others.

Trust in B2C E-Commerce Interface

Ye Diana Wang
University of Maryland, Baltimore County, USA

THE NATURE OF TRUST

Electronic commerce (e-commerce) is changing the way people make business transactions, especially in the business-to-consumer (B2C) area, and it is becoming a significant global economic force. Since Internet technologies and infrastructures to support e-commerce are now in place, attention is turning to psychological factors that affect e-commerce acceptance by online users and their perceptions of online transactions. One such factor is trust, seen to be key to the proliferation of e-commerce.

Trust has existed as long as the history of humans and human social interactions, and it has been studied long before the emergence of the Internet or e-commerce. With respect to consumer behavior, studies have mainly focused on trust and trust relationships in the off-line world and have emerged from numerous disciplinary fields since the 1950s (Corritore, Kracher, & Wiedenbeck, 2001). These disciplines, including philosophy, sociology, psychology, management, marketing, ergonomics, human-computer interaction (HCI), and industrial psychology (Corritore, Kracher, & Wiedenbeck, 2003), have together contributed an extensive body of literature on trust in general, and therefore, they are important grounding points for the examination of trust in the online world. However, "trust is an extraordinarily rich concept, covering a variety of relationships, conjoining a variety of objects," as Nissenbaum (2001, p. 104) has pointed out. Due to the complex and abstract nature of trust, each discipline has its own understanding of the concept and different ways to conceptualize it according to the features of a particular context.

Even with the diverse trust research, researchers from every discipline do acknowledge the value of trust and generally observe and accept four characteristics of trust. First, there must exist two specific parties in any trusting relationship: a trusting party (trustor) and a party to be trusted (trustee). The two parties, comprised of persons, organizations, and/or products, constantly evaluate each other's behaviors. Second, trust involves vulnerability. Trust is only needed, and actually flourishes, in an environment that is uncertain and risky. Third, trust decreases complexity in a complex world and leads people to take actions, mostly risk-taking behaviors. "Without trust people would be confronted with the incomprehensible complexity of considering every possible eventuality before deciding what to do" (Grabner-Krauter & Kaluscha, 2003, p. 787). And fourth, trust is a subjective matter. It is directly related to and affected by individual differences and situational factors.

The previously mentioned characteristics of trust make it especially needed in e-commerce because people perceive economic transactions in a virtual environment as posing a higher degree of uncertainty than in traditional settings. Most e-commerce transactions are not only separated in time and space, but are also conducted via limited communication channels and impersonal interfaces, making trust a crucial facilitator for people to overcome fear, risks, and complexity. Therefore, online consumers need trust as a mental shortcut to reduce the complexity of conducting business transactions with online vendors (Luhmann, 1989). Such trust occurring in cyberspace is commonly termed "online trust," and we limit the scope to the online trust that is pertinent to B2C e-commerce, namely, the trust that occurs for an individual Internet user toward a specific e-commerce Web site or the online vendor that the Web site represents. Derived from the general definition for trust (Rousseau, Sitkin, Burt, & Camerer, 1998), online trust can be defined as follows: *an Internet user's psychological state of risk acceptance based upon the positive expectations of the intentions or behaviors of an online vendor*.

There are almost certainly many potential sources of influence that promote or hinder online trust. However, the current article focuses on the HCI or interface design perspective in inducing online trust, that is, to use what consumers can see on an e-commerce interface to affect their feelings of trust toward the online merchant that the e-commerce interface represents.

ONLINE TRUST IN THE HCI LITERATURE

Online trust is a relatively new research topic and has recently drawn great interest from researchers in HCI and human factors. There are several main themes that the majority of the existing studies can be divided into. First, some studies attempt to understand the online consumer's mind by investigating the underlying elements, antecedents, or determinants that are pertinent to the formation of online trust. For example, Gefen (2002) examined trust from a multi-dimensional perspective. According to the researcher, the specific beliefs of integrity, ability, and benevolence were seen as antecedents to overall trust. Other research-

ers, such as Corritore et al. (2003), also proposed that the consumer could perceive trust before, during, or after the online transaction, and they further concluded that online trust was characterized by its stage of development.

The second stream of studies focuses on conceptualizing trust into theoretical models or frameworks and dividing trust elements into various dimensions. For example, the Model of Trust for Electronic Commerce (MoTEC), is proposed by Egger (2001). The model consists of four components: the pre-interactional filters taking place before any online interaction, the interface properties of the Web site, the information content of the Web site, and relationship management. The Cheskin/Sapient Report (1999) focused on Web site interface cues and presented a model of six building blocks of online trust. These six building blocks were seals of approval, brand, navigation, fulfillment, presentation, and technology. The building blocks could be further divided into a total of 28 components to establish perceived trustworthiness. Such studies provide a theoretical account for exploring and enhancing trust in an online context and often take the effects of customer relationship management into consideration.

The third stream of studies aims to validate those conceptual frameworks or trust scales, often by analyzing data acquired directly from the consumers (e.g., Ba & Pavlov, 2002; Bhattacherjee, 2002). The main objective of these studies is to theoretically derive and empirically validate a scale that can be used to measure either individual online trust or the trustworthiness of an e-commerce Web site. In developing such an instrument, as for developing any other kind of scale, the researchers need to stress establishing its reliability, content validity, and construct validity. Factor analysis, structural equation modeling, and multiple linear regression analysis are some of the most commonly used statistical analysis methods in those efforts.

And finally, the rest of the studies suggest Web design guidelines that are intended to enhance consumer online experience and induce the feeling of trust from the consumers (Karvonen & Parkkinen, 2001; Kim & Moon, 1998; Neilsen, 2000). In other words, the main goal for the researchers of these studies is to explore Web interface design implications to maximize consumer trust or, more precisely, trust perception. A representative study of this kind is the Nielsen Norman Group Report (2000), in which explicit trust-inducing guidelines — including graphic design, surface cue, and Web usability features — are provided based on a large number of user testing observations carried out by experts.

These preceding studies provide important insights into trust in an online context. However, the research field of online trust is still far from maturity and expected to be significantly substantiated and enhanced. For example, the terms *element*, *antecedent*, *dimension*, *determinant*, and *principle* are sometimes used interchangeably due to the lack of agreement on a clear definition for each term among researchers in the field. Nevertheless, this is the current body of work from which any potential implementation is to be derived.

BUILD ONLINE TRUST BY WEB DESIGN

To initiate and build a consumer's online trust is inevitably a challenging task. Due to the nature of the Internet, people nowadays browse different e-commerce Web sites as fast as they switch TV channels. Consequently, to succeed in e-commerce, online vendors must be able to convey their trustworthiness to first-time visitors and effectively and efficiently build trust in the eyes of consumers. This requires online vendors to implement optimal electronic storefronts that can attract potential consumers and induce their trust. According to Ang & Lee (2000), "if the web site does not lead the consumer to believe that the merchant is trustworthy, no purchase decision will result" (p. 3). In other words, applying trust-inducing features to the Web sites of online vendors is the most effective method of enhancing online trust, given the current state of knowledge.

Efforts have been taken to establish a framework that classifies various trust-inducing Web design features into three broad dimensions: visual design, content design, and social-cue design (Wang & Emurian, in press). The framework is not exhaustive in the sense that it does not attempt to capture every possible trust-inducing feature that web designers can apply. It is focused on articulating the most prominent set of trust-inducing features and presenting them as an integrated entity that can be empirically evaluated and appropriately implemented in Web design. *Table 1* illustrates the framework in detail, including the explanations and design feature examples.

All the trust-inducing interface design factors that are identified in the framework have been illustrated on a synthetic e-commerce interface and evaluated by 181 survey respondents (Wang & Emurian, 2004). Along with identifying the three dimensions, the factors were found to significantly contribute to online trust ratings. This has confirmed what most HCI researchers believe — as Kim & Moon (1998) pointed out — that informative emotions such as trust can be triggered by the customer interfaces and further aid decision making while using e-commerce systems. It may also be concluded that the three dimensions of the framework can act together to promote online trust and reflect the different aspects of Web interface design.

The first two dimensions, which are visual design and content design, are seemingly straightforward, and they have been traditionally the focus of the research that aims to promote online trust by Web design. The last dimension, the social-cue design dimension, is a relatively new design strategy being suggested by numerous researchers (Riegels-

Table 1. Framework of trust-inducing features

Dimensions	Explanations	Design Feature Examples
Visual Design	Defines the graphical design aspect and the structural organization of displayed information on the Web site.	• Use of three-dimensional and half-screen size clipart • Symmetric use of moderate pastel color of low brightness and cool tone • Use of well-chosen, good-shot photographs • Implementation of easy-to-use navigation (simplicity, consistency) • Use of accessible information (e.g., no broken links and missing pictures) • Use of navigation reinforcement (e.g., guides, tutorials, instructions, etc.) • Application of page design techniques (e.g., white space and margin, strict grouping, visual density, etc.)
Content Design	Refers to the informational components that can be included on the Web site, be they textual, graphical, etc.	• Display of brand-promoting information (e.g., prominent company logo or slogan, main selling point) • Up-front disclosure of all aspects of the customer relationship (company competence, security, privacy, financial, and legal concerns) • Display of seals of approval or third-party certificates • Use of comprehensive, correct, and current product information • Use of a relevant domain name
Social-Cue Design	Relates to embedding social and interpersonal cues, such as social presence and face-to-face interaction, into the Web interface via different communication media.	• Inclusion of a representative photograph or video clip • Use of synchronous communication media (e.g., instant messaging, chat lines, video telephony, etc.)

berger, Sasse, & McCarthy, 2003; Steinbruck, Schaumburg, Duda, & Kruger, 2002; Wang, in review). This approach is aimed to remedy the prominent problem of e-commerce known as "lack of human touch" that eliminates online shopping for a considerable number of people.

At least two reasons, or disadvantageous characteristics of e-commerce, contribute to such a problem. First, e-commerce transactions are mostly separated in space and time. Second, a Web site is the only primary and direct "contact point" that online vendors can rely on to interact and communicate with their customers. While the face-to-face interaction can help to establish and stabilize consumer trust in off-line situations, the business transaction in e-commerce is deficient in the personal communication dimension. Therefore, there is need to bring e-commerce interactions closer to off-line shopping experiences by implementing social and interpersonal cues that moderate the disadvantages of an impersonal e-commerce interface and induce online trust. It is such an initiative that compels the social-cue design dimension of the framework.

The social and interpersonal cues, being investigated and embedded into e-commerce Web sites, refer to voice, gestures, appearance, and other communication cues that have been found to have a strong impact on triggering people's trust in face-to-face encounters. Using richer communication media has been seen as a valid means for facilitating the conveyance of these interpersonal cues and providing more opportunities for personal contacts between consumers and online vendors. With the advancement of technology and the increase of bandwidth, a huge collection of communication media is presently available. However, to choose suitable communication media for adding social or interpersonal cues in e-commerce Web sites, designers need to be aware of the different features of each medium, such as channel availability, synchrony, and channel symmetry (Greenspan, Goldberg, Wimer, & Basso, 2000). When implementing social cues, special care should also be taken, as advised by Riegelsberger et al. (2003), to prevent online shoppers from being disappointed by elements lacking functionality other than giving cues of social interaction.

The existing research on interpersonal cues and online trust still remains preliminary. Most research only focuses on examining the trust-inducing capacity of photography, which is the simplest form of communication media to be employed in e-commerce, and the outcomes are found to be somehow contradictory (e.g., Riegelsberger et al., 2003; Steinbruck et al., 2002). Therefore, empirical evidence and valid methodologies are in great need in this research area to address a number of intriguing research questions.

CONCLUSION AND FUTURE DIRECTIONS

As e-commerce gains widespread attention and rapidly emerges as a competitive business form, online merchants are facing an urgent challenge of building and sustaining consumer trust on the Internet. While the issue has initiated numerous investigations for valid research methods and effective solutions by researchers from multiple disciplines, this article shows the merit of an HCI approach in confronting the challenge. Adding trust-inducing interface features and interpersonal cues in Web design has been proposed as a fruitful strategy for building online trust.

Based upon the present overview, five potential areas of suggested research include (1) the effects of culture on online trust; (2) the effects of domain (e.g., .com, .edu, .org) on online trust; (3) the reasons for losing online trust and the ways to repair it; (4) the importance of civil remedies for consumers in case of violations of privacy laws; and (5) the transferability of online trust from the Internet to other activities. In addition, there is obvious need for further investigation on the effects of social and interpersonal cues on online trust, including both methodology development and experimental testing. Finally, it should be pointed out that while well-crafted Web interfaces can induce trust in those who intend to purchase online, online vendors should also pay attention to other methods, such as customer relationship management (CRM) and off-line marketing strategies, to obtain consumer trust and nurture strong business relationships (Tan, Yen, & Fang, 2002).

KEY TERMS

Channel Availability: A feature of any communication medium. A communication medium's channel can be contextual, audio, visual, or any combination of the three. For example, telephone is an audio-only communication medium, while videoconferencing is an audio-visual communication medium.

Channel Symmetry: A feature of any communication medium. A communication medium affords symmetry if the recipient of a message can respond with the same type of message. For example, telephone and e-mail tools are symmetric (two-way) communication media, while television and Web sites are asymmetric (one-way) communication media.

Communication Media: The methods or tools in which information can be exchanged and communication can be facilitated. Examples include telephone, television, e-mail, Web sites, video conferencing, and instant messaging, to name a few.

Customer Relationship Management (CRM): An approach that recognizes that customers are the core of the business and that a company's success depends on effectively managing its relationship with them. CRM is about locating and attracting customers and thereby building long-term and sustainable relationships with them.

Electronic Commerce (E-Commerce): An emerging business form in which the process of buying, selling, or exchanging products, services, and information is undertaken via computer networks, including the Internet.

Online Trust: An Internet user's psychological state of risk acceptance based upon the positive expectations of the intentions or behaviors of an online vendor.

Synchrony: A feature of any communication medium. A communication medium is synchronous if the recipient of a message can respond immediately. For example, telephone and instant messaging are synchronous communication media; while e-mail and voice mail are asynchronous communication media.

Trust-inducing Design: The application of empirically verified features of a Web site to enhance a consumer's perception that the online vendor is trustworthy.

Trustworthy Web site: A Web site that reduces a consumer's perception of risk and that increases confidence in the online vendor's integrity.

Trust Management in Virtual Product Development Networks

Eric T.T. Wong
The Hong Kong Polytechnic University, Hong Kong

INTRODUCTION

Business-to-business partnerships are gaining rising attention in management and academic research. Increasingly, companies are advised to pursue their collaborative advantage (Dyer, 2000) in order to co-create world-class products, attract the most valuable customers and generate exceptional profits. Today, there is significant global overcapacity in most industries. In this environment of scarce demand, customers are becoming more demanding of customised and innovative products or services. With the advance of information and communication technology (ICT) and the resulting globalisation of markets and manufacturing, innovative product designs are generating new opportunities. In such a change-driven environment, a single manufacturer rarely provides everything on its own anymore. Rather, the most attractive offerings involve buyers and suppliers, allies and business partners in various combinations. Consequently, manufacturers or suppliers do not really compete with one another anymore. Rather, it is offerings that compete for the time and money of customers. The networked business can take different shapes ranging from integrated product development through a key player, to virtual production networks, strategic alliances, virtual organizations, extended enterprises, and so forth.

A review of business publications indicates that companies are extensively using ICT in their new product development activities. Based on an analysis of numerous industrial, high-tech, and business-to-business applications, it appears that ICT can facilitate new product development in a number of areas. These areas can include: speed, productivity, collaboration, communication and coordination, versatility, knowledge management, decision quality, and product quality (Ozer, 2000).

The number of strategic alliances between large, established firms and small, new ventures is on the rise, especially in industries affected by technological change. Theoretically, the combination of a smaller firm's innovative design capabilities with a larger firm's production system and financial prowess promises synergies that can contribute to both firms' competitive advantage, for example, Parts Manufacturers Approval (FAA, 2006) parts as an alternative to Original Equipment Manufacturer (OEM) parts in the aviation industry. Yet, not many of these partnerships result in successful collaboration.

New product development is inherently risky, particularly when new technology or emerging markets are involved. Although collaborative product development has been promoted as a means for reducing or at least sharing risk, such partnerships have their own limitations. Collaboration can also accentuate many of the risks inherent in product development projects. In the case of virtual production networks (VPN), this challenge is even greater because the new product development team spans geographical as well as organizational boundaries.

The basic hypothesis forwarded in this chapter is that a major cause for VPN failure is managerial, and therefore controllable and potentially avoidable. Although today's managers are well-trained in competitive behavior, cooperative processes in VPN require special trust management(TM) skills, skills that a majority of managers do not possess. As a result, cooperation often appears to be managed reactively, rather than being based on a deliberate, proactive cooperation strategy. For a VPN to be competitive and successful in a dynamic environment characterized by constantly changing customer demands and technological innovations, it must be capable of rapid adjustment in order to reduce the time and cost needed to deliver to the customer quality products. The main objective of this chapter is to propose essential guidelines for developing and maintaining partnership trust in Virtual Product Development Networks (VPDN) such that these networks can be managed in a proactive manner. In the following sections, the background of VPDN collaboration will be described, followed by an analysis of the key factors likely contributing to successful VPN collaboration. Based on findings reported in the trust and product development literature, basic requirements for developing and maintaining effective partnership trust in VPDNs have been proposed. Barriers likely to occur in practice are also outlined.

BACKGROUND

The advantages of VPDN collaboration can be significant. The pooling of resources and capabilities can generate synergistic growth between virtual organizations, either in terms of

developing a current product or service offering, or through the creation of an entirely new venture. Increased competitive power can help firms to leapfrog jointly over larger competitors, and generation of higher returns on investment levels can provide the means for further expansion into new market areas at relatively little cost. In an increasingly unpredictable and complex international arena, the flexibility and speed of entry associated with collaboration is opening up new opportunities and possibilities which outright investment through merger or acquisition cannot offer. Indeed, sharing the risks and costs of new product development through collaboration has been advocated by various authors. Securing access to new processes or technologies or gaining information for product development is another frequently mentioned benefit of collaboration. The apparently increasing complexity of technological and product development and convergence of industries provides a strong motive for such collaborative product development relationships.

Marketing considerations may also play an important role in collaborating for product development, especially in the face of increasing globalization of industries. The rapid rate of product obsolescence does, according to some, focus attention on securing rapid access to markets so that new products can be marketed virtually simultaneously in several regions. Collaborative product development relationships may also be seen as a means of overcoming various barriers to entry to foreign markets.

Collaboration can, however, have its shortcomings. History is strewn with the wrecks of failed partnerships left as a warning to the unwary. Many more struggle on without realizing their full potential, frequently to be ultimately bought out by one partner

or the other. With almost 50% deemed as failures, collaborative partnerships are proving to be complex relationships which demand a particular level of expertise and trust management skill in order to navigate the relationship through the hazards associated with this form of virtual network.

Such failures might be due to various causes. For example, there can be a leakage to collaborating partners of a firm's design and analysis skills, experience, and product knowledge that may form a significant part of the basis of its competitiveness. There is a danger that its partners not only acquire the competencies that the design partner brings to the product development, but also gain access to the knowledge and skills that the firm uses in other business areas. A VPDN partner may also fire the opportunism of its collaborators by providing information and insights into possible markets and future possibilities that otherwise may have been its exclusive domain.

Although collaboration is frequently suggested as a means of reducing the cost and duration of the product development process, one would need to consider the additional financial and time costs incurred in managing the collaboration, including the time involved in harmonizing what are likely to be fundamentally different management styles and budgeting processes of the collaborating parties. Furthermore, there can be significant potential opportunity costs because undue effort and resources are directed toward the collaborative product development project, such that the maintenance of the VPDN collaboration itself becomes the prime objective, at the expense of the specific product development. Given the small but growing number of studies reporting dissatisfaction with the outcomes of collaborative product development by one or more of the parties involved, it is understandable that attention should be directed toward key factors affecting the chance of success.

Defining success in product development has been the subject of much research attention and has been shown to be less than straightforward. Defining success in collaborative product development is similarly problematic, given that the perspectives of two or more organizations are involved. The most straightforward measure of the success of a collaborative product development project is likely to relate to whether or not the product was developed as planned and to cost and time allocations. The termination of an agreement cannot inevitably mean the collaboration has been unsuccessful, because the original objectives may have been met. Moreover, the objectives might change as product development progresses. It also has to be recognized that "success" in collaborative product development, as in any product development project, can be multifaceted. There can, for instance, be unintended advantageous side effects, whereas even a prematurely terminated collaborative product development project might yield beneficial experience and knowledge and assist in developing future products.

MAIN FOCUS OF THE CHAPTER

The main focus of this chapter is to examine factors affecting VPDN collaboration with the objective of proposing essential guidelines for developing and maintaining effective partnership trust in VPDNs.

Factors affecting VPDN Collaboration

There has been considerable research into the factors affecting both the success of product development and the outcome of collaborative projects (Lam & Chin, 2005; McDonough, 2000). A number of factors that appear to have some bearing on the success of collaborative ventures have been identified and these will be briefly reviewed here. It is recognized that some of these factors might also have an impact on product development per se, whether collaborative or not, but other factors referred to here are clearly of importance specifically to collaborative product development through the VPN.

A major factor relates to the choice of partner. A particular issue here is the compatibility of the respective cultures of the cooperating organizations. It was suggested that the partnering organizations must be able to communicate with each other, having a language that they all understand. They must have a working style which is complementary, in the way they go about reaching decisions, their problem solving style and so forth. Above all, their management styles must be compatible. There is also evidence suggesting that collaborations that are related to the existing activities of the production partners are more likely to be seen as successful, while others emphasize the value of general experience of collaborations as a factor that enhances the probability of future collaboration success.

Some researchers have stressed the importance of clearly establishing the ground rules for collaboration, such as ensuring that there are clearly defined goals, objectives, and responsibilities for the collaboration that are fully understood by all parties involved. Some of the literature stresses the necessity of preparing detailed and binding initial collaboration agreements in order that future ambiguity is avoided. Such advice corresponds with the recognition of the importance of early and upfront investment in any product development project. It also needs to be recognized, of course, that circumstances change and this alone suggests that there may be need for, first, frequent appraisal of the collaboration and, second, the scope for adaptability. The importance of establishing the limits to the collaboration has also been noted to avoid the transfer of general knowledge and experience during the process of joint product development. Some researchers advise collaborators to impose restrictions and exclusivity clauses in order to limit the transfer of core technologies.

There does, though, need to be a balance between protecting the proprietary interest of the firm while establishing trust and openness with its partners. This factor is regarded by many as a critical ingredient in the continuation and effectiveness of interorganizational relationships. The task for those involved in the management of collaborative product development is to balance these potentially conflicting issues as the project evolves. Related to the establishment of clear ground rules for collaboration is the corresponding need for the monitoring of progress such as through the establishment of milestones, significant points at which progress can be assessed. However, it is obvious, too, that at the outset it is difficult to plan for all the possibilities that might emerge as product development proceeds and this again highlights the need for frequent reappraisal and for a degree of flexibility.

The importance of allocating sufficient financial resources to a collaborative product development project is frequently emphasized, as has been the case for product development more generally. Of course, it is often the allocation of management time and effort that can have a disproportionate influence. The perceived mutuality of contribution and benefits from the various parties involved in a joint product development project has also been highlighted as important. A well managed collaboration, however, will not necessarily result in a profitable outcome. The broader context within which product development takes place is also likely to have a significant bearing. Changes in the partners' markets, in their competitive fields, in the range of technologies available, in the wider economic environment, or in the policies of government agencies can have a critical effect on the project, as can a redefinition of the collaborators' own missions and objectives. Maintaining the necessary external focus may, however, be awarded subsidiary importance given the administrative demands of maintaining the collaboration and the often overriding desire to ensure the collaboration per se is perceived by the partners as proceeding successfully.

Conflict, which affects NPD performance, is inevitable in collaborative NPD. Practicing effective conflict management improves NPD performance as well as helps maintain a long-lasting collaborative relationship. By incorporating the judgments of clients and suppliers using Analytic Hierarchy Process, Lam and Chin (2005) identified and prioritized four categories of success factors for conflict management. The results, based on the synthesized judgments, indicate that of all the factors, the most critical is communication management, followed by trust and commitment to the collaboration.

Existing theories give inadequate attention to differences among VPN members in recognition of these misalignments, interpretation of their origin, proposed corrective actions, and reconciliation of differences. It was found that lack of trust and increased diversity among team members exacerbate such differences (Susman, Gray, Perry, & Blair, 2003).

An effective interface between production and marketing is considered to be vital for the successful development and commercialization of new products. Studies in the U.S., Japan and the UK have, however, identified that conflict between engineers and marketers can act as a barrier to effective cooperation (Shaw, Shaw, & Enke, 2003). It was found that German engineers recognize the importance of trust, good understanding, common knowledge, integration and teamwork in building a good relationship with marketers. The main sources of conflict between German engineers and their marketing colleagues are differences in education and training and different goals and priorities.

To enhance the performance of collaborative product development a VPN must overcome such barriers as resistance to sharing proprietary information, and the not-invented-here syndrome. It may be seen from above that most of the success factors noted suggest that overcoming such barriers depends to a large extent on formal trust development processes. Within the ICT literature, only a handful of studies have examined the recent introduction of ICT applications aimed at helping virtual enterprises electronically collaborate (Mezgar, 2003, 2005; Ratcheva, 2006; Wong, 2005, 2006).

Of these studies, Mezgar (2003, 2006) and Wong (2005, 2006) have helped to advance theoretical understanding of how trust connects with security services and mechanisms and how it affects virtual enterprise operation, respectively. According to Wong (2005), because many organizations will become increasingly more reliant on geographically dispersed NPD teams in the future, companies will need to understand the essential conditions for successful trust building and maintenance in virtual enterprises. In a Pricewaterhouse-Cooper's study on corporate innovation in companies listed on the Financial Times 100, trust was ranked the number one differentiator between the top 20% of companies surveyed and the bottom 20% (Schaub & Altimier, 2006). The top performers' trust empowered individuals to turn strategic aims into reality. People are more innovative in a climate of trust. It is therefore expected that the development of a trust management framework would provide an opportunity for VPN partners to overcome the problems mentioned and eventually improve collaborative product development.

Trust Management Guidelines

Partnerships are distinct from ordinary relationships, as they require at least the restraint of partners from abusing power, a high level of trust and a cultivation of common norms. Trust has been regarded as the foundation of the digital economy (Keen, 2000; Mezgar, 2005; Wong, 2005). A virtual enterprise network is characterized by the impersonal nature of the online environment:

a) the extensive use of information and communication technology (ICT) as opposed to face-to-face transactions,
b) the implicit uncertainty of using an open technological infrastructure for transactions, and
c) the newness of the transaction medium.

Given these attributes, trust development in VPNs presents significant challenges because it is difficult to evaluate partners' trustworthiness without ever having met them (McDonough, Kahn. & Barczak, 2001). Moreover, as the life of many virtual teams is relatively limited, trust must quickly develop (Jarvenpaa & Leidner, 1999).

According to traditional studies, trust builds incrementally and accumulates over time. VPN business relationships, however, are characterized by project-oriented relationships that may entail no past history, nor any plan for future association. In these temporary relationships, time is a vital but often elusive component in the trust building process. This does not mean, however, that trust cannot be apparent in temporary groups. On the contrary, McKnigh et al. (1998) have shown that trust in initial relationships can often be high. Further, Jarvenpaa and Leidner (1999) argue that trust is maximally important in new and temporary organizations, because it acts as a substitute for the traditional mechanisms of control and coordination.

Creating a VPN takes more than just information technology. A study on issues of information technology and management concluded that there is no evidence that IT provides options with long-term sustainable competitive advantage. The real benefits of IT derive from the constructive combination of IT with organisation culture, supporting the trend toward new, more flexible forms of organization. Information technology's power is not in how it changes the organisation, but the potential it provides for allowing people to change themselves. Creating these changes, however, presents a new set of human issues. Among the biggest of these challenges is the management of trust between partner organisations in the VPN (Wong, 2005; Wong & Lau, 2002). Based on findings reported in the literature, a framework for trust management in a VPN can be developed through a serious consideration the following guidelines.

Common Business Understanding

In order to choose the appropriate virtual partners for a collaborative product development project, Fuehrer and Ashkanasy (2001) note that an important element in any business cooperation is the establishment of common business understanding. An earlier work suggests that there are three specifications necessary for the establishment of a common business understanding in the virtual context. The first is a clear product specification: the design, quality, and functionality of the product. The second is specification of the level of cooperation, which requires agreement about deadlines, liability, prices, profit allocation, and staff and resource input. The third is formal specification of agreements between the virtual partners. In a virtual organization, these specifications need to be communicated clearly between the partners to achieve a common business understanding. There is always varying uncertainty between members, however. Therefore, there is a need to guard against opportunistic behavior between the partners. This depends on the risk that the member is prepared to sustain as a potential loss, and also the partner's fear of opportunistic exploitation and the uncertainty of their behavior.

The three specifications (production, cooperation, and agreements between partners) can be achieved by negotiating relational contracts that guide the formation, operation, and dissolution of the virtual organization, thereby facilitating an increase in the level of collaboration-enabling trust. VPNs, like other organizations, create fiscal and legal issues that must be clarified, but they lack a formalized legal framework. Therefore, it is incumbent on the VPN's members to develop their own guidelines for the operation of the enterprise. Such agreements may include clarification of members' tasks and responsibilities, agreement on contracts, allocation of funds, potential liability, and how members will contribute their

expertise. In this sense, clear guidelines, spelled out in an early stage of the partnership, serve to reduce misperceptions and to foster the establishment of trust.

Other mechanisms to establish a common business understanding in VPNs include development of an organization handbook, design of a mutual Internet site, chat room technology, or the use of team addresses for e-mail. A specific example is Livelink, a software selected by Siemens to enable creation of a common business understanding through a standard computer interface.

The concept of common business understanding therefore shares similarities with Organizational Identity, which may be described as a set of distinctive and enduring traits that members associate with their organization. Scott and Lane (2000) have proposed that identity is determined in part by the nature of stakeholder networks. Common business understanding, however, is more akin to Barney's (see Barney et al., 1998, p. 103) broader concept of identity: "the theory organizational members have about who they are." In this respect, the author agreed with Gioia, Schultz and Corley (2000) that Organizational Identity is not necessarily a stable phenomenon, but mutates to suit the prevailing environment. In the virtual context, therefore, a common business understanding may be defined as a transient understanding between network partners as to what they stand for, about the nature of the business transactions that they engage in, and about the outcomes that they expect; their "vision."

Scott and Lane (2000) emphasize that a common business understanding requires the creation of a shared vision, together with communication of mutual aims through clear definition of the roles and expectations within the team, especially in the early stages of the partnership. In this respect, the process is typically initiated by agreement on a symbolic logo or design for a product or service. This is because understanding each member's role, together with group identification, determines critical behaviors such as willingness to cooperate with others, and willingness to engage in mutual goal setting. The VPN partners thus need rapidly to establish group identity and an awareness of mutual needs and expectations, along with the clarification of tasks and responsibilities. In traditional partnerships, awareness and identity are in part shaped by the legal framework that regulates organizational relationships, as well as by networks, artifacts, and the organization chart. In the case of the VPNs, however, mechanisms outside of the domain of traditional organizations need to be put in place to establish a common business understanding, which constitutes an important precursor of trust formation (Jarvenpaa & Leidner, 1999).

Ploetner and Ehret (2006) suggest that successful collaboration rests on a system-wide identification of benefits and that metrics and incentive systems constitute decisive barriers as soon as they no longer apply to system-wide benefits. Hence, the common vision for future benefits, that is, the development of new design capabilities, new products or new technologies, serves as a prime driver for VPDN collaboration.

These examples illustrate how the creation of a sense of shared meaning, member identification, and mission identity, especially in an early stage of the partnership, facilitates collaboration at an individual level and the operation and productivity of the VPN as a whole. As such, a common business understanding provides an essential condition for the development of trust within the organization. In effect, a common business understanding provides the virtual organization's members with an opportunity to share their perceptions of the organization's defined features, and creates a feeling of ownership and trust.

High Ethical Standards

Three factors uniquely characterize the virtual organization's position in regard to business ethics. Firstly, VPNs are rarely guided by pre-existing codified laws, where values and standards are written into legal systems enforceable in court. Because the organization's partners are not usually legally bound to the organization, any negative outcomes or perceptions attributed to poor business ethics could result in the organization's reputation suffering. Second, because VPNs are intrinsically temporary, corporate ethics are difficult to develop because members will typically be finishing one virtual collaboration and entering into another in a short period. Thirdly, VPNs are intrinsically boundary spanning in nature, so that they must incorporate a diversity of culturally-based values and morals.

Researchers focused on the notion of advances in ICT and the related effects on social behavior agree that unethical behavior in the virtual context is predominantly caused by technological changes and by the inside keepers of the information systems. They also agree that social behavior needs more than new laws and modified edicts, and that ethical issues will become increasingly important to enable business transactions to be carried out safely and securely. Although technology has been largely secured by advancing software and technology for virus detection, as well as en/decryption of information to ensure the security of business processes, Johnson (1997) notes that technology can never be sufficient to control all aspects of social behavior. Consequently, online behavior is predicated on an awareness and acceptance of ethical norms and behaviors. This can best be achieved through specification and clarification of the members' tasks, responsibilities and agreed sanctions for proscribed behavior.

Johnson (1997) posits further that the "only hope to control online behavior is for individuals to internalize norms of behavior," and suggests three rules for online ethics: (1) know and follow the rules of the forums participated in; (2) respect the privacy and property rights of others and, if there is any doubt, assume the user's desire for privacy

and ownership; and (3) respect interacting partners by not deceiving, defaming, or harassing them. Not surprisingly, these rules for online behavior are essentially identical to rules for off-line behavior. Indeed, there is no reason why the same ethical guidelines that apply to regular behavior should not be employed in respect to online behavior.

Pearson, Crosby, and Shim (1997) reported on ethical standards for the IS profession proposed by three major professional associations in this field. These associations share an agreed set of behavioral obligations to society, to colleagues, and to professional organizations. The standards aim to promote the principle that individuals within the professions act in an ethical and responsible manner in order to influence the success of their organizations (Pearson et al., 1997). Clearly, similar standards can be developed for the operation of individual VPNs specifying, for instance, the obligation to virtual organization members and clients.

Other possible mechanisms to promote ethical behavior in VPNs include formal codes of ethics, which comprise statements of prescribed and proscribed values or behaviors, and thus provide a strategic tool within organizations to inculcate and to demonstrate ethical standards. Ethical standards also fulfill a strategic external role through recognition by government agencies and insurance companies. Recent surveys show that in the case of VPNs, informal rules known as "netiquette" are usually in place, but a lack of a formal legal infrastructure means that a code of ethics is simultaneously both imperative and difficult to achieve. This is further compounded by different ethical standards and regulations between countries. Nevertheless, trust in interorganizational VPDNs clearly cannot be established until all members recognize that ethical standards are in place and are made aware of what the standards are.

Mutual Forbearance Between VPN Partners

Some researchers approach the issue of trust by defining cooperation as coordination effected through mutual forbearance. Forbearance is refraining from cheating. Cheating may take a weak form (failing to perform a beneficial act for the other party), or a strong form (committing a damaging act). The incentives for forbearance arise from the possibility of reciprocity, leading to mutual forbearance. Parties that are observed to forbear may gain a reputation for this behaviour, which makes them potentially attractive partners for others. The parties to a successful agreement may develop a commitment to mutual forbearance, which cements the partnership, and, in this way, mutual trust is created, which alters the preferences of the parties toward a mutually cooperative mode. Thus, short-term, self-interested behaviour becomes converted to cooperative trusting behaviour.

Demonstrated Capability of VPN Partners

In a VPDN participants will be more willing to share knowledge when they trust in others' ability. It is only natural that they would want to converse with others who have the knowledge and skills regarding the product development project at hand because VPDNs almost always center around a common theme.

Effective Communication and Interaction between VPN Partners

Through communicating with people, we calibrate them, we get a better sense of them and we understand their priorities. Members of VPDN can therefore increase the trust they are giving and the amount they will trust others, by actively seeking opportunities to communicate with other members.

Conflict Recognition and Reconciliation

It is widely acknowledged that effective integration of marketing, product design and manufacturing is vital for the successful development and commercialization of new products and services. The literature suggests, however, that there is much conflict between marketing and engineering personnel that can have a detrimental impact on integration and thus successful new product development (Shaw et al., 2003). A main reason for the existence of such kinds of conflicts appear to be the polarization of functions, with marketing and product designers wanting customized products, whereas the production department wants to manufacture standardized products (Susman et al., 2003). This phenomenon clearly needs to be addressed in order to improve the design-manufacturing interface. One way is to provide education and training for all VPDN partners. This will help different functions in the VPDN to become more sensitive to each other's needs.

Flexible Coordination of Design Activities

As product development involves processes mainly executed by humans, rigid forms of procedural control would create unnecessary conflicts between VPDN partners because people like to keep their freedom regarding the way they work. Product design, similar to other creative processes, evolves according to a kind of anarchic flow of activities. It is therefore necessary to support loosely constrained sets of business processes. Additionally, temporal interdependencies among activities would need to be considered. For example, in the case of product design and process planning, although both processes can proceed with some degree of concurrency

(e.g., process planning can start once the first draft of the engineering design is available), process planning cannot finish before product design finishes. Usually, some details of the process plan depend on the final commitments on the product model. One way of achieving coordination flexibility is through the use of a multi-agent approach (Camarinha-Matos & Afsarmanesh, 2003).

Realistic Expectations of VPN partners

Prior research has indicated that trust creation may be a history-dependent process in which trust accumulates and builds incrementally. Based on this concept, interview and questionnaire data obtained by Adobor (2005) on strategic partnerships from chief executive officers and senior management in the biotechnology, pharmaceutical and medical equipment manufacturing companies in North America showed that trust building in partnerships may be a sort of self-fulfilling prophecy in which initial expectations positively impact behavior and trust building. The results also show that there may be some optimal level of expectations. Both too low and too high an expectation was counterproductive to trust building. It is suggested that VPDN coordinators should develop reasonable product development targets, such that each partner will be able to form realistic initial expectations about each other's design output.

Assuming that most of the above-mentioned conditions have obtained top management support, it is expected that the mutual trust created would enhance the openness within a VPDN (i.e., freedom from censorship and willingness to express innovative ideas) and VPDN partners' ability to reconcile their differences and reach agreements on most of their product development projects.

FUTURE TRENDS

Current research on the management of trust in VPN has limitations. Most work was based on a limited number of case studies. These case studies cannot be considered representative of all VPDN because of their industrial and cultural biases. As most of these models are longitudinal, for generalization purposes it is necessary to test them against the behavior of VPDN over time, a difficult, costly and time-consuming exercise. A possible next step is to confront the above models with a richer, more widely dispersed set of cases, with more cultural and structural variety in the VPDN analyzed in order to investigate its degree of robustness.

While some studies (e.g., Pavlou 2002) posit positive relationships between trust and its consequences, these relationships are nonlinear. Given a minimum threshold for trust to become effective, it is important to recognize this nonlinearity.

Currently, a popular experimental paradigm employed by Human-Computer Interaction (HCI) researchers to assess trust between people interacting via computer-mediated communication covers social dilemma games based on the Prisoner's Dilemma (PD). HCI researchers employing this experimental paradigm currently interpret the rate of cooperation, measured in the form of collective pay-off, as the level of trust the technology allows its users to develop. Some researchers argue that this interpretation is problematic, because the game's synchronous nature models only very specific trust situations (Reigelsberger, Sasse, & McCarthy, 2003). Furthermore, experiments that are based on PD games cannot model the complexity of how trust is formed in the real world, because they neglect factors such as ability and benevolence.

It is noted from the literature that little theoretical explanation exists in order to understand the impact of trust in various forms of VPN relationships. It has been found that firms in horizontal alliances would display a lower level of organizational trust and a weaker relationship between interfirm cooperation compared to firms in vertical integration of alliances and that trust is unrelated to cooperation in horizontal alliances (Rindfleisch & Moorman, 2001). It was suggested that this different impact of trust could be due to higher opportunism, lower interdependency, and stronger institutional linkages among horizontal collaborators compared to their vertical counterparts. If this finding is substantiated by future empirical research in the VPN domain, researchers may need to reconsider the popular notion that trust is an essential component of all types of relationship exchanges in the VPN.

In view of the positive association between expectations and trust, finding out how VPDN partners form expectations about each other will yield important insights. Perhaps they are influenced by factors external to the VPDN relationship, such as the amount of technical investments, rate of technological progress or the reputation of partners.

CONCLUSION

Collaborative teamwork offers greater chance for VPDN to be successful in nowadays' agile competition. Trust models based on traditional familiarity would not meet the special needs of the VPDN, which is having a much shorter life cycle and involves a large number of partners who have never met before. Consequently, the VPDN partners must realize the need to effectuate this paradigm shift. This chapter identifies eight essential guidelines needed for effective trust management in a virtual environment: a common business understanding, high ethical standards, mutual forbearance between partners, capability of partners, effective communication and interaction within the VPDN, conflict rec-

ognition and reconciliation, flexible coordination of design activities, and reasonable expectations about VPDN partners. VPDNs with high levels of trust among their members can effectively utilize interactions and communication processes at their interfaces so members can learn together, and can develop shared mental models of reliability and a shared culture of safety. It is anticipated that the likely impact of trust management would imply continuous product innovation because trust plays an important synthesis role. VPDN with its flexible organizational structures can leverage the partners' ability and willingness to learn, thereby enhancing new product developments.

KEY TERMS

Virtual Enterprise: A temporary business organization set up between trading partners operating from geographically dispersed sites, for the duration of a common project. The design and manufacture of new products or services frequently requires the talents of many specialists. When many corporations combine their specialties to create a product or service, the result can be called a virtual enterprise. A virtual enterprise must be able to form quickly in response to new opportunities and dissolve just as quickly when the need ceases.

Virtual Private Network (VPN): A private communication network often used within a company, or by several different companies or organizations, to communicate confidentially over a publicly accessible network.

Agile: Being agile means being proficient at change, and allows an organization to do anything it wants to do whenever it wants. As virtual enterprises do not own significant capital resources of their own, this helps to make them agile, as they can be formed and changed very rapidly.

Ethical: Conforming to standards of professional or social behavior agreed by all members of a virtual enterprise.

Self-Fulfilling Prophecy: A predetermined idea or expectation one has toward oneself that is acted out, thus "proving" itself. For example, in the stock market, if it is widely believed that a crash is imminent, investors may lose confidence, sell most of their stock, and actually cause the crash.

Traditional Familiarity: Traditional familiarity combines an assumption of continuity with the past experience of a partner. Traditional trust therefore relies on the fact that VPN partners who could be observed as trustworthy in the past will display the same kind of behavior in the future.

U.S. Disabilities Legislation Affecting Electronic and Information Technology

Deborah Bursa

INTRODUCTION

The Americans with Disabilities Act (ADA) is the cornerstone legislation to address the civil rights of people with disabilities, including making products, services, and physical environments accessible to them. Almost everyone in the U.S. is familiar with the ADA, but designers of technology products and services need to be aware of accessibility standards that go beyond the ADA: specifically, Section 508 of the Rehabilitation Act and Section 255 of the Communications Act. These laws define accessibility standards and guidelines that impact the design of electronic, information, and telecommunication technologies, and they are intended to promote products and services that are as accessible to persons with disabilities as those without (Section 508, 1998). Furthermore, with the aging of the U.S. and world populations (Forrester, 2004), the number of people who want to use technology but cannot, because of disabilities, is on the rise. Designers of technology need to understand how modifications in traditional design will make products more marketable and usable by a wider range of customers. This article reviews important aspects of Sections 508 and 255, assistive technology and accessible design, and additional sources of information and training.

BACKGROUND

Key Implications of the Legislation

Section 508 of the Rehabilitation Act states that "each Federal department or agency, including the United States Postal Service…when developing, procuring, maintaining, or using electronic and information technology (EIT)…shall ensure…that individuals with disabilities…have comparable access" (Section 508, 1998). Section 508 required the Architectural and Transportation Barriers Compliance Board (also known as the Access Board) to develop accessibility standards for EIT, and it stipulated that the law applied to procurements after June 25, 2001 (Federal Acquisition Regulations, 2001).

The technology addressed in the Section 508 technical standards cover: "software applications; operating systems; Web-based intranet and Internet information and applications; telecommunications products; video and multimedia products; self-contained, closed products; and desktop and portable computers" (Federal Acquisition Regulations, 2001). The standards also address information and documentation including "product support in alternative formats, descriptions of accessibility and compatibility features in alternative formats, and product support services in alternative communications modes" (Access Board, 2001). Federal departments and agencies can be exempt from compliance only if they can show that compliance is an "undue burden" as a result of "significant difficulty or expense." Prior to the Section 508 amendments, Section 501 (federal employment) and Section 504 (federally funded programs and activities) of the Rehabilitation Act addressed accommodation of individuals. The amendments to Section 508 addressed the technology itself, that is, making it accessible to everyone right "out of the box" (although this does not necessarily eliminate the need for individual accommodation). It was thought that by making accessibility requirements a part of the federal procurement process, there would be financial incentives for companies to design products that meet these standards.

The Section 508 standards apply specifically to the United States government when purchasing, developing, maintaining, or using electronic and information technology. In addition, an increasing number of states purchase electronic products and services that conform to the Section 508 standards (or similar state-developed regulations or stan-

dards). Due to the complexity of the regulations and range of requirements, creators and vendors of technology products need information and training to ensure their products and services adhere to the 508 standards.

The Telecommunications Act of 1996, which was the first major overhaul of American telecommunications policy in nearly 62 years, added *Section 255* to the Communications Act of 1934. Section 255 requires telecommunications manufacturers and providers of telecommunications services to make their products and services accessible to and usable by people with disabilities if "readily achievable." The Federal Communications Commission (FCC) makes readily achievable determinations on a case-by-case basis, but generally, companies with more resources need to do more to make their products and services accessible to people with disabilities. When it is not possible to provide direct access, Section 255 requires manufacturers and providers to make their devices and services compatible with peripheral devices and specialized customer premises equipment (CPE) that are commonly used by people with disabilities, if readily achievable. Examples of specialized CPE include teletypewriters (TTYs) and assistive listening devices.

Section 255 also requires companies that develop telecommunications products and services to include the following activities as business practices:

- When the company conducts market research, product design, testing, pilot demonstrations, and product trials, it should include individuals with disabilities in target populations of such activities.
- Companies should work cooperatively with disability-related organizations.
- Companies should undertake reasonable efforts to test access solutions with people with disabilities. (Federal Communications Commission, 2002)

Unlike Section 508, Section 255 is not restricted to just the federal marketplace; it applies to telecommunications products and services purchased by anyone in the U.S. Section 508 covers a wide variety of disabilities: people who are deaf or hard of hearing, who have mobility or dexterity impairments, who have speech impairments, and those who have low vision or who are blind. Section 255 includes all of these impairments as well as cognitive disabilities. While the standards, guidelines, and directives associated with Section 508 and Section 255 may appear to complicate the product design process, often these challenges bring about innovation and new product ideas. In most cases, these innovations lead to product features that are desired by a customer market that is much larger than the disability community.

Disabilities and Applications

People with disabilities need different product and service features so they can access information and communicate with others at a level that is equal to those without disabilities. Often an assistive technology is needed by someone with a disability to overcome access barriers. For example, a text-to-speech software program, commonly called a "screen reader," is an assistive technology that allows someone who is blind to access electronic information, such as Web pages on the Internet. Designers of Web sites and software applications need to understand accessibility requirements so they can make their content accessible to users of screen readers. For example, Web sites and other software programs need to have text "tags" that describe every non-trivial image used in their applications. The screen reader reads these descriptions aloud so the user with low or no vision can understand the information being conveyed. These tags benefit sighted people too because the tag's text appears whenever they "mouse over" the image, which can help the users identify the function of an icon.

People who are deaf need visual assistance to access information that is typically delivered aurally. As a result of the Television Decoder Circuitry Act of 1990, televisions must now be manufactured with the circuitry necessary to show captioning. In this case, the viewer requires no assistive technology, and these caption-ready TVs are examples of making technology accessible "out of the box." Continuing the example related to Web site design, when sound is used to communicate information, there should be text to notify the user of the presence of sound and to describe the sound itself. Often the solution is as simple as a caption that says "music."

Another assistive technology is voice-to-text software, commonly called "voice recognition software," which assists those with motor or dexterity limitations to transmit information through speech. While this assistive technology was initially developed for people with disabilities, voice recognition is a popular feature for many technology products and is in high demand by the mass market.

Training for Accessible Design

Accessibility training is available to designers in several places around the country, and there is a wealth of information on the Internet. Web sites listed in the resources section of this article provide contacts for online training, courses, and conferences. Many of these courses are "hands on" so designers and information specialists can see the assistive technology software packages in action. Online training sessions are available through the national centers listed at the end of this article. Several centers have training materials

that can be downloaded or requested through the U.S. Mail. Professional societies, such as the Human-Computer Interaction (HCI) group of the Association for Computing Machinery (ACM), American Institute of Graphic Arts (AIGA), and the Industrial Design Society of America (IDSA) include peer-reviewed papers and research on related topics.

FUTURE TRENDS

It is important for information providers and designers to know the requirements and guidelines of Sections 508 and 255 before they begin a project. If they include people with disabilities early in their user-centered design processes, they can avoid the cost of retrofitting later. In addition, increased software and hardware capabilities will ease compliance through software that easily converts information to text, or sound to image.

CONCLUSION

Section 508 of the Rehabilitation Act and Section 255 of the Communications Act are the two primary federal laws that directly affect the design of accessible electronic, information, and telecommunication technology in the U.S. These laws go beyond the Americans with Disabilities Act by defining specific standards and guidelines that address the accessibility needs of people with disabilities. Designers of technology, therefore, should understand and apply these principles when designing electronic and information technology that will be sold to the federal government (Section 508), or when developing telecommunications products and services that will be sold to the public (Section 255).

It would be a mistake, however, to assume that federal legislation is the only factor driving the need for more accessible technology. The U.S. population is aging, and with the years come age-related disabilities such as visual, hearing, and mobility impairments. The appeal of accessible technology, therefore, extends to a larger portion of the overall market, and accessibility requirements should become an essential consideration in the technology design process.

KEY TERMS

Accessible Technology: "[T]echnology that can be used by people with a wide range of abilities and disabilities. It incorporates the principles of universal design. Each user is able to interact with the technology in ways that work best for him or her. Accessible technology is either directly accessible—in other words, it is usable without assistive technology—or it is compatible with standard assistive technology" (Knowledgebase entry from University of Washington: www.washington.edu/accessit/articles?110).

Assistive Technology: Any item, piece of equipment, or system that is commonly used to increase, maintain, or improve functional capabilities of individuals with disabilities. Examples include screen readers, teletypewriters (TTYs), and Braille keyboards.

Disability: Under the ADA, an individual with a disability is a person who: (1) has a physical or mental impairment that substantially limits one or more major life activities; (2) has a record of such an impairment; or (3) is regarded as having such an impairment.

Rehabilitation Act: A federal law that was created to empower individuals with disabilities to maximize employment, economic self-sufficiency, independence, and inclusion and integration into society. It also was enacted to ensure that the federal government plays a leadership role in promoting the employment of individuals with disabilities. You can read the text of the act at www.ed.gov/policy/speced/leg/rehabact.doc.

Section 255: A part of the Communications Act. Section 255 requires telecommunications manufacturers and providers of telecommunications services to make their products and services accessible to and usable by individuals with disabilities, if readily achievable. For more information, see www.access-board.gov/telecomm/html/telfinal.htm.

Section 508: A part of the Rehabilitation Act. Under Section 508, agencies must give employees with disabilities and members of the public access to information that is comparable to the access available to others. The law applies to all federal agencies when they develop, procure, maintain, or use electronic and information technology. For more information, see www.section508.gov.

Telecommunications Act: The first major overhaul of American telecommunications policy in nearly 62 years. This Act added Section 255 to the Communications Act of 1934. See www.fcc.gov/telecom.html for more information.

Universal Design: "A process of creating products (devices, environments, systems, and processes) which are usable by people with the widest possible range of abilities, operating within the widest possible range of situations (environments, conditions, and circumstances), as is commercially practical" (Vanderheiden & Tobias, 2000).

INTRODUCTION

The American legal system, along with many of its counterparts around the globe, is only beginning to grapple with the legal challenges of the knowledge age. The past decade has witnessed a multitude of new laws and regulations seeking to address these challenges and provide a common framework for the legal and technical professions. Those charged with information security responsibilities face a myriad of complex and often vague requirements. In this article, we establish a four-level taxonomy for information security laws and explore the major components of each level.

BACKGROUND

Mohamed Chawki, in a study of computer crime law, points out that the traditional definition of a computer crime as any crime that involves "the knowledge of computer technology for its perpetration, investigation, or prosecution" is far too broad for practical application (Chawki, 2005, p. 7). Virtually every crime involves computer technology at some point in the investigative process. For example, a common burglary should not be considered a computer crime merely because the booking officer entered data on the crime into a department information system. Similarly, the fact that the criminal looked up driving directions on the Internet should not make a bank robbery a computer crime.

We seek to clarify these issues by creating a general taxonomy of information security laws. Our taxonomy includes the following four levels:

- **Intellectual property laws** protect the rights of authors, inventors and creators of other intellectual works.
- **Computer-focused crime laws** define transgressions and applicable punishments for offenses where the use of a computer is intrinsic to the crime.
- **Computer-related crime laws** are those laws that involve the use of a computer but where the criminal activity is not defined by the use of a computer. This category also includes those laws that require the use of computers to assist in the investigation of a crime.
- **Industry-specific laws** do not apply to society as a whole but, rather, govern particular industries and are typically focused on protecting the confidentiality, integrity and/or availability of personal information.

It is also important to note that many information security crimes are prosecuted under traditional laws, rather than the specific laws presented in this taxonomy. Smith (2005) points out two examples of this: the charging of an individual with a felony offense for accessing an unprotected wireless network and a school district's charge of criminal trespass against 13 students who accessed laptops issued to them with an administrative password that was taped to the bottom of the machines.

In the remainder of this chapter, we seek to explore this taxonomy in further detail. While the taxonomy may be applied to any body of law, due to space constraints, this article limits the discussion to federal laws in the United States. A myriad of state and local laws, as well as the laws of other nations, may also be classified under this taxonomy.

INTELLECTUAL PROPERTY LAW

The legal principles protecting the rights of owners of creative works date back several centuries. As our society shifts from an industrial economy to a knowledge economy, these laws become increasingly important, as they protect the very essence of our economic engine. These intellectual property laws are critical to any information security program, as they provide the legal basis for protecting the intellectual property rights of individuals and organizations.

Copyrights

Copyrights protect any original work of authorship from unauthorized duplication or distribution. The Copyright Act defines eight categories that constitute covered works (Copyright Act, 1976). One of these categories, literary works, is broadly interpreted to include almost any written work. This category has traditionally been used to include computer software, web content and a variety of other works of direct interest to information security professionals.

Copyright protection is automatic upon the creation of a work. For works created after 1978, copyright protection lasts for 70 years after the death of the last surviving author.

Trademarks

Trademark law protects words, phrases and designs that identify the products or services of a firm. The essential characteristic of a trademark is that it must uniquely distinguish the trademark holder's goods or services from those of other providers. Therefore, trademarks may not be simply descriptive of the product or service but must contain the element of uniqueness. For example, it would not be possible to gain trademark protection on the term "blue automobile," while it may be possible to gain protection for the term "Blue Streak Automobiles".

Trademark protection is afforded by the Lanham Act (1946). The U.S. Patent and Trademark Office grants registrations with an initial duration of 10 years and the option to renew.

Patents

Patents protect inventions, processes, and designs. They grant the inventor substantial protection in the form of exclusive rights to the patented concept. To protect against the abuse of this privilege, the U.S. Patent and Trademark Office strictly governs the issuance of patents. The three requirements for patent protection are that the invention must be novel, useful, and nonobvious. Patents granted for inventions or processes are valid for 17 years while design patents are valid for 14 years (Patent Act, 1952).

Trade Secrets

The Economic Espionage Act of 1996 makes it illegal to steal, misappropriate, duplicate or knowingly receive or possess a trade secret without appropriate permission. Trade secrets include any information that "derives independent economic value, actual or potential, from not being generally known to, and not being readily ascertainable by proper means by the public" and are the subject of "reasonable measures to keep such information secret" (Economic Espionage Act, 1996).

When designing an information security program, it is essential to recognize that trade secrets are defined by the confidentiality protection afforded them. If an organization fails to take reasonable efforts to maintain the confidentiality of a trade secret, this protection is lost. This is a major departure from patent protection, which requires public disclosure of the invention. Public disclosure of a trade secret nullifies the protection afforded to that secret and effectively releases it into the public domain. Unlike patents, however, trade secrets enjoy indefinite protection under the law.

Digital Millennium Copyright Act

The Digital Millennium Copyright Act (1998) instituted a number of significant changes in U.S. copyright law. In addition to procedural changes required to implement World Intellectual Property Organization (WIPO) treaties, DMCA makes several modifications to the law designed to accommodate the changing digital environment of the Internet. For example, DMCA offers a safe harbor provision for Internet service providers, absolving them of liability for the infringing acts of customers, provided that they have policies to terminate the accounts of repeat copyright offenders and do not interfere with the technical measures used by copyright holders to protect their works. If providers meet these requirements, they are protected from liability caused by transitory communications, system caching, information residing on systems or networks at the direction of users and information location tools (such as search engines).

COMPUTER-FOCUSED CRIME LAW

Computer-focused crime laws center upon the transgressions and associated punishments when the use of a computer is intrinsic to the crime. When drafting computer-focused crime laws, legislators have the specific intent of outlawing the use of a computer to commit a crime. This category is distinct from the next category, computer-related crime laws, crimes in which the perpetrator may utilize a computer as a support tool. For example, a law prohibiting the use of a computer to eavesdrop on the electronic mail of an individual is a computer-focused crime law. It is the act of using the computer to eavesdrop that is the essential nature of the crime.

Computer Fraud and Abuse Act

Congress originally passed the Computer Fraud and Abuse Act of 2001 in 1986 and later amended it in 1994, 1996, and 2001 to reflect the rapidly changing digital environment. Originally intended to protect data contained on the computers of government agencies and financial institutions, later amendments expanded the scope to include any system involved in interstate commerce (Burke, 2001). Offenses under the Computer Fraud and Abuse Act include gaining unauthorized access to a computer.

Electronic Communications Privacy Act

The Electronic Communications Privacy Act (ECPA) of 1986 protects the rights of individuals who become the subject of electronic surveillance by government agencies or other third parties. It includes two separate components: the Wiretap Act and the Stored Communications Act (SCA).

The Wiretap Act makes it illegal to intercept (or attempt to intercept) any wire, oral or electronic communication outside of several specific circumstances identified in the law (such as when approved by a court order or when conducted as part of a quality assurance monitoring effort). The SCA protects communications stored on a computer against unauthorized access or alteration.

COMPUTER-RELATED CRIME LAW

The third category in our taxonomy, computer-related crime laws, includes laws that govern crimes which commonly involve the use of a computer but do not meet the criteria of a computer-focused crime.

Child Pornography Laws

Society has long held the tenet that any molestation or exploitation of children via the creation or distribution of pornography is objectionable and has codified this abhorrence in the law. Unfortunately, the growth of the Internet has led to an increased ability of child pornography traffickers to market their wares with a greater degree of anonymity. This technological shift required a corresponding shift in the law.

The majority of child pornography prosecutions take place under Title 18, Section 2252 of the United States Code (Waters & Harrell,1997). This law bans the interstate or foreign transportation of sexually explicit materials that involve minors and was amended specifically to include the transmission of such materials through the use of a computer.

The Child Protection and Obscenity Enforcement Act of 1988 requires that the producers of sexually explicit materials maintain documented records of the ages of all actors and models used in their productions.

Identity Theft and Assumption Deterrence Act

The Identity Theft and Assumption Deterrence Act of 1998 amended federal law to address computer-related elements encompassed by the crime of identity theft. Specifically, Congress outlawed the possession or use of electronic devices, computer hardware and computer software designed primarily for the production of false identity documents. This Act also modified the definition of "means of identification" under the law to include biometric data, electronic identification numbers, addresses or routing codes, and telecommunication identifying information or access codes.

USA PATRIOT Act

The Uniting and Strengthening America by Providing Appropriate Tools Required to Intercept and Obstruct Terrorism (USA PATRIOT) Act enhances the authority granted to the federal government when conducting counterterrorism operations and places additional requirements on service providers. In a legal summary of the act, Iuliano (2003) notes that the critical changes that impact information security programs are that the Act:

- Exempts voicemail from wiretap requirements, allowing law enforcement officials access through a search warrant
- Provides law enforcement officials with authority to track and monitor Internet traffic
- Increases penalties for computer-focused crimes

Communications Assistance for Law Enforcement Act

Law enforcement agencies have long employed the use of court-ordered wiretaps in investigations to obtain evidence of criminal activity. Up until the past two decades, agents could implement these wiretaps simply by attaching electronic eavesdropping devices to an analog telephone network. The emergence of digital and mobile communications devices increased the technical difficult of implementing wiretaps and caused Congress to pass the Communications Assistance for Law Enforcement Act (CALEA) of 1994. CALEA requires that communications providers cooperate with law enforcement efforts to obtain wiretaps and to do so in a manner that cannot be detected by the communicating parties.

For ten years, both the government and telecommunications providers interpreted CALEA to apply to voice communications over telephone networks. In a 2005 notice of proposed rulemaking, the Federal Communications Commission stated that the government intends to apply CALEA to Internet service providers (Federal Communications Commission, 2004). This new interpretation of CALEA raises a number of critical issues as it requires service providers to make substantial equipment investments in order to comply. For example, a coalition of higher education argued to the FCC that the proposed interpretation would impose an unjustified cost burden upon academia (Higher Education Coalition, 2005).

INDUSTRY-SPECIFIC LAW

In addition to the broad laws identified in the previous sections of this taxonomy, there are a number of laws that apply

to specific industries, due to their unique access to sensitive data. These include regulations on healthcare providers, financial institutions, public corporations, and others.

Child Online Privacy Protection Act

The Child Online Privacy Protection Act (COPPA) of 1998 regulates the conduct of business with minors using the Internet. It requires that businesses obtain parental consent before knowingly collecting personal information from children under the age of 13. It also requires that these online services provide parents with any information collected from their children, offers them the opportunity to revoke consent, and demands the removal of such information at any time upon parental request. As pointed out by Isenberg (2000), the cost of compliance with this Act may be steep. He illustrates this point through the case of SurfMonkey, a site which reportedly spent over $50,000 on COPPA compliance and instituted a 4,673 word privacy policy.

Health Insurance Portability and Accountability Act

In 1996, Congress enacted the Health Insurance Portability and Accountability Act (HIPAA). Among its many provisions, HIPAA implemented privacy and security requirements for healthcare providers, health insurance plans and health information clearinghouses. The Privacy Rule creates a new classification of data: protected health information (PHI) which includes several categories of data related to an individual's health.

The Privacy Rule requires that covered organizations only disclose PHI to authorized individuals and organizations. The HIPAA Security Rule provides five categories of safeguards that must be applied to electronic PHI (ePHI):

- Administrative Safeguards
- Physical Safeguards
- Technical Safeguards
- Organizational Requirements
- Policies and Procedures

HIPAA is one of the most comprehensive industry-specific laws and it provides a full blueprint for the protection of healthcare data. It also provides specific consequences for knowing and willful violations of the law. Anyone who obtains or discloses PHI in violation of HIPAA may be fined up to $250,000 and imprisoned for up to 10 years.

Gramm-Leach-Bliley Act

Just as HIPAA requires that healthcare fs protect the privacy and security of patient records, the Gramm-Leach-Bliley Act (GLBA) of 1999 requires that financial institutions protect the privacy and security of individual financial records. GLBA's Financial Privacy Rule requires that financial institutions provide customers with a copy of the institution's privacy policy. GLBA's Safeguards Rule requires financial institutions to design and implement safeguards to protect customer information.

Sarbanes Oxley Act

The Sarbanes Oxley Act (SOX) of 2002 instituted sweeping reforms in the way public corporations conduct business and report financial results. While the majority of SOX requirements pertain to financial reporting and traditional accounting controls, the law does specifically impact information security. The law requires that institutions implement sufficient information security controls to ensure the validity and reliability of financial reports. The broad applicability of this law to all publicly traded corporations makes it one of the highest impact information security laws of the past decade.

Payment Card Industry Data Security Standard

The Payment Card Industry Data Security Standard (PCI DSS) offers an interesting case of industry self-regulation becoming embodied in state law. In 2004, Visa, MasterCard, American Express, and Discover aligned their previously disparate merchant data security requirements into a uniform standard (PCI DSS) that applies to all businesses involved in the storage, processing or transmission of cardholder data. PCI DSS imposes twelve specific requirements (Payment Card Industry, 2005):

- "Install and maintain a firewall configuration to protect cardholder data
- Do not use vendor-supplied defaults for system passwords and other security parameters
- Protect stored cardholder data
- Encrypt transmission of cardholder data across open, public networks
- Use and regularly update anti-virus software
- Develop and maintain security systems and applications
- Restrict access to cardholder data by business need-to-know
- Assign a unique ID to each person with computer access
- Restrict physical access to cardholder data
- Track and monitor all access to network resources and cardholder data
- Regularly test security systems and processes

- Maintain a policy that addresses information security"

While PCI DSS does not carry the force of law in its own right, merchants who agree to accept payment cards are under a contractual obligation to comply with the standard's requirements and face severe fines of up to $250,000 in the event of a compromise.

There is also a recent trend among state legislatures to incorporate PCI DSS requirements into state law. The Minnesota State Legislature recently passed the Plastic Card Security Act making it illegal to store certain elements of cardholder data subsequent to transaction authorization (Plastic Card Security Act, 2007). At the time of this writing, both Texas (HB 3222, 2007) and California (AB 779) had pending legislation that would incorporate additional PCI DSS requirements into that state's body of law.

FUTURE TRENDS

As we have demonstrated, the landscape of federal information security law is quite complex and includes a number of overlapping regulations that apply to different industries, technologies, and constituencies. These laws have evolved significantly over the past three decades and matured in their understanding of the unique technological issues posed by the ubiquity of broadband Internet access. We expect that these laws will continue to evolve as technology does and that the United States will eventually adopt a broad-reaching information security and privacy law, similar to the European Union's Data Privacy Directive of 1995.

We also expect to see an increase in the already heightened public awareness of security and privacy issues. As consumers become more familiar with the present and future laws and regulations protecting the privacy and security of their personal data, we will see an increase in judicial activity on these issues. The courts will be used to test the existing enforcement provisions of information security laws in actions brought by the government and we will also likely see civil liability cases brought by private individuals, individually or as members of a class, seeking damages for negligent activity. This heightened awareness will serve a greater purpose – it will provide the stimulus necessary to bring information security reform to the forefront of industry.

CONCLUSION

It is important to reiterate that this article presents a snapshot in time of a rapidly changing landscape of information security laws. In addition to the laws presented in this section, a variety of other federal laws impact information security decisions. Further, there are a myriad of state, local and international laws that govern information security controls. In addition, private contractual relationships, such as PCI DSS, often impose specific information security requirements on individual business relationships or broad industries.

Information security is a rapidly developing field and the body of law regulating related activities is evolving with each development. The four-tier taxonomy presented in this article serves as a framework for understanding the context of existing and future information security laws.

KEY TERMS

Computer-Focused Crime Laws: Involve criminal acts where the use of a computer is intrinsic to the crime.

Computer-Related Crime Laws: Involve the use of a computer but where the criminal activity is not defined by the use of a computer.

Copyright: Protects any original work of authorship from unauthorized duplication or distribution.

Industry-Specific Laws: Protect the confidentiality, integrity and/or availability of personal information maintained by specific industries.

Intellectual Property Laws: Protect the rights of authors, inventors and creators of other intellectual works.

Patents: Grant exclusive use rights to the creators of inventions, processes and designs.

Trademark Law: Protects words, phrases and designs that identify the products or services of a firm.

Trade Secrets: Include any information that derives independent economic value, actual or potential, from not being generally known to, and not being readily ascertainable by proper means by the public and is the subject of reasonable measures to keep such information secret.

Ubiquitous Computing and Communication for Product Monitoring

Rinaldo C. Michelini
University of Genova, Italy

Roberto P. Razzoli
University of Genova, Italy

INTRODUCTION

The present discussion summarises the benefits provided with resort to IT instruments, by dealing with the delivery of *extended* artefacts, under the responsibility of *extended* enterprises. In view to establish the IT environment, one needs to address the market paradigm-shift, from earlier commodity- to mainly utility-based economics, having supply chains concerned by *products-services*, where the latter delivering often outruns the former. Outstripping the pertinent material flows, effectiveness quickly turns on the information flows, supported by networked organisations and cooperative set-ups, with mainly, a twofold outcome: (1) value added in totally new provisions, enhancing the supply effectiveness; (2) value added to the joined information and related transparency of overall environmental impact.

Ambient intelligence is technology-driven opportunity based on the user friendly exploitation of ubiquitous computing and communication (Riva, Vatalaro, Davide, & Alcañiz, 2005; Stephanidis, 2001; VanLoenen, 2003). Turning ambient intelligence toward collaboration activities and eco-compatibility certifying duties could be the winning option to support enterprise competitiveness, privacy protection and eco-system safeguard through cooperative organisations. The involved IT aids basically will move from the existing World Wide Web capabilities, enhancing the *extended* enterprise, with the qualifying functions of service engineering, and fitting out the on-duty incumbents by users' adaptive interfaces.

BACKGROUND

The IT options grant new prospects, as for manufacturing and market organisation, leading to new traded items, *products-services* or *extended* artefacts, by means of new industrial set-ups, the *networked* facilities. Indeed, the recalled concepts lead to address the ambient intelligence and the supporting IT processing Web options for enterprise cooperation and business deployment according to an innovative scenario to grant competitive advantage of richer or enhanced delivery with lifecycle transparent eco-conservativeness. This scenario corresponds to a shared vision aiming at development sustainability based on key aspects (Figure 1) where product on-duty properties and enterprise point-of-service responsibility are transparently reported, assuring the eco-impact data management under third-party certification.

The information set-up consistent with the sketched scenario faces two conditioning lines:

- technical feasibility incumbents, which can be dealt with by suitably implemented IC innovative aids;

Figure 1. Key aspects of the information frame for sustainability

• ***extended enterprise co-operative environment***, the net concerns operate with unified responsibilities, under headquarters ruling the traded provisions on their lifelong span;
• ***product-service unified data-frame***, the delivery of ***extended*** artifacts is primary achievement, and on-duty visibility is basic knowledge, to keep conformance-to-specification levels;
• ***total connectedness***, all authorized stakeholders are linked by communication infrastructures that deliver the right data at the right time, according to their permit and priority labels;
• ***supply-chain transparent reporting***, business productivity gives account, out of finance and lobar factors, also technology and natural resources (e.g., by the ***KILT*** model);
• ***eco-impact data management***, the entropy trend is monitored on the ***extended*** artefacts span, and assessed by acknowledged standards (e.g., the ***TYPUS*** metrics);
• ***third-party certification data-vaulting***, accredited bodies oversee downgrading on the ***extended*** artefacts, lifecycle, and charge consumers for the net natural capital depletion.

- politico-legal and socio-economical hindrances, which will evolve with sustainability consciousness.

Along the first line, the technical literature (Abowd, 2004; Ailisto, Kotila, & Strömmer, 2003; Ameri &Dutta,2004; Dekker & Scarf, 1998; Garetti, 2004; Michelini &Kovacs, 2005), deals with the networked infrastructure technology, namely, the IT aids that need be added to the supply chain for lifecycle management. These are enabling support of product data visibility and eco-consistency assessment, once politico-legal and socio-economical pertinent rules are established. The coherent description of the product impact, over the operation horizon, including reverse logistics, needs address the consumable decay, explicitly making account of involved natural resources.

The approach leads, for instance, to the *KILT* model (Michelini, Acaccia, Callegari, Molfino, & Razzoli, 1999; Michelini & Razzoli, 2004a, 2004b) linking the delivery, ***Q***, of the manufacture activity to the four inputs corresponding to all contributed capitals, say:

- ***K***, *know-how* or *technical capital*, the knowledge and technology exploited in manufacturing,
- ***I***, *invested financial capital*, traditional driving input of earlier industrial economical set-ups,
- ***L***, *directly engaged labour*, conventional work-force counterpart of industrial organisations,
- ***T***, *natural capital*, actually consumed tangibles to support the whole actual supply chain.

Return on invested capitals is built on all factors, and fair competition requires *equal opportunity* players, compelled:

- to bring out the dependence on tangible resources consumption ***T***, when pricing items;
- to equitably remunerate the direct labour ***L***, along the product-service supply-chain, dismissal included;
- to repay the fixed assets ***I***, for the share- and stake-holders profits;
- to exploit the underlying knowledge ***K***, both enterprise solid practice or non-proprietary technologies.

COOPERATIVE ORGANISATION FOR LIFE-LONG SERVICE

The earlier outlined scenario is consistent with new supply chains, delivering *products-services* supported by cooperating organisations. The changes open new business paradigms, based on product lifecycle management (Ameri & Dutta, 2004) and service engineering, embedding high-intensity information flow with intangibles value added and enhanced transparency of natural capital exploitation. These paradigms (Figure 2) encompass three layers: the business *networked concern*, the *extended* artefacts delivery layout, and the *certified visibility* set-up; the IT tools differ, as the horizons broaden, to include clients and controllers.

The manufacturer business concern has to deal with all layers, especially today, as the supplier responsibility expands to cover lifecycle conformance-to-specification prerequisites and dismissal requirements out of the *point-of-sale*. The *point-of-service* tasks address items operation properties on two facts: on-duty reliability for users' satisfaction and eco-impact control for environmental protection. This leads to widely expanding the domain of intervention of existing corporations with new tasks out of traditional workshops based on competencies up until new not dealt with, and mostly covered by providers timely taken in by users after the *point-of-sale*. The social interest of third parties, in environment protection and natural capital preservation, is new fact, entitling governmental regulations explicitly involving who conceives and brings out the traded goods. Then, the efficient answer brings to *extended* enterprises with the new business paradigms of *product-service* delivering.

Thereafter, the *service engineering* (SE) will appear as challenging duty, linked to the design steps by the *product-lifecycle-management* (PLM) for accessing the technical sheets for *point-of-service* and *point-of-dismissal* tasks.

Figure 2. Collaborative networks for lifecycle visibility

- The networked organization, granting the information service for customers, is required:
  - # to provide collaborative forms and behaviors for product life-cycle management;
  - # to rule conformance assessment and restoration within networked responsible bodies.
- The *extended* enterprise profits of a networked organization to expand buyers satisfaction:
  - co-operative design and shared knowledge make multi-technology *extended* artifacts possible;
  - lifecycle data pricing becomes relevant and *new* competition feature between companies.
- The sustainability assures *fair* trade conditions, provided that networks are available, in order:
  - to employ objective, world wide referenced, metrological standards (e.g., *TYPUS* metrics);
  - to record the artifact lifecycle behavior, controlled by independent certifying bodies.

Figure 3. Crafty techniques to improve the eco-conservativeness

Expansion of the artifacts on-duty availability, by *monitoring* maintenance options, through:
- *reactive mode*: at the failure diagnosis, the process self-ruling is started, enabling the up-keeping and repairing schedules;
- *proactive mode*: at the deviation from nominal conditions, the procedures for process regulation and duty fixing are accomplished.

Protraction of the artifacts operation life, after renovation or revision deeds:
- to re-vamp: the recovery of consistent functional state, by proper renovation and updating of every critical modules, according to enacted bylaws;
- to re-integrate: the restoration to the original state, by full revision and (possible) replacement of every defective modules.

SE distinguishes from PLM when the service providers are independent partners, and the supply refers to shared responsibilities; the two practices bear similar database, conception, planning, and implementation with emphasis on applied maintenance and restoring options (Figure 3) to achieve function reliability while improving eco-conservativeness. The present discussion is specifically turned on the IT aids, as these are enabling technologies of the prospected business paradigms shif, by means of innovative options such as ambient intelligence.

The ambient intelligence (AmI) shows how IT tools can be incorporated as invisible witness of people life, so that social interaction and product functionality will move foreground for further use. The AmI concept leads to cooperative settings, where entities communicate to each other. These entities can be humans, artificial agents, Web/grid services, virtual-objects representing real things (not only human beings), descriptions of human knowledge (knowledge-based systems), and so forth; the whole layout (Figure 4) leverages the full potentiality of net-centric facilities, for creativity improvement boosting innovative duties. The options support people to experience interaction with human and artificial agents in their working environments; they are basic help to grant lifecycle transparency by SE tasks routines for eco-conservativeness duties. By *ubiquitous computing*, the effective, pleasant, and unobtrusive presence of computing devices everywhere is supplied; by *ubiquitous communication*, the everywhere access to network and computing facilities is provided; by *intelligent user adaptive interfaces*, the perception of remaining in a natural world is preserved as the facility automatically adapts to the human preferences. The options are important when trying to understand the implications that AmI has on the world we live in, notably due to the ability of giving visibility of our current behavior.

The AmI potentials are in the invisible support of flexible and natural communication with other users or computers providing input and perceiving feedback by utilising indifferently all senses and communication channels. The *ubiquitous computing* aims at invisibly and unobtrusively means to free people from tedious routine jobs. In its final form, the concept leads to a computing device, which, when moving with the user, incrementally builds dynamic models of the changing environment and configures its services accordingly;

Figure 4. Ambient intelligence for real life monitoring

Ambient intelligence, AmI: convergence of ubiquitous computing and ubiquitous communication, with duty-driven interfaces, adapting to the users. Three facts deserve explanations:
ambient - the concept assumes the ability of *existing* or *be present on all sides*;
ubiquitous - it assumes that something exists *everywhere*, *at the same time*, *on a steady level*;
natural perception - it involves self-adaptation, to match *real-life conditions*.

The *ambient intelligence*, AmI, incorporates properties of:
• mobile (nomadic) computing, by multiple-function devices and remote interaction capabilities;
• distributed interactivity, to enable communication by invisible processing computer resources;
• self-adaptive multi-mode configuration, to deal with the current human behavioral habits.

Ubiquitous computing is roughly the opposite of virtual reality. Where virtual reality puts people inside a computer-generated world, ubiquitous computing forces the equipment to operate in the real world, automatically adapting with the people preferences.

it is able either to remember past patterns or proactively build up new ones. The *ubiquitous communication* is major change, promoting data transfer and allowing to integrate new modules like sensors or diagnosis modules by natural procedures. Distributed agents and wireless networking are enabling technologies by sensing-driven modules grouped into proper categories, say: visual recognition and output (e.g. face 3D gesture/location); sound-recognition and -output (e.g., speech, melody); scent recognition and output; tactile-recognition and output; other sensor technologies. By *profiling*, the ambient has the ability to personalise and automatically adapt itself, to any particular user behavioral patterns. Major importance is given to *natural-feeling* human and to multi-mode interfaces. Humans speak, gesture, touch, sense, and write in their interactions with other humans and with the physical world. The idea is that these *natural* actions are used as explicit or implicit input to AmI systems. The AmI services split on two-fold incumbents:

- to support restoring and maintenance duties for clients' satisfaction of the delivered *product-service*;
- to help data collection and vaulting for tangibles consumption assessment and certification.

All technical sides of the collaborative networked organisations are met by ambient intelligence. The links binding the three-parties net-concern where the eco-protection is dealt with (Figure 5) help explaining in which frames the ambient intelligence will represent the enabling innovation. Indeed, AmI provides the effective work-environment to maintenance technicians (Arnaiz, Arana, Maurtua, & Susperregi, 2004; Dekker & Scarf, 1998; Gross & Fleisch, 2004), giving access to ubiquitous and up-to-date views of the ongoing operations wherever the equipment or the operator is (enabling remote maintenance and lifecycle management) by user friendly and intelligent interfaces (running context-aware data acquisition).

When looking at *product-service* monitoring on the life-long span, one realises that implementing the AmI concepts will drastically change the SE environments. The *ubiquitous* property integrates into a unified scheme the different processes combining (human and virtual) entities leading to a product-oriented dynamic infrastructure. Benefits are: concentrating information on delivery; creating service-oriented bent for all steps in the lifecycle; performing supply chain information updates in real-time and in intelligent ways; promoting information sharing with easier access and management of operation data; enabling products to carry and to process information which affect their destiny; and the likes. The resort to full AmI vision will require developing large, sophisticated, heterogeneous, distributed systems built on flexible platforms capable of providing seamless networking to support the provision of value-added services to industry, individuals, and administrations. The resulting layouts covering several interacting embedded components will need to be ubiquitous, self-configuring, self-healing, self-protective, and self-managed; it will lead to appearance of new type of services: the AmI services.

Up until now, the *extended enterprise* concept has mostly been explored to foster a business architecture, and the inclusion of the *extended artefact* lifecycle service is considered as wily advantage in front of competitors. If manufacturers' responsibility would expand at the *point-of-service*, and, further, at the *point-of-dismissal*, the new scenario establishes requiring totally different organisations: the goods conformance assessment, out-of-client satisfaction, becomes legal prerequisite with connected prescriptions for the environment protection. The involvement of third party certifying bodies (Figure 6) is an obvious issue requiring proper upgrading of the networked infrastructure to grant the different, specialised accesses. Of course, the eco-conservativeness incumbents are even more important. To that purpose, the networked infrastructure shall assure varying topology link

Figure 5. The collaborative networks for sustainability

The collaborative infrastructure requires the interlinked participation of:

- **purveyors**, covering the entire *supply-chain*: materials provision, items manufacture, life-cycle upkeeping, backward recovery; the ecological responsibility is dealt with by clustering several firms within a factural alliance of co-operating multi-sectional interests businesses;
- **users**, purchasing *extended* artifacts (*products-services*), to profit of the delivered functions with reliability figure close to one; the payments shall include conformance certification at the point of service, after tax collection agaisnt tangibles depletion;
- **supervisors**, assuring *third party* incumbents for (today and tomorrow) environment and society protection; the certifying bodies report to govenmental authorities and use objective standards,

having access to the *extended* artifacts life-cycle databases.

The transparency of the environment impact is achieved by continuous monitoring and recording the actual running conditions, both, of the *forward* and the *backward* cycle.

The governmental agencies collect the charges for the net consumed tanbibles, following assessments of the authorized certifying bodies.

Figure 6. The third party certifying service

The third party certifying body operates:
• interacting with the collaborative network support, established by the extended enterprise to manage the extended artifact administration, with full visibility on the lifecycle data and proper security restrictions;
• verifying the monitoring and control network integrity, and providing conformance assessment records by progression statements, as partial estimates for T factor refunds, based on the TYPUS metrics;
• overseeing the extended enterprise accomplishments in terms of eco-charges payments, accounting progress balances, based on unified responsibility established by the two consumers parties indentation;
• guaranteeing data vault and privacy protection, with proper specifications in the case the certifying duty is transferred to a different body and/or the joint consumers parties modify the binding contracts;
• operating within an accreditation scheme, notified to national (government) authorities and international organizations, having worldwide acknowledgment.

The involvement of third party certifying bodies needs, of course, proper regulations, enacted by the national authorities, but suitably harmonized to assure worldwide equivalence.

between users and certifying bodies by friendly layouts not requiring on-process experts. Now, AmI provides all useful prerequisites: intelligent resource management; distributed knowledge with multi-layer computing; hierarchical access with priority assignment; automatic *profiling* and interface adaptation; no communication/computation programming requests, and so forth. Thus, we need to address:

- the management of the *extended* artefacts assuring effective servicing by *ambient intelligence*; and
- the full enabling of the *extended* enterprise with integration of collaborative communication.

The two facts need to be analysed on their technological feasibility and on their eco-benefits. The potentialities of any innovation are not fully exploited unless the enabling surrounding appears as the driving requirement supported by IT tools. In these conditions, the technology-driven options, such as AmI, become standard requisites for service-engineering, assuring effectiveness to *extended* artefacts provision, and powerful support for the supply chain monitoring under unified responsibilities with the specific charges on assessing the net resources consumption and environment impact.

FUTURE TRENDS

On longer terms, new means to create tangible resources to need be envisaged joining to better exploitation of material processes (the reverse logistics of *backward* cycle factories), possibly novel (***K***-driven) *technical* capital. In fact, the *knowledge* society by itself does not modify the entropy laws of the physical world; it simply widens the value-chain patterns adding high-intensity information. On earth, bio-processes only seem to violate this decay, and such technologies could promote regenerative trends with restoration of original assets and remediation of downgraded sites (by bio-mimetic industries). The scenario is taken with caution, as bio-manipulation is associated to Frankenstein's myth and the ubiquitous knowledge society with full monitoring of on-progress developments is a reasonable option to relax anxieties.

CONCLUSION

The turning of *ambient intelligence* toward collaboration duties and eco-compatibility certifying activities is explored as basic option, to join enterprise competitiveness, privacy protection, and eco-system safeguard through ubiquitous computing and communication. The facilities supported by collaborative infrastructures are analysed with focus on the transparency of consumable decay (by appropriate metrics) over the supply chain lifecycle horizon, dismissal, and reverse-logistics included (Dekker, Fleischmann, Inderfurth, & Van Wassenhove, 2004). The discussed IT options are consistent with the scenario describing the manufacturing activity by the *KILT* model; they grant novel paradigms as for business deployment and enterprise organisation leading to new traded items, *products-services* (or *extended* artefacts), by means of new industrial facilities, the *networked* companies; they assure a very effective surroundings to enable quantitative assessments aimed at monitoring and recording tangibles net yield along any material supply chains.

The presentation equivalently addresses *point-of-service* and *point-of-dismissal* incumbents, as both are considered for their falls-off in the material flows, when environment impact is dealt with. The IT networked options are developed

to fully exploit enterprise cooperation and to foster business deployment by means of the competitive advantage of *products-services* delivery with lifecycle transparent eco-consistency. When *point-of-service* incumbents are dealt with, useful practices are found by enhancing reliability by condition monitoring maintenance (Michelini, Crenna, & Rossi, 2001) and by expanding on-duty life by re-vamping and re-integration; when *point-of-dismissal* incumbents are considered, the very intriguing aspects of reverse logistics appear, which require deep understanding of the overall processes to weigh the ecological-return conservativeness, even when the economical-return is granted due to the enacted by-laws. In such context, the pervasive visibility on the supply chain progression provided by *ambient intelligence* is a powerful instrument to help selecting the legal setting for worldwide effectiveness.

KEY TERMS

Ambient Intelligence (AmI): is the convergence of ubiquitous computing, ubiquitous communication, and interfaces adapting to the user; it relies on provisioning *ubiquitous* computing (i.e., useful and unobtrusive presence of computing devices everywhere).

Condition Monitoring Maintenance (CMM): The maintenance intervention applies once the product state is recognised; it needs support of special diagnostics and prognosis tools and sophisticated knowledge-based systems.

Extended Artefact or Product-Service: Any supply joining manufactured commodities and enabling utilities. *Artefact*: any object made by man, especially with a view of subsequent use; something made with skill.

Interoperability: The ability of two or more systems, subsystems, products, or applications to work together and/or share information or inputs and outputs.

Lifecycle: The collective set of phases a product or system may go through during its lifetime (e.g., concept definition, development, production, operation and support, dismissal, decommissioning, and disposal).

Natural Language: Ordinary human language; unlike precisely defined computer languages, it is often ambiguous and is thus interpreted differently by different hearers.

Net Concern or Extended Enterprise: A group of companies that work together and act as a single business entity to satisfy a particular set of customer needs.

Product Lifecycle Management, PLM: The process of, or a system for, managing all data about a product as it moves through the all lifecycle, from materials provision, to on-duty requirements and dismissal.

Service Engineering, SE: The activity that deals with improving the design process of the service, supplied with the extended artefacts, developing and implementing the duties, which assure maintenance, restoring and conformance assessment on the lifecycle.

Underwater Wireless Networking Techniques

INTRODUCTION

Underwater sound has probably been used by marine specimens for millions of years as a communication capability among the members of a same species. It is said that in 1490, Leonardo Da Vinci wrote the following sentence: "If you cause your ship to stop and place the head of a long tube in the water and place the outer extremity to your ear, you will hear ships at a great distance from you" (Urick, 1983); being perhaps the first recorded experiments about hearing underwater sounds.

In 1826 on Lake Geneva, Switzerland, the physicist Jean-Daniel Colladon, and his mathematician friend Charles-Francois Sturm, made the first recorded attempt to determine the speed of sound in water. In their experiment, the underwater bell was struck simultaneously with ignition of gunpowder on the first boat. The sound of the bell and flash from the gunpowder were observed 10-miles away on the second boat. The time between the gunpowder flash and the sound reaching the second boat was used to calculate the speed of sound in water. Colladon and Sturm were able to determine the speed of sound in water fairly accurately with this method. (Colladon, 1893).

This experiment on sound propagation through water laid the foundation for underwater acoustic technology, which paved the way for the development of this technology up to our days. In 1906, Lewis Nixon invented the very first sonar-type listening device, increasing the demand of this technology during World War I to detect submarines. In 1915, the physicist Paul Langévin and the engineer Constantine Chilowski, invented the first sonar-type device for detecting submarines, called an "echo location to detect submarines," using the piezoelectric properties of the quartz. He was too late to offer any help to the war effort; however, Langévin's work heavily influenced future sonar designs.

After using underwater sound technology for measuring the proximity to the shore and other ships, researchers soon realized that, if the sound device was pointed down at the seafloor, the depth could be accurately determined. So, new applications of sonar devices were discovered, like active depth measuring (bathymetry), seafloor shape registering, search for geological resources (i.e., oil, gas, etc.), detecting and tracking fish banks, submarine archaeology, and so forth.

Although the underwater acoustic applications were mainly focused in ranging applications, exploration of seafloor and fishery by means of sonar devices, the interest in underwater multipoint communications was stressed in the 1990's, where synoptic, spatially sampled oceanographic surveillance has provided an impetus to the transfer of networked communication technology to the underwater environment. One of the former deployments was the autonomous oceanographic surveillance network (AOSN), supported by the US Office of Naval Research (ONR) (Curtin, Bellingham, Catipovic, & Webb, 1993). It calls for a system of moorings, surface buoys, underwater sensor nodes, and autonomous underwater vehicles (AUVs) to coordinate their sampling via an acoustic telemetry network.

BACKGROUND

Wireless networking technologies have experienced a considerable development in the last 15 years, not only in the standardization areas, but also in the market deployment of a bunch of devices, services, and applications. Among this plethora of wireless products, wireless sensor networks are exhibiting an incredible boom, being one of the technological areas with greater scientific and industrial development pace (Akyildiz, Sankarasubramaniam, & Cayirci, 2002). The interest and opportunity in working on wireless sensor network technologies is endorsed by (a) technological indicators like the ones published by MIT (Massachusetts Institute of Technology) in 2003 (van der Werff, 2003),

where wireless sensor network technology was defined as one of the 10 technologies that will change the world, and (b) economic and market forecasts published by different economic magazines like (Rosenbush, Crockett, & Yang, 2004), where investment in wireless sensor network (WSN) ZigBee technology was estimated over 3.500 nillion dollars during 2007.

Recently, wireless sensor networks have been proposed for their deployment in underwater environments, where a lot of applications like aquiculture, pollution monitoring, offshore exploration, and so forth, would benefit from this technology (Cui, Kong, Gerla, & Zhou, 2006).

Despite having a very similar functionality, underwater wireless sensor networks (UWSNs) exhibit several architectural differences, with respect to the terrestrial ones, that are mainly due to the transmission medium characteristics (sea water) and the signal employed to transmit data (acoustic ultrasound signals) (Akyildiz, Pompili, & Melodia, 2006). Then, the design of appropriate network architecture for UWSNs is seriously hardened by the conditions of the communication system and, as a consequence, what is valid for terrestrial WSNs is perhaps not valid for UWSNs. So, a general review of the overall network architecture is required in order to supply an appropriate network service for the demanding applications in such an unfriendly submarine communication environment.

Major challenges in the design of underwater acoustic networks are:

- Battery power is limited and usually batteries can not be recharged because solar energy cannot be exploited;
- The available bandwidth is severely limited;
- The channel suffers from long and variable propagation delays, multipath and fading problems;
- Bit error rates are typically very high;
- Underwater sensors are prone to frequent failures because of fouling, corrosion, and so forth.

In the next section, we discuss the main issues in the design of efficient underwater wireless sensor networks. Following a bottom-to-top approach, we will review the network architecture, highlighting some critical design parameters at each of the different network layers, and how to overcome the limitations and problems introduced by UWSN environments.

UNDERWATER WIRELESS NETWORKING TECHNOLOGIES

Basically, a UWSN is formed by the cooperation among several nodes that establish and maintain a network through the use of bidirectional acoustic links. Every node is able to send/receive messages from/to other nodes in the network, and also to forward messages to remote destinations in case of multihop networks. Every node may have one or several sensors that are actively recording environmental data that should be forwarded to special sink nodes, typically platforms or buoys at the surface. Sink nodes have communication channels to forward and/or locally store the collected data to the remote control station in the coast, typically through a radio frequency (RF) link.

So, the UWSN allows an interactive environment where scientists can extract real-time data from multiple distant underwater sensor instruments. After evaluating the obtained data, control messages can be sent to individual network nodes so the overall network can be adapted to changing situations.

Topology

In Partan, Kurose, and Levine (2006), taxonomy of UWSN regimes is proposed. They classify different UWSNs in terms of both spatial coverage and node density. For every kind of network topology, different architectural approaches have to be considered in order to improve the network performance (throughput, delay, power consumption, packet loss, etc.). So, it is important to design the network architecture taking into account the intended network topology.

Physical Layer: Acoustic Link

The most common way to send data in underwater environments is by means of acoustic signals, just like dolphins and whales use to do for communicating between them. Radio frequency signals have serious problems to propagate in sea water, as shown in Schill, Zimmer, and Trumpf (2004), being operative for radio-frequency only at very short ranges (up to 10 meters) and with low-bandwidth modems (tens of Kbps).When using optical signals, the light is strongly scattered and absorbed underwater, so only in very clear water conditions (often very deep) does the range go up to 100 meters with high bandwidth modems (several Mbps) and blue-green wavelengths.

Since acoustic signals are mainly used in UWSNs, it is necessary to take into account the main aspects involved in the propagation of acoustic signals in underwater environments, including (1) the propagation speed of sound underwater is around 1,500 m/s (5 orders of magnitude slower than the speed of light), and so the communication links will suffer from large and variable propagation delays and relatively large motion-induced Doppler effects; (2) phase and magnitude fluctuations lead to higher bit error rates compared with radio channels' behaviour, being mandatory the use of forward error correction codes (FEC); (3) as frequency increases, the attenuation observed in the acoustic channel

also increases, this being a serious bandwidth constraint; (4) multipath interference in underwater acoustic communications is severe due mainly to the surface waves or vessel activity, being a serious problem to attain good bandwidth efficiency. Several approaches were taken to combat multipath effects, being the use of multiple-input multiple-output (MIMO) transducer arrays (Freitag, Stojanovic, Singh, & Johnson, 2001), a good solution for reducing multipath effects and therefore increasing the link throughput.

Several works in the literature propose models for an acoustic underwater link, taking into account environmental parameters, such as salinity degree, temperature, depth, environmental interference, and so forth. In Harris and Zorzi (2007), you will find a clear description of the different issues that take part in the development of an acoustic channel model.

Medium Access Control (MAC) Layer

The main task of MAC protocols is to provide efficient and reliable access to the shared physical medium in terms of throughput, delay, error rates, and energy consumption. However, due to the different nature of the underwater environment, there are several drawbacks with respect to the suitability of the existing terrestrial MAC solutions for the underwater environment. In fact, channel access control in UWSNs poses additional challenges, due to the aforementioned peculiarities of underwater channels.

As shown in Akyildiz et al. (2006), existing MAC solutions are mainly focused on carrier sense multiple access (CSMA) or code division multiple access (CDMA). However, frequency division multiple access (FDMA) is not suitable for UWSNs due to the narrow bandwidth available in underwater acoustic channels, and the vulnerability of limited band systems to fading and multipath effects. Moreover, time division multiple access (TDMA) shows limited bandwidth efficiency because of the long time guards required in the underwater acoustic channel. Furthermore, the variable delay makes it very challenging to achieve a precise synchronization through a common timing reference.

CSMA Based

In general, CSMA-based protocols are vulnerable to both hidden and exposed terminal problems (Karl & Willig, 2005). In order to reduce the effects of hidden terminals, MAC proposals should include techniques similar to the ones used in terrestrial networks like MACA (Karn, 1990), which uses RTS/CTS/DATA packets to reduce the hidden terminal problem, and MACAW (Bharghavan, Demers, Shenker, & Zhang, 1994), which adds to the previous one an ACK packet at the link-layer, which can be helpful in an unreliable underwater channel. FAMA (Fullmer & Luna-Acebes, 1995) extends the duration of RTS and CTS packets in order to avoid data packet collisions, and so, contention is managed at both sender and receiver sides before sending data packets. The efficiency of these protocols is heavily impacted by propagation delays due to their multiple handshakes.

A number of adaptations have been proposed to adopt MACA, MACAW, and FAMA for underwater networks. In Molins & Stojanovic (2006), there was proposed the slotted FAMA approach, adding timeslots to the FAMA protocol to limit the impact of propagation delays. Kebkal, Kebkal, and Komar (2005) proposed a means to reduce the impact of propagation delay on FAMA- and MACAW-based protocols, with ACK and DATA packets simultaneously in flight. They also suggest an extension to FAMA, using CDMA for the RTS packets, to develop a collision-free FAMA protocol.

CDMA Based

CDMA is a contention-free multiple-access method that is promising for future underwater networks. In fact, CDMA is robust to frequency selective fading caused by multipath, since it is able to distinguish among signals simultaneously transmitted by multiple devices through codes that spread the user signal over the entire available band.

In Freitag et al. (2001), two code-division spread-spectrum physical-layer techniques for underwater communications in shallow water are compared, namely direct sequence spread spectrum (DSSS) and frequency hopping spread spectrum (FHSS). In the case of DSSS, limitations in temporal coherence of the channel affect the maximum spreading factor, leading to situations that may be better suited to FHSS signals. Conversely, the multipath resolving properties of DSSS minimize the effects of frequency-selective fading that degrade the performance of FSK modulation in FHSS systems.

More recently, Stojanovic and Freigtag (2006) reported very promising CDMA experimental results. An important caveat for this work, however, is that the received power for each of the users should be similar. If the received power for all users is not roughly similar, signals from distant users cannot be received successfully. This is known as the near-far problem, and requires the transmit power of each user to be controlled when switching the channel.

In Pompili, Melodia, and Akyildiz (2007) the authors propose a distributed medium access control (MAC) protocol called UW-MAC. It defines a transmitter-based CDMA scheme that incorporates a novel closed-loop distributed algorithm to set the optimal transmit power and code length to minimize the near-far effect. It compensates for the effect of multipath by exploiting the time diversity in the underwater channel, thus, achieving high channel reuse and a low number of packet retransmissions.

Network Layer

This layer is mainly responsible of routing packets to the proper destinations. So, a routing protocol is required when a packet must go through several hops to reach its destination. It is responsible for finding a route for the packet and making sure it is forwarded through the appropriate path. The way paths are selected for every source-destination pair will have a direct impact on the overall network performance.

Most of the routing proposals for UWSN are based on the ones developed for terrestrial ad hoc and wireless sensor networks. An overview of the different approaches proposed in the literature can be found in Abolhasan, Wysocky, and Dutkiewicz (2004).

Nevertheless, as stated by Akyildiz et al. (2006), proactive and reactive routing protocols are not suitable for UWSNs. The former introduce large-signalling packet exchanges every time the network changes, so that each network node knows the path to the rest of nodes. Concerning the latter, reactive routing protocols, these require a source-initiated flooding of control packets to establish the path(s), and so the latency to establish the path is usually high, being further amplified in the underwater environment due to the slow propagation of acoustic signals.

Therefore, it seems that geographical routing protocols are the most promising approaches for their use in UWSNs. However, the GPS (global positioning system) radio receivers (around 1.5 GHz band) do not work properly in underwater environments, as explained before. There are some works related to underwater localization, also required for AUV navigation systems, and the need of mapping sensor data with spatial localization becomes evident, representing an open problem that requires further research. So, in the following, we will briefly describe several examples of routing protocols especially devoted to underwater sensor network scenarios. Most of the proposals take into account the energy consumption constraint.

In Xie and Gibson (2001), a routing protocol for UWSNs is proposed, being able to initialize the network topology and work in a centralized manner at the surface station (typically the sink node). The paths to the sink are established by the central manager avoiding congestion, introducing quality of service (QoS) support, and managing the overall network energy consumption; it operates in a similar fashion to the point coordination function (PCF) of IEEE 802.11 networks.

Another proposal can be found in Xie, Cui, and Lao (2006), where a routing protocol called vector-based forwarding (VBF) is described. With VBF, each packet carries the positions of the sender, the destination, and the forwarder. Packets are forwarded along redundant and interleaved paths (routing pipes) from a source to a destination node, being robust against packet loss and node failure. Jointly with the routing strategy, a localized and distributed self-adaptation algorithm is proposed to enhance the performance of VBF. This algorithm allows the nodes to weigh the benefit of forwarding packets, reducing energy consumption by discarding low-benefit packets.

The solution proposed in Pompili et al. (Pompili, Melodia, & Akyildiz, 2006) relies on the use of virtual circuits that are established a priori between each source and sink. So, every packet associated with a particular connection follows the same path. This requires centralized coordination from a sink node (station usually located at the surface), and leads to a less flexible routing architecture. However, as other centralized proposals, it is able to exploit optimization tools in order to achieve optimal network layer performance with minimum signalling overhead. In order to increase the reliability of network due to potential node failures, the algorithm finds two paths, primary and backup virtual circuits, between every source-destination pair of nodes.

APPLICATIONS

As mentioned in the introduction, underwater sensor networks can enable a broad range of applications, following the same path as the terrestrial sensor networks. Therefore, we can use UWSN technology for

- *Ocean dampling networks*. Networks of sensors and AUVs with the ability to perform synoptic, cooperative adaptive sampling of the 3-D coastal ocean environment in order to build geology information databases.
- *Environmental monitoring*. UWSNs can perform pollution monitoring (chemical, biological, and nuclear), monitoring of ocean currents and winds, improved weather forecast, detecting climate changes, understanding and predicting the effect of human activities on marine ecosystems, and biological monitoring, such as tracking of marine biology activity or aquaculture industry.
- *Undersea explorations*. Underwater sensor networks can help at detecting underwater oilfields or reservoirs, determining routes for laying undersea cables, and assisting in the exploration for valuable minerals. Also, it can be used to find out wrecks, or as an invaluable tool for submarine archaeology.
- *Disaster prevention*. Sensor networks that measure seismic activity from remote locations can provide tsunami warnings to coastal areas, or study the effects of submarine earthquakes.
- *Assisted navigation*. Sensors can be used to identify hazards on the seabed, locate dangerous rocks or shoals in shallow waters, mooring positions, locating

submerged wrecks, and performing bathymetry profiling.

- *Distributed tactical surveillance.* AUVs and fixed underwater sensors can collaboratively monitor areas for surveillance, reconnaissance, targeting, and intrusion detection.

FUTURE TRENDS

Underwater sensor networks represent an emerging technology that needs a lot of research effort in the following years. The benefits that this technology would offer to maritime industry are invaluable. However, there are a lot of open issues that would require further research in the future.

More effort is required at the physical layer in order to develop efficient, low-power acoustic modems that are able to maximize the available bandwidth and minimize the delivery error rates by using proper FEC coders.

Currently, there are a lot of works related to MAC layer proposals, since this is one of the more sensible parts of the UWSN architecture. It seems that distributed CDMA-based schemes are the candidates for underwater environments, but it depends on many factors, such as the application and network topology. Also, MAC protocols should be designed taking energy consumption into account as a main design parameter.

With respect to routing protocols, they heavily depend on other design factors, such as network topology (even application requirements), node mobility patterns, and energy consumption. Up to now, geographically based routing algorithms seem to be the most adequate for UWSNs, despite requiring the use of localization schemes. Most of the research efforts should be applied to algorithms and protocols that detect and deal with disconnections due to failures, unforeseen mobility of nodes, or battery depletion. Due the underwater nature, cross-layer interaction between all layers should also be required, in order to make a better use of the available resources, and to be able to perform fast adaptations in such a continuously changing environment.

CONCLUSION

Underwater sensor networks are a very recent technology that tries to follow the same steps as terrestrial wireless networks in a very different and challenging network environment. There is an increasing interest in USWN technologies and their potential applications. However, there are several open issues to solve in order to provide an efficient and reliable data transport to the applications.

In years to come, it is expected that UWSNs technology is widely adopted by the industry, resulting in the deployment of new commercial products and solutions that will represent very important revenues to the maritime technology market.

KEY TERMS

AUVs (autonomous underwater vehicles): Those underwater vehicles able to navigate autonomously to collect sensor data in a specific control area. The most common use of these vehicles is related with the oil and gas industry, allowing one to obtain maps of the seafloor before starting to build the subsea infrastructure.

Direct Sequence Spread Spectrum (DSSS): A modulation technique where the data signal is multiplied by a pseudorandom binary sequence at a frequency much higher than that of the original signal, thereby spreading the energy of the original signal into a much wider band.

Frequency Hopping Spread Spectrum (FHSS): A modulation technique that can be described as a frequency modulation that is repeatedly changing the frequency of the carrier signal in the full available spectrum for transmission.

Hydrophone: A microphone designed to be used underwater for recording or listening to underwater sound. Most hydrophones are based on a piezoelectric transducer that generates electricity when subject to a pressure change.

MANETs (mobile ad hoc networks): Refer to those wireless networks composed of mobile nodes that can communicate between them without the need of any kind of infrastructure (base stations).

Point Coordination Function (PCF): A MAC protocol, used in wireless local area networks (WLANS), that relays a central coordinator, usually known as an access point (AP). The access to the medium is governed by APs unit allowing an ordered and collision-free access to the network.

Proactive and Reactive Routing Protocols: Represent two different styles of routing packets. The former ones maintain updated the routing info by periodically distributing routing info throughout the network. In contrast, a reactive routing protocol finds a route on demand by flooding the network with route request packets.

SONAR (sound navigation and ranging): A device that uses the properties of underwater sound propagation to communicate, navigate, or detect other vessels. It sends pulses of sound to probe the sea, and the echoes are then processed to extract information (shape, distance, composition, etc.) about the sea, its boundaries, and submerged objects.

WSNs (wireless sensor network): Can be defined as a particular case of MANETs in the sense that each node is required to record and wirelessly distribute environmental data obtained through a set of sensors attached to it. They are typically small and low-power consuming devices, and use to be deployed in high node density networks.

Underwriting Automobile Insurance Using Artificial Neural Networks

Fred Kitchens
Ball State University, USA

INTRODUCTION

As the heart of the insurance business, the underwriting function has remained basically unchanged for the past 400 years, since Lloyd's of London was a place where ship owners would seek out financial supporters. The two would contractually agree to share the financial risk in the unlucky event that the ship would be lost at sea (Gibb, 1972; Golding and King-Page, 1952).

In the modern insurance market, insurance underwriters perform a similar financial function on behalf of their respective insurance companies. Underwriters gather pertinent information and analyze their potential clients to determine whether or not they should underwrite the risk; and if so, what premium they would require for the insurance policy. Insurance companies employ actuaries to assist the underwriter in this process by studying past insurance losses and making predictive models for future risks. Using traditional statistical methods, insurance actuaries look for loss-contributing characteristics within the risk (Webb, Harrison, et al., 1992). When the actuaries find positive relationships between the policy characteristics and subsequent losses, they create "underwriting guidelines" for the underwriters to follow when analyzing potential clients and setting premiums (Malecki and Underwriters, 1986).

For hundreds of years, actuaries used pencil and paper to perform their statistical analysis It was a long time before they had the help of a mechanical adding machine. Only recently have they had the benefit of computers. As recently as 1981, computers were not considered important to the process of insurance underwriting. Leading experts in insurance underwriting believed that the judgment factor involved in the underwriting process was too complex for any computer to handle as effectively as a human underwriter (Holtom, 1981).

Recent research in the application of technology to the underwriting process has shown that Holtom's statement may no longer hold true (Gaunt, 1972; Kitchens, 2000; Rose, 1986). The time for computers to take on an important role in the insurance underwriting process may be upon us. The author intends to illustrate the applicability of artificial neural networks to the insurance underwriting process.

BACKGROUND

The American Institute for Chartered Property Casualty Underwriters (CPCU) reports that the most common considerations found in automobile underwriting guidelines are:

- age of operators;
- age and type of automobile;
- use of the automobile;
- operator's driving record;
- territory;
- gender;
- marital status;
- operator's occupation;
- operator's personal characteristics; and
- physical condition of the vehicle.

Traditionally, these comprise the core variables used in determining the acceptability, classifying, and rating of private passenger automobile insurance policies (Malecki and Underwriters, 1986).

Private passenger automobile insurance is well-suited for artificial intelligence applications applied to the underwriting function. There are three primary reasons for this:

- there is a fixed set of finite data used to make the underwriting decision;
- policies are highly standardized; and
- deviations from the standard insurance contract are rare.

In recent years, researchers have considered the application of computers to the process of automobile insurance underwriting. Two studies attempted to predict the acceptability of a given policy from a broad underwriting standpoint (Gaunt 1972; Rose 1986). Two other studies considered the possibility of predicting a loss on an individual-policy basis (Lemaire, 1985; Retzlaff-Roberts and Puelz, 1966). Another study focused the relationship between premium and customer retention from year-to-year. One study was designed to predict losses on individual policies using artificial neural networks (Kitchens, 2000).

The recent use of artificial neural networks represents what may result in the most accurate application of computers to the underwriting process. Originally developed in the 1940s, artificial neural networks were designed to replicate and study the thought process of the human brain (Cowan and Sharp, 1988). Early research showed that all processes that can be described with a finite number of symbolic expressions could be represented with a finite number of interconnected neurons (Wilson, Starkweather, et al., 1990). Thus, artificial neural networks also provide a means of economic problem solving.

The author believes that for a number of reasons discussed in the following section, artificial neural networks can be successfully applied to the insurance underwriting process in order to reduce the ratio of insurance losses to insurance premiums.

NEURAL NETWORKS FOR INSURANCE UNDERWRITING

Artificial neural networks were first developed in the 1940s as a mathematical model used to study the human thought process (Cowan and Sharp, 1988). In 1943, McCulloch and Pitts proved that all processes which can be described with a finite number of symbolic expressions can be represented in a network of interconnected neurons (Wilson, Starkweather, et al., 1990). This makes the artificial neural network a mathematical modeling tool in addition to a representation of the human brain.

Using a data set consisting of dependent and independent variables, an artificial neural network can be trained until it converges on an optimal solution for the dependent variable(s). If properly developed, the resulting model will be at least as accurate as traditional statistical models (White, 1989).

The insurance business, as practiced in the United States, has certain characteristics that produce less than optimal financial results. There are five basic reasons that the unique abilities of artificial neural networks can improve the underwriting process:

First, an artificial neural network model will be successful because the inequity of the current rate classification system will allow neural networks the opportunity to more accurately assess the risk level of each and every individual policyholder, rather than a class of policyholders (Wood, Lilly, et al., 1984).

Second, an artificial neural network model will produce improved results because current actuarial methods of study will benefit from the broad range of available tools, such as more recent developments in the field of artificial intelligence (Cummins and Derrig, 1993; Kitchens, 2000).

Third, an artificial neural network model will improve the current state of actuarial research. Traditionally, the primary method of research in this field has been to predict the *pure premium* (the amount of premium required to pay all of the losses in a given class of insured accounts, a.k.a. "relative rates"). In comparison, *actual premiums* include the pure premium along with other important factors such as profit margin and operating expenses. The traditionally used pure premium models follow an actuarial approach, but not necessarily an underwriting approach. While it is intended to reduce corporate loss ratios, current actuarial research does not take an underwriting approach to the process. A fresh perspective on the problem could produce improved results (Kitchens, Booker, et al., 2002).

Fourth, an artificial neural network will produce improved results because historically, statistical models used in predicting insurance losses have been able to produce only marginal incremental improvements. Given the current state of technology, the time has come for new insurance actuarial models to take advantage of the available speed and flexibility of artificial neural networks to solve what is clearly a complex problem, which will require extensive training and is likely to involve a complex architecture (Kitchens, 2000, 2004; Kitchens, Johnson, et al., 2001).

Fifth, even if the actuarial models are "perfect" (which the author contends they are not), the neural network should be capable of at least matching the current statistical results, if not improving upon them (Kitchens, Booker, et al., 2002). This is because artificial neural networks comprise a class of nonlinear statistical models whose processing methods are designed to simulate the functioning of the human brain (Hawley, Johnson, et al., 1990). The advantage of neural network models over other modeling methods grows with the complexity of the relationship between input and output variables; however, greater complexity of the underlying relationships between variables requires a more complex design (Lee, White, et al., 1993). Provided the appropriate network architecture, a neural network output function can accurately approximate any mathematical function (White, 1989). Further, a model can achieve any degree of desired accuracy if the neural network is properly designed (Funahashi, 1989).

NEURAL NETWORK MODELS: DESIGN ISSUES

Automobile accidents occur with a certain degree of randomness, and it is expected that they will be very difficult to predict on an individual-policy basis. Previous research has shown that an underwriter's ability to predict the actual value of a paid claim is exceedingly difficult, if possible at

all (Kitchens, Johnson, et al., 2001). However, a successful system needs only to predict the incident (occurrence) of a loss, not the dollar value. In addition, a successful model would not have to predict each and every accident, as long as the predictions that the model makes are accurate. In fact, a new model needs only to out-perform any current models in order to prove itself worthwhile. As an industry rule-of-thumb, the average loss-to-gross-premium ratio is approximately 60 percent. The rest of the collected premium is used to pay operating expenses and a small profit of approximately 3 percent (Kitchens, Jr., 1999). Thus, if a new model could reduce losses by 1 percent, it would represent a 33 percent increase in operating profit. If a corresponding decrease in operating expenses such as loss-adjustment expenses is incurred, the operating profit could be increased by as much as 53 percent. This in itself is not a justification for using artificial neural networks, but it is enough incentive to try nontraditional techniques.

As Data Mining and Knowledge Management grow in their importance to business, trade secrets grow as well. Description of new software such as *Risk Manager* by Valen Technologies has an uncanny resemblance to an artificial neural network. The company will not reveal the details behind their technology except to call it, "a predictive insurance underwriting software system" with "computational learning technology" (Stodder, 2005). While it is difficult, if not impossible, to say how much underwriting is currently performed by artificial neural networks, it is certainly a growing field. One prediction indicates that by 2009 as much as fifty percent of all insurance underwriting decisions will be automated using data mining technology (Betts, 2004). While it may be theoretically possible for a computer program to handle the underwriting function, the larger hurdles may be obtaining regulatory permission and gaining user acceptance of a non-human process. Aside from the highly regulated nature of the insurance industry, the human side must also be considered. In the 1970s and 1980s managers and regulators were reluctant to accept technology that made decisions for them. In the 1990s social acceptance started to turn. Two important features have lead the cause for acceptance. New applications do not require human intervention; the user is not required to "do" anything. And, new applications are configured to translate decisions into action (Davenport and Harris, 2005). A computer-based model that aids the underwriter in the decision-making process by suggesting an appropriate course of action is a step in the right direction. An artificial neural network as an underwriter's tool could be used in several ways: to help train new underwriters, to provide a suggested course of action, or to handle routine policies, allowing the underwriter to spend more time on more complex policies. As an underwriter's tool, a model should be useful, reliable, and convenient while providing information of value.

In the development of an artificial neural network model as an underwriter's tool, several things must be determined: the output required, the input variables, the type of artificial neural network, the architecture of the artificial neural network, and the interpretability of the output.

The underwriter's decision-making process boils down to two basic decisions. First, a decision must be made whether to accept or reject the risk. Second, if accepted, a decision as to the premium that will be charged.

Depending on the purpose of the model, the required output may place stringent requirements on the required input. One reason all previous models have had limitations on their applicability has been due to the lack of quantity or quality in the available data sets used to generate the model.

For purposes of insurance loss-prediction modeling, the Genetic Adaptive Neural Network Training (GANNT) algorithm is an appropriate choice. The GANNT algorithm is designed to overcome difficulties associated with the popular gradient and back propagation techniques (Dorsey and Mayer, 1994).

The genetic algorithm was first proposed in 1975 (Nygard, Ficek, et al., 1992). It was shown that the biological evolutionary process could be applied to an artificial mathematical modeling system (Konza, 1992). The concept is based on the theory that an optimization problem can be encoded as a list of concatenated parameters (nodal weights), which are used in the artificial neural network (Whitley, Starkweather, et al., 1990). The genetic algorithm works through a process of modeling founded on the biological process by which DNA replicates, reproduces, crosses over, and mutates (Crane, 1950). These procedures are then modeled in a computer-based algorithm to solve complex problems (Nygard, Ficek, et al., 1992). The actual operations of the genetic GANNT algorithm are explained in detail by Dorsey, Johnson, and Mayer (1991).

RESULTS

Recent research has shown that the automobile insurance underwriting process practiced in the United States is lacking in precision. Underwriters are not efficiently utilizing all of the information available to them. The current human-based underwriting process uses only a portion of the available information. In some cases, so much valuable information is overlooked that the remaining unutilized information can be used to make a more accurate accept/reject decision than the initial underwriter made (Kitchens, 2000,,2004). With the benefit of the flexibility and adaptability of an artificial neural network, the unutilized information may be used in the future to make more accurate and more precise underwriting decisions.

FUTURE TRENDS

Future research should be focused on two primary areas. First, to be properly trained, an artificial neural network requires data from both the "accepted" and the "unaccepted" policies. Thus, some effort needs to be focused on obtaining information about the policies that are currently being rejected by the underwriter. This is difficult information to obtain because insurance companies have no reason to track losses on policies they previously rejected. But this data will be valuable in the development of a more complete underwriting model.

Second, future research should go beyond the accept-or-reject decision and investigate the premium-setting decision. A model capable of second-guessing an underwriter's accept-or-reject decision might be capable of reducing an insurance company's losses. But a model that can both accept or reject and set the premium, might be capable of reducing the cost of underwriting, streamline the business process, and produce policies that are more appropriately priced. These are the loftier long-term goals (Davenport and Harris, 2005).

CONCLUSION

Since the process of insurance underwriting began 400 years ago, until recently the biological neural network (human brain) has been the fastest, most efficient, and most readily available information processing tool available. It has naturally been the tool of choice for underwriters when making accept-or-reject and pricing decisions on insurance policies.

In 1981, it was a common belief that computers could not be used to replace insurance underwriters (Holtom, 1981). In the past 20 years or so, computers and technology have made tremendous advancements. During the same time period, sophisticated mathematical models and the algorithms used to generate them, including the Genetic Adaptive Neural Network Training algorithm, have taken advantage of increased computing power and availability. Artificial neural networks and the technology used to run them have been shown to outperform the traditional human-based mental decision making practices, in both speed and accuracy, if only for limited domains and applications, such as insurance underwriting.

KEY TERMS

Actuary: A statistician who practices the collection and interpretation of numerical data, especially someone who uses statistics to calculate insurance premiums.

Artificial Neural Network: (commonly referred to as "neural network" or "neural net"**)** A computer architecture, implemented in either hardware or software, modeled after biological neural networks. Nodes are connected in a manner suggestive of connections between the biological neurons they represent. The resulting network "learns" through directed trial and error. Most neural networks have some sort of "training" algorithm to adjust the weights of connections between nodes on the basis of patterns found in sample or historical data.

Back Propagation: A learning algorithm for modifying a feed-forward neural network which minimizes a continuous "error function" or "objective function." Back propagation is a "gradient descent" method of training in that it uses gradient information to modify the network weights to decrease the value of the error function on subsequent tests of the inputs. Other gradient-based methods from numerical analysis can be used to train networks more efficiently.

Biological Neural Network: A network of neurons that function together to perform some function in the body such as thought, decision making, reflex, sensation, reaction, interpretation, behavior, etc.

Genetic Algorithm (GA): A class of algorithms commonly used for training neural networks. The process is modeled after the methods by which biological DNA are combined or mutated to breed new individuals. The crossover technique, whereby DNA reproduces itself by joining portions of each parent's DNA, is used to simulate a form of genetic-like breeding of alternative solutions. Representing the biological chromosomes found in DNA, genetic algorithms use arrays of data, representing various model solutions. Genetic algorithms are useful for multi-dimensional optimization problems in which the chromosome can encode the values for connections found in the artificial neural network.

Insurance: Protection against future loss. In exchange for a dollar value (premium), insurance is a promise of reimbursement in the case of loss. Contractual arrangement of insurance may be voluntarily or by government mandate

(such as minimum requirements for automobile insurance for licensed drivers).

Nodal Connections: Connections between nodes in an artificial neural network. They are communication channels that carry numeric data. They simulate the axons and dendrites used to carry electrical impulses between neurons in a biological neural network.

Node: A mathematical representation of a biological neuron. Multiple layers of nodes are used in artificial neural networks to form models of biological neural networks.

Risk: An individual or organization's exposure to a chance of loss or damage.

Underwriter: (Insurance Underwriter) An employee of an insurance company whose job duties include analyzing an application for insurance and making a decision whether to accept or reject the application. If accepted, the underwriter further determines the premium to be charged. Underwriters also review existing insurance contracts for renewal.

Unified Modeling Language 2.0

Peter Fettke
Institute for Information Systems (IWi) at the DFKI, Germany

INTRODUCTION

Mature engineering disciplines are generally characterized by accepted methodical standards for describing all relevant artifacts of their subject matter. Such standards not only enable practitioners to collaborate, but they also contribute to the development of the whole discipline. In 1994, Grady Booch, Jim Rumbaugh, and Ivar Jacobson joined together to unify the plethora of existing object-oriented systems engineering approaches at semantic and notation level (Booch, 2002; Fowler, 2004; Rumbaugh, Jacobson & Booch, 1998). Their effort leads to the unified modeling language (UML), a well-known, general-purpose, tool-supported, process-independent, and industry-standardized modeling language for visualizing, describing, specifying, and documenting systems artifacts.

UML is applicable to software and non-software domains, including software architecture (Medvidovic, Rosenblum, Redmiles, & Robbins, 2002), real-time and embedded systems (Douglass, 2004), business applications (Eriksson & Penker, 2000), manufacturing systems (Bruccoleri, Dieaga, & Perrone, 2003), electronic commerce systems (Saleh, 2002), data warehousing (Dolk, 2000), bioinformatics (Bornberg-Bauer & Paton, 2002) and others. The language uses multiple views to specify system's structure and behavior. Modeling tools supporting the development of UML diagrams are available from a number of commercial vendors and the open source community (OMG, 2006b; Robbins & Redmiles, 2000).

Table 1 depicts the origin and descent of UML. The recent version UML 2.0 supports thirteen different diagram types. Table 2 overviews the main concepts of each diagram, a more detailed description is given below. For a full description of all semantics see (OMG, 2005a, 2005b, 2006a, 2006c) respectively the available secondary literature (Fowler, 2004; Rumbaugh et al., 1998).

UML version 2, first planned for 2001 (Kobryn, 1999, p. 30), was finally completed in 2006. This major revision mainly focuses on language extensibility, language specification, language precision and expressiveness. Although the complete language specification was almost fully rewritten, this revision is primary an internal reorganization with just minor consequences for the end user. For example, the new diagrams mainly clarify and resemble existing diagram types.

The description of UML 2.0 consists of four separate documents (Kobryn, 2002):

- **Infrastructure:** This document is concerned with core language features. It specifies the base classes that provide the foundation for UML modeling concepts.
- **Superstructure:** Advanced topics such as component and activity modeling are defined by this specification. It describes the constructs that developers use to build UML models.
- **Object constraint language (OCL):** This specification describes the language used for invariants, operation specifications etc.

Table 1. History of UML (Fowler, 2004, pp. 151-159; Kobryn, 1999, p. 30)

Year	Version	Comments
1995	0.8	Origin of UML, so-called "Unified Method"
1996	0.9	Refined proposal
1997	1.0	Initial submission to OMG
1997	1.1	Final submission to OMG
1998	1.2	Editorial revision with no significant technical changes
1999	1.3	New use case relationships, revised activity diagram semantics
2001	1.4	Minor revisions, addition of profiles
2003	1.5	Adding action semantics
2005	1.4.2	Standardized by the International Organization for Standardization (ISO/IEC 19501:2005)
2005/6	2.0	Deep changes to meta-model, new diagram types, improved expressiveness

Table 2. UML diagram types

Focus	Diagram	Purpose	Main Concepts	Supported Since
Structure diagrams	Class	Object structure	Class, features, relationships	UML 1
	Object	Example configuration of instances	Object, link	UML 1 (unofficially)
	Component	Structure and connections of components	Component, interface, dependency	UML 1
	Composite structure	Decomposition of a class during runtime	Part, interface, connector, port	UML 2
	Package	Interrelationships between packages	Package, dependency	UML 1 (unofficially)
	Deployment	Deployment of components to nodes	Node, component, dependency	UML 1
Behavior diagrams	Use case	User interaction with system	Use case, actor	UML 1
	Activity	Procedural and parallel behavior	State, activity, completion, transition, fork, join	UML 1
	State machine	Change of events during object's lifetime	State, transition, event, action	UML 1 statechart diagram
Interaction diagrams	Sequence	Interaction between objects emphasizing sequences	Interaction, message	UML 1
	Communication	Interaction between objects emphasizing collaborations	Collaboration, interaction, message	UML 1 collaboration diagram
	Timing	Interaction between objects emphasizing timings	Object, timing constraint, state, event	UML 2
	Interaction	Interplay between activities and sequence interactions	Combination of sequence and activity diagram (see there)	UML 2

- **Diagram interchange:** The storage and exchange of model including the layout of UML models is covered by this specification.

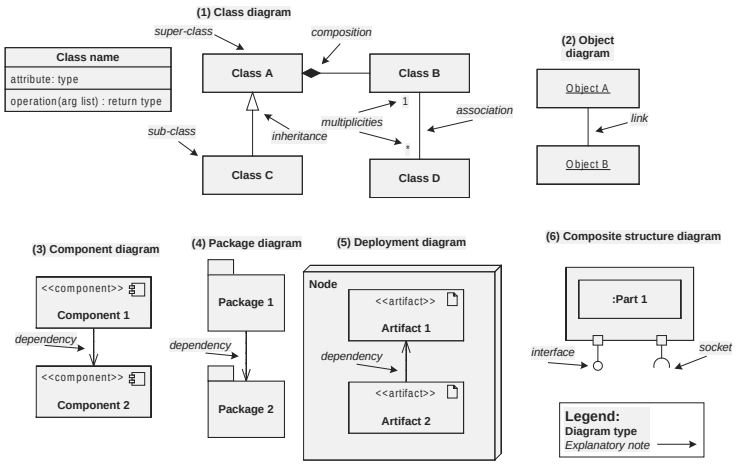
The specification of the UML is publicly available and maintained by the Object Management Group (OMG). OMG's standardization process is formalized and consists of several proposal, revision, and final implementation activities (Kobryn, 1999, p. 31f.). Note, UML 1.4.2 is adopted by the International Organization for Standardization, too.

BACKGROUND

There is a great deal of terminological confusion in the modeling literature. A modeling language or grammar provides a set of constructs and rules that specify how to combine the constructs to model a system (Wand & Weber, 2002, p. 364). It can be distinguished between an abstract syntax and a concrete syntax or notation of a language. While the abstract syntax specifies conceptual relationships between the constructs of the language, the concrete notation defines symbols representing the abstract constructs. In contrast, a modeling method provides procedures by which a language can be used. A consistent and suited set of modeling methods is called a methodology. A model is a description of a domain using a particular modeling language.

The UML specification provides an abstract syntax and a concrete notation for all UML diagrams as well as an informal description of the constructs' semantics. The UML's language specification is independent of but strongly related to other OMG standards such as Common Data Warehouse Model, XML Metadata Interchange or Meta Object Facility. A modeling method or a modeling methodology is not defined by the UML standard. Hence, the language is process-neutral and can be used with different software development processes.

Figure 1. UML structure diagram examples



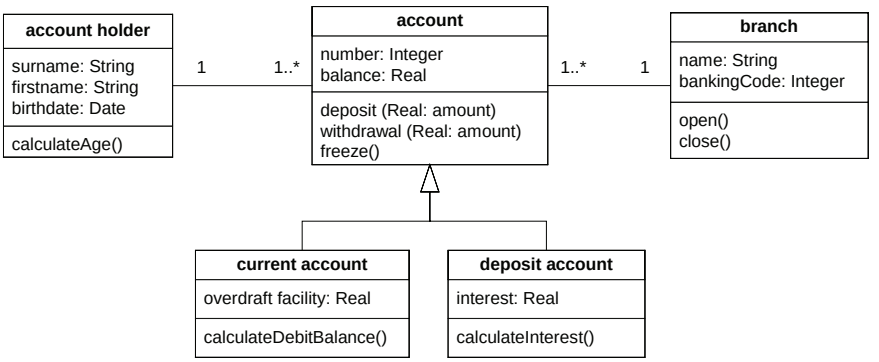
Conceptual modeling has a long history. Other modeling approaches that are to a certain degree accepted in practice, for instance the Entity-Relationship Model or flow charts, have a much more limited scope than UML. These approaches address just some aspects of systems' specification, namely data and process view. In contrast, UML supports the specification of static as well as dynamic aspects. Other approaches with a similar scope, e.g. Open Modeling Language (Firesmith, Henderson-Sellers & Graham, 1998), are not widely accepted in practice.

STRUCTURE DIAGRAMS

Structure or static diagrams describe the objects of a system in terms of classes, attributes, operations, relationships, interfaces and connectors (see Figure 1).

1. **Class diagram:** A class diagram can be viewed as a graph of several elements connected by static relationships. The main element is a class. Classes represent concepts within the system being modeled and are descriptors for a set of objects with similar structure, behavior, and relationships. An object represents a particular instance of a class. Each class has a unique name among other classes within a specific scope (usually a UML package). A class can hold several attributes and operations. Attributes have names and belong to particular types that can be simple data types such as Integer, String, Boolean as well as complex types (e.g., other classes). Operations are services offered by an instance of the class and may be requested by other objects during run-time. Different relationships between classes can be defined. Figure 2 depicts a class diagram for banking systems. An account is described by the attributes 'number' and 'balance'. The operations 'deposit', 'withdrawal', and 'freeze' are offered by an account. Each account is kept by a 'branch' and is assigned to a 'holder'. The classes 'deposit account' and 'current account' reuse the structure and behavior of the class 'account' (inheritance relationship). In addition, the specialized account classes define further feature, e.g. an object of the class 'current account' is described by the property 'overdraft facility' and offers an operation calculating the current debit balance.
2. **Object diagram:** An object diagram is an instance of a class diagram and depicts the state of the system at a point in time (e.g., a particular configuration of several objects). It contains objects including their actual values of attributes and links describing object references.
3. **Component diagram:** Component diagrams capture the physical structure of a software system during build-time. Components in UML are physical elements such as source, binary or executable modules and files respectively. Simple components can be aggregated to complex components to specify physical containment relations. Directed relationships between components specify that one component relies or refines the other. Such relationships are called dependencies.
4. **Package diagram:** Packages are grouping constructs that allow to group elements together into high-level units. Typically, packages are used to group classes. It is possible that one package is also be member of another package, so packages build a hierarchic structure. A package diagram visualizes the packages of a

Figure 2. Class diagram for banking systems



system. The sub-package relationship is shown by a nested package, dependencies between packages are depicted by dashed arrows.

5. **Deployment diagram:** While component diagrams primary show build-time dependencies of components, deployment diagrams show a run-time configuration of the system's components. In addition, a deployment diagram uses nodes representing a processing resource, for instance a server or workstation, that can execute system operations during run-time.
6. **Composite structure diagram:** This diagram shows how a class is hierarchically decomposed into several parts. The decomposed parts are typically represented by interfaces. Each part can support or require a particular interface. It is possible that a part implements an interface by using a delegating connector. Additionally, ports are used to group the required and provided interfaces into logical chunks that connect a component to other comments.

BEHAVIOR DIAGRAMS

Behavior diagrams describe the dynamics between objects of a system in terms of interactions, collaborations, and state histories (see Figure 3).

7. **Use case diagram:** A use case specifies a complete set of events within a system to fulfill tasks or transactions in an application from a user's point of view. In a use case diagram, a set of use cases, actors, and relationships between these elements are depicted. Several use cases may optionally be enclosed by a rectangle that represents the boundary of the containing system. An actor describes a particular role of a human or non-human user of the system being modeled.
8. **Activity diagram:** While state chart diagrams are used to specify the behavior of a single object, activity diagrams can describe behavior that crosses object boundaries. They are analogous to traditional flowcharts and are often used to document (business) processes or the dynamics inside a use case. So-called fork bars are used to describe activities that can be executed in parallel. Parallel activities get synchronized by so-called join bars. Guards are used to specify conditional forks that are only executed if particular conditions hold.
9. **State machine diagram:** Object behavior is represented by state chart diagrams that can specify the behavior of an entire object or a single method. A state describes a condition during the lifetime of an object. Transitions are relationships between two states describing that an object's state can change from the first to the second state. The change of a state is triggered by an event that occurs in the modeled system. There are two special types of states: An initial state identifies the point at which behavior starts when an object is created, a final state identifies the point at which behavior ends (end of object's lifetime).

INTERACTION DIAGRAMS

Interaction diagrams are all derived from the more general behavior diagrams and are used for meeting particular modeling requirements (see Figure 4).

10. **Sequence diagram:** Sequence diagrams describe interactions between different objects. An interaction consists of a partially ordered set of messages that are exchanged by the participants of that interaction. Sequence diagrams have two dimensions: The horizontal dimension represents the participants of the

Figure 3. UML behavior diagram examples

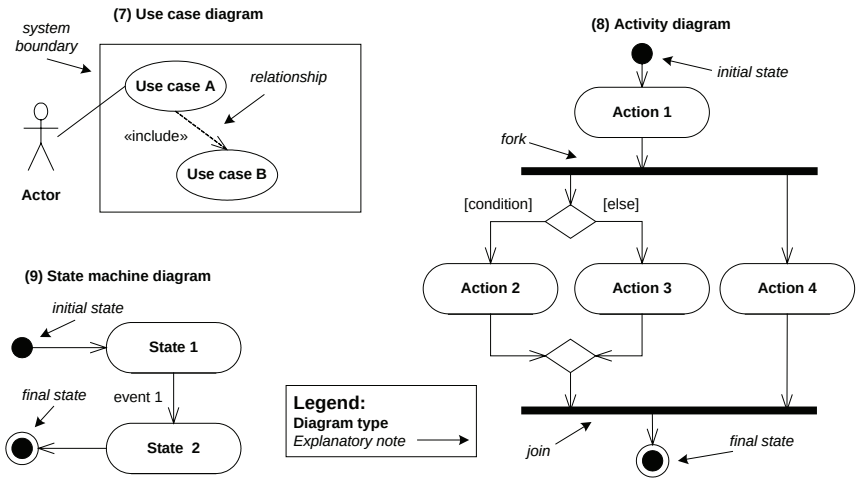


Figure 4. UML interaction diagram examples

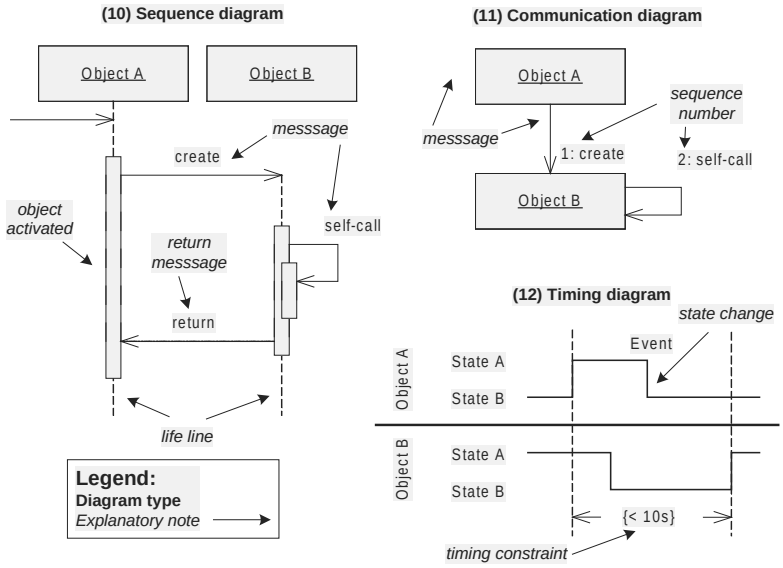

interaction; the vertical dimension represents the flow of time (usually time proceeds from up to down).

11. **Communication diagram:** Communication and sequence diagrams use the same underlying information and can easily be transformed into each other. While sequence diagrams emphasize the sequence of communication between objects, communication diagrams show the roles of the participants of an interaction and their relationships. A sequence number specifies the flow of messages in an interaction, so no time dimension is needed in this diagram. Simple communication patterns can be depicted by communication diagrams; sequence diagram can better specify complex message exchanges or requirements for real-time systems.
12. **Timing diagram:** This diagram focuses on timing constraints for a single object or multiple objects. Additionally to the information gathered by a state machine diagram, minimal or maximal timing constrains between the occurrence of events can be specified. For example, a specification might say that at least ten seconds must pass between two events.
13. **Interaction diagram:** An interaction diagram is a mix of activity diagrams and sequence diagrams (hence it is not explicitly shown in the Figure 4). One way to use this kind of diagram is to detail the activities of an activity diagram by a particular sequence diagram. These sequence diagrams show the flow of messages between objects during execution of the corresponding activity.

ADVANCED TOPICS

- **Object constraint language (OCL):** There is often a need to capture unambiguously system's semantics in a precise and rigorous way. OCL is used for that purpose. It is a formal textual language inspired by the 'Design by Contract' concept and provides concepts for the definition of constraints such as invariants, pre- and post-conditions (Cengarle & Knapp, 2004; Warmer & Kleppe, 2003).
- **Language specification and meta-model:** The UML itself is specified using textual descriptions and a four-layered meta-modeling approach (Atkinson & Kühne, 2002, pp. 291-296). In this approach, the semantic constructs at each layer are recursively refined. The top layer, the meta-meta-model (M3), provides a so-called Meta Object Facility (MOF) to specify meta-models on the next lower layer. The MOF is used on the meta-model (M2) layer to specify the concepts of UML diagrams, e.g. class diagram etc. The model (M1) and object (M0) layer are user-defined. The M1 layer specifies concrete UML models, the M0 layer instances of the former.
- **Extension mechanisms:** So-called heavyweight extensions are supported by MOF and carried out on the meta-model (M2) layer. Such extensions have great impact on the language and are not performed by a particular modeler. User extensions are usually lightweight extensions that are built-in mechanisms of the UML. Lightweight extensions comprise constraints (OCL expressions), tagged values (attached additional information to model elements), and stereotypes (most powerful lightweight mechanism ranging from concrete syntax modifications to semantics redefinitions (Berner, Glinz, & Joos, 1999)).

FUTURE TRENDS

There has been always a strong discussion about how UML should and should not evolve in the future (Engels, Heckel, & Sauer, 2001; Henderson-Sellers, 2005; Kobryn, 2004; Miller, 2002). These trends include:

- **Model driven architecture (MDA):** MDA promotes modeling through the whole system's life-cycle (Frankel, 2003). Its objective is to fully automate the system's development process.
- **Executable UML:** Executable UML enriches modeling concepts with execution semantics (Mellor & Balcer, 2002). This opens the possibility of software development without "classical" programming.
- **Model libraries:** UML is used to standardize domain specific models fostering the usage of reference models (Fettke & Loos, 2003a; Fettke, Loos, & Zwicker,Loos, 2007). Known reference models, e.g. OMG's Business Enterprise Integration or Finance Domain Task Forces, support model reuse.
- **Ontological analysis and semantics:** This research line evaluates UML from an ontological point of view and incorporates real-world semantics into UML constructs (Opdahl & Henderson-Sellers, 2002). The aim of an ontological evaluation is to examine whether all constructs of an ontology can be mapped onto the constructs of UML and vice versa.
- **Component-based development:** UML is primary an object-oriented language. To fully support component-based development, some enhancements are needed (Dahanayake, 2003; Fettke & Loos, 2003b; Kobryn, 2000). Particularly, component descriptions must include dependencies on other components, quality specifications for needed and offered services, and domain-specific semantics.
- **Tailoring UML:** The adaption of UML to particular needs of a development project is of high importance. There are already some ideas for tailoring UML (France, Ghosh, Dinh-Trong & Solberg, 2006, p. 61).

- **Empirical foundations:** Until now, the research on UML is mainly conceptual without any strong empirical foundation (see for counter-examples (Dobing & Parsons, 2005; Glezer, Last, Nachmany, & Shoval, 2005; Grossman, Aronson, & McCarthy, 2005)). Future research has to adesss important questions such as: How is UML used in practice? Are some constructs of UML not relevant for modeling practice? Does the use of UML improve information system quality and developers productivity?

CONCLUSION

Although almost everyone acknowledges the practical benefits of a standardized modeling language (e.g., protection of investments in technology, easier model exchange and reuse, better professional training (Frank, 1997, p. 13)), there are important opportunities that have to be challenged. UML's size (UML 2 has approximately 1000+ pages) and complexity is compared with other languages overwhelming (Erickson & Siau, 2004; Siau & Cao, 2001). Therefore users have difficulties in writing and reading diagrams (Agarwal & Sinha, 2003; Laitenberger, Atkinson, Schlich, & Emam, 2000) and tool venders have problems to fully support the UML standard. Furthermore, the maintenance of the standard is very expensive and error-prone, (e.g., Fuentes, Quintana, Llorens, Génova, & Prieto-Díaz, 2003 identified several hundred errors in UML's meta-model). Other authors criticize UML for its semantic inconsistency, construct ambiguity, notation inadequacy, and cognitive misdirection (Champeaux, 2003; France et al., 2006; Frank, 1998; Henderson-Sellers, 2002, 2005; McLeod, Halpin, Kangassalo, & Siau, 2001; Shen & Siau, 2003; Thomas, 2002; Wang, 2001).

On the other hand, UML is the de-facto standard for object-oriented modeling and an important milestone in software engineering. Modeling of software systems increases the degree of abstraction during system development tremendously. This change is similar to the replacement of assembly languages by high-level languages in the 1960s and 1970s. Today, high-level languages are not used in all but most domains. We predict that, in the future, UML has an analogous position as high-level languages have today. Hence, UML continues to play a major role in systems development.

KEY TERMS

Conceptual Modeling: an action describing a domain with the help of a particular artificial or formalized language.

Meta-Model: A meta-model is a model of model.

Methodology: A consistent and suited set of modeling methods providing procedures to apply the constructs of a modeling language.

Model: A model is a particular product of conceptual modeling. It is a description of a domain using a particular language.

Object-Oriented Analysis and Design (OOA & OOD): Software engineering approach to construct software systems by building object-oriented models that abstract key aspects of the target system.

Object-Oriented Programming (OOP): Object-oriented programming emphasizes the hiding or encapsulation of the inner state of objects and the specification of these objects by an interface. OOP languages support objects, classes and inheritance.

Reference Model: A reference model is a model representing a class of domains, e.g. a reference model for production planning and control systems. It is a conceptual framework or blueprint for system's development.

A University/Community Partnership to Bridge the Digital Divide

David Ruppel
The University of Toledo, USA

Cynthia Ruppel
The University of Alabama in Huntsville, USA

INTRODUCTION

Companies want employees with core values who ascribe to corporate values. Emotional intelligence (EQ) is used by companies in recruitment (Foote, 2001), and guides managers in dealing with team performance problems. Similarly, leadership requires refocusing on core values, which over time builds character (Badaracco, 1998). Thus, educational institutions should devote considerable attention to character building (Foote, 2001).

Service-learning is designed to help. Jacoby (1996a, p. 5) has defined service-learning as "…a form of experiential education in which students engage in activities that address human and community needs together with structured opportunities intentionally designed to promote student learning and development".

Service-learning is important in information technology where students need technical skills and experience, and a strong ethical foundation. Legal aspects of technology have not kept pace with technology; often IT people are confronted with complex ethical decisions. It has been argued that service-learning represents a "unique pedagogy…that enhances the ability of private sector managers to be effective stewards of society's moral authority" (Godfred, p. 364). Service-learning in colleges is tightly linked with K-12 education (Jacoby, 1996B) due to the growing number of at-risk children, a vested interest for colleges to improve the future students, and because students will view service-learning as an appropriate college activity if they benefited from it prior to college (Jacoby, 1996b).

A policy concern in the information age is the "digital divide," a gap between those who have easy access to technology and those who do not. References are made to information "haves" and "have-nots" in an age where information is equivalent to wealth (Holloway, 2000). The "have-nots" are in danger of exclusion from the new economy and marginalization into low-wage jobs (Dunham, 1999). In 2000, the President of the United States asked the IT community to help close this digital divide for moral reasons and to ensure that the economy flourishes with the availability of skilled workers (Shewmake, 2000).

This overview summarizes a five-phase service-learning project accomplished through a partnership between the University of Toledo and a local K-8 parochial/non-profit school. The students were primarily enrolled in a Systems Analysis, Design and Implementation course (SAD). This longitudinal project was undertaken to plan, design, and wire a network for the school and to assess and implement continuing and future computer needs. It allowed students to gain "real-life" experience while contributing to the growth of IT among children in a non-profit setting.

BACKGROUND

The school is a parochial school enrolling approximately 200-250 students. All grades have a dedicated classroom; a computer lab and library are also provided.

Existing computers consisted of a classroom set of older Macintosh computers in the 8th grade room. Each classroom had an older Macintosh computer for the teacher, all with unused LAN capability. The computer lab contained older Apple computers used in the primary grades for computer literacy and keyboarding skills.

Phase 1

The school had accumulated technology funds and hired a teacher with a Master's degree in Educational Technology. The teacher and principal agreed to participate in the project since an estimate from a local company exceeded the funds accumulated. While the teacher had pedagogic knowledge of computers, he did not possess the expertise to evaluate the quotation or analyze the technical aspects of the network. The school indicated that it hoped to apply for a grant, but needed technical information.

Students self-selected into the project: *The goal of the project was to educate themselves as to alternatives, costs and provide background information concerning networking to prepare a grant application.* They had the opportunity to examine the existing environment and interview stakeholders.

The instructor and students toured the building, including attic and closet locations where existing asbestos could not be disturbed. The stakeholders were asked to determine the number of "drops/connections" required in each room based on immediate and future use. Two drops were requested in each classroom — one for the teacher's computer and another for a classroom network. The group submitted a plan to the school including alternatives, costs, and technical information for the design of the campus network to be used for grant preparation.

Phase 2

Phase 2 included completing a grant proposal and the physical networking of the building. The wiring project was popular among students and required instructor selection to participate. Two students had experience, while others were chosen based on enthusiasm and desire to learn the "hands-on" aspects of networking.

Using the plan, a grant proposal was submitted providing evidence of the school's commitment and a plan for the educational use of the network. The university students' involvement was documented, and the authors were listed as consultants.

The grant writing was divided among the authors, the teacher, and the principal. Guidelines required a technology plan and a specific grant request. The accumulated funds were sufficient to wire the building without grant funding. Subsequently the maximum grant was awarded for continuation of the project.

The wiring plan included an Ethernet LAN in the 8th grade room and a campus LAN with connections in all classrooms and offices. Microsoft Windows NT Server 4.0 with Services for Macintosh (SFM) was chosen as the network operating system (NOS) based on the requirements of the heterogeneous network. With SFM, the Windows server appears as an Apple server to Macintosh clients.

The NOS was installed on a computer with a dial-up Internet connection, a temporary arrangement until high-speed access was available. Proxy server and content-filtering services were installed, providing low-bandwidth Internet access to all clients in the 8th grade classroom. Secure storage for network users was provided.

In wiring the building, a storage closet was used as the wiring closet where hubs were installed and all building wiring runs terminated. Since the computers were regularly used, work was partitioned into elements that could be done over a weekend to maximize availability for students and teachers. A file server for administrative applications and intranet e-mail was installed in the wiring closet with a tape drive to provide network backup.

Phase 3

The next step was to install high-speed Internet access for which the school receives state funding. The authors recommended the installation of a T-1 line (1.544 Mbps).

In 2001 the network consisted of three servers, each running Microsoft NT Server 4.0. A laser printer was available to over 50 network clients running various operating systems.

Phase 4

We now needed to recommend replacements for outdated equipment and provide information for equipment grant applications. Students self-selected into this project, and met with the stakeholders. The main issue was whether the replacement equipment should be Apple or Windows-based. Pertinent factors were educational needs, existing equipment, and available expertise. The group analyzed these factors together with their survey of surrounding schools to determine local norms. Their recommendation was Apple equipment.

After network completion, it was obvious that the computers were outdated. An early goal was to minimize expenses by leveraging existing equipment. An obsolete Web browser was installed since the machines' capabilities prohibited current versions. While slow, the clients provided Internet access where none existed before. In today's world, fast access is a necessity. Revenaugh (2000) suggests that access does not equal equity; just connecting a wire to a school does not mean it will be used well. Also, the browser security certificates had expired, so secure Web sites could not be accessed.

Phase 5

Using this recommendation, a second grant proposal was prepared requesting the maximum award to purchase new computers for the teachers. The replaced computers will be placed in the classrooms in small networks for student use.

Another group of students worked on designing a Web site for the school. A preliminary school Web site, created 2 years earlier, was out-of-date and the students were asked to produce an up-to-date, easily maintainable Web site.

CONCLUSIONS AND LESSONS LEARNED

There must be a close working relationship between the community organization and the university faculty. Trust

was necessary to order materials, remain in the building after-hours, and obtain quotations on behalf of the school.

Since this is a functioning organization, work cannot be left unfinished. Work must be analyzed and divided into tasks that can be completed within the available time. Student self-selection should be combined with faculty approval since the faculty member(s) have the ultimate responsibility for project completion.

Students appreciate being part of a project that benefits others. Food was provided on Saturdays, motivating the students and keeping them on site. The students had time to relax and discuss the project among themselves and with the instructors informally as recommended by the service-learning literature (Godfrey, 1999; Kenworthy-U'ren, 1999). During this time it was interesting to note their perceptions of how elementary education has changed since "their day". They even became attached to the classroom pets – feeding them, and so forth.

The school purchased materials on time and provided significant access to the building. They valued the students' work, since they had received a commercial bid. We recommend this procedure where applicable to eliminate the perception that free means valueless.

Choose the students both to ensure project completion and to make it a learning experience. From the volunteers, students were selected to ensure some students had necessary skills and also included inexperienced students. This facilitated a sharing of knowledge and maximized learning, giving the experienced students leadership opportunities.

Expect unanticipated problems. Since the building had been built in stages (to our surprise), we needed to wire through old exterior walls. Also, the 8th grade class rabbit ate through the cables and had to be sent to a new home. We recommend exploring insurance coverage for students involved in labor with the potential for injury.

It is important to seek knowledge from a variety of sources. Experience with Apple computers was limited among the students and the instructors. A student, not part of this project, was familiar with Apples and made relevant suggestions. Another former student, who works with Apple computers in his employment, supplied information, agreed to troubleshoot computers, and created a CD containing the software set-up for the computers. He showed the students how to install the set-up and was so impressed with one of the students that he arranged a job interview for the student, resulting in a job offer.

In the service-learning literature, one caveat is the time required of the instructor(s), particularly relative to the current faculty reward systems (Godfrey, 1999; Kenworthy-U'ren, 1999; Kolenko, Porter, Wheatley & Colby, 1996). The amount of instructor time and nature of instructor tasks varied according to the type of student projects undertaken. This is consistent with the findings of Bush-Bacelis (1998), who suggests that service-learning projects do not require more work, but a different type of work both for the students and the instructor. The wiring project required a significant amount of dedicated instructor time, as did the grant writing. However, students indicated they found the wiring project particularly fulfilling, especially since the feedback was a working network and a tangible skill set was learned.

Student Assessment

In group projects, students are asked to assess each member's contribution to the group. To assess the quality grade for those completing the physical wiring, the instructors were present in the building. For the more traditional projects, the instructor assessed quality and adherence to SAD principles after obtaining "perceived value and usefulness" feedback from stakeholders.

Benefits to the School

The age of the existing computers limited their usability, and the school did not have the funds to replace them. By placing them on a network, their useful life was extended. Due to limited funds and lack of technical knowledge the school was prevented from completing these projects.

Benefits to the Students

Kenworthy-U'ren (1999) suggests that service-learning projects should be grounded in experiential learning, not merely a service-related activity. These projects allowed the students' involvement in projects related to their career objectives. The students appeared determined to provide a quality product because it was being given to a "real" organization for decision making and to the next group who would use their work and attempt to "better it". These projects, if carefully planned, are win-win situations for the students and the community partner.

FUTURE TRENDS

The necessity of networking schools is becoming increasingly important and at lower levels such as primary school also. To continue to eliminate the digital divide, students, even grade school students, must be able to access and evaluate information to learn to make informed decisions. This project was designed to both give students "hands-on" experience and to provide access to young students so they can become familiar and comfortable with this access.

The technology in providing this access will continue to change. Many devices today are wireless devices (as schools can afford to purchase them), which would eliminate the need to wire the building and would use more current technology.

However, in a school setting, due to cost constraints, the available technology appears to change more slowly than a business environment would. The issues involved in setting up a wireless network may seem less involved since no physical wiring must take place, but different complex issues arise, such as providing coverage to all areas and methods of extending the signal on large campuses. So the exercise for the students becomes no less important.

KEY TERMS

Bandwidth: A measure of the data transmission capacity of a communications link.

Digital Divide: The term digital divide describes the fact that the world can be divided into people who do and people who do not have access to - and the capability to use - modern information technology, such as the telephone, television, or the Internet.

Ethernet: A communications standard (IEEE 802.3) for Local Area Networks (LAN). When a device wishes to transmit, it waits until the link is empty and then transmits. In the event that two or more devices transmit simultaneously (collision), all devices stop transmitting and wait a random time period before attempting to retransmit.

Heterogeneous Network: A network where network clients run a variety of operating systems. An example would be a network of machines running Windows, Unix, and Mac OS X.

Intranet: Computer network contained entirely within an organization.

LAN: Local Area Network. Group of computers and other devices sharing a single communications link. Typically, the longest distance between any two connections is a few kilometers. Usually owned by a single organization.

Network Operating System: An operating system for a computer designated as a server in a LAN. Manages network resources available to network clients such as printers, files and databases. Responsible for maintaining a database of names and addresses of clients attached to the network.

Service-Learning: A form of experiential education in which students engage in activities that address human and community needs together with structured opportunities intentionally designed to promote student learning and development.

Systems Analysis and Design Course (SAD): A course in which the student learns to understand how an information system can support organizational needs, how to design the system, build it and deliver it to users.

T-1 Line: A communications link that can be used for digital data transmission. Provides a data rate (bandwidth) of 1.544 million bits per second (Mbps).

Updated Architectures for the Integration of Decision Making Support Functionalities

Guisseppi Forgionne
University of Maryland, Baltimore County, USA

INTRODUCTION

Information systems research continues to examine ways to improve support for decision making. The evolution from simple data access and reporting to complex analytical, creative, and artificially intelligent support for decision making persists (Holsapple & Whinston, 1996). In the evolution, existing information systems still, and new intelligent systems have been created to, provide the desired decision making support.

By studying the existing, and new, systems' characteristics, advantages, and disadvantages, researchers and practitioners can better design, develop, and implement robust decision making support systems (Kumar, 1999). The original article facilitated such study by presenting and illustrating the underlying information system architectures for robust decision making support (Forgionne, 2005).

This article updates the original by offering additional contributions to the subject. New literature on intelligent decision making support is examined, and the relevant findings are discussed. The title has been modified slightly to reflect the updates.

BACKGROUND

Several frameworks have been developed to describe the human decision making process. The most popular is Simon's three-phase paradigm of intelligence, design, and choice (Simon, 1960). This paradigm seems to be the most general, implying virtually all other proposed frameworks, and the Simon paradigm appears to have best withstood empirical testing (Martinsons, Davison, & Tse, 1999). Such scrutiny, however, has suggested the expansion of the basic formulation to conclude with an implementation phase.

During the intelligence phase, the decision-maker observes reality, gains a fundamental understanding of existing problems or new opportunities, and acquires the general quantitative and qualitative information needed to address the problems or opportunities. In the design phase, the decision-maker develops a specific and precise model that can be used to systematically examine the discovered problem or opportunity. This model will consist of decision alternatives, uncontrollable events, criteria, and the symbolic or numerical relationships between these variables. Using the explicit models to logically evaluate the specified alternatives and to generate recommended actions constitute the ensuing choice phase. During the subsequent implementation phase, the decision maker ponders the analyses and recommendations, weighs the consequences, gains sufficient confidence in the decision, develops an implementation plan, secures needed financial, human, and material resources, and puts the plan into action.

A variety of individual information systems have been offered to support the decision-making phases and steps. Much can be learned about this support by examining the individual systems' components, architectures, and operations.

RENDERING EFFECTIVE DECISION MAKING SUPPORT

Issues, Controversies, and Problems

Decision making support has evolved over time and across disciplines (Mirchandani & Pakath, 1999). Initial support was offered by a decision support system (DSS). In the typical DSS, the decision maker utilizes computer technology to: (a) organize the data into problem parameters, (b) attach the parameters to a model, (c) use the model to simulate (experiment with) alternatives and events, and/or (d) find the best solution to the problem. Results are reported as parameter conditions (status reports), experimental forecasts, and/or recommended actions. Feedback from the user-controlled processing guides the decision maker to a problem solution, and created information and knowledge are stored as additional inputs for future or further processing.

The DSS concept presumes that the problem pertinent data and models have been created and stored in the system prior to use (Hooghiemstra, Kroon, Odijk, Salomon, & Zwaneveld, 1999). This concept also assumes that the user can utilize the computer technology to perform the technical processing operations and computations required by the system (Lawrence & Sim, 1999). In fact, DSS users rarely have the technical skill to recognize, capture, and process pertinent data and models or to interpret the results of the models' processing within the problem context (Raghunathan, 1999). In short, the DSS concept offers little direct support

for the intelligence, early design, and implementation phases of decision making.

To be useful, problem pertinent data must be identified, located, captured, stored, accessed, and interpreted (Seely & Targett, 1999). Data warehousing can facilitate access and reporting, while data mining can help with the interpretation function. An executive information system (EIS) can deliver these data access, reporting, and interpretation functions to the decision maker in an intuitive and appealing manner.

In a typical EIS, the decision maker utilizes computer technology to: (a) organize the data into specified broad categories, (b) view (slice and dice) the data from interesting perspectives, (c) generate "warnings" for the decision maker by scanning current trends, and (d) mine the data for less obvious relationships. Results are reported as category summaries (status reports), sliced and diced details (drill down reports), and/or suggested problem parameters (events). Feedback from the user-controlled processing guides the decision maker to a general problem understanding, and the created parameters are stored as additional inputs for further processing.

The user should exit EIS processing with a general understanding of the problem or opportunity and with relevant problem information (such as general objectives, range of decision alternatives, and range of pertinent events). Since additional decision analysis will be required to explicitly formulate the problem and complete the decision making process, an EIS directly supports only the intelligence phase of decision making.

Technical and domain expertise will be needed to recognize, formulate, and solve most complex and significant decision problems or opportunities. Although such expertise will be available within, and outside, an organization, the expertise may be difficult, costly, and time-consuming to locate, access, and utilize. Often, the corresponding knowledge can be acquired, embedded within a knowledge-based system (KBS), and the system can be used to capture, store, and deliver the expertise to the decision maker (Ayyub, 2001). A typical KBS captures and stores as inputs problem pertinent knowledge, either from experts, cases, or other sources, and the models (inference engine or reasoning mechanisms) needed to draw problem solution inferences from the knowledge. In the process, a KBS directly facilitates problem structuring (thereby supporting part of the design phase), the selection of alternatives, and the evaluation of the selections (hence supporting the choice phase of decision making).

Since decision making is a sequential and continuous process, learning will be essential to the successful completion of the process. Users will learn from their interactions with a KBS (or other individual decision making support system) and, in the process, gain skills that can be applied to further decision making tasks. Applying learning to the solution of the current problem, however, often will require system support (Bolloju, Khalifa, & Turban, 2002). Machine-learning systems (MLS) can provide such support by mimicking the learning processes of physical systems. In a typical MLS, the decision maker utilizes computer technology to: (a) organize the problem data, (b) structure (operationalize) the learning model, and (c) simulate learning. Results are reported as problem conditions (status reports), forecasted problem outcomes, and/or and an explanation of the learning logic.

Besides learning, creativity often is needed to successfully complete the decision making process (Keys, 2000). While the previous systems free decision makers to concentrate on the creative aspects of decision making, they do not provide direct support for the creative process (Savransky, 2001). Since decision makers may not be inherently creative, support for creativity can considerably enhance their decision making. A creativity enhancing system (CES) offers such support (Forgionne, Clements, & Newman, 1995). In a typical CES, the decision maker utilizes computer technology to: (a) organize (chiefly categorize and classify) problem ideas and concepts, (b) structure ideas and concepts into problem elements and relationships, and (c) simulate conceptual problem solutions. Results are reported as problem elements (status reports), the problem's conceptual structure (criteria, alternatives, events, and relationships), and/or forecasted outcomes from the conceptual analyses.

The major individual systems, and their primary and direct support, are summarized in Table 1. An examination of this table shows that none of the individual systems offers complete and integrated support for all phases and steps of the decision making process.

Table 1. Individual decision making support systems

System	Type	Support
Decision Support System	Individual	Specifying relationships between criteria, alternatives, and events; choice
Executive Information System	Individual	Intelligence; developing decision criteria; identifying relevant uncontrollable events
Knowledge-Based System	Individual	Develop decision alternatives; choice
Machine-Learning System	Individual	Logically evaluate decision alternatives
Creativity Enhancing System	Individual	Design; develop an implementation plan; put implementation plan into action

Table 2. Integrated decision making support systems

System	Type	Support
Intelligent Decision Support System (IDSS)	Integrates the functions of DSS and KBS (and/or MLS)	Developing decision alternatives; specifying relationships between criteria, alternatives, and events; choice
Executive Support System (ESS)	Integrates the functions of DSS and EIS	Intelligence; developing decision criteria; identifying relevant uncontrollable events; specifying relationships between criteria, alternatives, and events; choice
Whole-Brained Decision Support System (WDSS) and Group Decision Support System (GDSS)	Integrates the functions of DSS and CES	Gain problem/opportunity understanding; design; choice
Management Support System (MSS)	Integrates the functions of DSS, EIS, and KBS (and/or MLS)	Intelligence; design; choice

SOLUTIONS AND RECOMMENDATIONS

The need for complete and integrated decision making support has encouraged researchers to seek the synergistic effects that can be achieved by combining the functionalities of the individual systems. The result has been the development of the various integrated systems for decision making support summarized in Table 2.

Of particular note is the intelligent decision support system concept. In a KBS, knowledge is captured and stored in a well structured manner prior to system use. The same approach is used to capture and store the learning process within a MLS. This static approach works well when the decision involves a one-time problem, where a current action will be unaffected by previous choices, and have no influence on subsequent selections. When the problem is instead sequential, the decision maker must make a series of interrelated decisions over time or across decision stages. Under such circumstances, the system's knowledge and models must be restructured dynamically to reflect the new or changing reality and in real time to offer just in time decision making support (Gupta, Forgionne, & Mora, 2006).

To provide this dynamic intelligence, a new IDSS, called the intelligent just in time decision support system (IJDSS), has been offered (Conteh & Forgionne, 2005). In the IJDSS, a model, formed from technical and domain expertise, captures and stores problem pertinent knowledge and the explicit problem structure needed to evaluate decision alternatives. As the decision environment changes, the model is updated dynamically and in real time to reflect the new reality. The dynamically evolving model is used to simulate (experiment with) alternatives and events or find the best solution to the problem, with or without guidance from the system. Results are reported as parameter conditions (status reports), experimental forecasts, recommended actions, and explanations for the recommendations.

As Table 2 indicates, each integrated system, such as an IDSS or MSS, integrates the functionality of particular individual systems to provide decision making support. Even the IJDSS form of an IDSS has this characteristic. While the integrated functionality has created more complete and unified decision making support, the suggested synergies still leave significant gaps in decision making support. For example, an IDSS (or IJDSS) still leaves gaps in design support, while an MSS does not provide creativity support. With even more system choices available than previously, the decision maker and/or staff are forced to match the relevant functionality with his/her/their decision making support needs. Decision makers, and/or staff, may be ill equipped to make these selections and design, build, and implement the desired system.

An alternative strategy is to create one decision making support system that synthesizes the main features and functions for the various decision making support systems. The decision technology system (DTS), which is presented in Figure 1, has been proposed to support this alternative strategy. As Figure 1 illustrates, a DTS has a database, knowledge base, and model base. The database contains the data directly relevant to the decision problem, including the values for the uncontrollable events, decision alternatives, and decision criteria. The knowledge base holds problem knowledge, such as formulas for converting available data into the problem's parameters, guidance for selecting decision alternatives and problem relationships, or advice in interpreting possible outcomes. The model base is a repository for the formal (tabular, graphic, conceptual, or mathematical) models of the decision problem and the methodology for developing results (simulations and solutions) from the formal models.

Decision-makers utilize computer technology (hardware and software) to process the inputs into problem-relevant outputs. Processing will involve:

a. **Organizing Problem Parameters:** Accessing the data base, extracting the decision data, and organizing the

information in the form needed by the solution model and methodology;

b. **Structuring the Decision Problem:** Accessing the model base, retrieving the appropriate decision model, and operationalizing (attaching organized parameters to) the decision model;
c. **Simulating Policies and Events:** Using the operationalized decision model to perform the computations needed to simulate outcomes from user-specified alternatives and then identifying the alternative (or alternatives) that best meets the decision criterion (or criteria) among those tested;
d. **Finding the Best Problem Solution:** Accessing the model base, retrieving the appropriate solution method, and using the retrieved method to systematically determine the alternative (or alternatives), among all possible alternatives, that best meets the decision criterion (or criteria).

The DTS can use problem ideas, concepts, and knowledge drawn from the knowledge base to assist users in performing these processing tasks.

Processing will generate status reports, forecasts, recommendations, and explanations. The status reports will identify relevant uncontrollable events, decision alternatives, and decision criteria and show the current values for these problem elements. Forecasts will report the events and alternatives specified in the simulations and the resulting projected values of the decision criteria. The recommendations will suggest the values for the decision alternatives that best meet the decision criteria, and the corresponding criteria values, under current and forecasted values for the uncontrollable events. Explanations will justify the recommendations and offer advice on further processing. Such advice may include suggestions on interpreting the output and guidance for examining additional scenarios.

Input feedback from the processing provides additional data, knowledge, and models that may be useful for future decision making. This feedback is provided dynamically to update the models and parameters in real time within external intervention. Output feedback (which can include outcomes, cognitive information, task models, and what-if, goal-seeking, and other types of sensitivity analyses) is used to extend or modify the original analyses and evaluations. Often, computer-based system agents will be used to provide the dynamic and real time input and output feedback for the user.

Figure 1's general DTS architecture can support all phases of the decision making process in a complete, integrated, and continuous manner. Critical problem data can be captured in a DTS database, and the system can be used to organize this captured information, generate timely focused reports, and project trends. Such processing helps the decision maker to quickly monitor the decision environment, set objectives, and evaluate the processed information for opportunities or problems, thereby supporting the intelligence phase of decision making.

The DTS, augmented by the managers' (or perhaps staff) insights and judgments, can be used to process captured constructs and frameworks into criteria, events, and alternatives needed to formulate a model of the decision problem. Additional processing with the captured statistical methodologies can estimate the parameters required to operationalize the formulated decision problem model, thereby supporting the design phase of decision making. The formulated models, again augmented by the managers' insights and judgments, are used to evaluate alternatives in a systematic and analytic fashion and to recommend alternatives, thereby supporting the choice phase of decision making.

Decision technology systems can provide the analyses in vivid detail with tables, graphs, and other supporting material. Such supporting material will increase the decision maker's confidence in the recommendations, improve the decision maker's perception of support system effectiveness, and enable the decision maker to better explain, justify, and communicate the decisions during implementation, thereby supporting the implementation phase of decision making.

Along with the original analyses and evaluations, DTS feedback loops increase the users' confidence in the recommendations and enable the decision-maker to better explain, justify, and communicate the decisions during implementation. The loops also support decision making in a continuous and dynamic manner (Forgionne, 1999, 2000).

FUTURE TRENDS

Realizing the DTS promise presents significant technical and management challenges. Problem pertinent data, models, and knowledge must be identified, located, retrieved, and captured (Balasubramanian, Nochur,, Henderson, & Kwan, 1999). Intelligent data warehousing and mining can support the data retrieval tasks, and it may be possible to adapt these methodologies for model and knowledge retrieval support. Differences in data, knowledge, and model structures, however, may necessitate the development of new methodologies for knowledge and model retrieval tasks.

Also, it will be challenging to collect and deliver the tools and to manage the design, development, and implementation effort. Agents and object-oriented methods can be used to capture the tools and make them available for system operation in the dynamic and real time manner suggested by the IJDSS concept (Gupta et al., 2006; Siskos & Spyridakos, 1999). The resulting system, however, will profoundly challenge the nature of the decision maker's work as well as altering the structure of the organization. By providing complete

and integrated decision making support, a DTS will enable the decision maker to perform technical tasks previously outsourced to specialists. The result may be an organization with fewer hierarchical levels and smaller staffs.

CONCLUSION

Over the years, support for decision making has taken a variety of forms. As the forms have evolved, decision making support has become more comprehensive and integrated. Today, there are many system choices available, and matching the appropriate system to the particular problem or opportunity has created a new task for management.

The evolution has illustrated the synergistic value that can be achieved through higher levels of functional integration. This article has presented a concept, the DTS, that can offer a mechanism to consolidate the advances and promote a revolution in management. The proposed system has also created significant research opportunities—determining the best integration strategy, identifying the best design and development tools to achieve the strategy, and examining the impact of integrated decision support on management, decision making, and organizational structure, among others. It also clarifies the needs to: (a) have effective and efficient information reporting and communication systems in place and (b) to integrate the decision making support systems with information reporting and communication systems.

KEY TERMS

Artificially Intelligent Systems: Information systems that help users manage data and models by delivering virtual expertise and other forms of artificial intelligence in support of these tasks.

Creativity Enhancing Systems: Information systems that are designed to offer creative tools that help users formulate problems and perform other creative tasks in decision making.

Decision Making Process: The process of developing a general problem understanding, formulating the problem explicitly, evaluating alternatives systematically, and implementing the choice.

Decision Support Systems: Information systems that interactively support the user's ability to evaluate decision alternatives and develop a recommended decision.

Decision Technology Systems: Information systems that are designed to support all phases of the decision making process in a complete and integrated manner.

Executive Information Systems: Information systems that access, report, and help users interpret problem pertinent information.

Integrated Decision Making Support Systems: Information systems that integrate the functions of one or more individual (stand-alone) decision making support systems.

Intelligent Just-in-Time Decision Support Systems: Information systems that provide expertise just in time to support the decision making process.

Knowledge-Based Systems: Information systems that capture and deliver problem pertinent knowledge to users.

Machine-Learning Systems: Information systems that mimic the human learning process and deliver the knowledge to users.

Usability Engineering of User-Centered Web Sites

Theresa A. O'Connell

Elizabeth D. Murphy
U.S. Census Bureau, USA

INTRODUCTION

For Web sites to succeed, they must be user-centered. A user-centered focus throughout Web site development life cycles promotes Web site usability. This is accomplished through usability engineering carried out within the context of software engineering.

BACKGROUND

Starting with an understanding of users, and proceeding in concert with software engineering, usability engineering promotes user success and satisfaction. In this section, we introduce principal concepts of Web site usability engineering.

Users

In the context of this chapter, users are people who interact with Web sites. The term *user* is restricted to the intended users of a Web site. It excludes usability engineers (UEs), the site's providers, and others who have any stake in the Web site. Users of Web sites differ across many dimensions, for example, age, gender, technology experience, intellectual or aesthetic preferences, interaction styles, and abilities.

Usability

A definition of usability, from the International Organization for Standardization (ISO), underlies UEs' focus on users' needs and their goal of meeting users' needs through usability engineering. ISO defines usability in specific contexts of use: efficiency, effectiveness, and user satisfaction (ISO, 1998). Efficiency and effectiveness are components of user success. Satisfaction is an equal factor for usability: Usability = user success + user satisfaction.

The ISO definition implies that usable software must be accessible to users with special needs. Accessibility is a subdomain of usability in which users have physical and/or cognitive disabilities. Accessibility enables people with disabilities to experience success and satisfaction with software to a degree comparable to that enjoyed by people without disabilities (W3C, 2005).

User Participation in Web Site Development

Usability engineering relies on close interaction with users at strategic points where their input is crucial. Techniques span the software development life cycle. Examples include focus groups, interviews, surveys, design discussions, and observing as users interact with prototype Web sites. Collection of human performance data is key to evaluating users' success. Typical measures of human performance include accuracy and speed of task completion. These measures of user success complement, and often contrast with, self-reported ratings of user satisfaction.

Mental Models

From experiencing computers and Web sites, users build mental models, that is, psychological representations of the ways in which computers and Web sites work (Carroll, 1990; Johnson-Laird, 1983). Highly experienced users have mental models of different categories of Web sites, for example, entertainment and informational sites. Novice users, however, may not have differentiated their mental model of Web sites into unique categories. UEs help designers make user-interface design consistent with frequent users' expectations from prior experience with other Web sites. This consistency helps novices develop expectations as a basis for forming mental models that will apply across other Web sites. This is not to imply, however, that all user groups will have congruent mental models. Realistically, the mental models of different users and user groups will have some commonalties, yet, at the same, time exhibit many individual differences.

USER INTERFACE

A user interface (UI) is software that people use to interact with technology. The UI encompasses more than what users see or hear. In the broadest sense, the UI is the virtual place where the user's mental model meets the designers' system model (Bolt, 1984.) Aligning these models is a goal of usability engineering (Norman & Draper, 1986).

Usability Engineering

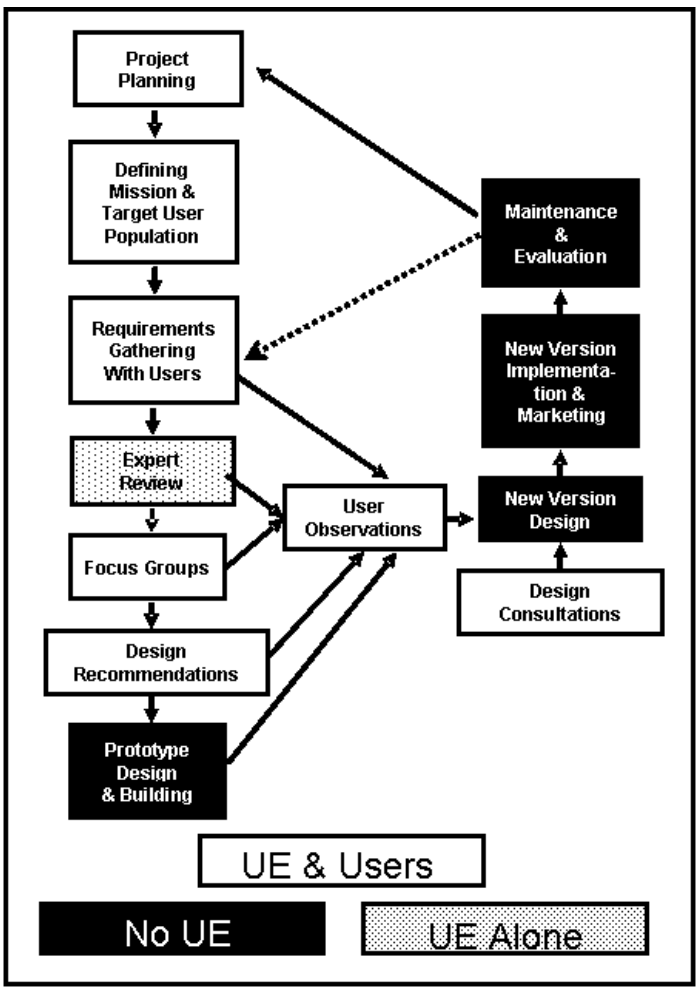
Usability engineering is a set of defined, user-centered processes grounded in research-based principles. Its purpose is to raise the potential for user success and satisfaction and, thereby, to support Web site providers' goals. UEs must understand a complex set of user variables to promote user success and satisfaction.

UEs' work is user-oriented, but usability engineering goes beyond user advocacy. UEs must also understand organizational and project goals. They must work within the structure of software development life cycles.

Usability Principles

With roots in human factors, usability engineering also draws on disciplines such as software engineering, linguistics,

Figure 1. A software development life cycle showing UEs interacting with users. Cited resources demonstrate how some usability engineering processes can be integrated into a software development life cycle (Addelston & O'Connell, 2005, Hix & O'Connell, 2005, Mayhew, 1992, O'Connell & Murphy, 2007). Next, we focus on usability engineering activities in four life-cycle critical iterative process areas: project planning, requirements definition, design, and evaluation/testing.



biology, cognitive psychology, information technology, and graphic design. These fields' diverse contributions converge in research-based usability principles and widely accepted guidelines for achieving usability (e.g., Koyani, Bailey, Nall, Allison, Mulligan, Bailey, & Tolson, 2003; Mayhew, 1992; Shneiderman & Plaisant, 2004). Usability principles are constantly updated in response to new research and technologies (e.g., O'Connell & Choong, 2008).

Usability principles trace to human capabilities and limitations. For example, to accommodate users with color vision deficiencies, one usability principle tells us never to rely solely on color to convey meaning. Another usability principle warns designers not to overload human working memory. Two goals of user-interface design are to capitalize on human capabilities and to compensate for human limitations.

Software Engineering

Software engineering is the "application of a systematic, disciplined, quantifiable approach to the development, operation, and maintenance of software" (IEEE, 1990, p. 70). On large Web site projects, software engineers typically oversee both the technical and management aspects of development by following life cycles that stipulate, for example, a project's phases, methods, activities, inputs, outputs, milestones, documentation, and risk-mitigation strategies.

A shared understanding of users' attributes and needs underpins the collaboration necessary to incorporate user-centered processes into software engineering processes. Usability engineering processes are compatible with software engineering processes. If software engineering is to develop useful tools, it must incorporate usability engineering. Books could be written about multimillion and multibillion dollar software engineering projects that failed because of inattention to usability. It is entirely possible for software to fulfill functional requirements and not be usable.

INTEGRATING USABILITY ENGINEERING INTO SOFTWARE-ENGINEERING LIFE CYCLES

Life cycles are structured frameworks for software development activities. For usability engineering to be fully integrated into Web site development, its practices must be integrated into software development life cycles from the start. Engineering usability up front reduces the need for changes after programming because user-centered design (UCD) is more likely to capture users' needs. Results include increased productivity, flatter learning curves, longer and repeated visits, increased profits, and decreased costs (e.g., Bias & Mayhew, 2005; Kalin, 1999; Mayhew 1999). Software engineering and usability engineering life cycle processes occur in parallel with compatible activities and outputs. They share the goal of producing usable Web sites.

In a Web development life cycle, each activity has goals, inputs, processes, and products. Each activity passes output into subsequent activities. Usability engineering has corresponding activities for most software engineering activities. Within each activity, usability engineering and software engineering processes occur simultaneously. Activity sequence and frequency can vary. For Web sites, when all the activities have been completed, it is not unusual for the life cycle to start again, resulting in a frequently updated Web site that adapts to changing user needs. Next, we focus on usability engineering activities in four life-cycle critical iterative process areas: project planning, requirements definition, design, and evaluation/testing.

Project Planning

The project plan is a blueprint for all Web site development activities. If usability engineering and user involvement are not addressed from the start in the plan's schedule and budget, they have little chance of later inclusion.

As a result of usability engineering's unique contributions during planning, the Web site's design will consider the user; the life cycle will be hospitable to user-centered processes; and the project will have a framework not only for funding and scheduling, but also for building usability into the product (Murphy, Nichols, Anderson, Harley, & Pressley, 2001).

Requirements Definition

In software engineering, requirements definition is a set of processes that identify and document a Web site's goals in terms of how the site will fulfill its providers' vision by delivering information and functionality. Usability engineering adds the users' perspective to verify that users' needs and expectations are met.

Requirements definition brings UEs face-to-face with targeted users during interviews, focus groups, and observations. Close interaction with users is key because existing documentation often omits users' real-world practices. The Web requires designing for a wider range of users than a project can usually involve. Therefore, UEs rely on usability principles and knowledge of human capabilities and limitations within the context of Web use.

Usability engineering processes during requirements definition start by considering users and their needs within the context of the Web site's intended offerings. As other team members set performance and system-function requirements, UEs investigate whether proposed content will meet both providers' goals and users' needs. For an existing site,

UEs address what worked and what did not work for its users not only in terms of content, but also in terms of layout and navigation.

Requirements definition produces artifacts such as user profiles, user classes, and user task descriptions and, most importantly, usability requirements that become a check list for everything that must be accomplished to promote successful and satisfactory user experiences. Critically, the underlying information architecture of the site must be logical from the user's perspective. This may mean that more than one path should lead to the same content because different user groups conceptualize the content differently.

User Profiles and Classes

Requirements definition starts by creating user profiles, documenting user attributes such as computer literacy; subject matter expertise, and experience with site functionality; physical and cognitive capabilities and limitations; education; mental models; interaction styles; goals; and tasks–all factors that impact human computer interaction. In user class analysis, UEs allocate user profiles into groups according to shared attributes.

UEs track the findings of these processes to the site's intended content to assure that its presentation empowers users to achieve their goals at the site. For example, during user class definition, UEs specify groups of people with disabilities, associating needed assistive devices with the user group. Assistive devices may include screen readers, screen magnifiers, and alternative means of entering data.

User Task Descriptions

In behavioral and cognitive task analysis, UEs describe users' goals and tasks. UEs study existing documents and observe users to learn the steps and sequences they take to accomplish goals. Behavioral task analysis documents observable tasks such as receiving and inputting information. Cognitive task analysis documents users' mental transformations and decisions.

Task analyses specify steps and work flows, describing the user experience, beginning-to-end. For example, when users must fill out an online form, UEs identify necessary initial steps, such as receiving an information package in the mail, locating the site's URL, and locating the user's login number, all long before the user navigates to the form.

Use Cases

Use cases are an output of requirements definition. They are formal descriptions of ways a product can be used. For each module of a system, use cases describe common processes and their prerequisites; steps users and the system will take; and resultant changes. Use cases help to ensure that the system supports frequent processes, that processes are relatively straightforward, and that the system architecture reflects the process structure.

Use cases do not accommodate the fact that users use software in ways that developers do not expect, based on cues from the UI in the context of the moment. Use cases do not stress cognitive tasks; therefore, they do not always represent users' natural interaction behaviors. UEs add value to use cases by making user-centered recommendations that would be missed otherwise. For example, the UE will recommend avoiding having each screen accommodate only one use case. UEs assure that screens accommodate users' own work flows, not someone else's model of required interactions.

Usability Requirements

Web sites have functional, system-performance and usability requirements. Functional requirements define what a Web site is supposed to do. System performance is a measure of how well the Web site does what it is supposed to do. Usability requirements address user interaction with the Web site. Usability requirements stipulate, for example, that users can purchase a product, making no more than one error, and that the site must receive a satisfaction rating of seven out of a possible nine. Some usability requirements are yes/no, for example, the Web site will provide anchor links on every page at its top two levels. Others are quantified, for example, users will be able to navigate, with only one click, from a product description page to an order placement page. Measurable usability requirements become goals for assessing the design against users' needs during usability evaluation (Whiteside, Bennett, & Holtzblatt, 1990).

In setting usability requirements, UEs view the site's goals through the lens of users' needs. Consider a case where the site aims to enhance the organization's image by showing its Chief Technology Officer talking about a new technical approach. For users with hearing impairments, the UE introduces a requirement for captions.

Some requirements are standards driven. Standards can be defined by the site provider, for example, an in-house standard for displaying the company logo. Standards can come from groups such as ISO. Sometimes requirements are legally mandated. For example, the UIs of some US federal government sites must comply with Section 508 of the Rehabilitation Act of 1973, as amended in 1998 (US Government, 1998), which gives accessibility requirements.

A Web site can fulfill all functional and system-performance requirements, yet still not be usable. In the end, it is the user's experience of a Web site that determines whether the site has achieved the product vision; so, usability engineering promotes a perspective that incorporates the product

concept, but expands the understanding of targeted users and their needs.

Design

UCD focuses on accommodating user attributes that impact how users will interact with the Web site. Its goal is to achieve user success and satisfaction by incorporating users' perspectives into design. Throughout the life cycle, UEs perform design consultations on iterative products, informing design with knowledge of users and usability principles.

UCD processes, called interaction design, consider ways that users attempt to accomplish goals at a Web site. UEs base interaction design on all that they have learned about the users. Usability principles inform UCD decisions. Consider a site intended for senior citizens who expect a prominent link to articles about leisure activities for seniors. UEs apply usability principles on legibility for older users with decreased visual acuity and recommend a large font and a strong contrast between the font and background colors (e.g., Czaja & Lee, 2003).

Incorporating user input from requirements definition, UEs participate in designing the site's information architecture. An information architecture sets out paths that users follow within and between pages in a Web site. The UEs' role is to assure that the information architecture facilitates navigation and makes finding information natural for users.

UEs know how to manage the impact of features such as animations on users with disabilities. For example, it is simple, but detrimental to usability, to give an information site a bright colorful background with flashing bold titles. UEs recommend treatments that accommodate the biological impacts of such an approach, thereby reducing the potential for the eyes to become fatigued because they are unable to focus on flashing elements (Travis, 1991).

UEs bring to UCD an understanding of semiotics, the science of signs and symbols. When incorporating icons into a UI design, for example, it is important to use standard icons and to test designs for user comprehension. If an icon is used to mean something different than the user expects, it will likely cause confusion. With effort, users can learn arbitrary meanings for icons, but they easily forget arbitrary meanings. Such icons need text labels to clearly indicate the actions that will occur when they are activated. (Horton, 1994).

Participatory design is a UCD process in which users offer opinions on mock-ups or prototypes. A typical participatory design process is card sorting (Usability.gov, 2008). Users sort terms to be used in the Web site into groups that they name. UEs combine results from all participants through a statistical technique. Applying usability principles, UEs then derive a meaningful user-centered organization of Web site topics, that is, the site's information architecture.

We distinguish between *user-centered* design and inappropriate *user-driven* design (UDD) where user input translates directly into design directives. In turning user requests into design decisions without looking at them in light of usability principles, UDD runs a high risk of producing Web sites that do not meet users' needs. Another UDD pitfall is requirements creep that extends schedules and strains budgets as users add inappropriate features and functions that can have a negative impact on their experience at the site (Andre & Wickens, 1995).

Evaluation/Testing

In software engineering, verification is iterative testing against requirements. Validation is end-of-life-cycle testing against requirements. Usability evaluation is a set of verification and validation (V&V) processes that are applied in conjunction with other V&V activities. In addition to checking for conformance to usability requirements, iterative usability evaluation has the goal of assessing a wide range of user experiences at the site. When performed early in the life cycle, evaluation keeps the door open for new requirements based on the way real users interact with the site.

Usability evaluation is not a matter of simply asking users what they like or dislike about a site. Key user-centered usability evaluation processes entail observing users interacting with a Web site. Activities for user observation include writing a test plan; identifying participant users and their task expectations; working with site providers to set usability goals for each user group and task; defining tasks; writing scenarios (statements of goals that never tell users how to achieve those goals); writing user satisfaction surveys; preparing ancillary materials such as consent forms; carrying out the observations; collecting success and satisfaction data from participants; analyzing data and reporting findings (Lazar, Murphy, & O'Connell, 2004).

Nothing speaks louder about the quality of a Web site than the experiences of its users. During usability evaluation, UEs often employ click-capture software; record numbers and types of user errors; document latency periods when users pause for a significant period of time, pondering what to do next; and record critical incidents when users must stop work. Observing users interacting with the site, developers and stakeholders see the need for changes.

Using a method called *think aloud*, UEs encourage users to talk about their expectations and reactions while they work with a Web site (Boren & Ramey, 2000; Van Waes, 2000). The output is metric data on user success accompanied by anecdotal data, the users' own comments on what they were doing and why, and what they think of the site. UEs are specially trained to put users at ease during observations and to facilitate the users' evaluation experience.

After usability observations, users often complete satisfaction surveys on site components that they have experienced. These surveys collect ratings on a numerical scale to produce metric data. They also offer opportunities

for users to elaborate on their experiences. UEs never rely solely on satisfaction data, but use it to inform analysis of data collected during user interactions with the Web site. UEs interview users about their experience at the end of the session. Interviews also give users opportunities to bring up points that no one else has anticipated.

It is unusual to hold formal usability observations at every iteration. Indeed, some projects find user observations cost-prohibitive. However, other simple, less expensive processes incorporate the user perspective. In an expert review, one or more UEs independently assess an interface against their understanding of users; usability principles; and applicable laws and standards. When more than one UE has performed the expert review, they discuss and prioritize their findings. Another kind of expert review employs automated accessibility tools to inspect the Web site's UI code for conformance with accessibility regulations, and to recommend remedies.

Life cycles typically include several V&V iterations. Usability evaluation produces recommendations to improve the potential for user success and satisfaction with the UI. The principal benefit is an understanding of how users interact with the site (Dumas & Redish, 1999). A unique benefit of usability engineering is the coordination of these recommendations with other organizational and project goals.

FUTURE TRENDS

Usability engineering is increasingly recognized as an integral part of Web site development. The field will continue to refine its usability principles and life cycle activities to address evolving Web technologies and user-interaction behaviors.

CONCLUSION

Usability engineering is rigorous, process-based, and addresses needs of site providers as well as users. Software engineering and usability engineering processes include simultaneous, complementary activities whose products can benefit later activities without impacting schedules. Usability engineering is the means to providing successful and satisfactory experiences for Web site users while fulfilling the goals of the site's providers.

This paper reports the results of research and analysis undertaken by U. S. Census Bureau staff. It has undergone a Census Bureau review more limited in scope than that given to official Census Bureau publications. This report is released to inform interested parties of ongoing research, and to encourage discussion of work in progress.

KEY TERMS

Accessibility: A subdomain of usability; enables people with disabilities to experience success and satisfaction with software to a degree comparable to that experienced by people without disabilities.

Evaluation: The process of assessing user-interface (UI) software for its ability to support users' success and satisfaction in meeting their goals; not simply a matter of asking what the user likes and dislikes, but a process of collecting and analyzing human performance data (e.g., accuracy, task-completion times) and ratings of user satisfaction with the "look and feel" of the user interface; results of evaluation inform development of recommendations to improve the UI design.

Life Cycles: Structured frameworks for software development activities.

Mental Models: Users' psychological representations of the components and behavior of, for example, processes, products, services, and relationships.

Software Engineering: Application of a systematic, disciplined, quantifiable approach to the development, operation, and maintenance of software (IEEE, 1990, p. 70).

Usability: The potential for user efficiency, effectiveness and satisfaction, or simply, user success and satisfaction, when interacting with technology.

Usability Engineering: A set of defined, user-centered processes, grounded in research-based principles.

Usability Evaluation of E-Learning Systems

INTRODUCTION

The traditional approach for designing user interface for information systems[1] has focused on the capabilities of the technology. This "technology-centered approach" has frequently neglected the actual user requirements. The focus of such a design philosophy is to create interface systems that are based on opportunities presented by the capabilities of technology. In contrast, the user-centered design starts with the requirements of the end users and exploits the capabilities of technology to address users' needs, preferences and abilities. There is no doubt about the fact that such a shift from "technology-centered approach" to "user-centered approach" has increased the *usability* of the designed systems. However, in the context of e-learning systems, user-centered design is, in itself, not adequate to meet all the learner's needs. In addition to being user-centric, in terms of convenience, e-learning systems must also achieve the desired "learning outcomes". Thus, usability of e-learning systems has wider connotations compared to other information systems. The design for such systems, which aims at satisfying the learning needs more closely, is often referred to as learner-centered design (LCD) and goes beyond the usual user-centered design.

Usability evaluation which refers to a series of activities that are designed to measure the effectiveness of a system as a whole, is an important step for determining the acceptance of system by the users. Usability evaluation is becoming important since both user groups, as well as tasks, are increasing in size and diversity. Users are increasingly becoming more informed and, consequently, have higher expectations from the systems. Moreover "system interface" has become a commodity and, hence, user acceptance plays a major role in the success of the system. Currently, there are various usability evaluation methods in vogue, like cognitive walkthrough, think aloud, claims analysis, heuristic evaluation, and so forth. However, for this study we have chosen *heuristic evaluation* because it is relatively inexpensive, logistically uncomplicated, and is often used as a discount usability-engineering tool (Nielsen, 1994). Heuristic evaluation is a method for finding usability problems in a user interface design by having a small set of evaluators examine an interface and judge its compliance with recognized usability principles.

The rest of the chapter is organized as follows: we first look at the definition of e-learning, followed by concepts of usability, LCD, and heuristics. Subsequently, we introduce a methodology for heuristic usability evaluation (Reeves, Benson, Elliot, Grant, Holschuh, Kim, Kim, Lauber, & Loh, 2002), and then use these heuristics for evaluating an existing e-learning system, GETn[2]. We offer our recommendations for the system and end with a discussion on the contributions of our chapter.

BACKGROUND

E-Learning

According to MSN Encarta, electronic learning (e-learning) is "the acquisition of knowledge and skills using electronic technologies such as computer and Internet-based courseware and local and wide area networks". E-learning applications can be broadly classified into two categories: *offline learning,* where learning is imparted through the use of digital media devices like CD-ROMs, DVDs, and so forth, and *online learning*, where learning is imparted through computer networks using Web-based tools like, virtual classrooms, digital collaboration (discussion forum, chat, electronic bulletin boards, listserv, etc.). Web-based learning operates in a computer-networked environment and many of these systems make use of the Internet. In this chapter, we restrict our discussion to the usability of Web-based learning management systems (LMS). Such LMS not only offer online courseware, but also track participants' progress in learning.

Usability of E-Learning Systems

The ISO 9241 (1998) defines usability as "the extent to which a product can be used by specified users to achieve specified

goals with effectiveness, efficiency, and satisfaction in a specified context of use." Usability is the quality attribute that assesses the *ease of using* the application by users to accomplish their specified goals effectively, efficiently, and with a high level of satisfaction. In addition to ease of use, a usable e-learning system should be *useful* for the learners in accomplishing their learning task (Venkatesh, Morris, Davis, & Davis, 2003). Usability analysis helps increase the likelihood of a system being classified as not only easy to use but also useful from the learners' perspective.

Apart from the two basic objectives highlighted above, researchers have suggested several additions to the usability model. Constantine & Lockwood (1999) highlighted that a usable e-learning system must achieve: learnability, rememberability, efficiency in use, reliability in use, and user satisfaction. An effective e-learning system should be interactive and provide feedback, have specific goals, motivate users, communicate a continuous sensation of challenge, provide suitable tools, and help avoid distractions interrupting the learning stream (Costabile, De Marsico, Lanzilotti, Plantamura, & Roselli, 2005). Incorporating feedback, curiosity, comprehensiveness, and challenges in the e-learning system can help achieve the motivational aspect of usability (Shilwant & Haggarty, 2005). The *usability* definition for e-learning is incomplete without incorporating *learnability* aspect into the systems. Hence, in addition to being user-centric, e-learning systems should be designed with a learner-centric approach.

Learner-Centered Design

Learnability is defined as the ease and speed with which users can figure out the way to use a product (Soloway, Guzdial, & Hay, 1994). To incorporate learnability into the usability framework, learner-centered design (LCD) was proposed by Soloway and Pryor (1996). The key to developing effective e-learning systems is to adopt the LCD methodology, which targets to help learners acquire knowledge efficiently and effectively even through an e-learning tool, which is new for them. Since learners do not undergo extensive training before using the e-learning system, system design should be such that the learners can focus on the "actual learning" and not on "learning to use the e-learning system".

In LCD, the design process considers a variety of learner categories due to differences in personal learning strategies, experiences in the learning domain, and motivations in affording the learning task (Ardito, De Marsico, Lanzilotti, Levialdi, Roselli, Rossano, & Tersigni et al., 2004). The designer must also consider prior knowledge and self efficacy (computer skills) of the learner and focus on learners' needs and goals in a simple way. For example, the use of multimedia files as instructional mode should not overwhelm the users and disrupt their learning process. The e-learning interface design should also integrate various pedagogical methodologies and traditional teaching strategies. The aim should be to help learners achieve their learning objectives in a more productive, efficient and effective way.

USABILITY EVALUATION IN E-LEARNING

Usability evaluations in the case of e-learning systems are difficult to employ due to the time, budget, and knowledge constraints. Consequently, there is a lack of e-learning usability studies, which has adversely influenced e-learning design and development in practice.

Feldstein (2002) pointed out that producers and consumers of e-learning applications have no standardized means to evaluate the extent to which any e-learning application is usable. The norm generally followed for assessing usability is the *satisfaction level* of the user. This may not be a fair indicator of the actual usability because it does not take into account the *learning objectives*. A user may be satisfied with attributes of the system, other than those achieving learning outcomes. Hence there is a need for understanding e-learning usability in greater detail.

Heuristic Usability Testing

Feldstein (2002) suggested the use of "heuristics" for testing the usability of e-learning systems. Heuristic usability testing techniques offer simple and cheap means for assessing e-learning systems. Nielsen (2000, 1994) offered a set of simple usability heuristics, which focus on giving timely and useful feedback. Notess (2001) pointed out that heuristic evaluations hold promise for online learning but the challenge for most types of online learning is that established sets of heuristics do not exist. Many researchers are of the view that Web design heuristics that have developed around e-commerce can be suitably modified and used for the evaluation of e-learning systems. Squires & Preece (1996) established the ineffectiveness of simple heuristic usability testing and highlighted that Web design heuristics have to incorporate various learning theories and pedagogical guidelines to be effective for e-learning. They added socio-constructivist tenets to Nielsen's (1994) heuristics and proposed a set of heuristics for "learning with software" (Squires & Preece, 1996). In due course, taking into account usability as well instructional design features, Reeves, et al. (2002) expanded and customized Nielsen's (1994) ten heuristics developed for software in general, to enunciate fifteen heuristics for evaluating e-learning systems (Table 1), which we use in our current study.

Table 1. Reeves fifteen heuristics for evaluating e-learning programs

No	Heuristic	Description
Protocol for heuristic evaluation of e-learning programs		
H1	Visibility of system status	The e-learning program keeps the learner informed about what is happening, through appropriate feedback within reasonable time.
H2	Match between system and the real world	The e-learning program's interface employs words, phrases and concepts familiar to the learner or appropriate to the content, as opposed to system-oriented terms. Wherever possible, the e-learning program utilizes real world conventions that make information appear in a natural and logical order.
H3	Error recovery and exiting	The e-learning program allows the learner to recover from input mistakes and provides a clearly marked "exit" to leave the program without requiring the user to go through an extended dialogue.
H4	Consistency and standards	When appropriate to the content and target audience, the e-learning program adheres to general software conventions and is consistent in its use of different words, situations, or actions.
H5	Error prevention	The e-learning program is designed to prevent common problems from occurring in the first place.
H6	Navigation support	The e-learning program makes objects, actions, and options visible so that the user does not have to remember information when navigating from one part of the program to another. Instructions for use of the program are always visible or easily retrievable.
H7	Aesthetics	Screen displays do not contain information that is irrelevant and "bells and whistles" are not gratuitously added to the e-learning program.
H8	Help and documentation	The e-learning program provides help and documentation that is readily accessible to the user when necessary. The help provides specific concrete steps for the user to follow. All documentation is written clearly and succinctly.
Usability and Instructional Design Heuristics for evaluation of e-learning Programs		
H9	Interactivity	The e-learning program provides content-related interactions and tasks that support meaningful learning.
H10	Message design	The e-learning program presents information in accord with sound information-processing principles.
H11	Learning design	The interactions in the e-learning program have been designed in accord with sound principles of learning theory.
H12	Media Integration	The inclusion of media in the e-learning program serves clear pedagogical and/or motivational purposes.
H13	Instructional assessment	The e-learning program provides assessment opportunities that are aligned with the program objectives and content.
H14	Resources	The e-learning program provides access to all the resources necessary to support effective learning.
H15	Feedback	The e-learning program provides feedback that is contextual and relevant to the problem or task in which the learner is engaged.

Heuristic Evaluation of GETn System: An Illustrative Application

In this section we demonstrate the applicability of Reeves (2002) fifteen heuristics for evaluating an existing e-learning system GETn (acronym for Get Knowledge!). GETn is a widely known, well-established and leading global enterprise, which has been in this industry for the last thirty-five years and has partnered with a pool of leading technology and content partners. GETn is a web-based interactive and self-paced tutorial in a simulated environment. It offers a wide variety of courses: self-improvement courses such as improving communication skills, listening skills, relationship skills and IT courses for the use of various softwares like adobe photoshop, and so forth. The progress status of the learner for a particular topic is marked by symbols, which denote "not started", "started", "completed" and "mastery". It is highly interactive and gives an immediate feedback after each response from the user.

Method

Heuristic evaluation involves having a system examined independently by not more than two to five evaluators who understand the system's goals and have good knowledge of established usability guidelines. These evaluators develop a list of items that they must address, creating a structured format for the evaluation. Their reports typically turn up some major and some minor usability flaws, without ranking them by importance.

Table 2. Heuristic evaluation and recommendations for GETn

Heuristics	Violation of Heuristics	Recommendations
Visibility of system status	**No** display of percentage of course completion (progress status). **No** alert message to inform the learner that the system has been idling. This erroneously inflates the training hours.	**The** progress status bar should be incorporated to motivate learners. **Pop-up** messages should periodically alert learners about the inactivity of the lesson and ask them if they intend to continue.
Match between system and the real world	**No** logical classification of training courses into categories based. They are just arranged in alphabetical order. **Learner** does not know how the current score is computed. **No** glossary/index for quick references is available.	**The** courses should be classified into learning categories to facilitate quick access and choice by the learner. **The** methodology for computing scores should be made clear to the learners. **Glossary** and indexes should be made available online to facilitate quick cross-referencing.
Error recovery and exiting	**No** provision for error recovery when learner accidentally clicks on other tasks or exits from the topic while he/she is in the midst of learning. Learner has to restart that particular topic all over again.	**System** should have an alert pop-up message to confirm exit and should also allow learners to return to the last screen attempted.
Consistency and standards	Nil	Nil
Error prevention	**No** instructions for setting up GETn are displayed on the login screen to connect users to the training plan. **System** error often reported on course completion due to un-attempted items. The course does not display "completed" status.	**Instructions** for setting up should be shown on the login page to inform the users. **System** should avoid "uncompleted" status by pointing out the specific uncompleted or overlooked tasks, in a timely fashion so that learners are not frustrated doing the whole course again.
Navigation support	**No** option to "expand" contents to view all the sub-topics simultaneously. **No** search facility provided. **No** print option for course material. **Bookmark** option not available.	**Contents** menu should include "expand" and "collapse" options for quick viewing. **Should** have options for searching topics. **Print** option should be provided. **Bookmark** option should be provided for subsequent referencing later.
Aesthetics	**Viewing** window is small and has a fixed size. Users cannot adjust the screen size.	**Should** allow learners to adjust the screen size depending on their preferences.
Help and documentation	**No** provision for online or e-mail help. **Instructions** for downloading content are not clear.	System should provide online help, like live chat, and also provide help e-mail addresses. **Downloading** options should be clearly highlighted to enable offline learning also.
Interactivity	**No** synchronous and asynchronous tools for collaborative learning such as chat, discussion forums, resulting in no opportunity to learn from others.	**Discussion** forums, live chat, and other collaborative features should be incorporated so that learners can effectively gain knowledge through social learning.
Message design	**Important** concepts and topics are neither highlighted in the title nor in the body	**Important** concepts and key words should be highlighted. This is similar to teachers emphasizing the key concepts.
Learning design	Nil	Nil
Media Integration	**Use** of video is minimal.	**Videos** should be incorporated so as to make the learning processes more interesting and captivating.
Instructional assessment	Nil	Nil
Resources	**No** links to other resources such as good Web sites.	**Useful** and good resources such as recommended readings and useful Web sites should be listed for learners to pursue the course further.

continued on following page

Table 2. continued

Heuristics	Violation of Heuristics	Recommendations
Feedback	**Feedback** is rather brief.	**Elaborate** feedback should be given after each test or exercise.
	No option for sending feedbacks to instructors and experts by e-mails or any other means of communication.	**Provision** for sending feedbacks to relevant persons should be incorporated to have their expert comments for better learning.

For our GETn e-learning system, Reeves (2002) heuristics were chosen, as they are formulated specifically for e-learning systems. Two of the co-authors of this chapter did separate usability evaluations, after which the results were reconciled. The reported violations of heuristics (Table 2) are the ones which were either recorded or agreed to by both evaluators. This gave some objectivity to our subjective evaluations. We present our results and also recommendations in Table 2.

Discussion

From the heuristics evaluation results (Table 2) we see that even for well-established e-learning systems (like GETn) the usability standards may not be up to the desired level. Hence, there is an imperative need for firms manufacturing e-learning systems to have a systematic usability evaluation in order to have a better impact on the learners.

Heuristic usability evaluation can be employed extensively without any concerns about the cost aspect, since it is an inexpensive, quick, and reliable means of evaluation. However, as suggested by Reeves, et al. (2002) heuristic evaluation is not sufficient to determine whether an e-learning system is "learner-centered" or not, since heuristic approach is based only on the views of the experts. The evaluation techniques of e-learning systems should include learners' perceptions as well. Heuristic evaluation is not a replacement for the actual usability testing with the users of the systems. It is only an initial assessment done by the experts, developers or designers.

FUTURE TRENDS

As the issue of integrating usability and learning is still in its infancy, more research needs to be conducted in order to develop and standardize the usability evaluation methods for e-learning. The major challenge is to provide a usability evaluation technique, which incorporates learners' perceptions, integrates usability and instructional design, and at the same time is simple, cheap and reliable.

Extending the usability evaluation techniques a Systematic Usability Evaluation (SUE) technique has been proposed recently (Ardito, et al., 2004; Costabile, et al., 2005). SUE methodology aims to provide reliable evaluation by systematically combining inspection with user-based evaluation. Future designers of e-learning systems can also bring in the concept of *personas* (Shilwant & Haggarty, 2005)**,** to help them focus on the needs of end users throughout the design process. These developed personas serve as proxy users, when actual users are not available for testing. Newer techniques of usability like Microsoft Usability Guidelines (MUG), which are being used for Web sites and wireless Web sites, can also be adapted to the context of e-learning systems (Venkatesh & Ramesh, 2006; Agarwal & Venkatesh, 2002).

CONCLUSION

To design a good and usable e-learning system that is effective, efficient, learnable, and has high user satisfaction, designers have to put users and their needs in the forefront. Pedagogical methodology, instructional strategies, and also the learning context should be incorporated in the design process. Although developing an attractive and easy to use, system interface is essential, the focus of e-learning systems should be on "learning outcomes" rather than satisfying the user only with a good interface. Designers or developers should pay special attention to the learning goals and needs of the users, instructional strategies, and quality of learning. This chapter discusses the applicability and usefulness of a simple and inexpensive usability evaluation technique, namely, heuristic evaluation. E-learning software designers are looking for ways and means of providing better products to their customers, and this chapter helps them understand

one such way without a heavy cost burden. As already discussed, actual user studies are more realistic, but due to cost constraints many firms do not actually conduct them for their products. Moreover, user studies can be done only when the product is actually ready for use. On the other hand, heuristic evaluation is a useful inexpensive evaluation technique, which can be employed even before the final product is launched in the market.

KEY TERMS

E-Learning: According to MSN Encarta, e-learning (or electronic learning) is "the acquisition of knowledge and skill using electronic technologies such as computer and Internet-based courseware, and local and wide area networks." In other words, it is learning through electronic means where knowledge and skills are transferred either through the computer networks or through digital media like CD-ROM, DVDs, and so forth. In the Web environment, users may use virtual classrooms, digital collaboration, discussion forums, chat rooms, and so forth, to obtain information and facilitate learning.

Heuristic Evaluation: Heuristic evaluation is a method for quick, cheap, and easy evaluation of a user interface design by comparing the system to a set of identified heuristics.

Learnability: Learnability is defined as the ease and speed with which the users get familiar with the use of a new product. With high learnability, users can intuitively learn to use a product without training or manuals. However, in the context of e-learning, the definition of learnability includes

the ability of users to effectively learn and retain the skills and knowledge.

Learner-Centered Design: Learner-centered designs focus on developing a learner's understanding, rather than on improving usability, of the designed system. In the context of e-learning systems, the focus is more on the achieving the "learning outcomes."

Personas: Personas are archetypal users of an intranet or Web site that represent the needs of larger groups of users in terms of their goals and personal characteristics. They represent the real users and help guide the designers in making decisions about the system designs and functionalities. Personas represent behavior patterns by identifying user motivations, expectations, and goals from the system. Although personas are fictitious, they are based on knowledge and profiles of real users.

Usability: The ISO 9241 defines usability as "the extent to which a product can be used by specified users to achieve specified goals with effectiveness, efficiency, and satisfaction in a specified context of use."

User-Centered Design: It is a design approach in which the emphasis is on the users' requirements and not on the designers' capabilities. User-centered design helps achieve a high level of usability.

ENDNOTES

1 'Systems' can be hardware or software, however, in our paper, we use it for software systems.

2 This is a fictitious name to hide the real identity of the e-learning software.

Usable M-Commerce Systems

John Krogstie
IDI, NTNU, SINTEF, Norway

INTRODUCTION

Today, the PC is only one of many ways to access information resources. Traditional computing technology has become more mobile and ubiquitous and more and more computing tasks are possible to do using new types of mobile devices.

According to Siau, Lim, and Shen (2001), the essence of m-commerce (also termed "mobile information systems") is to reach customers, suppliers, and employees regardless of where they are located and to deliver the right information to the right person(s) at the right time. The ability to develop and evolve usable m-commerce systems is becoming increasingly critical for enterprises.

BACKGROUND

M-commerce systems differ from more traditional information systems along several dimensions (Krogstie et al., 2004). We have grouped the differences into three areas:

1. User-orientation and personalization
2. Technological aspects including convergence and need for multi-channel support
3. Methodology for development, evolution, and operations to ensure organizational returns

User-Orientation and Personalization

M-commerce systems often address a wide user-group, which means that user-interface aspects should feature prominently and early in the design process and often need to be very simple. A number of examples exist indicating that complex services often do not get adopted (Blechar, Constantiou, & Damsgaard, 2005; Steinert & Teufel, 2005). Input and output facilities of the end-user device may be severely restricted (no keyboard, small screen-size, etc.) or based on new modalities (speech-recognition and -synthesis). This means that personalization of mobile information systems becomes increasingly important, both at the individual level where user-interface details are tailored to personal preferences and hardware, and at the work-group level where functions are tailored to fit the team's preferred way of working.

Personalization means information systems that both automatically adapt themselves to the preferences and context of the user, and that can be explicitly tailored by users. The main goal is to achieve usability of the applications on all possible interfaces, based on adaptation to the different physical devices. This calls for intelligent, adaptive, and self-configuring services that enable automatic context-sensitivity and user profiling (Hella & Krogstie, 2006).

Technological Aspects Including Convergence and Multi-Channel Support

Mobile devices still have limited processing, memory, and communication capacities compared to what one are familiar with on traditional PCs. Performance considerations therefore is still important, as is bandwidth analysis. Analytically-based predictive methods are necessary in order to assess a large number of alternatives during the design (Gruhn & Köhler, 2006). M-commerce systems also pose new challenges to achieving information systems dependability. The new mobile devices provide integration and convergence of technologies into a wide range of innovative mobile and multi-modal applications. Mobile and other new technologies provide many different ways to offer the same or similar services. Thus, there is a need for novel approaches for the development and evolution of applications on and across different mobile and traditional platforms.

Methodology for Development and Operations to Ensure Organizational Return

M-commerce systems are often radically different from the existing systems. They therefore reward an increased focus on idea generation early in the requirements and design process. Understanding the mobile users requirements for new services is thus of large importance. One needs both to be able to develop these systems and to address the major hurdles for the deployment of applications and services (Amberg, Wehrman, & Zimmer, 2004). Another effect of the radically new approaches is that the introduction of m-commerce systems often spawns several other initiatives for changing other information systems and processes within an organization. It is important to focus on the interoperability of services and seamless access to corporate and government resources from the mobile devices (Pernici, 2006). A model-driven approach appears to be a promising approach to address many of these methodological challenges.

STATUS FOR MODEL-DRIVEN DEVELOPMENT AND EVOLUTION OF USABLE M-COMMERCE SYSTEMS

When speaking about model-driven system development, we refer to models developed in languages that have the following characteristics:

- The languages are diagrammatic with a limited vocabulary (states, classes, processes etc).
- The languages utilize powerful abstraction mechanisms.
- The languages have a formal syntax and semantics. The formal semantics is either operational enabling, for example, generation of other models including executable programs or mathematical enabling advanced analyses.
- The languages are meant to have general applicability across problem domains.

Although most software developers are aware of model-driven methodologies, they are traditionally mostly used in initial development stages. Newer approaches such as model-driven architecture (MDA) and especially service-oriented architecture (SOA) on the other hand appear to be changing this (Pernici, 2006).

In general, a model-driven approach to information systems development can be argued to have the following advantages (Krogstie & Sølvberg, 2003):

- Explicit representation of goals, organizations and roles, people and skills, processes and systems
- An efficient vehicle for communication and analysis
- Basis for design and implementation
- Readily available documentation as a basis for extensions and personalization

One striking aspect in connection to contemporary information systems development and evolution is that there is an increasing demand for shorter development time for new products and services (Pries-Heie & Baskerville, 2001). This is specifically important for m-commerce systems, where the convergence of different platforms continuously creates opportunities for new functionality. Some would argue that this highly dynamic situation would make model-based approaches impractical. To the contrary, we claim that this means that systems must be developed for change, which make model-based techniques specifically useful.

We can identify the following areas for potentially increased utility of techniques developed as part of model-driven development:

- **User-orientation and personalization:** Traditionally, support for workers performing nomadic processes has not been provided. Recent approaches to workflow modeling is starting to take the specific aspects of m-commerce systems into account (Modafferi, Bentallah, Casati, & Pernici, 2005; Sørensen, Wang, & Conradi, 2005). Functions of the mobile information system should be tailored to fit the user's preferred work processes, which typically involve other persons. To support teamwork, raising awareness of the status of knowledge resources is increasingly important in a mobile setting. To enhance social mobility, organizations and industries need to develop "social ontologies," which define the significance of social roles, associated behaviors, and context (Lyytinen & Yoo, 2002). Given that knowledge resources include both individuals and technology that can be mobile, one should look into interactive systems to improve group performance. Wegner's interaction framework (Wegner, 1997) was inspired by the realization that machines that must interact with users in the problem solving process can solve a larger class of problems than algorithmic systems computing in isolation. The main characteristic of an interaction machine is that it can pose questions to human actors (users) during its computation. The problem solving process is no longer just a user providing input to the machine, which then processes the request and provides an answer (output), but rather is a multi-step conversation between the user and the machine, each being able to take initiative. A major research question in this area is how to specify and utilize interaction machines on a multi-channel platform. Process support technologies are a natural choice for enabling interaction machines. Such technologies are typically based on process models, which need to be available in some form for people to alter them to support their emerging goals. Thus, interactive models should be supported (Krogstie & Jørgensen, 2004). The outset for this thinking is that models can be useful tools in a usage situation, even if the models are changing and incomplete. The user is included as an interpreter and changer of the models.
- **Technological aspects including convergence and multi-channel support:** There is a multitude of competing technologies available for providing the underlying infrastructure and access devices for distributed and mobile applications. A central element when addressing this is the development of model based specification techniques that are powerful enough to be used as a basis for the development of systems on a large number of technical platforms, but still general enough to represent the commonalties at one place only. One interesting approach is the use of architectural patterns (Risi & Rossi, 2004). A major initiative within

object management group (OMG) is on model-driven architectures (MDA) where both platform independent and platform specific modeling notations, including refinement techniques and mappings between platform independent and platform specific notations, are specified. Meta-modeling techniques and domain-specific modeling (DSM) have found a special application for the design of mobile phone software for some time already (Kelly & Pohjohnen, 2003). It could be argued that mobile information systems are a particularly good area for using domain-specific modeling:

- The software (on the client side) is partly embedded and thus needs a higher reliability than traditional software and can be supported by restricting choices through the application of modeling rules and code-generation.
- You need many very similar variants of the same application.
- There are a number of standards to adhere to, and the technology and standards change rapidly.

Model-based development can be used to support dependability analyses (i.e., the use of methods, techniques, and tools for improving and estimating dependability) such as risk analyses, probabilistic safety assessment, testing, formal walkthrough, simulation, animation, exhaustive exploration, and formal verification.

The new separation between content and medium found in m-commerce systems serves as a major challenge. Generally, the context should be explicitly modeled to maintain an overview of, analyze, and simulate the multitude of possibilities open for adapting to the context and the use of context traces (Henricksen, Wishart, McFadden, & Indulska, 2005). For the more general use of mobile applications, it is also important to be able to adapt these systems to the user at hand, thus making a case for simple user-models to guide the adaptation. Banavar and Bernstein (2002) highlight the importance of semantic modeling in this respect.

Over the recent years, work within user interface modeling has focused increasingly on mobile and multi-channel user interfaces (Vanderdonckt, 2005). This is often done to facilitate some level of common models for both the mobile and more traditional user interfaces. A central element in this is the development of model-based approaches that are powerful enough to form the basis for the development of user-interfaces on the multitude of platforms needed, but still general enough to represent the commonalties in a single place. One approach is to define user-interface patterns with general usability principles as powerful building blocks (Nilsson, 2002).

- **Methodology for development to ensure organizational return:** Siau et al. (2001) highlights as an important application-oriented research area the development of m-commerce business models. In order for m-commerce to succeed, it is vital to ensure that all the related applications and services can be accessed with ease and at little cost. Thus, in addition to externalizing the business models in the manner of independent computing, it is important to integrate these models with the internal enterprise models and enterprise architecture in order to pinpoint the links to, for example, internal systems for the efficient billing of services provided.

M-commerce systems are often radical and therefore reward an increased focus on idea generation early on in the development phase. This also means that services or situations in which to anchor problem analysis efforts such as using as-is analysis as a starting point for to-be design do not always exist. Technology in the field still develops rapidly, which means that idea generation should not be limited by currently available technologies. One needs to enhance the techniques for modeling of scenarios to take this into account (Skattør, 2005). Applications of the new technology call for highly distributed systems that comprise new user-interface systems on the client side, new and existing back-end systems, as well as new bridging systems (which port information between other systems). The new technologies therefore highlight the need for principled, long-term IS-architecture management and for integrating architecture management with software development methodologies. Often there is a need to interface with existing enterprise systems and architectures to enable the new workflow. Another aspect is how to integrate the user-interface models discussed above with other parts of the requirements and design model, for instance the entity model, process model and goal model. On both the process and the user-interface side, the challenges can be attacked by extending existing approaches to modeling, although research is needed to investigate the techniques that should be extended and how they could be best adapted to the new problem areas.

FUTURE TRENDS

The large-scale application of m-commerce is just getting started and increasingly work is done to provide usable m-commerce systems or on model-based development and evolution of usable m-commerce systems. As 3G- (UMTS-) and WLAN-infrastructures now are available in many locations providing higher bandwidth and constant connection to the network from virtually everywhere, the number of m-commerce applications is predicted to explode as will the number of users of complex applications on a mobile

platform. Thus, the need for evolving best practice within systems development will be increasingly important.

CONCLUSION

We have highlighted the need for adapting and extending modeling-based approaches to ensure usable m-commerce systems in this chapter. We are not starting this work from scratch, it is possible to build on existing work within the usability, user interface, and modeling fields, specifically on techniques for modeling of functional and non-functional requirements, data modeling, process modeling, user-centered design, model-driven architectures, service-oriented architecture, requirements specifications of web-applications, domain-specific modeling and dependability analysis.

KEY TERMS

M-Commerce: A technological approach to reach customers, suppliers, and employees regardless of where they are located and to deliver the right information to the right person(s) at the right time.

Mobile Computing: The capability to physically move computing services with us.

Mobile Information Systems: Information systems that include end-user terminals that are easily movable in space, are operable independent of location and have wireless access to information resources and services.

Multi-Channel Information Systems: Information systems that are to be used by different types of end-user equipment such as traditional PC, PDA, and a mobile phone in an integrated manner.

Nomadic Computing: The use of computers while on the move.

Pervasive Computing: An environment where computers have the capability to obtain information from the environment in which it is embedded and utilize it dynamically

Ubiquitous Computing: An environment where computers are embedded in our natural movements and interactions with our environments. Combines mobile and pervasive computing.

Use Cases in the UML

Brian Dobing
University of Lethbridge, Canada

Jeffrey Parsons
Memorial University of Newfoundland, Canada

INTRODUCTION

The unified modeling language (UML) emerged in the mid-1990s through the combination of previously competing object-oriented systems analysis and design methods, including Booch (1994), Jacobson, Christerson, Jonsson, and Overgaard (1992), Rumbaugh, Blaha, Premerlani, Eddy, and Lorensen (1991) and others. Control over its formal evolution was placed in the hands of the object management group (www.omg.org), which recently oversaw a major revision to UML 2.0 (OMG, 2005). The UML has rapidly emerged as a standard language and notation for object-oriented modeling in systems development, while the accompanying unified software development process (Jacobson, Booch, & Rumbaugh, 1999) has been developed to provide methodological support for applying the UML in software development.

Use cases play an important role in the unified process, which is frequently described as "use case driven" (e.g., Booch et al., 1999, p. 33). The term "use case" was introduced by Jacobson (1987) to refer to a text document that outlines "a complete course of events in the system, seen from a user's perspective" (Jacobson et al., 1992, p. 157). The concept resembles others being introduced around the same time. Rumbaugh et al. (1991), Wirfs-Brock, Wilkerson, and Wiener (1990), and Rubin and Goldberg (1992) use the terms "scenario" or "script" in a similar way. While use cases were initially proposed for use in object-oriented analysis and are now part of the UML, they are not inherently object-oriented and can be used with other methodologies.

The official UML 2.0 documentation (OMG, 2005) includes some examples of use case diagrams, which provide an overview that shows which "actors" are involved in each use case. However, the only indication of the "text document" format is that "use cases are typically specified in various idiosyncratic formats such as natural language, tables, trees, etc." (UML, 2005, p. 574). However, virtually every book on the UML offers some format suggestions for use cases (sometimes termed "use case narratives" or "use case descriptions" to clearly distinguish them from diagrams). Together, the use case diagram and narrative are referred to as the "use case model." There are now several books focusing on use cases including Adolph and Bramble (2003), Armour and Miller (2001), Bittner and Spence (2003), Cockburn (2001), Denny (2005), and Övergaard and Palmkvist (2005) along with a few Web sites, notably Cockburn's (http://www.usecases.org). Thus, use cases seem to be well established within the UML despite the lack of any officially endorsed format from the OMG.

BACKGROUND

A use case "describes the system's behavior under various conditions as the system responds to a request from one of the stakeholders" (Cockburn, 2001). A use case should have a clear goal and describe what should happen (but not how it should happen) as users interact with the system. Common examples would include a customer renting a video, purchasing an item, withdrawing funds from a bank account, etc. The use case also identifies the main "actors" involved which, in the previous examples, could include the customer, employees (e.g., rental clerk), a device (bank machine), time (clock), etc. The use case must provide something of value to one or more actors; otherwise there would be no need for it. While the main use case narrative would describe a successful rental, purchase, or withdrawal, alternative outcomes would handle problems such as rejected credit cards, insufficient funds, etc.

The use case differs from typical structured requirements analysis tools that preceded it in two important ways. First, the use case is largely text-based (with the use case diagrams playing a minor role). Structured analysis emphasized the importance of graphical tools, such as work flow and data flow diagrams. The UML has not abandoned diagrams; thirteen are now included with UML 2. The class, activity, communication (previously collaboration), sequence, state machine (previously statechart), and use case diagrams have always played important roles. But use case narratives are text-based so that "users and customers no longer have to learn complex notation" (Jacobson et al., 1999, p. 38).

Second, use cases focus on complete transactions, from initiation to achievement of the defined goal, from the user's perspective. In particular, a use case has a goal, which comes from the goals of those who will be using the system (Cockburn, 2001). This keeps the focus on the key

requirements and helps facilitate communication with the system's intended users. In UML terminology, a use case is initiated by an actor, usually a person in a particular role (e.g., cashier) but actors can also be external systems or devices. A single use case can involve many actors.

Consistent with an object-oriented approach, use cases can also have generalizations and include and extend relationships. Generalizations allow a child use case to override the behavior of its parent use case in certain situations, but are "not widely used" according to Arlow and Neustadt (2004). An "include" relationship is generally used when the same steps are required by several use cases (e.g., logging into a system), in order to avoid repetition. An included use case is dependent on base use cases and "never stands alone" (Booch et al., 1999, p. 221). An "extend" relationship exists when a base use case incorporates another use case depending on certain conditions, such as exceptional situations where including the additional detail in the base use case adds too much complexity.

Writing use cases may seem simple enough because they are text-based. However, as discussed in the next section, the content and format of use cases vary somewhat among published books and articles. Those new to use cases would be well advised to read at least a couple of the books devoted to use cases (referenced previously) before incorporating them into a system development project.

ISSUES

Use cases have been all but universally embraced in object-oriented systems analysis and development books written since Jacobson et al. (1992). Despite this strong endorsement, there are many variations on Jacobson's original theme. First, there is a difference in content. Use cases, at least during the analysis phase, were intended to be a conceptual tool. The use case should emphasize "what" and not "how" (Jacobson et al., 1994, p. 146). This principle was not strictly followed by much of the early literature, including Jacobson et al. (1992, p. 162) who referred to a display "panel," "receipt button," and "printer" in one of their previous examples. Constantine and Lockwood (2000) distinguish "essential" use cases containing few if any references to technology and user interface implementation, from "concrete" use cases that specify the actual interactions. Others make a similar distinction using the terms "business use cases" and "system use cases." While this provides flexibility, developers need to be careful about what type of content is appropriate at any given time.

Second, there are several variations proposed for use case formats. While the first use cases in Jacobson et al. (1992) were written as a paragraph of text, most others have adopted numbered steps. Soon after, Jacobson et al. (1994, p. 109) did so as well. There also seems to be more acceptance of including exception and error steps, which were less common in earlier books.

Third, the granularity of use cases varies from coarse (few use cases) to fine (many). In principle, use cases should offer "measurable value to an individual actor" (Jacobson et al., 1994, p. 105) and "the collected use cases specify the complete functionality of the system" (White 1994, p. 7). But how to determine the number of use cases this requires is not easily articulated. While Dewitz (1996) uses 11 use cases in her video store example, the IBM object-oriented technology center (1997) has 24. Kulak and Guiney (2000, p. 37) suggest that "most systems would have perhaps 20 to 50 use cases and some small systems even fewer." But, as they later point out (p. 88), "there are no metrics established to determine correct granularity." Övergaard et al. (2005, p.45) suggest the same range (20-50) for "a normal medium-sized system." Armour et al. (2001, p. 244) claim that large systems may have hundreds of use cases.

Fourth, the level of detail within each use case also varies. For example, both Kulak et al. (2000, p. 125) and Armour et al. (2001, p. 125) recommend limiting the length of the flow of events to two pages of text, but the latter also note that some practitioners prefer a few longer use cases to many short ones. Bittner et al. (2003) suggest they are typically 5 to 15 pages, but with 60 to 80% of the content handling exception and error conditions. Jacobson et al. (1999) advocate an iterative development approach in which both the number of use cases and their level of detail increase as the work progresses. They suggest that only the most critical use cases (less than 10%) be detailed in the first (inception) phase. As analysis progresses and requirements become firmer, additional use cases can be added and each can be expanded to include considerably more detail. For example, Kulak et al. (2000) have identified four levels. However, knowing what should be a use case, how much detail is appropriate at each phase, and when to stop are important issues that are difficult to resolve precisely.

To further complicate the issue, some of those who favor fewer or less detailed use cases supplement them with "scenarios." Rumbaugh et al. (2005, p.579) say that "a scenario may be used to illustrate an interaction or the execution of a use case instance." "Add a customer" is a use case. Adding a specified customer with a particular name, address, etc. is a scenario. Others use scenarios to provide further detail on exception handling and other special cases (e.g., customers with missing, improbable, or unusual data) (Bennett, Skelton, & Lunn, 2001) rather than alternative paths in the use case. How many scenarios, alternate paths, and exception paths should be developed, and what their role should be in developing class diagrams, is not clear. A minimalist approach to use cases combined with extensive scenarios and paths may still result in a large and very detailed set of specifications.

While the general consensus seems to be in favor of a smaller set with relatively brief descriptions, "use case modeling concepts may be applied very informally and loosely or very rigorously and formally" (Armour et al., 2001, p. 70). The difficulty is determining when each is appropriate. Stories about organizations mired in hundreds or even thousands of use cases suggest that some limits need to be applied. Users will not read, or at least not properly understand, long and complex use cases. But a smaller set may be insufficient to fully capture the requirements. Thus, the two key roles of use cases, to gather requirements and to support development of the Class and other diagrams, may conflict somewhat and the ideal set of use cases for each role are perhaps different.

Fifth, several surveys have found that use cases are not always used with the UML. Grossman, Aronson, and McCarthy (2005) reported 93% of developers used use case narratives, Zeichick (2002) reported 89% used use case diagrams, and Dobing and Parsons (2006) found 93% for diagrams and 85% for narratives. However, these figures are based on developers, not projects. Only 44% of developers reported that use case narratives are used on two-thirds or more of their projects (Dobing et al., 2006). Thus, some projects are clearly not "use case driven" as recommended by Booch et al. (1999, p. 33) and most of the UML literature. However, this survey also found that clients are much more involved with other UML diagrams than the UML literature would suggest. How the absence of use cases affects project outcomes is unknown.

In a related issue, use case narratives have been primarily designed for communication between system analysts and clients, while other diagrams (particularly the class diagram) are used by analysts to communicate with programmers. While it might appear that anyone should be able to understand a use case narrative, Arlow et al. (2004, p. 92) point out that programmers may lack the necessary domain expertise and vocabulary. But because of their technical nature, they argue that clients have difficulty comprehending most of the other key UML diagrams. Thus, there is a potential communication disconnect that can occur when clients and developers are relying on different UML artifacts to understand the proposed system.

FUTURE TRENDS

Use cases, and the use case driven approach when using the UML, seem to be overwhelmingly accepted in the UML literature but, as previously noted, not by all practitioners. Better tools may encourage greater use, as well as help to standardize the ways in which use cases are written and used. Many developers are still relying largely on word processors to develop use cases. A closer integration with other UML diagrams would help ensure consistent specifications across all of them and greatly facilitate changing the specifications when modifications are required.

There remains considerable opportunity for researchers to examine issues in use case writing, particularly format, granularity, level of detail and usage. Perhaps the most fundamental issues deal with the effectiveness of use cases in their two key roles, communicating with users and supporting development of UML diagrams (particularly the class diagram). How effective are use cases in helping users find incomplete or incorrect specifications? More importantly, how effective are they at helping find better ways to do things? Do use cases support creative problem-solving?

Table 1 summarizes a research framework for studying the need for, and effectiveness of, use cases in the UML.

CONCLUSION

In summary, review of the literature shows some variation in how use cases are defined and used. This is not surprising, given their (and the UML's) relatively short history. But these differences can also be attributed to the lack of a theoretical foundation. The UML began with as a "best practices" approach (Booch et al., 1999, p. 449) and has continued to

Table 1. A framework for empirical research on use cases

Research Question	**Primary Independent Variable**	**Primary Dependent Variable**	**Methodology**
Do design/implementation details in use cases impede process redesign efforts?	Use case structure	Process innovation	Experiment; Case study
Can class diagrams be effectively extracted from use cases?	Use cases	Class diagram completeness	Case study; Experiment; developer surveys
Do use cases facilitate communication between developers and users?	Communication medium (use cases or class diagrams)	User understanding domain coverage	Experiment; user surveys

develop that way. The authors of books on the UML and use cases generally offer little more than their experience as evidence that their approach works. While a valuable contribution, research is needed to support these "best practices" claims (which are sometimes inconsistent).

KEY TERMS

Actor: An actor plays one or more roles in relation to a set of use cases. An actor could correspond to a job title (e.g., purchasing agent, sales clerk) or can be non-human (e.g., another system, device, or database). Each actor in a use case must be directly involved at some point and is not merely a stakeholder (someone or something that is affected by the success or failure of a particular transaction).

Use Case: A use case describes a way in which a system can be used to provide value to one or more actors. They take a client perspective, focusing on how users will interact with the system.

Use Case Description: See use case narrative.

Use Case Diagram: The use case diagram shows one or more use cases (by title) and the actors involved in them. This provides an overview of the use case structure and also shows how each actor is involved in a system.

Use Case Model: Together, the use case diagrams and use case narratives form the use case model. This identifies all the actors and describes the functionality of the system.

Use Case Narrative: A use case narrative is a largely text-based description of a use case that could be supplemented with decision trees or other easily understood notations. The description should be written in the user's language, and thus provides an important communication tool between developers of systems and the intended users. Narratives follow a structured format, typically using a numbered sequence of steps for the main activity accompanied by preconditions, post-conditions, alternative or exception paths, etc.

Use Case Scenario: A scenario, as specified in the UML, is an instance of a use case that can help illustrate its use. For example, a single use case (rent video) might have different scenarios for renting a video to a child, a new customer, an existing customer with overdue videos, etc. However, the term is also used in other ways outside the UML.

The Use of Electronic Banking and New Technologies in Cash Management

Leire San Jose Ruiz de Aguirre
University of Basque Country, Spain

INTRODUCTION

The use of new information and communication technologies (ICT) as a business tool has increased rapidly for the past 10 years (Bonsón, Coffin, & Watson, 2000; Claessens, Glaessner, & Klingebiel, 2000; Vasarhelyi & Greenstein, 2003). More specifically, financial software, e-banking, and the Internet, as core aspects of the various technologies used, have become driving forces behind the expansion of firms and the development of cash management. New technologies are considered as one of the most attractive ways for businesses to increase revenue and achieve economies of scale that can reduce unit costs (Ballantine & Stray, 1998; Barajas & Villanueva, 2001; Daniel, 1999; Daniel & Storey, 1997; Deyoung, 2001; Downes & Muy, 1998; Faulder, 2001; Jayawardhena & Foley, 2000).

There are different studies about the use of ICT in the management of the enterprise that explain the obtaining of enterprise performance. Brynjolfsson and Hitt (2000) and Nájera (2005) have done a review of these works and a classification of these types of researches. Unfortunately, there are not specific works or empirical researches about the use of e-banking in cash management; consequently, this work is focused in this.

The rest of the chapter is structured as follows. The theoretical foundation on which the study is based is explained in Section 2. Section 3 presents the data and the analysis procedure used to conduct the empirical study. The main results of the investigation are shown in Section 4, and Section 5 presents conclusions. The chapter ends with a list of bibliographical references.

THEORETICAL FOUNDATION: E-BANKING IN FINANCIAL PRACTICES

Three different periods can be distinguished in the development of ICT in cash management (Williams, Chen, & Russell, 1997). In period one, prior to the 1970s, treasurers engaged in accounting and in managing the cash-flow of their companies, and did not use IT tools in their work. Period two, from the 1970s to the 1990s, is characterised by a vision based on corporate relations and integrated systems. Since the 1990s we have moved into period three, the era of networking, in which the responsibilities of cash managers have come to include the use of electronic banking and new technologies to obtain the efficiency in their financial decisions because the great advantages for business management entailed by the development of technology. Internet is a space that can be shared freely at zero expense. However, the introduction of new technologies needs to be analysed thoroughly if business management efficiency is to be maximised (Levinsohn, 2001).

In this context, specifically, electronic banking management becomes an essential function in which information can be obtained electronically on market conditions, financial products, trends, and financial services. Financing and investment of treasury deficit and surpluses is optimised by comparing the terms of the different financial products on the market, and then contracting products online (Mooney & Pittman, 1996; Vasarhely & Greenstein, 2003; Welch, 1999).

In short, financial services based on new technologies use the e-banking as a single communication standard and thus, obtain economies of scale (Barajas & Villanueva, 2001; Eije & Westerman, 2002; Mishkin & Strahan, 1999) and positive synergies at treasury departments that were formerly difficult to achieve.

METHOD AND SAMPLE

To draw up the explanatory model of e-banking use in cash management, we used an exploratory factorial analysis of variables with Version 14.0 of the SPSS program.

In the following table, we have described the sample that is considered representative of the population of Spanish firms. This study was conducted on Spanish firms with more than 10 employees. The sample was chosen by proportional allocation according to criteria of company size (defined by the number of employees) and sector of activity. The total number of firms used was 501, and the error is smaller than 5%, necessary in this type of study.

Table 1. Acknowledgements: The sample

SAMPLE	THE CLASIFICATION OF THE SAMPLE	RANDOM ERROR	INFORMATION COLLECTION TECHNIQUE. TIME
501 valid questionnaires. The interviewed person was the finance manager or cash manager.	Criteria: company size (defined by the number of employees) and sector activity.	± 3, 52% with a confidence level of 95,5%, p=q=0.5,	Telephone's interview. June of 2005.

RESULTS

The results indicate that the new technologies more utilized by firms to financial practices are financial software, Internet and electronic banking. Furthermore, these results have permitted us to develop an explanatory model of the use of electronic banking to treasury management.

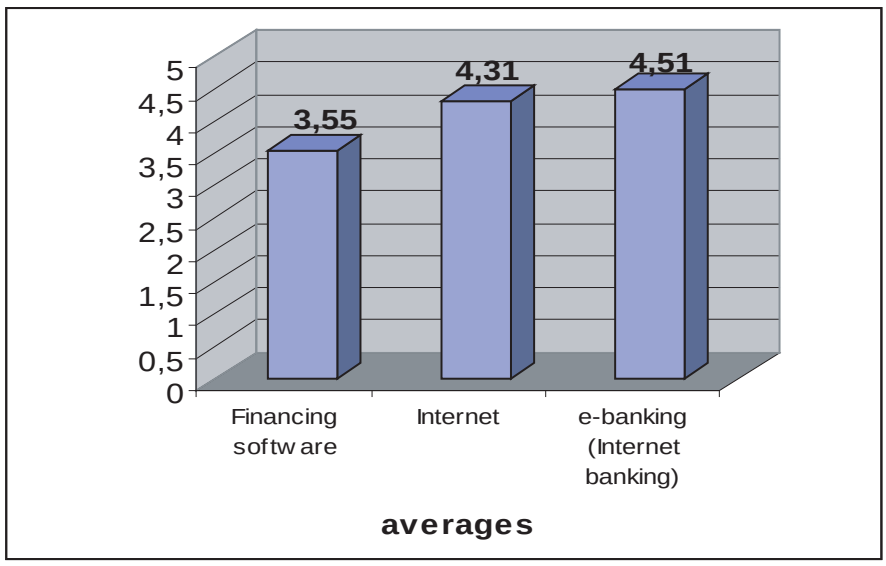
Preliminary Results

The Use of ICT in Cash Management

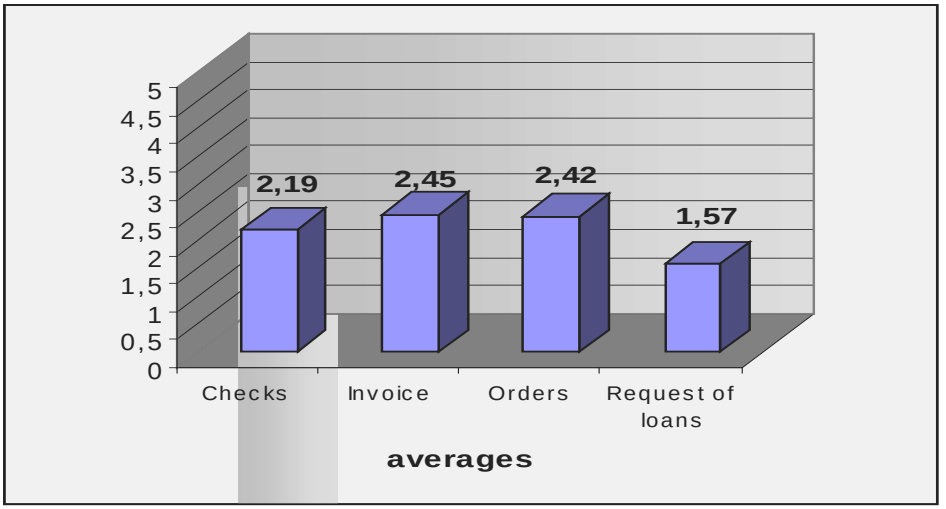
The ICT's most widely used in financial operations and more specifically, in treasury management are financial software, the Internet, and e-banking, though it is the introduction of the Internet into all areas of corporate life that has been the major revolution of the past 10 years. All these technologies entail benefits for financial management, so the next step is to analyse their average levels of use and determine which ICT's are most widely used in this area (see Graph 1).

This analysis shows that e-banking (Internet banking) is the most widely used tool in treasury operations, with treasury managers awarding it an average score of 4.512 out of 5. The second highest score is that of the Internet, with 4.312, followed by financial software with an average of less than 4. Specifically, e-banking is used habitually by 73.1% of the firms analysed, the Internet by 65.5% and financial software by 44.6%.

Graph 1. The level of utilization of ICT in cash management: Averages



Graph 2: Electronic financial instruments: Averages



Electronic Financial Instruments

In this sense, we analyzed electronic financial instruments, the financial instruments via e-banking mostly used by the companies. Concretely, four financial instruments have been analyzed that are emitted via electronic bank; the check, the invoices, the orders, and the request of loans (see Graph 2). The scale has been used starts in 1, which represents the smallest use, and finishes in 5, the most used.

The invoice (2,45) is, on the average, the financial instrument emitted by e-banking that is used more, followed by the orders (2,42) and checks (2,19). The request of loans (1,57) via electronics is considerably inferior. These data, in general, denote that the financial instruments via e-banking are not used habitually in the companies, although the electronic invoices and orders are used.

Explanatory Model: E-banking in Cash Management

Exploratory Factorial Analysis

The basic assumptions underlying factorial analysis, linearity, normality, and homoscedasticity, are conceptual rather than statistical. Therefore, from a statistical point of view, these assumptions can be obviated in the awareness that their fulfilment causes a drop in the correlations observed (Hair, Anderson, Tatham, & Black, 1999). However, these correlations are still sufficient if it is determined that factorial analysis is appropriate. This can be done by analysing the Kaiser-Meyer and Olkin (KMO) measurement and examining the whole correlation matrix, contrasting it with Bartlett's sphericity test.

The results shown in Table 2 are satisfactory for both tests, so an exploratory factorial analysis can be performed for e-banking.

These results (Table 3) show that the eight variables for the use of e-banking in treasury management can be grouped into two components with minimal information loss. The first component explains 41,728% of the variance, the second 28,725%. In all, this grouping into two factors explains 70,453%[1] of the overall variability of the sample.

Saturations lower than 0.6 in absolute value have been eliminated.

An analysis of the sensitivities in Table 4 shows that for the first component, *negotiation with financing institutions, management of the financing of treasury deficit, management of the placement of treasury surpluses and interest-rate, and exchange-rate risk management* have high, positive values. Considering the significance of these variables, this component seems to be reflecting aspects concerned with ***advances use of e-banking in cash management.***

Use of e-banking in *collects and payments management, day-to-day control of banking positions, short-term treasury forecasts, and monitoring of banking positions at the value*

Table 2. Determining factor of the correlation matrix, KMO, and Bartlett´s test

Kaiser-Meyer-Olkin simple suitability measure		,806
Bartlett´s sphericity test	Chi-square	1004,000
	fd	28
	p-value	,000

Table 3. Principal component analysis. Final statistics with three components of rotate variables

Management of the placement of treasury surpluses	,772	
Interest-rate and exchange-rate risks management	,764	

data can be grouped around the second factor as ***basic use of e-banking in cash management.***

The Explanatory Model of Use E-Banking in Cash Management

The use of ICT in cash management is expanded in the last decade. The electronic cash management is focused in the use of new technologies and particularly, e-banking in treasurer's financial practices that permit they obtain more information to select the best financial decision that is conduced to obtain economic scales in the enterprise and reduction of transaction cost with positive synergies. There are two levels to use e-banking, the first level, basic e-banking is only used in the repetitive actions of the cash managers, the second level, we have denominated advance e-banking, and it is used in strategic financial practices (Graph 3). Is important to use e-banking in two levels, but nowadays some enterprises, small and medium principally, have not used advance e-banking to cash management.

CONCLUSIONS

The ICT more utilized by firms to financial practices is electronic banking. The principal electronic financial instrument that enterprises use to cash management is the invoice. Furthermore, these embrace not only the most repetitive treasury functions denominated as basic e-banking referred to use of e-banking to collect and payment management, but also they are used in treasury management functions that depend largely on corporate decisions and are strategic rather than operational denominated as advance e-banking.

U

KEY TERMS

Cash Management: The cash management corresponds to the obtaining of available the necessary one, at the suitable moment, to the smaller possible cost for which the treasury is planned, is decided what short-term financing and investment to make, analyze the relations with the financial organizations and the risks are managed. In addition, the pursuit and the analysis of the management of the circuit of collections and payments are essential, along with the enterprise culture.

E-Banking: The electronic bank consists of the use of electronic channels by means of which the financial institutions can send products or offer the banking services. Between the services and products, they are possible to be included, deposits, financial management of accounts, warnings, payments of electronic accounts, and provision of other products of electronic payments.

Electronic Cash Management: It is possible to be defined as the set of procedures and practices of integrated management of treasury with the developments in the technologies of the information.

Electronic Financial Instruments: They consist of financial products that are contracted, emitted, and paid without the use in paper of financial documents.

ICT in Cash Management: It consists of the use of different techniques, such as Internet, Intranet, software, electronic bank, and the bank by Internet, with object to essentially obtain the efficiency of the management of treasury by means of the reduction of costs.

Information and Communication Technologies (ICT): The ICT has defined as the grouping of the technologies of information, that they are characterized by the technologies of registries of contents (computer science, communications, Telematics), and the technologies of the communication, that essentially group the radio, the television and the telephony.

Internet Banking: From the global concept of electronic bank, we considered that the bank by Internet consists of the use of the Internet channel like communication channel, banking product distribution, and hiring on the part of the financial organizations.

ENDNOTE

[1] The number of factors extracted was determined by prioritising the "percentage of variance" criterion over the "latent root" criterion so that with commonalities above the set minimum of 0.5 it was decided to select the number of factors necessary to explain at least 60% of the variance.

The Use of ICTs in Small Business

Stephen Burgess
Victoria Universtiy, Australia

INTRODUCTION

This article examines the main drivers and barriers facing small business owner/managers in the manner in which they use information and communications technologies (ICTs) within their businesses. The early part of the article examines the notion of what is meant by small business. The discussion then moves onto describing some of the drivers and barriers to the use of ICTs in small business and the implications of these to small businesses.

BACKGROUND

What is Small?

When studying the use of ICTs in small business, the range of definitions used to describe small business ranges from micro businesses to small and medium sized enterprises. This range can make it extremely difficult for researchers to match up different small business studies. A 2003 study by members of the information resources management association special research cluster on small business and information technology (Burgess, 2003) found that:

- Definitions of small business ranged from less than 20 (Australasia), 50 (Europe), and 100 (North America) employees (with some definitions including annual turnover and asset levels)
- Definitions of micro business ranged from less than 5 to less than 10 employees
- Definitions of medium business ranged up to 200, 250 and 500 employees

A common acronym used to represent small and medium sized businesses is SME. There is some argument as to whether the term is of any use at all given the vast differences between small and medium sized businesses. Still, there continue to be studies that examine the use of ICTs in SMEs.

For my purposes, small businesses are those businesses with 20 employees or less. However, most small businesses are micro businesses (Fillis, Johansson, & Wagner, 2004a), made up of less than five employees.

Size is Important!

Why is it so important to consider the size of the business? A number of studies suggest that there is a relationship between the size of a business and its level of adoption of ICTs (McDonagh & Prothero, 2000). There is also a relationship between the size of a business and the different characteristics it will have that can lead to the successful use of ICTs (Igbaria, Zinatelli, Cragg, & Cavaye, 1997; Pollard & Hayne, 1998). As such, research findings based upon traditional information systems in larger businesses are not necessarily directly applicable to small businesses. This will be touched upon again later in the article.

DRIVERS AND BARRIERS TO THE USE OF ICT IN SMALL BUSINESS

The literature around the area of small business and information technology is rife with what is now a fairly accepted list of barriers to the successful implementation of ICTs in small businesses. These barriers typically include (Igbaria et al., 1997; Management Services, 1997; McDonagh et al., 2000; Pollard et al., 1998):

- The cost of ICTs—this is perhaps not so much of an issue these days (well, in developed countries anyway)
- Lack of time to devote to the implementation and maintenance of ICTs
- A lack of ICTs knowledge combined with difficulty in finding useful, impartial advice
- Lack of use of external consultants and vendors
- Short-range management perspectives
- A lack of understanding of the benefits that ICTs can provide, and how to measure those benefits
- A lack of formal planning or control procedures

What about small businesses and e-commerce? Small businesses do face a series of barriers that they need to overcome before moving into the digital economy. These are (Taylor & Murphy 2004b):

- Many SMEs are unaware of the potential of e-commerce to enhance their business.

- Some SMEs occupy clearly defined (and small) niche markets that they are satisfied with. They do not need the extended connectivity provided by the Internet. In addition, small businesses may be happy with their existing activities because they are adequate enough to enable to maintain a particular "lifestyle" (Fillis et al., 2004a).
- There are still perceptions of unresolved security and privacy issues related to use of the Internet.
- Many SMEs lack the necessary skill base to engage in the digital economy.
- The perceived high initial and ongoing costs associated with ICTs and e-business can be seen as a barrier. This is also supported by Fillis et al. (2004a).
- Many SMEs cannot experiment with ICT investments like larger businesses. They need to be sure that there will be returns for the e-commerce investments they make.

Having identified some of the barriers to the successful use of ICTs, there is also a fairly common list of drivers that are listed in the literature that appear to indicate a greater chance of successful implementation of ICTs in small businesses.

Some of these factors are (Naylor & Williams, 1994; Yap & Thong, 1997; Swartz & Walsh, 1996; Zinatelli, Cragg, & Cavaye, 1996):

- The involvement of owner/managers in the implementation of ICTs
- The involvement of users (employees) in development and installation
- The training of users
- The use of disciplined planning methodologies in setting up applications
- The number of analytical/strategic (versus transactional) applications being run
- The level of ICTs expertise within the organisation
- The role of the external environment (especially consultants and vendors)

In relation to e-commerce, Mehrtens, Cragg, and Mills (2001) developed a model of Internet adoption using an innovation theory approach, suggesting that the decision to adopt was a based upon:

- **Identifying perceived benefits:** These can take the form of:
  - Efficiency benefits from the *relative advantage* that the Internet can provide over traditional methods
  - Employees gathering information in a more effective manner
  - A tool to build the image (or "brand") of the business
- Organisational readiness:
  - The level of Internet knowledge in the business amongst non-IT professionals, for instance the owner/manager; an Internet aware owner might support or initiate Internet adoption.
  - The suitability of systems within the business to access and use the Internet. Historically, smaller business sizes have been identified as a factor in lower ICT adoption rates and Internet technologies (Martin & Matlay, 2001). One important aspect here is if the infrastructure is available for businesses to take advantage of ICTs. This can especially be important in rural and remote areas and developing countries.
- External pressure:
  - From existing users, particularly customers but perhaps external business partners (such as suppliers).

We can now examine some of the factors mentioned in these lists more closely.

FACTORS IN THE ADOPTION OF ICT BY SMALL BUSINESSES

Role of Owner/Manager

One of the key factors leading to successful use of ICTs in small businesses identified in the previous section was the involvement of small business owner/ managers in the ICTs implementation.

There is some evidence to indicate that managers in small businesses are less likely to know how to use ICTs effectively or to keep up with the latest trends in ICTs than their counterparts in larger businesses (Pollard et al., 1988). Igbaria et al. (1997) cite a number of references to support the view that management support can promote the acceptance of ICTs. They found that the support of management positively affected the perceived ease of use and the perceived usefulness of ICTs within the small business.

The motivation of owner/managers is a key factor in shaping the e-business development of a small business. Their perceptions can range from highly positive entrepreneurial viewpoints to very conservative stances. The orientation of the business and the owner/manager can affect the level of Internet connectivity of the business. Business that exhibit entrepreneurial characteristics are more likely to adopt e-business (and will do so at a faster rate) (Fillis et al., 2004a). An important finding from Lee's (2004) study is that owner/managers with higher computer self-efficacy were more likely to adopt Internet applications. Indeed, Martin et al. (2001) suggest that the managerial knowledge,

skills, and experience of owner/managers can make a crucial difference in identifying Internet opportunities.

In a study of 59 Irish SMEs, Barry and Milner (2002) determined that the owner/manager was the principal driving force behind the decision to adopt e-commerce. Decision making within small businesses is often based upon owner/manager intuition rather than on the basis of market data gathered by the business (Schlenker & Crocker 2003).

One of the barriers identified earlier that hinder the effective use of ICTs in small businesses is a lack of formal planning and control methodologies. This relates to a lack of knowledge of how to plan effectively, lack of time and money to seek this knowledge, lack of time to apply ICTs even if they have the knowledge and a lack of understanding that they even need the knowledge! Small businesses are, however, concerned with issues relating to how they can operate more effectively and efficiently and/or how they can grow (El Louadi, 1998). One of the problems is that management practice in small businesses is often based on the short term and is informal and ad hoc. Much of the time is spent "surviving," so that little time can be devoted to examine ICTs projects (Pollard et al., 1988).

Location

Why is location important when considering the use of ICTs in small business? The major answer to this is a combination of *resources* and *distance***.** The further you are away from resources, the longer it takes and the more it costs to get them. This can particularly be the case with hardware and software purchases, training, and support.

Another reason for examining location is *culture***.** Some countries, and even different regions within countries, have their own traditions and their own established ways of doing things. This can influence the behaviour of small businesses and the manner in which they use ICTs.

In addition, distance from customers provides problems in relation to logistics, the regular requirement for a personal touch in closing sales or providing service and problems in relation to differing language and culture (Schlenker et al., 2003).

Developing Countries

Small businesses make up a major portion of businesses in developing countries (in some countries the percentage is higher than in developed countries). One of the major barriers faced by small businesses in developing countries is access to information, especially information used in decision-making. Another problem is the lack of data sources from which to obtain the type of information required. Problems with the technological infrastructure of developing countries only exacerbate this (Sawyerr, Edbrahimi, & Thibodeaux, 2000).

Taylor et al. (2004b) point to significant differences between e-business adoption in developed and developing countries. Many business people in developing countries are disillusioned with substandard telecommunications infrastructures, as well as a lack of expert advice and support systems in general (Schlenker et al., 2003). In relation to connecting to the Internet, the infrastructure in many countries is either not available or costs too much to connect to. Thus, new initiatives tend to occur in urban areas where affordable connections are available (Warren, 2004).

Rural Small Businesses

Some of the problems facing rural small businesses are similar to those facing small businesses in developing countries. One of the benefits that the Internet may provide is remote access to many desired ICTs resources such as training (Gallagher, 1999). A year 2000 survey of Australian small businesses revealed that 29% of metropolitan small businesses had a Web site, compared to 20% of rural small businesses. The main reason given by rural small businesses for not having a Web site was that they did not have access to the skills needed to design, build, and maintain a Web site (Telstra Corporation and NOIE, 2000). By 2005, the divide had increased, with 54% of metropolitan small businesses having Web sites, compared to 37% of regional small businesses (Sensis, 2005).

Martin et al. (2001) report that businesses located in rural regions of the UK had less access to ICT advice. SMEs in London and the Southeast region of the UK are more likely to have a Website than in other regions (Taylor et al., 2004b).

Industry

There is some relationship between the industry that small businesses are involved in and the types of ICTs that they use.

The level of e-business activity will vary across small businesses in different industry sectors (Fillis, Johansson, & Wagner, 2004b). In a study of the usage of ICTs by 24 businesses in Northern Ireland spanning the retail, construction, distribution, and wholesale industry areas Shiels, McIvor, & O'Reilly, (2003) discovered differences in the usage of ICTs in separate industry groupings. In some instances, they attributed these to the nature of their business operations and the type of customer they target. Martin et al. (2001) suggest that micro businesses specialising in business services are more likely to adopt ICTs than similar sized manufacturing businesses. Fillis et al., (2004b) expect that small businesses in the ICT industry would have a higher degree of uptake and usage of ICTs than non-ICT businesses. Small farms in the UK have rather low Internet connectivity rates. One of the reasons is a lack of suitable on-farm hardware. As at 2003,

a significant proportion of farms still did not have a PC, and for those that did many were old and slow (Warren, 2004). The hotel industry is an information intensive industry. As such, ICTs are a key enabler in distributing information and facilitating transactions (O'Connor & Frew 2004).

In a study of 129 SMEs in New Zealand, Al-Qirim and Corbitt (2002) found that a higher proportion of businesses in the ICT and business services industries had adopted applications using Internet technologies.

Working Out the Benefits of ICTs

Another barrier to the successful use of ICTs in small businesses is a lack of understanding of the benefits that ICTs can provide and how to measure those benefits. The most common way used to determine the level of ICTs success is to measure small business user satisfaction with information technology. Such measures of user satisfaction have one major problem—they are linked with user expectations (Naylor et al., 1994). For instance, an owner/manager understanding the strategic benefits that ICTs can provide may be less satisfied with a simple transactional system than an owner/manager who is unaware of these strategic benefits. This is despite the possibility that they may be reviewing systems that perform in a similar manner. Again, the problem falls back to a lack of proper knowledge about the advantages that ICTs can provide.

Success can vary in relation to industry and culture. The measurement of success can be measures such as quality of life, company culture, and maximising profits or generating revenues. The idea of quality of life as a goal is favoured by many smaller businesses and public organisations (Schlenker et al., 2003). In fact, Schlenker et al. (2003) suggest that 70% of businesses in the SME sector are more concerned with "quality of life" than the value of their stock. Their primary purpose is to generate an income for their owners rather than maximise revenues.

The value of technology to a business may therefore be in how it can assist management and employees to define, operationalise and measure success (Schlenker et al., 2003).

It is important to distinguish between the evaluation of a potential ICT investment in relation to determining whether or not to invest in it and the ongoing evaluation of an ICT project after it has been implemented. Similar issues affect both types of activities as the difficulties involved in assessing the financial value of ICT systems to a business are well documented. These systems often generate indirect, qualitative and contingent impacts that are difficult to measure in monetary terms. The projects often cross organisational boundaries and are related with investments in other investment projects, making the ICT component difficult to isolate (O'Connor et al., 2004).

Employee Skills and Training

Factors relating to a lack of knowledge of ICTs or lack of understanding of the benefits of ICTs have been mentioned a number of times already in this article. Human capital in small businesses is seen as being an important factor in recognising ICT opportunities and adopting them. Businesses where employees have a lower understanding and knowledge of ICTs have difficulties in understanding the usefulness of ICTs (Martin et al., 2001). Barry et al. (2002) suggest that human resource issues are perhaps the most important factor to consider when implementing new technologies in an SME. Businesses with a mix of technological and business skills are generally better placed to exploit e-business opportunities (Fillis et al., 2004a).

In relation to development of e-business systems, Taylor et al. (2004a) observe that Web-based systems development is different to other types of ICT development and requires a wide range of skills. Taylor et al. identified the skills sets required for e-commerce projects in the SME sector, incorporating technical, business, and overlapping skills and knowledge.

Developing Skills and Knowledge in Small Businesses

Barry et al. (2002) have identified a number of predominant features of SME training:

- Very small businesses are the least interested in providing training.
- Training is often considered to be too general and not specific enough to the needs of SMEs.
- SMEs face disincentives to train employees. They have less potential to offer the higher pay and benefits that accompany increased expertise.
- SMEs are often not aware of their training needs and are not capable matching needs to suitable training options.
- Training in SMEs is more likely to be informal than formal—with the more formal approaches providing too many constraints in relation to the consumption of time and other resources.

Barry et al. (2002) found that the owner/manager was a catalyst for organisational e-commerce training in SMEs and that some 85% of the 59 Irish SMEs in their study did provide training, but most of it was delivered internally and was informal in nature.

In a case study of three small businesses, Taylor et al. (2004a) encountered the following techniques for developing e-business skills:

- Hands-on experience
- Short courses
- Higher education courses
- Technical manuals
- Viewing the Web sites of other businesses; this allowed a benchmarking exercise to be performed against rival e-business Web sites.
- Consulting experienced staff—mainly external ICT consultants or external software house staff.

Simpson and Docherty (2004) discuss the role of personal business advisors (small business consultants in the UK)—who typically had marketing or finance backgrounds but could not equal the knowledge of the owner/manager in their particular industry. Also, their fee structures were not quite suited to small businesses.

Another option for small businesses, especially ones that may feel isolated, it to set up a mentoring system where mentors are able to provide external and relevant experience and impartial advice (Simpson et al., 2004).

Building Capacity through External Sources

Small business managers perceive more uncertainty in their environment than their counterparts in larger businesses. Effective management of external information can help them to reduce the level of uncertainty that they feel (El Louadi, 1998).

In many instances, small businesses have to rely on the ICT expertise of vendors and/or consultants because of a lack of internal ICT expertise. Igbaria et al. (1997) have found that good external support provided by vendors and/or consultants, such as technical support, training and a harmonious working relationship can reduce the risk of ICTs failure in small businesses.

There is a view, however, that vendors and consultants do not understand the small and medium business market and that the level of support provided by them is only adequate or less than adequate (Management Services, 2000). Careful selection of vendors and/or consultants is vital.

Governments worldwide are beginning to realise the importance of the small business community. The role of government in developing countries has already been touched upon in this article. ICTs are one of the areas that are the subject of increased government resources, through improved information programs, increased training opportunities and technology support grants and awards.

As time goes on, governments are increasingly becoming aware of the importance of small businesses to their economies and are providing increased resources to their support. This has resulted in various support programs for small businesses that have directly or indirectly resulted in improvements in the use of ICTs by small businesses. It is anticipated that this trend will continue. There is also an increasing awareness of the importance of the efficient and effective use of ICTs by small businesses by the research community. There continues to be increased amounts of research being carried out in the field, which can only lead to greater understanding.

CONCLUSION

This article has introduced a number of issues related to the use of ICTs in small businesses. When looking at small business research, it is important to determine what the researcher's view of "small" actually is. This is so that proper comparisons can be made across studies.

Drivers and barriers in relation to the use of ICTs were identified for small businesses as being common areas covered in the literature. The importance of owner/managers, the location of the business, differences between industries, and employee skill levels and training were discussed.

KEY TERMS

Medium Business: This term is used to describe businesses that are too large to be considered as being small and too small to be considered as being large. This somewhat vague description is matched by the varying definitions of "medium" sized business there are around. In relation to use of IT, medium sized businesses usually exhibit more of the characteristics of larger businesses than smaller ones.

Micro Business: This term is used to describe very small businesses. Many of these are operate as family businesses. They form the majority of businesses.

Owner/Manager: In most small businesses, the owner/manger is the driving force behind the business, and as such can be the catalyst for change in the business that occurs through or around IT. In some small businesses, the positions of owner and manager are separated.

Small Business: "Small business" can be measured by number of employees, annual turnover and/or assets. It usually represents those businesses with up to 20, 50, or 100 employees (depending upon the region being investigated). This term encompasses micro businesses.

SME: This acronym is used to refer to small and medium sized enterprises as a collective group.

User Modeling and Personalization of Advanced Information Systems

Liana Razmerita
University of Galati, Romania

INTRODUCTION

Enterprise information systems are among the key enablers of the leadership agility on competitive market places and therefore the design of advanced information systems (IS) is a continuous challenge for modern organizations. IS can include knowledge management systems (KMS), customer relationship management solutions, business-to-business applications, e-commerce, e-government or e-learning systems. Advanced IS featuring intelligence have recently implemented as complex applications with modular architecture relying on Web services, Semantic Web technology integrating user modeling, machine learning approaches, and/or agent-based technology. Personalization and more recently contextualization have emerged as key issues for achieving intelligent features in advanced IS.

In general, the goal of personalization is to improve the efficiency of interaction with the users, to simplify the interaction, and to make complex systems more usable. Blom (2000) distinguishes between two main roles of personalization: (1) to facilitate work and (2) to accommodate social requirements. In the first category he includes enabling access to information content, accommodating work goals, and accommodating individual differences, while the second category contains eliciting an emotional response and expressing identity.

This chapter presents a set of personalization techniques for IS. The second section provides background information related to personalization of IS, and it proposes a set of personalization mechanisms. In the third section, these personalization mechanisms are exemplified in the context of KMS. The fourth section outlines future work related to personalization of IS. Finally, the fifth section summarizes the main ideas presented in this article.

BACKGROUND

Personalization techniques enable IS to adapt their structure and content to match the needs and preferences of users based on a user model, which is stored, inferred, or updated dynamically. A simplified form of a user modeling system including personalization mechanisms is represented in Figure 1.

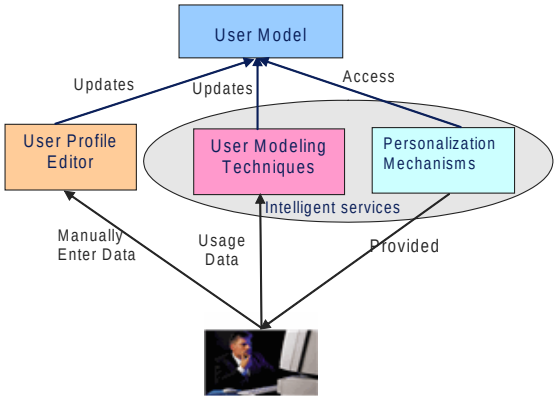
The user modeling server acquires and maintains the user's data through a user profile editor (explicitly) and through different user modeling techniques (implicitly). Among the most used techniques for implicitly constructing user models, acquiring user data, and deriving new facts are: logic-based techniques, stereotype-based reasoning, machine learning techniques, and reasoning with uncertainty (using either Bayesian networks or fuzzy logic techniques). User modeling techniques for personalization mechanisms are extensively overviewed in Razmerita (2003).

The following definition is proposed for personalization of IS: "Personalization of Information Systems is the process that enables interface customization, adaptation of the functionality, structure, content or/and presentation and modality in order to increase its relevance for its individual users." ISs can include customization and/or adaptive personalization features.

- **Customization is usually initiated by the user.** The user decides to select or exclude certain options from the interface. It is usually associated with interface customization. Many of the actual IS include customization features based on the user's preferences.
- **Adaptive personalization.** These features are triggered by the system, based on the user's interaction with the system, or based on the user's data available in the system. User's data are usually addressed as user profiles or user models. User models can be created by the users, who enter their data explicitly, or they can be inferred by the system. In the later case, the system tracks the user's activity with the system and infers characteristics of the user interacting with the system. These characteristics (e.g., domains of interest, goal) are further used for providing personalized interaction.

Agent-based systems can be used beyond adaptive personalization with different objectives. Agents can support users to perform different tasks, or they can perform tasks delegated by the users (e.g., intelligent information agents, personal assistants); they can search and guide users to find different knowledge assets (e.g., information filtering agents), or they can enhance learning processes (e.g., pedagogical agents) (Brna, Cooper, & Razmerita, 2001; Greer et al., 2001; Maes, 1998).

Figure 1. User modeling and personalization mechanisms



Important application areas of personalization include customer relationship management (Alpert, Karat, Karat, Brodie, & Vergo, 2003; Ardissono & Goy, 2002; Kobsa, Koenemann, & Pohl, 2001; Schafer, Konstan, & Riedl, 2001), educational software (Brusilovsky, 2001; Clark & Mayer, 2003), and information search and retrieval (Ardissono, Goy, Petrone, & Segnan, 2003; Kurki, Jokela, Sulonen, & Turpeinen, 1999; Tanudjaja & Mui, 2002; Waern, 2004,). Personalization has already proven its utility in e-commerce and e-learning. Fink and Kobsa (2001) provide data from communication reports showing that personalization based on purchased data and personal data has a considerable payoff in customer relationship management. Techniques for selection of relevant items according to the user's profiles in e-commerce are described by Ardissono and Goy (2000). In the following, a set of adaptive features that can be integrated in IS are identified and classified. Adaptation techniques can be classified in three categories: (1) adaptation of structure, (2) adaptation of content, and (3) adaptation of modality and presentation (Kobsa et al., 2001). These personalization techniques enable users to spend less time to search and retrieve relevant knowledge.

Adaptation of Structure

Adaptation of structure refers to the way in which the hypermedia space is structured and presented to the different groups of users. Fischer (2001) provides some insights in the design of human-centered systems supported by user modeling techniques. He emphasizes that high functionality applications must address three problems: (1) the unused functionality must not get in the way; (2) unknown existing functionality must be accessible or delivered at times when it is needed; and (3) commonly used functionality should not be too difficult to be learned, used, and remembered. Taking into account these principles, apart of a global view or a default view of an IS, several types of personalized views and layouts can be designed and integrated into the system. "Personalized views are a way to organize an electronic workplace for the users who need an access to a reasonably small part of a hyperspace for their everyday work" (Brusilovsky, 1998, p.).

Adaptation of Content

The users give different relevance to information/knowledge assets according to their goals, interests, background, or hobbies. Adaptation of content refers to the process of dynamic tailoring the information that is presented to the different users according to their specific profiles (e.g., needs, interests, level of expertise, etc). It enables the user to filter, retrieve, or rank relevant documents according to the user's characteristics. Adaptation of content relies on techniques for information filtering, information retrieval, information visualization, and adaptive hypermedia. Adaptation of content can include: filtering of content; personalized recommendations; personalized hints or automatic summarization; and optional detailed information. These techniques are further exemplified in the context of KMS.

Adaptation of Presentation and Modality

Adaptation of presentation empowers the users to choose between different presentation styles such as different layouts, skins, or fonts. Other preferences can include the presence or absence of anthropomorphic interface agents, the preferred languages, and so forth. Different types of sorting, bookmarks, or shortcuts can also be included in a highly functional system. Adaptation of presentation traditionally overlaps

with interface customization, but recently new modalities for information visualization have emerged.

Information portals such as Kartoo, Brain, and ClusterMap incorporate a graph-based view of the user interface. These new forms of information visualization go beyond a tree-based view of documents or knowledge assets using two or three dimension spatial representations. Documents can have associated visual cues to present information about documents, or they can be related with other documents, people, or institutions through relationships. These new forms of visualization have a higher expressive power of information visualization and an associated higher level of interactivity. Techniques for adaptive information visualization have been proposed by the Lighthouse system (Leusky & Allan, 2004).

Adaptation of modality enables changes from text to other types of media to present the information to the user (image, video, animations, or audio)—if they are available in the system. In modern adaptive hypermedia different types of media can present the same content. Adaptation of modality enables the automatic selection of the media type based on various criteria such as: cognitive style, learning style, preferences, physical abilities or disabilities, and so forth.

PERSONALIZATION TECHNIQUES APPLIED IN THE CONTEXT OF KMS

Adaptation of structure can be designed in the form of personalized views or layouts. These personalized views can be designed as domain-oriented subsystems of the KMS. Fischer (2001) argues that high functionality applications have often migrated to a collection of domain-oriented subsystems containing their own forms or templates. For instance the system can offer a personalized view of the corporate knowledge based on the interest areas and the knowledge of the users or based on the role and competencies of the users. For a KMS two main types of personalized views are proposed:

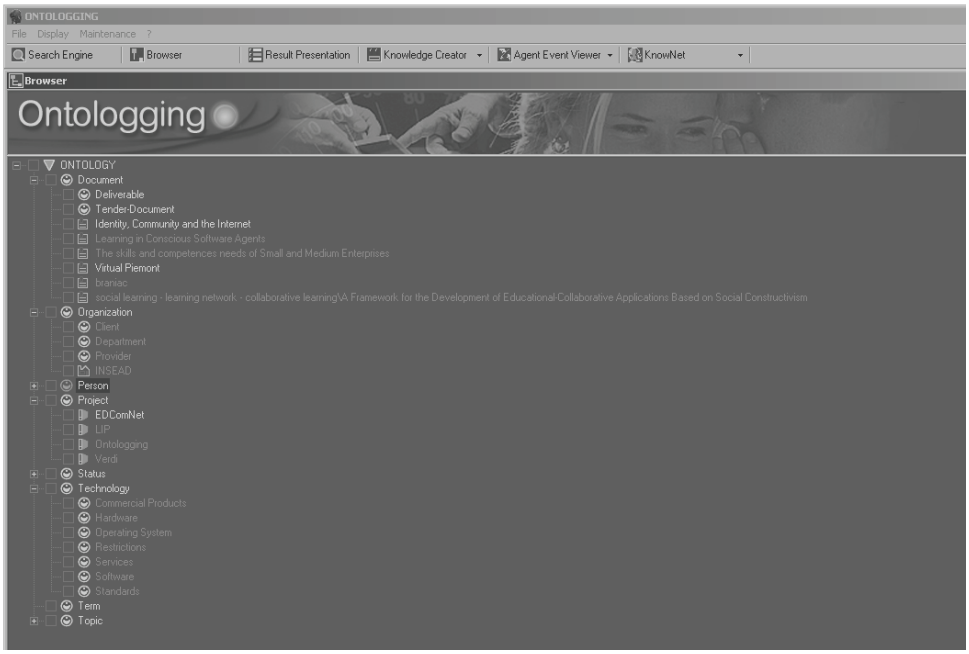
- **Personalized views based on the job title.** Based on the role of the users and the associated work tasks, different layouts can be designed. Taking into account the job titles and the most important associated work tasks, several stereotyped views can be designed. A set of richer features and complex functionality can be associated with certain jobs. Similar to a system administrator, a knowledge manager or a knowledge engineer has access to a richer functionality than a normal end user. Simplified views with limited functionality can be offered to other categories of users.
- **Personalized views based on the interest areas and the knowledge of the users.** This implies the possibility of selecting different views or subdomains of the domain ontology/taxonomy. In an ontology-based KMS the domain ontology or the corporate memory can be made up of different subontologies. For example, financial experts could have the possibility to select the finance ontology, ignoring other parts of the domain ontology. The distributed user interface of Ontologging system is designed using XML-driven components. The interface includes a "template mechanism" to customize a personalized view. The distributed user interface includes two main layers: (1) the user interface layer and (2) the component layer. The user interface layer consists of: search interface; browse interface; property edition and upload; result presentation interface; document download; and agent management interface. Thus through this template mechanism the different work units can personalize their view of the organizational memory or select parts of it, which are related to their expertise, interests, and so forth. Figure 2 represents the "tendering process" ontology of the Ontologging[1] system.

In a more sophisticated approach, the system is in charge with the selection of relevant knowledge assets for the user (the most suited items). The system evaluates how closed the knowledge assets match to the user's background and interests, and it presents the best ones. In an ontology-based KMS the system selects the concepts which match with the user's background and interests. A subontology of the domain ontology is further displayed to the user.

In a KMS, recommender systems, information filtering agents, and collaborative filtering techniques can be employed for adaptation of content. More appropriate for the use within KMSs are the following techniques:

- **Filtering of content.** Techniques for filtering the content help the user to select and retrieve information. Different systems integrate various filtering mechanisms. Among the well-known engines enabling filtering and automatic classification of content are: Verity ("Verity," 2003) and Autonomy (Autonomy, 2003). For example Autonomy integrates techniques such as: "active matching and content matching." Active matching enables users to enter the task and to extract a list of relevant documents for the task at hand. Content matching extracts conceptually related documents.
- **Personalized recommendations.** These recommendations inform users about available relevant information in the system. Recommendations can be provided via human (collaborative filtering) or artificial agents. In the category of recommender systems based on collaborative filtering Xerox research developed systems such as Knowledge Pump (KPump) and CWall (Snowdon &

Figure 2. A view of the domain ontology in the Ontologging system



Grasso, 2002). KPump allows users to submit recommendations of URLs, local files (via upload), or text. A recommendation consists of a rating and, preferably, a comment, along with the user's classification of the item into one or more communities. In turn, the KPump calculates a personalized set of recommendations for a user for each community to which he/she belongs. Communities are built based on domains of interest: "a community is a set of domains of interest plus the people in the organization with that set of interests."

- **Personalized hints for marking presumed interests.** Different types of agents or services can inform the users about new knowledge assets available in the system related to their interests and expertise (e.g., notification agents, etc.). Different relevant events can also be delivered to the users based on their interests and hobbies.

Let us have a look at some specific examples. All users interested in a certain domain (e.g., knowledge management) can be notified by the agents about various events related to their domain of interests. The domain of interest corresponds to the interest area in the user ontology. For instance, let us consider the following event: Mr. Popescu is in charge of a new project in the area of knowledge management. The notification agent system tells all users interested in knowledge management (via pop-up or e-mail depending on their preferences) that: "George Popescu from Competence Center team has started a new project in the area of Knowledge Management."

Another example: when Mr. Ionescu submits a new document into the system all users interested in knowledge management are notified that: "A new document related to knowledge management authored/submitted by Adrian Ionescu is available in the system."

- **Optional detailed information and automatic summarization.** Techniques of automatic summarization enable the automatic generation of summary from a certain piece of content. Autonomy is an example of a KMS embedding techniques of automatic summarization (Autonomy, 2003). This summary can be displayed by default to the users based on his/her preferences. Filtering certain parts of the documents could be provided based on semantic annotations associated with the document. For example, paragraphs of documents can be annotated in order to adapt the content of the displayed pages according to the user's interests and preferences. Techniques for tailoring Web pages according to the user's characteristics relate to research in the domain of adaptive hypermedia.

FUTURE TRENDS

Personalization is required by the end users of IS, and it is a step forward to overcome the "one size fits all" design of most of the actual IS. A key issue for integrating personalization is the access to the user's data, associated user model-

ing techniques, or collaborative filtering techniques. As the process of user modeling is limitative and sensitive, due to privacy issues, personalization techniques of successful systems such as Amazon or e-Bay rely on relatively simple collaborative filtering techniques.

Research on personalization of IS has opened many research issues. Future work will explore the possibility of reusing a user's profile for personalization and contextualization across different types of IS, new user modeling mechanisms combined with more complex personalization strategies, personalization of Web data extraction, and new collaborative approaches for personalization. The design of advanced IS and associated personalization techniques has recently converged with Semantic Web research. "Semantic Web enabled information systems will extract relevant information from the Web, process and combine different pieces of distributed information in such a way that the content selection and presentation fits to the individual needs of the user" (Baumgartner et al., 2005, p.)

CONCLUSION

Personalization techniques rely on the user's characteristics; captured and named user models; or user profiles and relate to specific objectives of various types of IS. In an e-commerce system personalization support for a potential client to retrieve relevant items corresponding to his/her goal, needs, and preferences are essential. KMSs aim to motivate people to create knowledge and submit new knowledge assets in the system; to stimulate collaboration and knowledge sharing between knowledge workers; to alleviate information overload; to simplify business processes and work tasks; and so forth.

The paper has proposed and exemplified a set of personalization techniques that can be applied for various types of IS. Personalized services for IS have been classified in: adaptation of structure; adaptation of content; and/or adaptation of presentation and modality. The use of personalization techniques has been exemplified in the context of KMS.

I argue that personalization has a utility function and a conviviality function (Razmerita, 2005). From the utility perspective, personalization helps fitting the functionality of the system to the user's needs, and personalization reduces the information overflow by providing users with the most relevant information.

From the conviviality perspective, personalization helps to bridge the gap between the designer's view of the system and the end user's view of the system and to take into account the user's preferences.

However, personalization techniques rely on the access of user's data (such as preferences, goal) available in the system, or on associated user modeling techniques that enable inferring dynamically the user's characteristics. The evaluation of Ontologging project has emphasized that even end users perceive personalization as an important feature to be integrated in IS; they are concerned with privacy issues and users want to be in control of their user profiles.

KEY TERMS

Adaptive Hypermedia: Adaptive hypermedia is the dynamic generation of hypermedia spaces tailored to the characteristics and preferences of the different users.

Knowledge Management System (KMS): KMS are IS dedicated to manage organizational knowledge.

Information System (IS): IS is defined as "a system consisting of the network of all communication channels used within an organization" (Wordnet).

Ontology: Ontology is a specification mechanism used for knowledge representation based on a shared conceptualization.

Personalization: The personalization of IS is the process that enables interface customization, adaptations of functionality, structure, content, and modality in order to increase its relevance for its individual users.

User Model: A user model is an explicit representation of the system of a particular user's characteristics that may be relevant for personalized interaction.

INTRODUCTION

A major theme of Information Science and Technology research is the study of personalization. The key issue of personalization is the problem of understanding human behaviour and its simulation by machines, in a sense that machines can treat users as individuals with respect to their distinct personalities, preferences, goals and so forth. The general fields of research in personalization are user modeling and adaptive systems, which can be traced back to the late 70s, with the use of models of agents by Perrault, Allen, and Cohen (1978) and the introduction of stereotypes by Rich (1979). With the wide progress in hardware and telecommunications technologies that has led to a vast increase in the services, volume and multimodality (text and multimedia) of content, in the last decade, the need for personalization systems is critical, in order to enable both consumers to manage the volume and complexity of available information and vendors to be competitive in the market.

BACKGROUND

The goal of personalization is to endow software systems with the capability to change (adapt) aspects of their functionality, appearance or both at runtime to the particularities of users to better suit their needs. The recent rapid advances in storage and communication technologies stress the need for personalization. This need is more evident in consumer-oriented fields, like news content personalization systems, recommendation systems, user interfaces, and applications like home audiovisual material collection and organization, search engines in multimedia browsing and retrieval systems, providing services for personalized presentation of interactive video content. Among these applications, some are Web-based, but there are also versions for PDAs and mobile devices (Tuoriniemi & Parkkinen, 2007) and mobile devices.

In this article, current approaches of user modeling and user profile representation are discussed, and then the focus is on methods for automatic learning of user models and profiles. The presented learning approaches cover a wide range of machine learning (vector-based or probabilistic) methods and also extend to support the most recent advances in personalization systems such as collaborative filtering, ontology-based user modeling and user social context.

OVERVIEW OF LEARNING AND ADAPTATION METHODS IN PERSONALIZATION SYSTEMS

User Modeling–User Profile Representation

User modeling describes the process of creating a set of system assumptions about all aspects of the user, which are relevant to the adaptation of the current user interactions. This can include user goals, interests, level of expertise, abilities and preferences. The most reliable method of user modeling is by explicit entry of information by the user. In most practical systems, this is too time-consuming and complex for the user. Hence implicit user modeling, based on analysis of past and current user interactions, is critical. The user profile is a machine-processable description of the user model.

The information included in user profiles can be divided into a number of categories such as user demographic information, semantic interests, context and location information, and privacy and user interface preferences (Heckmann & Krueger, 2003). Semantic preferences reflect user preferences for particular content topics. User interests and semantic user preferences are the most important source of information widely used in the personalization systems. More specifically, user interests are distinguished between *short-term* that are determined by a particular user interaction or current context, and *long-term* interests which are determined by the user behaviour and preferences over a longer period of time. User interests can also be classified into *gradual* (as a result of user experience), *abrupt* (as a result of an external stimulus) or *repetitive*. Loeb (1992) mentions two types of repetitive changes, *repetitive but predictable* (according to time of day) and *repetitive but unpredictable* (according to user mood).

There is a variety of structures and paradigms that have been used in the academic literature and in commercial personalization systems for the representation of the knowledge and information concerning the user, including the ones listed below. *Attribute-value pairs* are a fundamental data representation in many computing systems and applications. The advantage of such a structure is that it is an open-ended data structure, thus allowing for future extension without any need for modification. In such situations, all or part of the data model may be expressed as a collection of tuples (attribute name, value), where each element is an attribute-value pair. Several attempts have been put forward to standardize this type of user information structure, such as the IEEE Personal and Private Information (PAPI) (PAPI, 2002) and IMS Learner Information Package (LIP) (IMS, 2001).

The *vector space model* (VSM) is an algebraic model used for information filtering, information retrieval, indexing and relevancy rankings. It resembles the attribute-value pairs, but it has a more mathematical structure, in the sense that each element (term, or generally attribute) has a corresponding value or weight representing it and the vector has length and direction, both used, for example, in a similarity metric. The space of all vectors is often called vector domain or domain model. It has been extensively used in documents retrieval and indexing (Salton, Wong, & Yang, 1975). This representation approach has also been followed in a variety of personalization systems (Billsus & Pazzani, 2000; Lawrence, Almasi, Kotlyar, Viveros, & Duri, 2001; Ricci, Arslan, Mirzadeh, & Venturini, 2002).

One of the earlier representation approaches in user modeling has been the use of *stereotypes*. Stereotyping consists of creating a set of prototypical user profiles that represent the features of classes of similar users (Rich, 1979). Instead of keeping an individual model for each user, users are classified into the stereotypical description that best matches their individual characteristics, from which they inherit additional properties and rules.

The need to automatically learn user profiles has given rise to the use of more complicated representation methods such as the *classifier-based models*. These are based on decision trees, neural networks, inducted rules and Bayesian networks. Decision trees classify instances by sorting them down the tree from the root to some leaf node, which provides the classification of the instance. Each node in the tree specifies a test of some attribute of the instance and each branch corresponds to one of the possible values for this attribute (Cho, Kim, & Kim, 2002). In contrast to the limited decision trees representation range, artificial neural networks can represent real-valued, discrete-valued and vector-valued functions. The classifier-based models often take as input the *usage history and ratings*. The usage history is a log of the user transaction or interaction with the personalization system, which can be seen as a form of implicit user profile. It is a very practical model used in learning and adapting the user profile (Kang, Lim, & Kim, 2005).

Finally, the recent emerge of the Semantic Web technologies has led to *ontology-based representation* in user profiling. The Semantic Web vision of a next generation Web provides the mechanisms to identify those resources that better satisfy the requests not only on the basis of descriptive keywords but also on the basis of knowledge. The most common ways of representing semantic user profiles are the ontology-based and description logic based representations (Baldoni, Baroglio, & Henze, 2005). In recent work, semantic Web languages, such as Resource Description Framework (RDF), Ontology Web Language (OWL) are used to represent users and their semantic preferences. Gauch, Chaffee and Pretschner (2003) exploit hierarchical structures in ontologies to imply generalizations of user preferences upward in topic hierarchies (e.g., interest in football implies interest in sports).

Automatic Acquisition and Adaptation of User Models–User Preferences

The different representation approaches lead to a variety of methods used for the automatic acquisition and adaptation of user models, which are being presented in this section. Acquisition and adaptation models of user interests is a research area of steadily increasing importance, as it allows intelligent computer systems to adapt to users' information needs in a personalized way. Several machine learning approaches exist to build user profiles, such as Bayesian classifier, nearest neighbor, decision trees, neural networks and genetic algorithms (Pohl & Nick, 1999).

The classifier-based models are related to the use of *Classifier-Based (Statistical) Learning Methods*. The method most widely used in user profile learning is the Bayesian learning, which provides a probabilistic approach to inference. It is based on the assumption that the quantities of interest are governed by probability distributions and that optimal decisions can be made by reasoning about these probabilities together with observed data. Bayesian learning methods are among the most practical approaches. The Naïve Bayes algorithm is the simplest form of probabilistic model for learning and classifying. It can easily be estimated by training data and in some cases it outperforms other learning methods (Billsus & Pazzani, 2000, pp. 147-180).

Decision tree learning is a method for approximating discrete-values target functions, in which the learned function is represented by a decision tree (Cho, Kim, & Kim, 2002).

In the case of the stereotypical user models, there are different methods of *Learning Stereotypical Sequences of User Interactions* depending on the purposes of the recommender systems: *Collaborative recommendations systems* are based on demographic, geographic and semantic information and they have manually predefined user-stereotypes. Other systems first build a data base of user profiles using the usage log (Azman & Ounis, 2004). In *marketing-based recommendations systems*, the demographic and usage log data can be used to discover rules that capture the truly personal behaviour of a user by means of data mining algorithms. Grouping similar profiles and creating a cluster representative set of rules firstly avoids the privacy problems and secondly reduces the computation during the recommendation process (Wei, Moreau, & Jennings, 2005). Finally, the *social matching recommender systems* match people to each other instead of recommending items to people. The system first creates different set of similar users and then builds a model (i.e., stereotype profile) for each set of users (Terveen & McDonald, 2005).

The user profiles represented with vector space models are related to learning methods based on the user's *relevance feedback*. The term feedback is normally used to describe the mechanism by which a system can improve its performance on a task by taking account of past performance. Adaptive systems using relevance feedback have to choose how relevance feedback should be represented, acquired and used. There are three different methods for representing the relevance feedback. *Boolean relevance* describes whether a document is relevant or not relevant (Objective feedback) vs. useful or not useful (Subjective feedback) to the user. *Multi valued relevance* has been proposed by Bookstein (1983) where the possible relevance classes might be: Very Relevant, Relevant, Indifferent, Irrelevant, Very Irrelevant. In

Quasi-Ordered Relevance, the Document Preference Relation (Wong & Yao, 1990) method relies on a quasi-order of documents. For each pair of documents, the user can either prefer one to the other or have no opinion.

Once the relevance feedback is acquired, there exist multiple formulas that propose to reweight the terms used in the initial query (query reformulation). In vector processing methods, the most commonly used is the Rocchio formula presented in Salton and Buckley (1990), where the new query vector is the vector sum of the old query vector plus the vectors of the relevant and non relevant documents. An extension of this formula proposed by Salton and Buckley (1990), called Ide, eliminates the normalization of the number of relevant and nonrelevant documents and allows limited negative feedback from only the top-ranked nonrelevant document.

In the case of the ontology-based user models, the learning process needs to exploit the deeper ontological knowledge about the underlying domain, thus allowing the personalization systems to handle heterogeneous and complex objects based on their properties and relationships and to automatically explain or reason about the user models or user recommendations. During the learning process, the concepts represented in the ontology are rated according to user-specified preferences such as semantic relevance, syntactic relevance, and categorical match (Kerschberg, Kim, & Scime, 2001).

The learning methods in the ontology-based user models are often enhanced with one of the most expressive and human readable representations for learned hypotheses, which is to use sets of if-then rules. One important special case involves learning sets of rules containing variables. First order rules are more expressive than propositional rules. In general, in many cases it is useful to learn the target function represented as a set of if-then rules that jointly define the function. One way to learn sets of rules is to first learn a decision tree, then translate the decision tree into an equivalent set of rules; one rule for each leaf node in the tree (Mobasher, Dai, Luo, & Nakagawa, 2001). Another method is to use a genetic algorithm that encodes each rule set as a bit string and uses genetic search operators to explore this hypothesis space. There are also a variety of algorithms that directly learn rule sets (Mitchell, 1997).

In all the above-mentioned learning methods, content filtering agents attempt to alleviate information overload by identifying which items a user will find worthwhile. Content filtering focuses on the analysis of item content and the development of a personal user interest profile.

However, to overcome the problem of handling end users solely as units and missing possible information and trends beyond those within the scope of user's history, *collaborative filtering* learning methods are introduced. Collaborative approaches find and recommend information sources for an individual user that have been rated highly by other users who have a pattern of ratings similar to that of the user (Pazzani, 1999). Each technique has advantages and limitations. Current methods for collaborative filtering can be divided into two categories: memory-based, which use all of the available data when making recommendations, and model-based methods which, at some point, learn a statistical model from data and use that model for predicting user interests. Collaborative filtering has a number of advantages over Content-based filtering methods. The quality of memory-based collaborative filtering algorithms typically increases with the size of the user population, and Collaborative filtering recommendations benefit from improved diversity when compared to Content-based filtering recommendations (Claypool et al., 1999). For a start, memory based algorithms are not suitable for recommending new items or one-off content items because these techniques can only recommend items already rated by other users. On the other hand, the model based methods can use smoothing methods to give prior probabilities to items without any ratings. Collaborative filtering matches people with similar interests and then make recommendations on this basis. Collaborative filtering is based on a statistical analysis of patterns and analogies of ratings obtained explicitly or implicitly from user system usage. Typically, for each user a set of nearest neighbors is defined using the correlation between past ratings. Collaborative filtering techniques can be classified to two categories according to the source of information; the user-based and item-based collaborative filtering. The main deficiency of user-based collaborative filtering systems is that they usually make recommendations from very thinly scattered data. In item-based filtering, there are techniques for computing item-item similarities and for obtaining recommendations from them. Linden, Smith, and York (2003, p. 76) follow this approach in Amazon's recommendation system. The main advantage of the item-based approach over the user-based one is its scalability. A combination of the two approaches can be seen in the work of Renda and Straccia (2005).

A further extension of the collaborative filtering approaches is to exploit the *social user context*, which is mainly composed of the user's relationships with other users. Social Information filtering exploits similarities between the tastes of different users to recommend (or advise against) items. It relies on the fact that people's tastes are not randomly distributed: there are general trends and patterns within the taste of a person as well as between groups of people. The basic idea is that the system maintains a user profile, a record of the user's interests (positive or negative) in specific items. It compares this profile to the profiles of other users, and weighs each profile for its degree of similarity with the user's profile. Mika (2005) presents the advances in exploiting the opportunity of semantically-enriched network data.

PERSONALIZATION IN COMMERCIAL APPLICATIONS

Personalization, besides its value in the research field, has also been deemed as an important part of many commercial applications due to the innovation in the services it provides. An example of automatic personalization in commercial systems is Amazon.com's personalized recommendations (Linden, Smith, & York, 2003). Google Inc. has also filed two U.S. patents on personalization technologies for Web search (Badros & Lawrence, 2005; Zamir, Korn, Fikes, & Lawrence, 2005). The Leiki concept aims at combining personalized user interfaces, communities and content targeting (Pennanen & Alatalo, 2001). The Leiki platform is applied as a personalized news service. MovieLens, http://movielens.umn.edu/login, is a free Web-based movie recommendation service provided by the GroupLens research team from the University of Minnesota. It works by matching together users with similar opinions about movies using a collaborative filtering algorithm. TiVo is a television show collaborative recommendation system (Ali & van Stam, 2004, pp. 394-401). The success and innovation of TiVo relies in their personalised television-viewing service, which recommends or automatically records programmes based on user preferences.

FUTURE TRENDS

Mobile ad-hoc networks, wireless broadcasting and open mobile applications are three prominent examples in which computation and communication intermingle with the real world changing the role of context information. Context includes user activities, goals, abilities, preferences, and surroundings.

Current personalization systems do not fully support such flexible and self-adapting models based on context. Thus, future research opportunities within the field of automatic personalization systems include the study of context-aware systems as well as seamless mobility, which is the key future trend in distributed mobile environments. These areas involve research in privacy and sharing of context informa-

tion and also in the synchronization of user profile between different devices.

CONCLUSION

In this article, the state of the art on the user modeling and user profile representation was presented. More specifically, the standardization and categorization of user profiles was introduced, along with the information included in user profiles and user profile structures. Then, the emphasis is given to the automatic learning of user profiles, where different approaches are being discussed. Automatic learning of user profiles is the current trend in the academic literature and also the key requirement of the current and future commercial personalization systems.

KEY TERMS

Acquisition and Adaptation of User Profiles: The automatic creation and adaptation of a user profile by monitoring the user interaction with the system and employing efficient machine learning algorithms.

Collaborative Filtering: The method of making automatic predictions (filtering) about the interests of a user by collecting information from other similar users.

Content-Based Filtering: The method of making recommendations to a user by matching user profile entries to content attributes.

Machine Learning: The method for processing a training input and offering support for decision based on this input.

Personalization: Delivery of content according to the individual user's needs, characteristics and preferences.

User Modeling: The process of creating a set of system assumptions about all aspects of the user, which are relevant to the adaptation of the current user interactions.

User Profile: A machine-processable description of the user model.

Using an Architecture Approach to Manage Business Processes

Shuk Ying Ho
The University of Melbourne, Australia

INTRODUCTION

Business process management has long been a topic of great interest in operations management research. Early research on business process management focuses on workflow analysis and process optimization. These types of research evaluate and analyze a predefined set of procedures from a process perspective. That said, with a list of activities, constraints and criteria, the procedural workflow are specified and examined. Then, process analysts come up with suggestions to optimize the process and speed up the workflow. Research findings are widely applied in production and logistics; however, some works are criticized as being too rigid and only suitable for a stable business environment (Burns, 1993).

With the recent advances of information technologies (IT), research topics, including enterprise resource planning (Hong & Kim, 2002), computer integrated manufacturing (Burns, 1993) and total integrated management (Azhashemi & Ho, 1996), have become popular. Technologies are now playing a more significant role in organizations than before. They help organizations achieve higher competitive advantages, and facilitate the operations in all functional areas, such as marketing and sales, cash receipts, purchasing, cash disbursement, production and logistics and human resources (Valiris & Glykas, 2004). Transactions and financial data are gathered and stored, and technologies make data available for operational units and management to make decisions. Operations are sped up and an enduring dialogue in the intra- and inter-organizational contexts is built.

Technologies, on one hand, create substantial values to organizations. On the other hand, technologies are moving too fast, resulting in a rapidly-changing business environment. With the rapidly-changing environment, organizations face challenges. From a technological point of view, new technologies emerge and organizations conduct business in a more dynamic environment (Neiderman, Brancheau, & Wetherbe, 1991). For instance, although the Internet provides rich opportunities for organizations to exchange information, it greatly reduces the switching cost of users. This results in fierce competitions among organizations. Organizations have to reduce their costs in the hope of remaining competitive. Moreover, communities, such as W3C and IEEE, constantly propose new technology standards. Among various standards, Web services are the most dominant. Sets of Web services standards, such as extensible markup language, were put forward in the early 2000s. An organization can use these standards to easily integrate multiple systems across platforms. The standards also allow various organizations to share data and applications (Coetzee & Eloff, 2007). Much research (e.g., Moitra & Ganesh, 2005) explores how Web services increase the flexibility of business processes. At present, many technology leaders, such as Microsoft, IBM, Google and Amazon, have already adopted Web services. With high external pressure, other organizations are likely to follow the technology trend and quickly adopt Web services to maintain their competitive advantage.

New technologies not only shape the operation and business environments, but also influence government regulations that pose new requirements and constraints on business processes. With transactions migrating to a computer platform, IT frauds become a concern for process analysts, management and auditors. Thus, the federal government proposes new regulations. For instance, Section 404 of the Sarbanes-Oxley Act (SOA) expands the significance of internal controls of processes. It explicitly states that managers and auditors are responsible for enacting and enforcing proper internal controls throughout their organizations. Technologies become a means to achieve improved quality of operational controls, and the ultimate objective of using technologies in business processes is to achieve high effectiveness, high efficiency and high security of organizations.

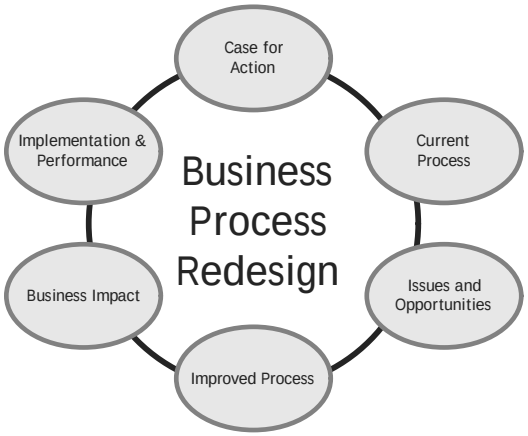
The article describes an architecture approach for business process management, and is organized as follows: first, we review the literature on architecture. Next, we outline a de facto standard for the architecture approach, and highlight the strength of using an architecture approach. Finally, we describe future trends, and conclude the article.

BACKGROUND

Business Processes and Their Importance

A business process is defined as a set of related, structured activities, or a chain of events, that produces a specific out-

Figure 1. General steps in business process redesign



come for a particular user or users. This set of activities is in pursuit of a common goal. Typical business goals include receiving sales orders, marketing services, selling products, delivering services, distributing products, invoicing for services, accounts receivable, purchasing and accounts payable. Business processes directly support organization strategies, and hence the processes are valuable corporate assets.

To tackle the challenges by the rapid changes in technologies, presumably, organizations are required to evaluate business processes on a regular basis. As a result, organizations are paying more attention to supporting business process management and redesigning the processes to adapt to the new environments (Davenport & Stoddard, 1994). Figure 1 depicts the general steps of business process redesign.

During business process redesign, organizations have a specific case for examination. They identify the processes of interests and evaluate the opportunities and constraints. They improve the processes by integrating them into new technology platforms, and processes are redesigned in the hope of cutting costs, improving controls, speeding up the operations and achieving higher efficiency in the interactions between the internal processes and interactions of the processes with the environment (Arlbjorn, Wong, & Seerup, 2006; Hofmann & Reiner, 2006). Process redesign can help to achieve strategic advantages. Thus, it is not surprising to see the increasing amount of resources that organizations invest in redesigning their business process (Tinnilä, 1995).

Prior research shows that most organizations are not familiar with business process redesign and change management. Also, they do not have a structured methodology for process redesign. However, even if a few organizations adopt a structured methodology, some researchers criticize that their methodology is prescientific and ad hoc (Valiris & Glykas, 2004), and most approaches cannot provide a holistic view from management and operations (Avison & Wood-Harper, 1990). In the following, we will provide a high-level architecture approach, which is influenced by organizational theories, IS development and existing work in business process redesign. Architecture views are representations of the overall system that are meaningful to all stakeholders, such as management board, chief information officer, users, designers and analysts, in the enterprise. It also provides a holistic approach to help stakeholders gather relevant and sufficient information for business process redesign.

An Architecture Approach

The word, architecture, originates from Latin. It is the art and science of building structures. In recent years, the word, architecture, has been used in application coordination (King, 1995), software management (Greefhorst, Koning, & Vliet, 2006) and enterprise management (Johnson, Lagerstrom, Narman, & Simonsson, 2007). It is the abstraction used to deal with complexity. By extension, the term "architecture" has come to denote the art and discipline of creating an actual, or inferring an implied or apparent plan of any complex object or system. Architecture is analogous to a blueprint for the object or the system. It details how the design is to be divided into individual functional components and the way in which these components are to interact to provide the overall functionality. According to IEEE Standard 1471-2000, architecture is "the fundamental organization of a system embodied in its components, their relationships to each other, and to the environment, and the principle guiding its design and evolution."

In the context of an organization undergoing business process redesign, architecture is a blueprint which specifies data architecture, business architecture, technical architecture and process architecture. An architecture approach is usually taken by large enterprises. As an organization grows in complexity and size, several factors hinder its abilities to solve the problems that it faces. The point is rapidly reached where the factors that come into play in structuring and conducting the business of the enterprise become too numerous and complex to manage. When dealing with such complex systems, a complicated problem is usually broken into subsets or domains, which is less complex and more manageable. This helps to make sure the orchestration of the interaction among those subsets or domains. Thereby, an architecture approach is typically adopted by large enterprises. We refer to it as *enterprise architecture*. Enterprise architecture is a specific type of architecture and can be considered to be the description and documentation of the current and desired information and technology environment, and its relationship to processes and business strategy. It coordinates various facets, including process models, diagrams or textual documents (Puschmann & Alt, 2005).

ARCHITECTING AN ENTERPRISE

Major Issues when Architecting an Enterprise

Enterprise architecture is a means for describing processes that connect business structures. Its objective is to let the stakeholders of the organization have a clear vision of the desired future state of the entire system, including such dimensions as business strategies, process design and technology infrastructure. To achieve this vision, all stakeholders must have a common context both for diagnosing the needs for changes and for managing the process of changes. Hence, the common context acts as an integrating force for the multitude of apparently disparate changes to be made. It is where the concept, architecture, comes in.

There are four dimensions in enterprise architecture. They are data architecture, business architecture, technical architecture and process architecture. These dimensions provide a holistic view of an enterprise (see Figure 2). *Data architecture* defines how data is stored, managed and used in an enterprise. It establishes common guidelines for data operations and thus it is possible to predict, model, gauge, and control the flow of data in the enterprise. It provides the basis for business architecture, technical architecture and process architecture. *Business architecture* structures the accountability over business strategies and activities prior to any further effort to structure individual aspects. *Technical architecture* refers to hardware and software architecture. It is the structured process of designing and building technology hardware at enterprise level. Issues including the legacy systems, middleware and network communications are all within the scope of hardware architecture. Technical architecture also deals with software architecture, which focuses on functions of the software programs and data transfer between programs. *Process architecture* is the structural design of general process systems and covers process design, logistics, policy and procedures. The overall inputs, outputs and functionality of the process architecture are also specified.

The enterprise architecture approach facilitates the business process management by providing frameworks and methodologies to support: (1) a shared understanding of business functionality and data usage across the virtual enterprise; (2) a baseline from which applications can be deployed or integrated in a coordinated fashion; (3) a context for performing business-driven process and information modeling; (4) an understanding of how business models drive the creation of functional IT and data models; (5) the capability for planners and business owners to communicate and exchange requirements with IT; and (6) the ability for chief information officers to understand and respond to dynamic business impacts on the IT environment (Johnson et al., 2007).

When architecting the enterprise, stakeholders generally have concerns about cost, value, risks, time, control and so

Figure 2. An overview of enterprise architecture

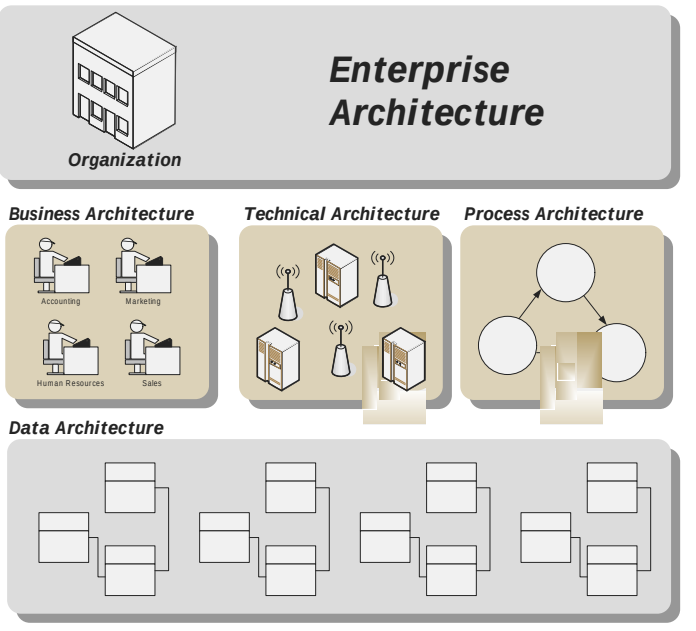


Table 1. Examples of typical questions raised by architects and top management

Process issues	*Performance* ● Is IT making the business more agile? ● Is significant improvement of information technology actually possible? ● Is full advantage being taken of the progression in hardware technology and software techniques? ● Is there an ongoing program for rationalizing systems? *Expertise and Resources* ● Can we identify the solutions specialists in our organization? *Risk and Security* ● What are the possible risks? What are their levels of damages? ● Are security and availability risks fully managed?
Strategy issues	*Cost and Return on Investment* ● Is the value of IT investments being measured? If so, by how? ● Are the results of these investments as good as possible? ● How can the finite resources be most effectively used? ● Is the asset value of IT understood and acceptable? *Impacts on Business Strategies* ● Is information technology focused on business outcomes? ● Is the business strategy being realized?
Policy issues	*Governance* ● Are our key development partners independent? ● How does the organization deal with increasing regulatory requirements?

forth. Table 1 shows a list of typical questions raised by the stakeholders.

Technologies Related to the Architecture Approach

Tools supporting architecture are commonly available. One of the most widely applied tools is Zachman Framework for Information Systems Architecture by John Zachman (Zachman, 1987). The Zachman Framework is an enterprise-class framework which provides a formal and highly structured way of defining an enterprise. It has a series of views describing how business planners and owners envision IT requirements, and how designers and developers view a logical or physical implementation of those same requirements.

The Zachman Framework is made up of two dimensions. The first dimension contains six aspects by using the basic communication interrogatives (What, How, Where, Who, When, and Why). The second dimension consists of six viewpoints by six groups of stakeholders (Planner, Owner, Designer, Builder, Subcontractor and Worker). Table 2 presents the six aspects and the six viewpoints.

Figure 3 shows a picture of the Zachman Framework. There are 36 (=6×6) cells in the framework model. The intersecting cells depict the related documentation modeling techniques or technology to address the questions by the stakeholders. The framework draws stakeholders' focus to relevant domains and stimulates them to ask relevant questions. It also organizes descriptive artifacts of an enterprise, such as models, pictures, diagrams, or textual documents, and classifies them into one of the 36 cells.

Apart from the Zachman Framework, other enterprise-class frameworks are available. They include the Information Framework (Evernden, 1996); the Open Group Architecture Framework (Open Group, 2006); and the Methodology for Architecture Description (Meinema, 1999). These are all de facto standards. Architects decide to use which framework based on criteria, such as their expertise and organizational practice.

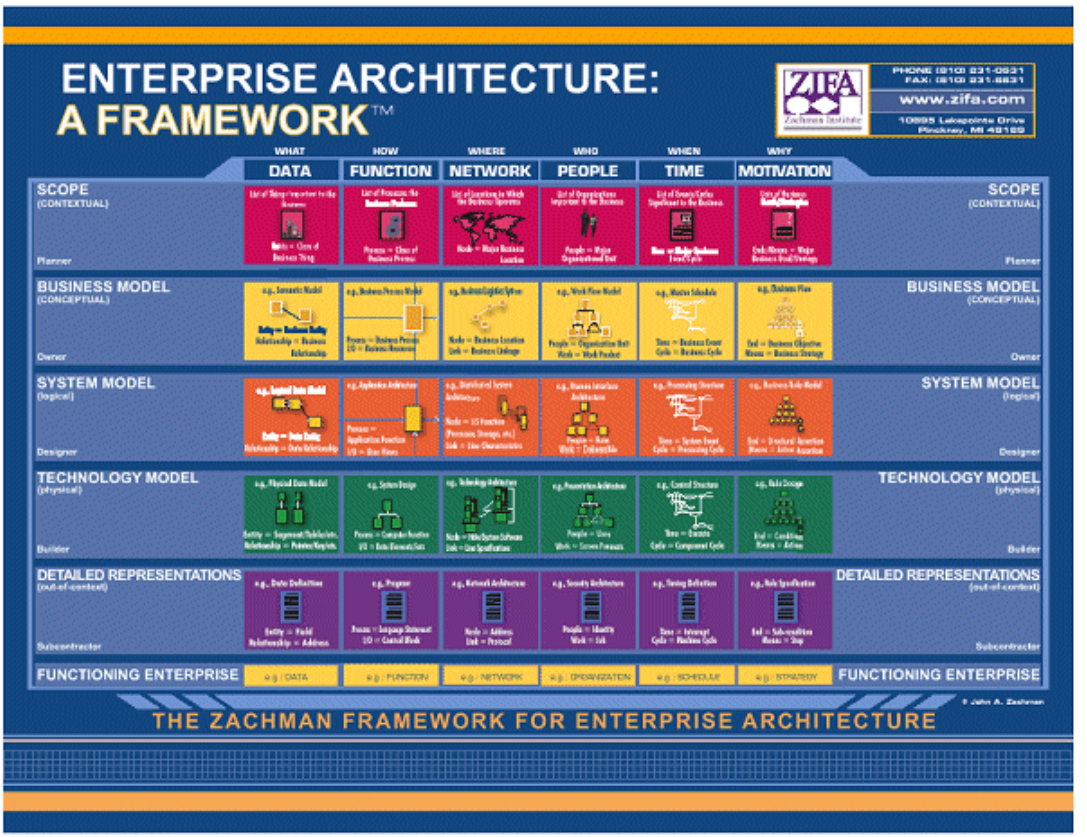
Reasons to Adopt an Architecture Approach

To deal with global competition, organizations seek ways to regularly reconsider their IT environments and optimize

Table 2. The six aspects and the six viewpoints of the Zachman Framework

The Six Aspects	1. The Data aspect - What? 2. The Function aspect - How? 3. The Network aspect - Where? 4. The People aspect - Who? 5. The Time aspect - When? 6. The Motivation aspect - Why?
The Six Viewpoints	7. The Scope (Contextual) viewpoint aimed at the planner 8. The Business Model (Conceptual) viewpoint aimed at the owner 9. The System (Logical) viewpoint aimed at the designer 10. The Technology (Physical) viewpoint aimed at the builder 11. The Detailed Representations (Out-of-Context) viewpoint aimed at the subcontractor 12. The Functioning Enterprise viewpoint aimed at the worker

Figure 3. The Zachman Framework (Reference: http://www.opengroup.org/architecture/togaf8-doc/arch/chap39.html)



their business processes. Organizations redesign their information systems and business processes, in the hope of reducing the cost and helping themselves respond to a changing environment rapidly.

Enterprises taking an architecture approach to redesign their process can achieve the following benefits: Firstly, enterprise architecture allows the business and IT to work together as harmoniously as the business and finance do. It

provides a set of tools, the common language for which is needed to allow the stakeholders to become partners with the same mission (Zachman, 1987). With an enterprise architecture approach, organizations describe and document the current and desired information and technology environment, and its relationship to business strategy and processes, thus providing a platform for better quality and quicker decision making.

Secondly, it provides a means for the business and IT to communicate effectively, ensuring that IT is supporting the business. Effective communication leads to a clear understanding of the current IT situation and how well it fits the business. It also facilitates IT planning so that all impacts on the business are clearly understood.

Thirdly, an architecture approach allows a business to be more flexible and agile, thus enabling a quick and cost effective response to changes in the environment. The approach also helps to manage the business risk relating to the use of IT, and reduce the risk of problems with technology and how it is applied.

FUTURE TRENDS

Managing business processes, in particular for an enterprise, is a challenging task because business processes interact with data, technology infrastructure and business strategies. While careful planning typically goes into its design, architecture actually emerges as a result of implementing business processes with the consideration of aspects from various stakeholders. It is a de facto standard and provides the capabilities for executing business strategies, and understanding this emergent architecture is of paramount importance.

Further research can be conducted to improve the architecture framework. One of the limitations of the framework is its complexity. Organizations have to invest time and resources to fill in each cell of the framework, and sometimes, not all information in all cells are important. Attempts by researchers and practitioners can be made to simplify the framework. They can prioritize the dimensions of the framework and customize the framework to different industrial domains. We believe the simplified version will be very useful to medium-sized firms.

CONCLUSION

The fierce competition of business leads to a strong need of improving and adapting business processes to the new environment. This chapter introduces an architecture approach of business improvement. We particularly focus on the enterprise architecture approach and its related technologies. We also provide explanations to address the importance of an architecture approach and how it helps to improve business process management. Currently, enterprise architecture is still considered to be a costly and highly sophisticated technology, which requires input from the management board, chief information officer, users, designers and analysts. With the high complexity of business activities and continuous awareness of situations, we believe an architecture approach will gain significant attention in the near future.

KEY TERMS

Blueprint: It is a document to detail how the design is to be divided into individual functional components and the way in which these components are to interact to provide the overall functionality.

Business Process: A business process is defined as a set of related, structured activities, or a chain of events, that produces a specific outcome for a particular user or users. This set of activities is in pursuit of a common goal.

Business Architecture: It structures the accountability over business strategies and activities prior to any further effort to structure individual aspects.

Enterprise Architecture: It is a specific type of architecture and can be considered to be the description and documentation of the current and desired information and technology environment, and its relationship to processes and business strategy.

Data architecture: It defines how data is stored, managed and used in an enterprise, and establishes common guidelines for data operations.

Technical architecture: It refers to hardware and software architecture.

Process architecture: It is the structural design of general process systems and covers process design, logistics, policy and procedures. The overall inputs, outputs and functionality of the process architecture are also specified.

Zachman Framework: It is a tool supporting enterprise architecture, and was developed by John Zachman.

Using Audience Response Systems in the Classroom

David A. Banks
University of South Australia, Australia

INTRODUCTION

Audience response systems (ARS) are increasingly being introduced into educational settings, having previously proved their value in business. These systems make use of hand-held numeric input devices to allow students to enter data in response to questions or statements displayed on a public screen. The captured data is displayed on a public screen and enables both academics and students to immediately see how the whole group has responded. The anonymity afforded by an ARS encourages individuals to fully participate without fear of ridicule or loss of face.

The low cost ARS technology is simple to use by both students and academics, can be used with large (up to several thousands) or small groups and has applications in all topics of study and at all levels of study. ARS are highly portable, require little set-up time and are easy to use by anyone who has had some experience with software such as PowerPoint.

AUDIENCE RESPONSE SYSTEMS

ARS comprise hand-held input devices that transmit data to a receiving device connected to a personal computer. Software processes the datum and presents it in a variety of formats to the participants for discussion. Key components of the system are:

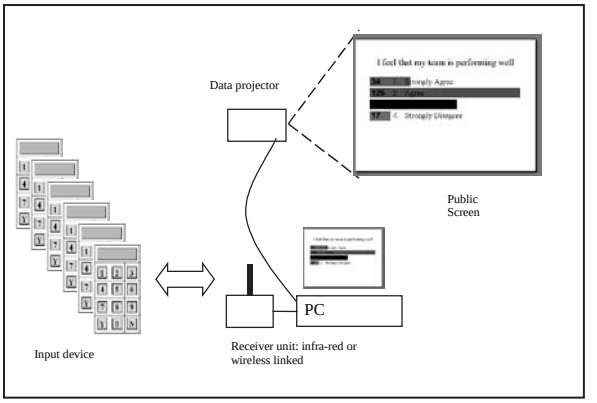
- **Hand-held input devices:** A variety of sizes and designs exist, from the credit-card size keypad with basic numeric input (Figure 1) through to systems that include a display screen to provide feedback to the user.
- **Receiver:** Utilizes infrared or other wireless communication media to collect data from the keypads.
- **Software:** Manages collection and processing of data and supports display of the data in a variety of presentational formats. The software may be embedded in other container software such as PowerPoint. The output from the system is usually displayed on a public screen via a data projector (Figure 2).

ARS IN HIGHER EDUCATION

Draper and Brown (2004, p. 20) suggest that "The dream of personal teaching is really about adaptive teaching; where what is done depends on the learner's current state of understanding." ARS can provide timely feedback to support this adaptive teaching goal, but Draper and Brown make the point that this can only be achieved through ap-

Figure 1. Credit-card size kepdad (Source: KEEpad Pty Ltd)

Figure 2. ARS components



propriate pedagogic design and action and not through the technology alone. In one-to-one or small group settings the learning facilitator may have a sense of the current state of the learner if the learner feels sufficiently comfortable in revealing it. With large groups in more formal settings the availability of cues to the learning facilitator can be more limited. The immediate feedback that an ARS offers can publicly identify differences or similarities of opinion within groups and provide a trigger for further discussion or analysis of data and re-adjustment of pacing or content. Audience Response Systems can be used with both large (hundreds of participants) and small groups (Banks, 2006) to support lectures, workshops, seminars, and to explore a wide range of subjects. They can be used at undergraduate and postgraduate levels, and within traditional and post-modern paradigms. Subject areas that value discussion, debate, multiple interpretations and direct challenges to accepted wisdom can benefit from this technology, but equally an ARS can be used in subject areas where demonstration of understanding of a fixed body of knowledge is vital. ARS can be used for formative and summative assessment, in the gauging of preliminary level and subsequent stages of understanding of a subject and in the exploration of the concepts that underpin critical issues.

Mitchell (2001) suggests that ARS can be used for mechanistic purposes such as monitoring class attendance via individual handsets, providing instant marking and feedback and for gathering data that can be used to support research activities related to classroom processes. McCabe, Heal and White (2001) used an ARS to support computer-assisted assessment (CAA) approaches with mathematics students and consider that it not only reinforced existing CAA activities but also served as a valuable tool for motivating higher levels of student learning. Hunt, Irving, Read and Knight (2003) used an ARS in a first-year information systems unit, in a decision-making subject in a third-year psychology course and also with second-year BS Pharmacy students. In the pharmacy course questions were posed via the ARS and the resulting answers were displayed and discussed by the whole group. A key issue here is that what is being sought is not necessarily a 'correct' answer but instead an examination and exploration of all possible answers and the reasons that individuals give for selecting a specific answer. The students expressed enthusiasm for the system, particularly in its ease of use, the ability to discuss answers immediately after making their choice and in the way it helped students identify where further reading was required. Importantly they also found it to be both easy and fun to use.

Post graduate HRM and MBA students using case-based approaches supported by an ARS indicated that the level of participation and number of ideas generated and explored was greater than usual and that the influence of individual personalities was greatly reduced. (Jones, Gear, Connolly, & Read, 2001). The students also observed that the technology was simple to use and to some extent became 'invisible' to the users. Williams (2003) notes that students on an MBA course using an ARS were strongly in favor of the technology and had negative views about passive learning approaches that simply involved reading or listening. Uhari, Renko and Soini (2003) reported that 80% of students studying a pediatrics course felt that an electronic voting system helped improve their learning and enhanced questioning during lectures. Witt (2003) found that 87% of students studying statistics for a psychology course saw more benefits than disadvantages in the use of keypads. Judson and Sawada (2002) reported that students consistently indicated that they are more likely to attend class, are challenged to think more deeply and feel that staff using such technologies learn more about them as individuals.

The anonymity afforded by ARS provides an opportunity for engaging students in sensitive subject areas where they may normally be reluctant to raise their hands. For example,

Wired News (2005) reported that Cheit used an ARS in an Ethics and Public Policy class at Brown University (USA) to explore the question 'Are you morally obliged to report cheating if you know about it?' The ARS quickly captured around 150 student responses indicating 64% in agreement with the statement and 35% in disagreement. The actual data captured here is of less significance, in this context, than the opportunity that is raised for discussion and for students to appreciate their own position in the light of others. The data captured during sessions such as this may prove useful for longitudinal studies of changing student attitudes or the responses of a variety of groups to such questions.

Although ARS are typically associated with large groups they can also offer useful support for small groups (Birdsall, 2002; Ward, Reeves, & Heath, 2003). Banks (2003) discusses the use of an ARS to support a diagnostic peer-review process with groups of around five students. This process offers an opportunity for students to become aware of the perceptions of their peers of their performance against a number of agreed group performance indicators. The use of this diagnostic session early in the course allows problems to be surfaced and identified, solutions discussed and action plans developed before any major tensions negatively affect the groups. One interesting effect that needs further investigation is the observation that overseas students who would normally be unwilling to engage in open discussion about the way they were perceived by others, or how they perceived others, would be willing to 'talk through the screen'. The ARS-based process seems to have produced a de-contextualization that allowed them to talk about themselves without embarrassment. ARS can also be used to support scenario-based activities (Banks & Bateman, 2004) that encourage groups to reflect on the ways in which individuals and groups perform and to act as a trigger for discussion of issues of communication, trust, negotiation, and teamwork in general.

ISSUES IN THE USE OF ARS IN HIGHER EDUCATION

Benefits of Anonymity

In groups where a number of different cultures are represented there is a danger that in traditional face-to-face settings some students will not offer an answer for fear of 'loss of face'. Some shy students may also feel inhibited in large groups and thus not feel able to contribute to the discussion. The anonymity afforded by these systems provides an opportunity for these potentially disadvantaged students to fully participate in the learning process. Chaitman (2005), however, cites the view of Bill Lewis, a computer science lecturer at Columbia University, that "Students will become more involved in their class and their own lives if they're not anonymous," More research is needed in this area.

More than Just the Numbers

Using ARS to collect numeric data from the individual keypads for testing or feedback purposes is an obvious asset. However, in more discursive learning environments the 'shape' of the collected data patterns is more useful in triggering critical discussion. Differences in displayed score patterns may indicate differing worldviews or interpretations of the data and this can provide an opportunity for reflection, sharing of views, critical thinking and deep learning. 'Flat' data may suggest that an ambiguous question has been asked whereas responses that locate at extreme ends of the scale, or are bipolar, suggest strong or opposing views that are worthy of further exploration.

Process vs. Content

The greater emphasis on process and engagement may lead to a feeling that some content has to be abandoned (Slain, Abate, Hodges, Stomatakis, & Wolak, 2004). This may be a useful outcome as it leads academics to consider what material needs to be included in any given part or mode of a course, and about what needs to be explored face-to-face and what can be supported by other mechanisms outside contact time. Slain et al. comment that their ARS based approach did suggest that there was a greater need for students to attend sessions having read appropriate material. Consideration of the balance of face-to-face, external and blended modes may offer improvements to the learning environment that go beyond the technology itself.

Question, then Question Again

By asking a question a number of times and critically evaluating the distribution of the ARS responses it becomes possible to explore the reasons for the differing or changing responses. Gauging the responses of students through the use of an ARS allows for quick and multiple loops around the material if learning appears to be problematic. D'Inverno, Davis & White (2003) report that the use of an ARS suggests that typically around 40% fail to identify the correct answer to simple questions, and that if the same question is asked again around 20% still provide the wrong answer. (They do, however, suggest that there may be some deliberate entry of incorrect answers as not all students feel that the technology offers them benefit).

Accessibility/Equity for All Students

Even though the cost of keypads is already low, and falling, the provision of one keypad per student clearly represents a large investment and technology management issue for an educational institution. Ownership of keypads by the institution also raises the problem of issuing and collecting

the keypads before and after learning sessions, maintenance and so on. One way to overcome this problem is to make the students responsible for the keypads. This can be achieved through the currently developing approach of providing students with shrink-wrapped packages of textbooks and keypads, the cost of the keypads being built in to the package purchase price. However, Stone (2004) notes that "Adding the clicker as a required supplement bundled with the new textbook not only helps sell new texts, it stifles sales of used copies that take away from publisher revenues … Further, clickers provided by most publishers won't work without activation, so the used clicker has little market value."

Standards

The number of systems available has grown dramatically in recent years. If different departments in an institution adopt an ad hoc approach to the adoption of these systems, the resulting collection of different brands will lead to incompatibility (Branen, 2005; Stone, 2004). Appropriate policies will need to be implemented to provide a managed environment.

- **Reliability:** Ideally the technologies can be taken into a room and quickly set up for use. In practice a number of problems have been reported in both set-up and operation. Delays impact upon the view that students gain of such systems, Branen (2005) noting that students in a Marketing class felt the systems to be 'an inefficient use of time' due to the wastage of fifteen minutes every day getting them to work. It is also noted that Infra Red keypads were not always detected by the system, leading to problems when they were used as a way of checking attendance or for assessment exercises.
- **Multiple choice:** ARS encourage the use of multiple choice questions and the apparent simplicity of implementation of such questions needs to be balanced against the need for careful design of the questions themselves. (Barrow & Blake, 2004). The development of approaches that allow publishers test banks linked to some books to be quickly converted into an ARS presentation may also raise concerns despite the potential benefits.

Current Developments

A number of systems that utilize personal digital assistant (PDA) technology and mobile phone technology are currently being developed to support text and graphical input, further increasing the versatility and power of these systems (Pelto, & Pelton, 2006; Jones, Marsden, & Gruijters, 2006; Dominick & Bishop, 2006). Many existing keypad vendors are developing their products so that the basic software can be used with virtual keypads implemented on networked PCs. For example one vendor has a virtual keypad that can be used with PDAs, laptops and networked PCs to provide all of the functions of the normal keypad plus text messaging, moment to moment polling and fastest response slides (KEEpad.com). As ARS continue to develop they will also start to link into Web-enabled learning systems to provide support for fully blended learning environments.

CONCLUSION

Considerable time and effort is being invested in distance learning via the Web, but it is equally important that the benefits of technology are applied to support and enhance more traditional face-to-face learning environments.

ARS technology provides educators with an opportunity to supplement their existing teaching and learning strategies in a way that provides them with improved, immediate and dynamic insight to the progress of learners. Students have an opportunity to engage with learning in an active way that helps them see how they, and their peers, are performing on a moment-to-moment basis. The opportunities for learning to be a shared experience are improved and there is the potential for engagement with subject material at a deeper level.

There are many research questions that need to be explored as this technology is introduced. These will include the potential for the use of the technology to promote deep learning, the long-term reactions of students to the technology versus the initial novelty factor, their effectiveness at different levels of study and in different subjects, and many other areas of concern will offer many opportunities for investigation. The use of frequent in-course evaluations rather than a single exit evaluation will allow student concerns to be addressed in a more timely way and will also allow discussion to take place between teacher and learner about both the evaluation instrument and the meaning of the captured data.

KEY TERMS

Anonymity: A feature of an ARS that can protect the identity of a participant. The default state is 'anonymity', but it is possible to collect unique keypad identifiers if the response of a specific individual or group is required (e.g. for attendance or testing).

Audience Response System (ARS): An electronic system designed to support and enhance face-to-face group interaction by means of individual hand-held communication devices. May also be referred to by a variety of names, including Classroom Response Systems, Student Response Systems, Interactive Response Systems, Interactive Student Systems and Electronic Voting Systems.

Group Decision Support System (GDSS): A collection of hardware and software used to support decision-makers.

Keypad: A hand-held device that allows a participant to communicate data to an Audience Response System. Also known as clickers or zappers.

Receiver or Base Station: A device that provides communication between the keypads and the ARS software. Increasingly these are permanently mounted in large lecture theatres to reduce set-up time.

Using Ontology and User Profile for Web Services Query

Jong Woo Kim
Georgia State University, USA

Balasubramaniam Ramesh

INTRODUCTION

Web services have received much attention because of their potential for realizing service oriented architecture (SOA). As the number of Web services increase exponentially, discovering Web services that satisfy user's specific needs has become a difficult task. In fact, the ability to find relevant Web services has been recognized as a key challenge in the realization of the potential of service oriented architectures.

The first step in the creation of system using SOA is to find relevant Web services which can be integrated or composed to provide the desired functionality (Kim & Jain, 2005). For example, developing a travel reservation application would require developers to search several Web services such as airline booking, hotel reservation, car rental, and weather forecasts. The commonly used UDDI-based Web services discovery approach is based on keyword search. Developers have to search for Web services using keywords such as "airline," "hotel," and "hotel" separately. This approach does not provide convenient search environment and deliver satisfactory query results to users because it does not take into account the context of the search (Zhou, Chia, & Lee, 2005). As the number of Web services grows explosively, it is almost impractical, if not impossible, for the user to efficiently analyze and combine the results with a keyword-based search approach (Matskin & Rao, 2002).

Ontology is a conceptualization of a domain into a human-understandable and machine-readable format. It consists of terms, their definitions, and axioms relating them (Gruber, 1993). Since ontology is the foundation for the semantic Web, which has been proposed as a mechanism to manage semantics and context of the World Wide Web, it can be used to improve the discovery of Web services by modifying or expanding query terms (McIlraith & Martin, 2003). However, little research has been done on the creation and use of ontology for Web services discovery. Our research seeks to address this void.

Furthermore, individual users may have unique preferences and needs even though they use seemingly similar queries to retrieve relevant Web services. User profiles can be used to capture these preferences and needs such that the queries return results that are of specific relevance to them. We propose the development of a query system that can incorporate user profiles so that queries accurately represent user's preferences and needs.

This chapter is organized as follows: In the next section, we discuss related research and various challenges and issues in Web services discovery. Then, we present several types of ontology and user profiles that may be used in the discovery process. Finally, we introduce a system architecture and discuss future trends and conclusions.

BACKGROUND

In this section, we provide background information about ontology and user profiles which can be used to address some of the challenges involved in Web services discovery.

Web Services

A Web service is an interface that describes a collection of operations that are network accessible through standardized XML messaging specifications such as SOAP, WSDL and UDDI. It provides open XML-based mechanisms for application interoperability, service description, and service discovery (Kim & Jain, 2005). A large number of Web services are already available on the internet, making Web services discovery a major task in service-oriented business application development. A widely used approach for discovering Web services is based on UDDI (Bin, Yan, Po, & Juanzi, 2005). UDDI uses a keyword based discovery feature which may not provide satisfactory query results because it does not take into account the context of the query. Recent research has proposed the use of ontology based query to improve the accuracy and relevance of search results (Bin et al., 2005; Maximilien & Singh, 2004; Zhou et al., 2005).

Ontology

The term ontology originally defines a philosophical discipline. As a branch of the philosophy, ontology deals with

the nature and organization of reality. Today, ontology is not only created by philosophers but also by computer scientists. In computer science, the term ontology is defined as the explicit specification of a conceptualization (Gruber, 1993). In other words, ontology represents the knowledge related to one or more domains in a way that may be interpreted by both for humans and computer programs. Ontology can support a variety of applications including the development of common understanding, enabling the reuse of domain knowledge, information extraction and concept tagging, knowledge management and intelligent systems (Noy & McGuinness, 2001).

User Profile

In the search for relevant Web services, which takes into account the context of the search, the profile of the user can play an important role. Integrated with the user's background and needs, a search can provide more personalized results (Storey, Sugumaran, & Burton-Jones, 2004). Such a search can exclude a large portion of irrelevant Web services by taking into account the user's particular interests.

When a query is contextualized, it produces results that account for (1) the meaning of query terms in the context in which they are used and (2) the user's preferences. In the development of a contextualized query, ontology can minimize the use of wrong concepts in the query whereas use profiles can help constrain the concepts requested (Storey et al., 2004) to those of interest to the user.

USING ONTOLOGY TO IMPROVE WEB SERVICE DISCOVERY

In this section we introduce several types of ontologies and propose that these ontologies may be used in a systematic manner to improve Web services query. We introduce several methodologies to create domain ontology which is a key ontology for Web services discovery.

Systematic Use of Ontology

Web services search can be improved by expanding users' original query with ontology (Storey et al., 2004). Different types of ontologies that can help improve queries are shown in Table 1 with examples. ResearchCyc is a general ontology that can handle terms which are independent of specific domains. In a similar fashion, existing upper-level ontologies such as SUMO or the Cyc Top-Level Vocabulary can be used for handling universal concepts such as time and space (Niles & Pease, 2001).

Linguistic ontology can handle a synonym in a query. Users may employ different terms to describe the same concept. In Web services discovery, a query system has to consider synonyms of terms used in a query as well as in the description of the Web services specified in the WSDL. For example, WordNet can be used as a thesaurus to cover extensive number of synonyms. Similarly, application ontologies can play a major role of improving users' query. Finally, search results can be improved with the use of domain ontology (Bin et al., 2005).

When there are a huge number of Web services, a query may return a large number of Web services which provide basically the same functions. Then, these results need to be organized by some criterion such as the quality of service (QoS). QoS ontology can help a query system rank order Web services according to the QoS level specified by user (Zhou et al., 2005). Although QoS typically represents non-functional requirements such as reliability and scalability, a QoS ontology can help formulate a more comprehensive assessment of quality (Maximilien & Singh, 2004; Zhou et al., 2005). Maximilien and Singh (2004) distinguish three ontologies for QoS: upper, middle, and lower. The QoS upper ontology describes general quality concepts such as quality measurement and relationships, whereas the QoS middle ontology captures several domain independent quality concepts such as availability, interoperability, and security. Domain-specific quality requirements are specified in the lower QoS ontology.

In summary, ontologies identified in Table 1 may be used to modify a user's query in Web services discovery. The user of such an ontology enhanced discovery process may provide feedback on whether the modifications to the query are appropriate. Through such an interactive process, a more comprehensive and appropriate query may be created.

Ontology Development

Existing ontologies shown in Table 1 are an excellent starting point for the development of an ontology based query system. Creating and using the first three ontologies in Table 1 is relatively easy compared with the rest of ontologies. Domain ontologies such as DAML ontology are also being developed as a part of large common-sense ontology. In fact, several ontologies which capture the same domain knowledge with different perspectives may be developed. Domain ontology needs to capture and represent concepts and their relationships shared among users. Therefore, the creation of domain ontologies is considered a time-consuming and difficult task (Cristani & Cuel, 2005; Noy & McGuinness, 2001). To reduce time and effort required to develop ontology, several methodologies have been proposed.

Cristani and Cuel (2005) classify ontology creation methodologies (such as DOLCE, OTK, TOVE, etc.) as top-down and bottom-up. Top-down methods start with an abstract view of domain and expand it with detailed specifications. Bottom-up methodologies start from the specification of a

Table 1. Types of ontology

Type	Task	Ontology
General ontologies	Represent general knowledge, independent of specific domain	ResearchCyc
Linguistic ontologies	Represent linguistic knowledge: different meanings of a given word, synonymy and antonym relationships between terms.	WordNet
Upper-level ontologies	Related to universal concepts like time and space	SUMO or Cyc Top-Level Vocabulary
Domain ontologies	Reflect a specific domain, independent of tasks	
Application ontologies	Imbedded in application, driven by tasks	The logical schema of a database
QoS ontology	Represent the level of non-functional requirements	DAML-QoS Ontology

certain task and obtain generalization. The choice of a methodology is dependent on the specific context and the needs of the application (Cristani & Cuel, 2005). For Web services discovery, the choice of methodology is influenced by the whether the Web services is in public UDDI or private UDDI. With a public UDDI, top-down methodology for ontology development is appropriate because public UDDI has to cover a broad range of topics. On the other hand, a bottom-up methodology is appropriate for a private UDDI because an organization running a private UDDI dedicated to specific domains may have very specific and detailed requirements from users. The bottom-up approach has been successfully used to develop ontology from text documents (Maedche & Volz, 2001; Shamsfard & Barforoush, 2004). Applying this methodology to Web services, we can create domain ontology from a collection of documents such as WSDL specifications. However, a challenge to this approach is the lack of adequate text documents. The amount of information available in WSDL specifications of Web services might be limited because developers tend to express the features of Web services succinctly. The other challenge is the time and effort required for the creation of a domain ontology.

Given these challenges involved in domain ontology creation for Web services query improvement, we propose two methodologies. Following Storey and Kim (2006), we propose a semi-automatic methodology. As this methodology uses World Wide Web as its resources, it can be easily applied to create a domain ontology for Web services. The proposed methodology shown in table 2 includes six steps: *(1) Identification of category, (2) specification of target domain keywords, (3) crawling and scanning relevant Web pages, (4) extraction of concepts, (5) clustering extracted concepts, and 6) construction of domain ontology*.

The six-step methodology has been used to create domain ontologies with less time and effort compared with manual development proposed by Storey and Kim (2006).

The second involves the pruning of a large common-sense ontology such as Cyc. Using keywords used in the domain, we can gather information related to those terms from a common-sense ontology, thereby creating relatively large domain ontology. Because this domain ontology is usually large and may contain unnecessary concepts, pruning methodologies proposed by Kim, Caralt, and Hilliard (2007) may be used to create a smaller domain ontology by removing irrelevant concepts. Then, developers can modify the domain ontology to suit their needs.

Tools for Creating and Managing Ontology

For ontology development and management, several tools and standards are available. Various tools for ontology editing and management include Protégé-2000, SWOOP, KAON, WSMX, OWL-S Editor, and OntoManager (Cristani & Cuel, 2005). The domain-independent languages used to specify ontologies in these tools include RDF(S), DAML+OIL, OWL, and KIF. Among these, OWL is considered a de facto standard for the semantic Web. OWL enables users to richly express ontologies and reason with this knowledge because it provides more comprehensive vocabulary for expressing meaning and semantics when compared to other standards such as RDF. For example, to more richly describe classes and properties, relations between classes and characteristics of properties are included in OWL. Ontology development tools can be used with the two approaches for domain ontology creation proposed in the previous section.

Using User Profiles to Improve Web Services Discovery

The role of user profile in improving the quality of search has long been investigated (Korfhage, 1984). The interactive development of a query can be made more effective by taking into account user's different preferences that are specified in a user profile.

Several types of user profiles and methods to create them have been proposed in the literature. Two types of

Table 2. Six-step methodology for ontology creation tools for creating and managing ontology

Steps	Activity
1. Identification of category	Identify category of target Web site using DMOZ or Clusty.
2. Specification of target domain keywords	Specify target domain (or Web sites) with initial domain keywords.
3. Crawling and scanning relevant Web pages	Collect Web pages identified relevant from step 2.
4. Extraction of concepts	Retrieve and organize words according to criteria such as frequency and TFIDF.
5. *Clustering extracted concepts*	Analyze the relation among concepts and cluster them.
6. *Construction of a domain ontology*	Create a domain ontology.

categorization of user profiles have been commonly used in prior research. One divides user profiles as knowledge-based or behavior based (Kuflik, Shapira, & Shoval, 2003). User's knowledge in the form of semantics is reflected in knowledge-based profiles whereas records of user's actions are used to create behavior-based user profiles (Middleton, Shadbolt, & De Roure, 2004). Knowledge-based profiling employs static models of users and dynamically matches each user to the closest model. To obtain the knowledge required for such matching, questionnaires and interviews are often used. Behavior-based profiling captures the user's behavior as a model. Machine learning techniques are employed to discover meaningful patterns in user's behavior (Kobsa, 1993).

User profiles may also be classified according to the level at which preferences are aggregated: (1) personal, (2) stereotype (i.e., held by a class of individuals), or (3) community (i.e., held by an entire community) (Middleton et al., 2004).

As community level profile is less likely to be useful for a specific user and context, we recommend the use of individual and stereotype level profile for query improvement. Further, depending on the expertise level of user, a query system can decide which level of group profile is appropriate (Storey et al., 2004). Queries of domain experts tend to be very stable and accurate. Therefore the query system should use only query terms provided by domain experts. In contrast, initial queries created by novices tend to be obscure and unstable. Therefore, the query system should use the expert stereotype profile first and then use the personal stereotype later. User profiles can be collected by both directly and indirectly depending on the user's expertise in a domain (Storey et al., 2004). When user is an expert in a certain field, direct method can provide accurate user profile information. However when user has little expertise in a certain field, it is difficult to collect profile information. To cope with this challenge, a novice profile can be created indirectly by using practice queries in a given topic.

A METHODOLOGY FOR THE CREATION AND USE OF USER PROFILES

We introduce a five-step methodology for the creation and use of user profiles that takes into account the recommendations made above. This methodology has been adapted from related research on the use of user profiles to improve search on the World Wide Web (Storey et al., 2004). Table 3 shows the five steps and relevant activities.

The five step methodology described above can be readily used in conjunction with the approach for the creation and use of domain ontology described in the previous section. Together, they synergistically help improve the retrieval of appropriate Web services.

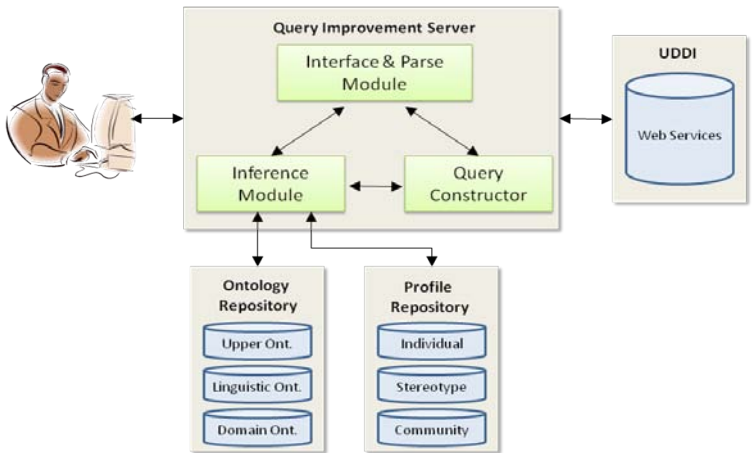
System Architecture and Scenario

Figure 1 shows the architecture of our proposed system for ontology and user profile driven Web services query. It consists of three modules and two repositories: (a) interface and query parser module, (b) inference module, (c) query constructor module, (d) ontology repository, and (e) user profile repository. The interface and query parser module interacts with a user to receive user's original query and deliver the result to the user. In addition, this module parses the user's original query. The inference module receives the terms from the interface and parse module. Interacting with ontology repository, the inference module tries to find synonyms and relationships between terms. Then, it uses the user profile information to further expand the query. The expanded query is used to search the Web services repository

Table 3. Five-step methodology for query development using profile

#	Steps
1	**Identify approach:** UDDI determines user's domain knowledge level from either interaction with user or previous records. Depending on user's level of domain knowledge, UDDI may suggest a delegated or user-driven query development.
2	**Identify appropriate type of user profile:** In case of a delegated query, UDDI determines a type of user profile (e.g., personal, stereotype, community). In case of a user-driven query, UDDI determines a type of user profile if a user is a novice.
3	**Identify terms from profile to increase query:** Unless user is an expert and chooses a delegated query, UDDI provides semantically relevant terms so that user can expand his/her query to increase accuracy of query.
4	**Execute query:** UDDI executes the query developed in step 3.
5	**Obtain feedback:** UDDI receives a feedback from user. When user is not satisfied with the query result, a new query creation procedure will be started.

Figure 1. System architecture



located in UDDI. Finally, the interface and parse module presents the selected Web services to the user.

We illustrate the use of the system with the following scenario in which ontology and user profile information are used to develop intelligent query. Suppose the user is interested in renting a GPS equipped car and creates a query which simply includes the terms "renting a GPS." When this incomplete query is used to search travel related Web services, if the UDDI does not have a specific Web services for renting a GPS, the query system will return no useful results. In contrast, our system establishes that (1) it does not find any Web service for renting a GPS, (2) it finds that GPS is part of a car from the domain ontology, and (3) it find that there is a Web service for renting cars. It will, therefore, return Web services that are relevant for renting a car.

The system selects the car reservation Web service by using the heuristic "if a specific Web service that describes an action A (reserve) for a concept C (GPS) does not exist, then such an action tends to be specified in the Web service that describes the same action A (reserve) over a concept C' (car) that includes C (GPS).

User profile information can be used to further improve query results. If the user profile information shows that the user lives in Atlanta and prefers discounted services, then the system presents only Web services from companies which are located in Atlanta and which offer a discount.

FUTURE TRENDS

For better support in Web services discovery, Web services need to be annotated in a semantically accurate manner. WSDL which is commonly used for this purpose is not descriptive enough to richly describe Web services. New standards such

as Web Services Agent Framework (WSAF) (Maximilien & Singh, 2004) and Web Services Modeling Framework (WSMF) (Fensel & Bussler, 2002) offer much promise.

Ontology can be used in Web services matchmaking to support composition (Zhou et al., 2005). For matchmaking, QoS ontology such as those focused on availability, interoperability, and security are promising.

A query may potentially be expanded with several domain ontologies. Research on ontology pruning and refactoring (Conesa & Olive, 2004) can support ontology expansion while creating accurate queries.

Further research on the appropriate ways to categorize user profiles is needed. Also, the relative effectiveness of knowledge-based or behavior-based user profile in improving Web services discovery needs to be empirically examined. In addition we are currently investigating the effectiveness of different levels of aggregation of user (e.g., individual, stereotype, and community) in the context of search for Web services.

CONCLUSION

Ontology and user profile can be used to improve Web services search by expanding query with more relevant terms which accurately represent context and user's preferences and needs. We identify several types of ontologies which capture different level of contextual information. The use of these ontologies in a systematic manner can help represent the context of a search in a query. While domain ontology may be very effective in improving queries, their creation requires a lot of time and effort. We introduce two methodologies to help create domain ontology with minimal effort. In addition, user profiles can further improve query results by capturing user's preferences and needs. We introduce a five-step methodology for the effective use of user profiles in the search for appropriate Web services. Finally, we propose an architecture for a system that incorporates our approach using ontology and user profile. The approach and system described here are aimed at achieving effective and efficient search for Web services.

KEY TERMS

Ontology: A conceptualization of a domain. It is consisted of entities, attributes, relationships and axioms in a format which is human understandable and machine-readable.

Ontology Pruning: A method used to delete the elements of an ontology that are irrelevant.

SOA: An architectural style whose goal is to achieve loose coupling among interacting software agents. A service is a unit of work done by a service provider to achieve desired end results for a service consumer.

SOAP: An XML-based protocol to access objects from Web services.

TFIDF: A value to evaluate how important a selected term is within documents.

UDDI: An XML-based registry for businesses to publish and search Web services.

User Profile: User information representing his or her preferences and needs.

WSDL: An XML-based language used to describe Web services

Using Prolog for Developing Real World Artificial Intelligence Applications

Athanasios Tsadiras
Technological Educational Institute of Thessaloniki, Greece

INTRODUCTION

Artificial Intelligence Applications are becoming crucial for enterprises that want to be successful by having the advantage of using high information technology. The development of such applications is assisted by the use of high level computer programming languages that are closer to the programmer than to the computer. Such a programming language is Prolog.

Prolog is a logic programming language (Clocksin & Mellish 2003) that was invented by Alain Colmerauer and Phillipe Roussel at the University of Aix-Marseille in 1971. The name *Prolog* comes from *programmation en logique* (i.e., "programming in logic" in French). Together with LISP, they are the most popular Artificial Intelligence programming languages. Prolog was generated by an attempt to develop a programming language that extensively uses expressions of logic instead of developing a program by providing a specific sequence of instructions to the computer. Theoretically, it is based on a subset of first-order predicate calculus that allows only Horn clauses (Bratko, 2000). The control of the program execution is based on Prolog's built-in search mechanism that in fact is an application of theorem proving by first-order resolution.

BACKGROUND

Prolog has a clear contribution in solving a series of **Artificial Intelligence** (**AI**) problems (Sterling & Shapiro, 1986). There are many features that make **Prolog** suitable as a programming language for developing AI applications (Luger, 2002). Some of them are:

- **Declarative nature:** Programming in Logic using Prolog, remove the imperative (serial order) nature of other languages and allow programmer to solve a problem by describing the problem itself rather than defining a solution. The programmer writes programs by declaring the facts and the rules that apply to the problem in hand and then makes queries in order for Prolog to return valid solutions. This high level of abstraction makes **Prolog** suitable for AI applications where the programmers should give emphasis on the problem itself rather than on the computer idiosyncratic commands that they should impose to the computer system. **Prolog**'s built-in search mechanism takes the control of the program execution, leaving the programmer to concentrate on the problem itself.
- **Backtracking:** Even when a search path ends at a dead end, the backtracking mechanism of **Prolog** retreats back down the search path to try another path. This feature makes Prolog exceptionally suitable for a number of search problems that AI faces. It also provides the additional advantage of finding more than one solution of the problem, in the case that backtracking is forced, after finding a first solution. Because a great number of AI problems can be represented as a problem of finding the right path in the search space, the built-in depth first mechanism of Prolog, accompanied with backtracking, make **Prolog** suitable for such applications.
- **Don't care and don't know nondeterminism:** In the execution of a Prolog program, the nondeterminism feature is really apparent. Although the rule that will execute is the first one that matches the goal, we can ask for more than one solution. Using the backtracking mechanism, alternative rules will apply and other valid solutions will be found. This introduces: a) "don't know nondeterminism" implying that all possible ways to find the solutions will be followed because the execution does not know how to find the solution, or b) "don't care nondeterminism" meaning that we just need one solution and we do not care which solution is that among the many that exist. Both of these types of nondeterminsm are considered useful in AI applications, especially for those dealing with logic.
- **Recursion**, instead of **Iteration:** Because iteration constructs are not provided in **Prolog**, recursion should be used instead. The simplicity of solving problems recursively makes Prolog programs smaller and understandable even when coping with large, real life **AI** problems. Additionally, many AI problems are recursive in nature, increasing the suitability of Prolog.
- **List handling mechanism:** The data structure of List is very important for handling AI problems (e.g., LISP which is also used for solving AI problems, stands for

"LISt Processing"). Lists are built-in in Prolog while in most other languages they are not, making faster and easier the writing of Prolog programs that require list handling. List's recursive nature allows the extensive use of recursion in problem solving, providing an additional advantage for solving AI problems with Prolog.

- **Pattern matching** and **unification:** The use of unification to find the most general common instance of two formulas or patterns makes pattern matching a build-in feature of **Prolog**. This intelligent feature can assist AI problem solving where in many cases the decisions that are made are based on situation matching. This Prolog ability can be found really helpful in specific areas of AI, such as natural language processing, computer vision and intelligent database search.

PROLOG AND ARTIFICIAL INTELLIGENCE APPLICATIONS

The features described above make Prolog suitable for developing applications that solve **AI** Problems. Such an area is that of **Decision Support Systems**. Rules that support decisions can be expressed as Prolog rules, declaratively in pure logic, making development and maintenance of these systems mush easier. An example of a successful decision support system is the "Options Trading Analysis System" (OTAS, Lassez, McAloon, & Yap, 1987), used for the analysis of stock options and investment strategies. OTAS automatically generates and analyzes investment strategies based on standard vertical option combinations. Its main elements are: a portfolio maintenance module that creates and updates portfolios and provides expert recommendations, a numeric database containing stock market data, a symbolic database containing rules describing standard options combinations and a linear algebra module for the analysis of options combinations.

Except from financial decisions, medical decisions can be supported by similar systems written in Prolog. The OSM medical decision support system for general practitioners (Fox, Glowinski, Gordon, Hajnal, & O'Neill, 1990) is such an example. OSM supports a number of knowledge and information retrieval functions, providing the user with rapid access to textual information from text sources, knowledge bases or patient database. The system incorporates a version of the Oxford Textbook of Medicine, a 300-author general medical reference work, and uses its indexes to retrieve text.

Decision support systems can also take the form of a computer based advisor. For example, the RoadWeather Pro (Reiter, 1991) is used as an Expert Weather Advisor written in Prolog that permits mouse point-and-click manipulation of weather "objects," thereby allowing forecast upgrades based upon recent observational data received from sensors or human observers. This decision support system estimates weather-related effects on highway maintenance operations, as well as on airports, transportation, recreational activities, agribusiness and so forth. Its purpose is to be used as a user-interactive 24-hour weather prediction system for snow and ice control.

Another major **AI** area that Prolog contributes is that of **Natural Language Processing.** Pattern matching capabilities and the declarative nature of grammar definitions, make Prolog a handy and powerful tool for processing natural language. For example, CAT2 (Sharp, 1991) is a unification-based natural language processing system, designed for analysis, generation and translation of natural language sentences. CAT2 is used for multilingual machine translation and for automatic translation of informative texts although the emphasis has been on European Commission texts, as well as general purpose texts. It embodies a particular formalism for natural language processing, as well as a grammar development environment. Grammars have been written for English, German, French, Spanish, with experimental versions for Russian, Greek, and Japanese.

The Logic-based Machine Translation system, LMT (McCord, 1982, 1986) is another such application. This is a machine translation system for translating English to German. The system is based on a grammatical formalism called Modular Grammars based on slot filling techniques, which includes some automatic semantic translation and handling of metagrammatical rules. The principle aim of the system is to translate computer manuals from English into German.

Among the various **AI** applications using Prolog, many **Knowledge-based Systems** can be found. This is because, in most of the cases, knowledge in such systems is expressed in the form of rules. These rules can be easily expressed in **Prolog** syntax. After that, by using unification and Prolog search mechanism, inference can be done. AGATHA Electronic Diagnosis Knowledge Based System (Allred, Lichtenstein, Preist, Bennett, & Gupta, 1991) is such a system. Its aim is to test and diagnose complex printed circuit boards. Agatha uses a suite of smaller subsystems, each one of them customized to diagnose a particular kind of test, something that is necessary due to the diversity and complexity of the various tests. Agatha could reason about the test results as well as suggest further tests to run.

Moreover, Gunga Clerk (Woodin, 1989) is an example of a Legal Knowledge-based System written in Prolog. This system is a substantive legal knowledge-based advisory system in New York State Criminal Law, advising on sentencing, pleas, lesser included offences and elements. Gunga Clerk is designed to accept key facts of a criminal case and provide guidance to attorneys and judges as to statutory rules affecting sentence parameters, regulation of plea bargaining, identification of lesser included offences,

and offences chargeable based on designated conduct. Explanations include citations to legal authority and display of chains of legal inferences.

Another example of a Knowledge-based System written in Prolog is the ISCN Expert (Cooper & Friedman, 1990). This Health Knowledge-based System is able to interpret chromosomal abnormalities and allows geneticists to better reference and interpret chromosomal abnormalities such as those which result in Down Syndrome, mental retardation or physical disabilities. It interprets the International Human Cytogenetic Nomenclature, which is the standard notation used to represent human chromosomal abnormalities. These notations, each representing a person's genetic layout, are maintained in a computerized registry for reference and comparison against each other.

Prolog can also contribute to the area of **Intelligent Search in Large Databases.** This is because the only way to run a Prolog program is by making a query. This built-in feature can be used in order to make complex and efficient queries in large databases. An example of a database system coping with Prolog is ADAM (Gray, Kulkarni, & Paton, 1992; Paton & Diaz, 1991). ADAM is a general purpose object-oriented database, with emphasis on extensibility with new modeling constructs by using metaclasses. It adds the ability to structure Prolog programs and data using the object-oriented paradigm.

It is a fact that every **AI** problem that can be represented using graphs can be handled by Prolog search and backtracking mechanism. Having such an advantage, various Prolog systems have been developed to solve **Graph Theory Problems**. Conceptual Graph Tools (CGT, Wermelinger & Lopes, 1991), for example, is a Prolog-based knowledge representation system that has a partial implementation of Sowa's Conceptual Structures. As Sowa (1984) states, Conceptual Structures "are a system of logic with a graph based formalism that aims for a very wide expressive power. Its primary purpose is to serve as an intermediate language between natural language and other formalisms including database query languages [...] and predicate calculus." CGT includes predicates to implement the most important operations on conceptual graphs, like the canonical formation rules and the propositional inference rules. CGT reads and writes conceptual graphs using their linear notation. It also provides facilities to manipulate graph databases.

Another **AI** area where Prolog is used is that of **Scheduling and Planning**. The "Generate & Test" technique and the pattern matching mechanism of **Prolog**, make the test of candidate generated solutions a much simpler task. CAS/FPS, Computer-aided Synthesis of Flexible Production Scheduling (Csukas, Kozar, & Arva, 1989), for example, is a Prolog-based system that is used for the Production Planning and Scheduling of Multiproduct (Batch) Plants. Using multicriteria design, the system provides a computer-aided synthesis of the production plans and schedules from the possible building elements. In Prolog represented structural models, the various solutions are synthesized from the "free" active and passive elements of the structural model.

The OMAR, Operative Management of Aircraft Routing system (Torquati, Paltrinieri, & Momigliano, 1990) is also written in Prolog. It is an interactive Aircraft Scheduling system designed for the predictive scheduling of the Alitalia Fleet. The salving strategy that it uses combines network consistency and tree search techniques.

The unification and pattern matching mechanism of Prolog can also be found useful for **AI** problems of **Computer Vision**. Such a system written in Prolog is GEONS (Fairwood, 1991). The purpose of this system is to recognize the class of a 3-D volumetric primitive object in an image description which consists of curve properties and relations. The two-dimensional images of 3-D volumetric primitives are "input" in the form of facts about curves, lines and their properties and relationships (e.g., curved/straight, connectivity). This program models, in a qualitative way, (a) the 3-D objects, (b) the model-scene projection relationships, and (c) the image structure. These declarative models constitute a "parser" for the input curve data which is analyzed by the program to recognise the appropriate category of geometric primitive.

Prolog can also be useful for developing AI applications of **Game Playing.** The search space generated by games can be searched by Prolog's search mechanism, augmented by the backtracking feature. An example of such a Prolog system is the PYTHON (Sterling & Nygate, 1990). This intelligent system is used for recognizing and performing squeeze plays, an advanced strategy in the game of bridge. It performs, in its limited domain, at a truly expert standard, comparable to players of national ranking. PYTHON's core recognizes when a simple squeeze exists according to well-established theory. The core was extended to handle more complicated squeezes, also described by theory, making PYTHON's performance truly expert. Furthermore, methods were added for recognizing and executing squeezes not covered by existing theory by analogy with the other methods.

It should be also mentioned that Prolog's inference mechanism is suitable for developing applications coping with **Reasoning**, especially qualitative reasoning. GARP-General Architecture for Reasoning about Physics (Bredeweg, 1989), for example, is an integrated approach to qualitative prediction of behaviour. Given the description of a system (usually a physical system) GARP predicts the states of behaviour that the system will go through, in qualitative terms.

FUTURE TRENDS

Prolog is a successful logic programming language for developing AI applications. This will not change in the following

years, especially with the integration of **Prolog** with Internet applications and other computer languages such as Java. For example, the JIProlog (Java Internet Prolog, Chirico 2006), a Java platform Prolog interpreter which integrates Prolog and Java languages can add much of the functionality of Java to Prolog making Prolog programs easily delivered through Internet, all over the world. Furthermore, Prolog is a high level computer language that is closer to human than the computer machine. This type of languages is more probable to be used in the future because of the computer science trend of making computers friendlier to the users.

CONCLUSION

The logic programming features of **Prolog** make it suitable for developing programs coping with a wide variety of AI problems. The declarative nature of **Prolog**, accompanied by aspects such as backtracking, unification and pattern matching, recursion, the list handling mechanism and the built-in inference mechanism, provides the programmer with important and useful tools in order to confront AI problems.

The use of Prolog in the Internet and its integration with languages such as Java is a new and promising challenge for Prolog programmers that will give Prolog new potentials.

KEY TERMS

Declarative Programming: Programming in the form of passive data structures such as facts and rules which can afterwards be used by active inference mechanisms. On declarative programming, the programmer states what is to be computed, and not how this is to be computed.

Backtracking: Backtracking occurs when in a search tree, the end of a search path is reached without a solution being found, and then the algorithm retreats back to a different path.

Don't Care Nondetermination: Solving a problem having in mind that just any one solution is enough. We do not care if there are other solutions or which one of the solutions we find.

Don't Know Nondetermination: Solving a problem having in mind that the execution of the program does not know how to find the solution, so all possible ways to find the solutions can be followed.

Generate and Test: A trial and error method of problem solving where a possible solution is generated and tested to check if it is successful. If it is not successful, then another possible solution is generated and tested and this goes on until a satisfactory solution is found. The solution found may not be optimal and not all possible scenarios are tested.

Iteration: The repeated execution of the same process a given number of times or until a specified result is obtained.

Recursion: The definition of a program in terms of itself. This gives the program the ability to call itself.

Unification: The process of finding the most general common instance of two expressions. This is the pattern matching technique used by Prolog computer language to match goals and subgoals in a program.

Video Content-Based Retrieval

Waleed E. Farag
Indiana University of Pennsylvania, USA

INTRODUCTION

Recently, multimedia applications have undergone explosive growth due to the monotonic increase in the available processing power and bandwidth. This incurs the generation of large amounts of media data that need to be effectively and efficiently organized and stored. While these applications generate and use vast amounts of multimedia data, the technologies for organizing and searching them are still immature. These data are usually stored in multimedia archives utilizing search engines to enable users to retrieve the required information.

Searching a repository of data is a well-known important task whose effectiveness determines, in general, the success or failure in obtaining the required information. A valuable experience that has been gained by the explosion of the Web is that the usefulness of vast repositories of digital information is limited by the effectiveness of the access methods. In a nutshell, the above statement emphasizes the great importance of providing effective search techniques. For alphanumeric databases, many portals (Acuna, Marcos, Gomez, & Bussler, 2005) have become widely accessible via the Web. These portals use search engines that adopt keyword-based search models in order to access the stored information, but the inaccurate search results of these search engines is a known issue.

For multimedia data, describing unstructured information (such as video) using textual terms is not an effective solution because they cannot be uniquely described by a number of statements. That is mainly due to the fact that human opinions vary from one person to another (Tešic & Smith, 2006), so that two persons may describe a single image by totally different statements. Therefore, the highly unstructured nature of multimedia data renders keyword-based search techniques inadequate. Video streams are considered the most complex form of multimedia data because they contain almost all other forms such as images and audio in addition to their inherent temporal dimension.

One promising solution that enables searching multimedia data in general, and video data in particular, is the concept of content-based search and retrieval (Deb, 2005). The basic idea is to access video data by their contents—for example, using one of the visual content features. Realizing the importance of content-based searching, researchers have started investigating the issue and proposing creative solutions. Most of the proposed video indexing and retrieval prototypes have the following two major phases (Marques & Furht, 2002):

1. The **database population phase** consists of the following steps:
   - *Shot Boundary Detection:* The purpose of this step is to partition a video stream into a set of meaningful and manageable segments (Hanjalic, 2002), which then serve as the basic units for indexing.
   - *Key Frames Selection:* This step attempts to summarize the information in each shot by selecting representative frames that capture the salient characteristics of that shot.
   - *Extracting Low-Level Features from Key Frames:* During this step, some of the low-level spatial features (color, texture, etc.) are extracted in order to be used as indexes to key frames and hence to shots. Temporal and other features (e.g., object motion) are used also.
2. In the **retrieval phase,** a query is presented to the system that in turns performs similarity matching operations and returns similar data (if found) back to the user.

It is worth mentioning that a growing trend in current content-based retrieval systems is the application of contextual constraints to enrich those systems with additional metadata (Davis, King, Good, & Sarvas, 2004). The use of context makes video retrieval systems both content-based and context-based systems at the same time. Besides, context-based techniques try to improve the retrieval performance by using associate contextual information, other than those derived from the media content (Hori & Aizawa, 2003).

In this article, each of the above stages will be reviewed and expounded. Background, current research directions, and outstanding problems will also be discussed.

VIDEO SHOT BOUNDARY DETECTION

The first step in indexing video databases (to facilitate efficient access) is to analyze the stored video streams. Video analysis can be classified into two stages (Farag & Abdel-Wahab, 2002b), *shot boundary detection* and *key frames extraction.* The purpose of the first stage is to partition a

video stream into a set of meaningful and manageable segments, whereas the second stage aims to abstract each shot using one or more representative frames.

In general, successive frames (still pictures) in motion pictures bear great similarity among themselves, but this generalization is not true at boundaries of shots. A shot is a series of frames taken by using one camera. A frame at a boundary point of a shot differs in background and content from its successive frame that belongs to the next shot (except in the case of gradual transitions). In a nutshell, two frames at a boundary point will differ significantly as a result of switching from one camera to another, and this is the basic principle that most automatic algorithms for detecting scene changes depend upon.

Due to the huge amount of data contained in video streams, almost all of them are transmitted and stored in compressed format. While there are many algorithms for compressing and representing digital video data, the MPEG family (Watkinson, 2004) is the most famous one and the current international standard. In MPEG, spatial compression is achieved through the use of a Discrete Cosine Transform (DCT)-based algorithm similar to the one used in the JPEG standard. In this algorithm, each frame is divided into a number of blocks (8x8 pixel), then the DCT transformation is applied to these blocks. The produced coefficients are then quantized and entropy encoded, a technique that achieves the actual compression of the data. On the other side, temporal compression is accomplished using a motion compensation technique that depends on the similarity between successive frames on video streams. Basically, this technique codes the first picture of a video stream (I frame) without reference to neighboring frames, while successive pictures (P or B frames) are generally coded as differences to those reference frames. Considering the large amount of processing power required in the manipulation of raw digital video, it becomes a real advantage to work directly upon compressed data and avoid the need to decompress video streams before manipulating them.

Several research techniques were proposed to perform the shot detection task for both cuts and gradual transitions. For instance, template matching and histogram comparison are commonly used. Statistical models are also proposed as in Hanjalic (2002). Farag and Abdel-Wahab (2002b) proposed the use of supervised learning systems in order to detect shout boundaries. Moreover, other techniques such as finite state machine and support vector machines are used to identify various types of transitions (Liu, Gibbon, Zavesky, Shahraray, & Haffner, 2007).

KEY FRAMES SELECTION

The second stage in most video analysis systems is the process of *key frames* (KFs) selection (Deb, 2005), which aims to abstract every shot using one frame or more. Ideally, we need to select the minimal set of KFs that can faithfully represent each shot. KFs are the most important frames in a shot, hence they may be used to represent the shot in the browsing system as well as be used as access points. Moreover, one advantage of representing each shot by a set of frames is the reduction in the computation burden required by any content analysis system to perform similarity matching on a frame-by-frame basis, as will be discussed later. KFs selection is an active area of research in visual information retrieval, and a quick review of some proposed approaches follows.

Clustering algorithms are proposed to divide a shot into M clusters, then choose the frame that is closest to the cluster centroid as a KF. Cooper and Foote (2005) introduced the use of linear discriminant analysis to select representative frames. The VCR system (Farag & Abdel-Wahab, 2002a) employs two algorithms to select KFs, *accumulated frames summation* (AFS) and *absolute luminance differences* (ALD). The AFS is a dynamically adapted algorithm that uses two levels of threshold adaptation, one based on the input dimension while the second level relies on a shot activity criterion to further improve the performance and reliability of the selection. AFS employs the accumulated summation of luminance differences of corresponding *direct current* (DC) coefficients in successive frames. The second algorithm, ALD, uses absolute luminance difference between the summation of all DC terms in a frame and the same summation of the next frame. It utilizes a statistical criterion for the shot-by-shot adaptation level. A comprehensive review and classifications of video abstraction techniques introduced by various researchers in the field is presented in Truong and Venkatesh (2007). That work reviewed different methodologies that use still images (key frames) and moving pictures (video skims) to abstract video data and provide fast overviews of the video content.

FEATURE EXTRACTION

To facilitate access to large video databases, the stored data need to be organized; a straightforward way to do such organization is through the use of index structures. In case of video databases, we even need multi-dimension index structures to account for the multiple features used in indexing. Moreover, we are in need of tools to automatically or semi-automatically extract these indexes for proper annotation of video content. Bearing in mind that each type of video has its own characteristics, we also need to use multiple descriptive criteria in order to capture all of these characteristics.

The task of the feature extraction stage is to derive descriptive indexes from video data content such as from selected key frames in order to represent the original data. These indexes are then used as metadata, and any further similarity

matching operations will be performed over these indexes and not over the original video data. Ideally, content-based retrieval (CBR) of video should be accomplished based on automatic extraction of content semantics, which is usually a difficult task. Thus, most of the current techniques only check the presence of semantic primitives or calculate low-level visual features. There are mainly two major trends in the research community to extract indexes for proper video indexing and annotation. The first one tries to automatically extract these indexes, while the second trend performs iconic annotation of video by manually (with human help) associating icons to parts of the video stream. One example of the latter trend uses a multi-layered representation to perform the annotation task where each layer represents a different view of video content. On the other hand, works on the first trend, automatic extraction of content indexes, can be divided into three categories:

- *Deriving indexes for visual elements using image-indexing techniques*—For example, using the color and texture as low-level indexes.
- *Extracting indexes for camera motion (panning, zooming, etc.)*—Generally, optical flow is used in such techniques.
- *Deriving indexes for region/object motion*—One system detects major objects/regions within the frames using optical flow techniques.

Color and texture are commonly used indexing features in many indexing systems. Moreover, they are among the proposed descriptors in the MPEG-7 standard (Manjunath, Salembier, & Sikora, 2002). Color feature extraction can work directly on the original decoded video frame or on its DC form. One technique converts the color space of DC video frames (YCbCr in the case of MPEG) to the traditional RGB color space, then derives color histograms from the RGB space. Deriving the histogram can be done in many ways. An efficient technique uses some of the most significant bits of each color component to form a codeword. For instance, the most significant two bits of each color component can be selected and concatenated to form a 6-bit codeword. This codeword forms a 64-bin color histogram that is used as the color feature vector. This histogram is a good compromise between computational efficiency and representation accuracy.

Many techniques are proposed in the literature to perform texture feature extraction. Some of them use auto-regression and stochastic models, while others use power spectrum and wavelet transform (Bimbo, 1999). The main disadvantage of these techniques is they are computationally expensive.

THE RETRIEVAL SYSTEM

The basic objective of any automated video indexing system is to provide the user with easy-to-use and effective mechanisms to access the required information. For that reason, the success of a content-based video access system is mainly measured by the effectiveness of its retrieval phase. The general query model adopted by almost all multimedia retrieval systems is Query By Example (QBE; Marchionini, 2006). In this model, the user submits a query in the form of an image or a video clip (in the case of a video retrieval system) and asks the system to retrieve similar data. QBE is considered to be a promising technique since it provides the user with an intuitive way of query presentation. In addition, the form of expressing a query condition is close to that of the data to be evaluated.

Upon the reception of the submitted query, the retrieval stage analyzes it to extract a set of features, then performs the task of similarity matching. In that task, the query-extracted features are compared to the features stored in the metadata, then matches are sorted and displayed back to the user based on how close a hit is to the input query. A central issue here is how the similarity matching operations are performed, and based on what criteria (Farag & Abdel-Wahab, 2003). This central theme has a crucial impact on the effectiveness and applicability of the retrieval system.

Many techniques have been proposed by various researchers in order to improve the quality, efficiency, and robustness of the retrieval system. Some of these techniques are briefly reviewed below:

- *Relevance Feedback:* In this technique the user can associate a score to each of the returned clips, and this score is used to direct the following search phase and improve its results (Oerlemans, Rijsdam, & Lew, 2007).
- *Clustering of Stored Data:* Media data are grouped into a number of clusters in order to improve the performance of the similarity matching.
- *Use of Linear Constraints:* To come up with better formal definitions of multimedia data similarity, some researchers proposed the use of linear constraints that are based on the instant-based-point-formalism.
- *Improve Browsing Capabilities:* In this technique KFs and mosaic pictures are used to allow easier and more effective browsing.
- *Use of Time Alignment Constraints:* The application of this technique can reduce the task of measuring video similarity to be equivalent to finding the path with minimum cost in a lattice. The latter task can be accomplished using dynamic programming techniques.

- *Optimize Similarity Measure:* Defining optimized formulas to measure video similarity instead of using the exhaustive similarity technique in which every frame in the query is compared with all the frames in the database (a computationally prohibitive technique).
- *Human-Based Similarity Criteria:* This technique tries to implement some factors that most humans probably use to assess the similarity of video data (Farag & Abdel-Wahab, 2003).

Many of the above techniques end up calculating the similarity between two frames. The equation below is one example of how similarity between the colors of two frames (*I* and *M*), represented by their color histograms, can be calculated using the normalized histogram intersection (Farag & Abdel-Wahab, 2003). Each histogram is scaled before applying the equation in order to account for variations in the dimension of video frames. If Sim approaches 0, the frames are dissimilar, and if it tends toward 1, the frames are similar in color.

$$Sim(I, M) = \frac{\sum_{i=1}^{n} \min(I_i, M_i)}{\sum_{j=1}^{n} M_j}$$

where:

n = the number of bins in the color histogram, and
min(Ii, Mi) = the intersection between the ith bin values in both frames.

FUTURE TRENDS

Some of the important issues under investigations are surveyed briefly in this section. There is still a need for efficient algorithms to parse video streams containing gradual transition effects. Detecting semantic objects inside video frames and successfully correlating them to other extracted low-level features are open challenges that need to be addressed. Bridging what is called the semantic gap is one of the most promising areas of research in visual information retrieval. Moreover, multi-dimension indexing structure is one area that requires further examination. Research in effective and efficient techniques for assessing the similarity of video data, in particular those that capture human notions of multimedia similarity, is very crucial to the advancement in the field. Investigation of methodologies for performance evaluation of multimedia retrieval systems and the introduction of benchmarks such as the TRECVID effort are two other areas that need more research. Also, the application of human-computer interface techniques and information visualization strategies in order to include the user intelligence requires further investigation. Finally, the recent introduction of various standards for representing digital video data, such as the MPEG-7 standard, calls for in-depth evaluation of the effectiveness of these standards in improving the performance of video retrieval systems. Moreover, research on how to optimize the use of tools and techniques provided by these standards to enhance current systems and how to properly apply these standards in various domains is a promising trend.

CONCLUSION

In this article, we briefly reviewed the need and significance of video content/context-based retrieval systems and explained their four basic building blocks. Current research topics and future work directions were covered as well. The first stage, the Shot Boundary Detection, divides video streams into their basic shots. Each shot is then represented by one or more key frame(s) in a process known as key frames selection. The feature extraction stage, the third one, derives descriptive indexes such as color, texture, shapes, object motion, and so forth from video content and stores these feature vectors as metadata. Finally, the retrieval system accepts a user query, compares indexes derived from the submitted query with those stored in the metadata, then returns search results sorted according to the degree of similarity to the query. In the end, we need to emphasize the importance of content/context-based video retrieval systems and assert that there is still a considerably large number of open issues that require further research to achieve more efficient and robust indexing and retrieval systems.

V

KEY TERMS

Content-Based Access: A technique that enables searching multimedia databases based on the content of the medium itself and not based on keywords description.

Context-Based Access: A technique that tries to improve the retrieval performance by using associate contextual information, other than those derived from the media content.

Key Frames Selection: The selection of a set of representative frames to abstract video shots. Key frames (KFs) are the most important frames in a shot, hence they can represent the shot in both browsing and similarity matching operations, as well as being used as access points.

Query By Example: A technique to query multimedia databases where the user submits a sample query such as an image or a video clip and asks the system to retrieve similar items.

Retrieval Stage: The last stage in a content-based retrieval system where content features are extracted from the submitted query then compared with those stored in the metadata. Finally, matched ones are returned to the user.

Shot Boundary Detection: A process with the objective of partitioning a video stream into a set of meaningful and manageable units.

Video Indexing: The selection of indexes derived from the content of the video to help organize video data and metadata that represents the original video stream.

Video Shot: A sequence of contiguous video frames taken using the same camera.

Videoconferencing for Schools in the Digital Age

Marie Martin
Carlow University, Pittsburgh, USA

INTRODUCTION

Wallis and Steptoe (2006) tell of a "dark little joke" that is bandied about among certain educators. It recounts the tale of Rip Van Winkle, who on reawakening in 2006 after his hundred years' sleep, experiences utter bewilderment until at last he finds solace in the familiar environment of a classroom, where teaching is going on as it did back in 1906.

The story is amusing. The message is blunt. In the middle of the first decade of the 21st century, despite ongoing technology-driven societal transformation, schools are still functioning largely in the easily recognizable traditional model of the industrial era (Steinkuehler, 2006; Veletsianos, 2007). The rush to computerize the classroom has generally not brought about a corresponding change of mindset on the part of educators (Cuban, 2006; Spector, 2000; Shaffer, Squire, Halverson, & Gee, 2005; Thornburg, 2003). Schools are failing to address the needs of the Net generation of learners (Barnes, Marateo, & Ferris, 2007; van 't Hooft, 2007). These **digital learners** who have grown up in a technology-saturated world that has defined and shaped their way of learning find school irrelevant and boring (McCombs, 2000).

By drawing on the literature and on case studies from within the experience of the author and other educators in Northern Ireland (NI), this article seeks to demonstrate that **videoconferencing,** alone as well as alongside other technologies, and used with appropriate **pedagogy,** can help transform the traditional classroom and make it a place hospitable to the learning needs of the Net generation.

BACKGROUND

Higher education led the way in the use of **videoconferencing** in education by introducing it into distance learning courses (Anderson & Rourke, 2005; Hayden, 1999). Although the technology has been available to schools since at least the early 1990s (Cole, Ray, & Zanetis, 2004), it has generally remained underutilized and undervalued (Anderson & Rourke; 2005; Comber, Lawson, Gage, Cullum-Hanshaw, & Allen, 2004). In addition, there is a dearth of specific research on the use of videoconferencing in the K-12 classroom (Anderson & Rourke; 2005; Heath & Holznagel, 2002). However, much of the literature on videoconferencing in higher education is relevant to teaching and learning in the pre-tertiary sector. Coventry (1995) writes that the effectiveness of videoconferencing for learning lies in exploiting its capacity to facilitate effective learning through enabling dialogue. She defines learning as "a social process involving the active construction of new knowledge and understanding through individual learning and group and peer interaction" (Part Two: 1). This resonates closely with how **digital learners** actually learn (Barnes et al., 2007).

Rowan (2000) identifies a significant barrier to the uptake of videoconference technology by classroom teachers,viz a lack of information concerning the ways in which it can operate within an educational program. She lists three crucial points for teachers wishing to use videoconferencing which, again, would help to engage digital learners: the need for **interaction** to keep students engaged; the need for videoconferencing to be part of a **multimode delivery**; and the need for teaching with videoconferencing to be integrated with new teaching methodologies and with appropriate professional development.

A recurring warning in both higher education and specific K-12 literature is that the acquisition of technology does not guarantee acceptance and effective use (Greenberg, 2004), nor does sophisticated technology necessarily equate with an effective learning experience (Coventry, 1995). Generally, research findings focus on the primacy of **pedagogy**, and highlight three main points: the need to set the learning goals first; the need to become familiar with the unique capabilities of videoconferencing, enabling real time interactive visual and verbal communication between two or more sites; and the need to be aware that **videoconferencing** challenges the traditional teaching and learning paradigm, requiring a **pedagogy** that will exploit its capabilities and achieve the learning goals. The key to this is **interaction** which must be designed into the distant lesson plan and fostered throughout the videoconference (Amirian, 2003; Anderson & Rourke, 2005; Comber et al., 2004; Greenberg, 2004).

Another recurrent theme is the potential of **videoconferencing**, particularly when used with other technologies, to address the needs of learners with different **learning styles** (Heath & Holznagel, 2002). Yet another theme is the need for teacher training, both technical and pedagogical, in the use of **videoconferencing** (Coventry 1995; Greenberg, 2004;

Rowan, 2000) and for **student scaffolding** (Amirian, 2003; Anderson & Rourke, 2005).

In terms of achievement, there is little research on quantifiable outcomes (Comber et al., 2004). Cavanaugh (2001) reports that videoconferencing yields better learning outcomes, when used as a supplement to other technologies and other approaches to enable more reality-based learning. An equally constant theme is the enhancement of "soft" skills or "portable" skills by good **videoconferencing**–mediated learning experiences. One study from the UK on a major *Videoconferencing in the Classroom* project (Comber et al., 2004) makes the significant point that these **"life skills"** are perceived by teachers as feeding into performance gains. Another study from Ireland has found that special needs students in particular gain enhanced self-esteem, motivation, and improved communication and social skills, as well as greater attention to task, from regular experience of **videoconferencing**, and that this is by far their preferred technology (Abbott, Austin, Mulkeen, & Metcalfe, 2004).

GOOD PRACTICE FROM NORTHERN IRELAND

Videoconferencing has remained in the **"early adopter"** phase for the last 15 years (Greenberg, 2004). The barrier identified by Rowan (2000) still exists and teachers remain unsure how to use videoconferencing effectively. There is, however, much isolated good practice in many parts of the world, but it is generally not widely disseminated. To encourage more fruitful and creative take-up, this good practice needs to be made more easily available. Teachers like to hear it from teachers. In this spirit, I offer a few—out of many (Martin, 2002, 2005)—case studies from Northern Ireland. They cover the period from the mid-1990s to the present day. They are selected to give an idea of how **videoconferencing** can be used in the classroom to meet the needs of 21st century learners. Taken together, they exemplify many of the good pedagogical strategies identified by the literature.

Global Awareness and Curriculum Enrichment through Collaboration at the Elementary Level

This case study involves a small rural school with partners in Denmark and Italy. Learning goals were set first by the teachers and the project was developed as an integral part of the schools' history and geography curricula. The schools met regularly by multipoint **videoconference** to allow the grade 4 students to socialize, and to engage in interactive learning events. The teachers used the **videoconference** as a **virtual staffroom** where they met to plan the content of the next phase and to devise strategies for **interaction**, for variety of pace, and for different learning styles. They were enthusiastic about exploiting the capabilities of the technology to enrich and extend the learning experiences of their students. They also began to explore the implications for teachers of this new learner-centered approach, seeing the traditional "sage on the stage" role as being ill-suited to the new learning environment. The students were motivated by the "hard fun" aspect of preparing work for a real audience. They deepened their understanding of their history and geography syllabus, and developed cultural awareness, and communication and presentation skills. The principal of the NI school pointed out how greatly the videoconferencing learning environment had widened the horizons of his students, most of whom had never been out of Northern Ireland and were not likely to be in the near future.

Extending the Learning Environment through Collaboration between Students with Special Needs

A recent project, involving two schools for students with severe learning difficulties (SLD) in different parts of Northern Ireland, set out to explore the potential of **videoconferencing**, together with text conferencing for the more able, to support effective distant collaborative learning in the SLD environment. The project was on the theme of "My town." The aim was to give students, whose experience of the outside world was necessarily limited, a sense of their own and other places. The students communicated once a week by videoconferencing. The teachers used the technology as a **virtual staffroom** where they met regularly for discussion. Teacher enthusiasm for this technology, their willingness to change their **pedagogy** to exploit its potential, and their commitment to **student scaffolding** both before and during the virtual lessons were the key success factors.

The outcomes were very encouraging. Videoconferencing was experienced as being inclusive of all the children, including those with little or no oral skills who used body language to communicate, or who had their more articulate peers interpret for them. It increased their motivation and improved their concentration. Students with serious behavioral difficulties remained totally attentive and engaged throughout the 30-minute sessions. Both classes perceived videoconferencing as fun. It brought a new way of learning into the classroom. It awakened their curiosity about their distant peers and the distant town. Videoconferencing also whetted their appetite for a physical encounter with their virtual friends. This happened subsequently on two very happy occasions, with each school hosting the visit of the other.

Accessing and Sharing Experts

The capability of **videoconferencing** to overcome the barriers of distance, time, and expense, and to engage students enthusiastically in authentic learning was demonstrated in a multipoint linkup between 70 A-Level (grade 12) politics students from schools in Northern Ireland, their peers in New Jersey, and the House of Representatives in Washington, DC. From here, a senior U.S. Congressman held a "town meeting" with both groups of students, answering their questions about the U.S. constitution and the workings of the House, while an Irish expert on the British and Irish situation responded from the Irish site to the questions of the U.S. students. To accommodate the "intimate" nature of communicating by videoconference (Coventry, 1995), a panel of six students at each site interacted with the experts. Very thorough preparation of content and student scaffolding in advance of the conference, including raising awareness of the unique capabilities of videoconferencing, and development of presentation skills, led to a completely student-centered learning experience. During the preparatory phase, NI school district personnel liaised between the schools and the experts. Questions were sent in advance and the interactive nature of the conference was emphasized. Understanding was reached that information was to be delivered in "nuggets" rather than as a lecture. Effective chairing during the videoconference ensured a high degree of dialogue and **interaction** between students and experts and between students and their distant peers. Following the panel discussion, a roving radio microphone enabled the "town meeting" to be opened to the large group of observers at both sites. The two sets of students then had the opportunity to discuss their new learning and to build on previous knowledge. The whole "meeting" was a superb example of exploiting the potential of videoconferencing to meet the needs of **digital learners** by facilitating learning as a social process, enabling "hard fun," active construction of meaning through dialogue in a social process of group and peer interaction as described by Coventry (1995) and Hayden (1999).

Virtual School Day

A Virtual Day experiment was undertaken in 2007 by two NI schools. A number of students from both schools accessed learning from home, using **videoconferencing** and Learning NI—the Northern Ireland online managed learning environment—on which teachers had posted the lessons for collaborative learning that day. Videoconferencing enabled students to take part in classes being held at each school and to have brief tutorials with teachers. It was also used for collaborative work between the two schools. This experiment demonstrated that the use of **videoconferencing** as part of what Rowan (2000) describes as a **"multimode" delivery** had allowed good learning to take place. The informal evaluation indicated that students particularly enjoyed the independent and collaborative learning that the technologies enabled. Teachers saw great potential in this media-rich approach and realized how it would challenge the tradtional teaching and learning paradigm.

Teachers-as-Learners

In addition to being used to facilitate distance professional development courses within Northern Ireland (Martin, 2000), **videoconferencing** has occasionally provided an invaluable global dimension to the formal development of teachers-as-learners. An example of good practice in this domain was the delivery by a panel of three math specialists from a U.S. university, of part of an in-service course for primary school numeracy (math) coordinators in a school district. The focus was parental involvement in numeracy. Again, the strategy of a panel followed by open discussion was used. On each side, the panel comprised faculty, practising teachers, a parent and a student. This enabled the issues to be viewed from a variety of perspectives and fostered a high degree of **interaction.** Teachers subsequently reported that the experience had promoted their professional development, raised their self-esteem, widened their horizons, and helped them appreciate the value of videoconference as a technology for learning.

FUTURE TRENDS

In terms of technology, the future of **videoconferencing** is bright. Earlier criticisms of unreliability, complexity and cost are no longer valid (Arnold, Cayley, & Griffith, 2002) and with the advent of Internet Protocol (IP), calls are free. Technology convergence and mobile technologies will hasten anytime-anywhere conferencing, while the combination of videoconferencing with video streaming technologies is already enabling archiving of conferences as well as facilitating observation by a wider audience who can provide feedback through other media (Arnold et al., 2004). In addition, microwave radio and video links are beginning to enable videoconferencing from open space locations (Martin, 2008).

The future also looks brighter in terms of the adoption of videoconferencing in schools. Greenberg (2006) estimates that about 25% of U.S. schools have been equipped with videoconferencing. In Northern Ireland, where the technology infrastructure is supplied free, a basic videoconferencing system is in the process of being rolled out to all schools. Some schools are also purchasing high specification dedicated videoconferencing units.

Ultimately, what matters, however, is what mindset we will bring to **videoconferencing**. The main barrier to its effective use will be what Thornburg (2003) calls the "hu-

man challenge," getting educators to change their thinking about learning and the role of technology, so that schools will come to embody the spirit, not of the past, but of the future (Papert & Caperton, 1999).

There are signs that this is beginning to happen. The New Commission on the Skills of the American Workforce has released a "blueprint for rethinking American education" to better prepare students for the challenges of the global economy (Wallis & Steptoe, 2006). In Northern Ireland, the new thinking has led to the revised curriculum with its reduction of prescribed content and its emphasis on providing students with the skills necessary for life and work in the 21st century (Department of Education, 2005). Here, videoconferencing is increasingly being seen as a technology that can help meet these 21st century learning needs.

CONCLUSION

The literature and the case studies make it clear that videoconferencing can address the new needs of **digital learners** and help prepare them for the new market place, as well as being inclusive of the needs of learners with special needs and of teachers-as-learners. The case studies in particular give us grounds for hoping that schools, like Rip Van Winkle, may at last be awakening from a hundred years' sleep and becoming more aware of the need for that change of mindset and **pedagogy** that will exploit the unique capabilities of videoconferencing and allow it to help transform learning in the 21st century classroom.

KEY TERMS

Digital Learners: Also known as the Net generation, technology-savvy students who have grown up immersed in technology and whose way of learning is shaped by this.

Early Adopters: Teachers who embrace new technologies at an early stage and experiment with its use in the classroom.

Pedagogy: The science or theory of teaching young people.

Talking Head: A teacher who uses videoconferencing in lecture-style format without interacting with learners at the remote site.

Twenty-First Century Skills: Skills required by the global market place, such as communication, ability to work in teams often across cultures, problem solving.

Videoconferencing: Audiovisual communication, either point-to-point (between two sites) or multipoint (between more than two sites), that enables interaction and application sharing between people in real time.

Virtual Staffroom: Meeting place for geographically separated teachers, where interaction is made possible by videoconferencing or computer technology.

Viewing Text-Based Group Support Systems

INTRODUCTION

"[T]he word is not necessarily what it seems…." (Bialik, Revealment and Concealment, 2000, p. 17)

With interdisciplinary approaches leading to new and enriched perspectives, we argue that an encounter between information technology (IT) and sociology will result in a heightened understanding of the problem of textual ambiguity in text-based computer-mediated communication (CMC)[1] in general and in group support systems (GSS) in particular. Such approaches where IT meets sociology have already been taking place in other areas of group research (e.g., see Ahuja & Carley, 1998). "[W]ith the global and technological transformations of the workplace" (Aakhus, 2001, p. 341), as IT and the Internet gain wide acceptance throughout society as well as the global economy (e.g., see Friedman, 2000) and as CMC and computer-supported cooperative work (CSCW) become commonplace, both information systems (IS) scholars and sociologists have increasingly studied the patterns of human behavior in virtual groups. This article[2] is an attempt to advance that effort. Specifically, the purpose of this article is to apply the insights of Georg Simmel—an early and oft-neglected German theorist of sociology working in the late nineteenth and early twentieth centuries—on written communication to text-based GSS, which are interactive computer-based information systems that support and structure group interaction and intellectual teamwork (see also Ackermann & Eden, 1994; Fjermestad, J., 2004; Klein, 2000; Klein & Dologite, 2000; Nunamaker, 1997; Poole & DeSanctis, 1990; Zigurs & Buckland, 1998), "promot[ing] communication, collaboration and coordination among teams of people" (Ahalt, 2000, p. 1159).

BACKGROUND: COMPUTER-MEDIATED COMMUNICATION AND TEXTUAL AMBIGUITY

CMC research has pointed out that, unlike face-to-face (FTF) communication, CMC is distinguished by the absence of contextual (also referred to variously as situational or emotional) cues, which contributes to miscommunication, misunderstanding, misinterpretation, and distortion of the text message (e.g., see Sproull & Kiesler, 1986). In particular, text-based CMC media generate a written message unaccompanied by nonverbal communication. Nonverbal communication refers to "the exchange of information and meaning through facial expressions, gestures, and movements of the body" (Giddens & Duneier, 2000, p. 96; see also Schaefer, 2001, pp. 71-72), which are known as nonverbal cues. Nonverbal communication also includes verbal cues, or voice patterns, such as loudness, pitch, rate, and tone.

According to Easterbrook (1995, p. 6), contextual cues "are used [in FTF communication] for constant feedback and as a signalling mechanism …, indicat[ing] whether the listener is hearing, and understanding." Text-based CMC does not convey the context and emotional nuances that are necessary for an accurate understanding of the text message. For example, by e-mail and other text-based CMC, the pitch and tone of voice, hand motions, facial expressions, and eye movements are absent, often leading to textual ambiguity, which undermines the accuracy of the message.

Research from a variety of disciplines has recognized the significant role that facial expressions, body language, and voice patterns play in giving context to words. By way of illustration, Gottman (1994), investigating facial expression of emotion in married couples, reported that eye rolling by one spouse following comments by the other spouse is an important indicator of a troubled marriage and a strong predictor of divorce. In contrast to FTF interactions, text-based CMC forecloses the facial and vocal expression of emotion.

GROUP SUPPORT SYSTEMS AS LEANER MEDIA

With e-collaboration having assumed a pivotal role in organizations, a widely-used type of text-based CMC media is GSS, which have been used as e-collaboration tools to assist in intellectual teamwork in such activities as problem solving, decision making, idea generation, strategic planning, conflict resolution, and negotiations. GSS have been defined

as "networked, computer-based systems designed to facilitate structured, interactive discussion in a group of people communicating face-to-face or remotely, synchronously or asynchronously" (Davison & Vogel, 2000, p. 3; see also Aiken & Carlisle, 1992; Anson, Fellers, Kelly, & Bostrom, 1996). GSS, which permit "a group of users to collaborate electronically, sharing and updating a common database while allowing for intergroup communications" (Ullrick, 2000, p. 11; see also Hopkins, 1998, p. 96, note 5) are text-based in that "[g]roup member type their contributions into the system, which immediately makes each contribution available to all other participants" (Davison & Vogel, 2000, p. 3). Thus, what participants in a GSS-supported see is the written text without the benefit of contextual cues to serve as an *explication de texte* of sorts.

As GSS is a text-based e-collaboration tool, we suggest that it is worthwhile to analyze GSS in terms of media richness theory, which asserts that different media differ in their ability to transmit information, convey meaning, and change understanding (Daft & Lengel, 1984, 1986; see also Bastress & Harbaugh, 2003; Kahai & Cooper, 2003; Martz & Reddy, 2005; Simon & Peppas, 2004; Stenmark, 2002; Ware, 2000). Media with multiple contextual cues (e.g., body posture, gazes, voice) and rapid feedback are denoted as "rich," while media with few or no contextual cues and without quick feedback are classified as "lean."

Under many, but not all, circumstances (see Kock, 1998), media richness is an important determinant of the effectiveness of groups engaged in intellectual teamwork and collaboration. According to Majchrzak, Rice, King, Malhotra, and Ba (2000, p. 45):

Because of the kind of information they can transmit (nonverbal cues, etc.), some channels (face-to-face, videoconferencing, etc.) are particularly suited for tasks that are unanalyzable, non-routine, equivocal and involve manageable amounts of information. Unanalyzable tasks that teams might perform include strategic direction-setting, brainstorming, and conflict resolution.

FTF communication, from the perspective of media richness theory, is rich because of the multiplicity of nonverbal and verbal cues, which can be used to clarify and interpret the spoken message. By contrast, text-based GSS are generally leaner media to the extent that there is an absence of these multiple contextual/emotional cues. However, it should be noted, that multiple cues need not be absent in all GSS configurations. Kock (1999, p. 14) characterized the difficulty of enriching GSS through added features by noting "the persistent attempts of developers of commercial group support software, through adding features to their products, to achieve the elusive communication richness of face-to-face interaction."

In discussing the characteristics of electronic media, Yamauchi, Yokozawa, Shinohara, and Ishida (2000, p. 330) commented:

[E]lectronic media make it difficult to transmit equivocal messages, whose ambiguity in meaning permits multiple interpretations, because of the limited amount of communicative cues and sluggish interaction …. Face-to-face informal conversations are the richest medium and thus easily accommodate equivocal messages while written messages are more rigid and convey less information.

TEXT-BASED GSS THROUGH THE PRISM OF SIMMELIAN SOCIOLOGY

We now consider GSS, a staple of twenty-first century IT, from the vantage point of early twentieth century Simmelian sociology. Simmel has been "generally considered the most neglected of the founders of modern sociology" (Marshall, 1998, p. 601), although over the past two decades he has received increasing recognition in the law review literature (e.g., see Froomkin, 1996; Nagan & Hammer, 2004; Patterson, 1988; Reisman, 1983; Seul, 2004; Warner, 2005; West-Newman, 2005). We argue that Simmel anticipated media richness theory and the studies on the absence of contextual cues in CMC media, in his analysis on written communication. Contrasting the letter with FTF communication, Simmel (1908/1964, p. 353) asserted:

Individuals in physical proximity give each other more than the mere content of their words. Inasmuch as each of them sees *[emphsasis on original] the other, is immersed in the unverbalizable sphere of his mood, feels a thousand nuances in the tone and rhythm of his utterances, the logical or the intended content of his words gains an enrichment and modification for which the letter offers only very poor analogies. And even these, on the whole, grow only from the memories of direct personal contact between the correspondents.*

This insight represents a basis with which to view and analyze written communication, which, for Simmel, fails to convey the information, predominantly of an emotional nature, embedded in verbal and nonverbal cues. (For a recent paper on Simmel and cyberspace communication, see Bogard, 2000.) The absence or paucity of these contextual cues make letters prone to ambiguity, which, in Simmel's view, is a "sociological categor[y] of first rank" (p. 354). In terms of media richness theory, written communication is a lean communication medium as it is without the interpretive glosses provided by multiple contextual cues and rapid feedback. Simmel, thus, was an advocate of media richness theory *avant la lettre*.

Writing within the legal tradition, law scholar Jeffrey Rosen (2000), in investigating privacy in the workplace, applied Simmel's thought on letters to e-mail, where verbal and nonverbal cues are not available to supply emotional background to the text message, thus making the text message highly susceptible to being "wrenched out of context" (p. 76). According to Rosen, "e-mail shares the informality of a conversation, but like a letter, lacks the contextual accompaniments that provide clues to meaning in face-to-face encounters" (p. 76). Employing a Simmelian analysis, Rosen (p. 75) argued:

Messages sent by e-mail are often far more impetuous than face-to-face conversations, where "situational cues," such as body language and facial expressions, from the person with whom we are conversing temper what we say. Because e-mail messages are often dashed off quickly and sent immediately, without the opportunity for second thoughts that ordinary mail provides, they may, when wrenched out of context, provide an inaccurate window on someone's emotions at any particular moment.

Taking the works of Simmel and Rosen as our starting point, we extend the Simmelian analysis to text-based GSS, which we argue is, in many respects, similar to e-mail. Synchronous (same time) GSS messages are generally "dashed off quickly and sent immediately" without much deliberation. Even asynchronous (different times), GSS messages are often composed quickly without careful crafting. Moreover, the text messages in GSS, both synchronous and asynchronous, are without "contextual accompaniments" (Rosen, 2000, p. 75) that convey the emotional nuance of the text and clarify its meaning. As in letters, "a lack of all those accompaniments — sound of voice, tone, gesture, facial expression" (Simmel, 1908/1964, p. 354) are a source of ambiguity in text-based GSS messages because by doing without these accompaniments, GSS messages are without "[t]hese powerful denoters of information" (McNeil, Robin, & Miller, 2000, p. 701).

FUTURE TRENDS

Recently, an increasing amount of scholarly attention has been directed to GSS-supported and online focus groups. Hughes and Lang (2004) noted the following:

[I]n the few years that Internet communications have become widely acceptable, substitute cues have been developed which are already to some extent standardized and familiar to experienced online users. We have found that emoticons [also known as smileys or graphic accents] …, typographical cues …, standard acronyms …, all-uppercase text …, and interjections … are spontaneously introduced by group members to richen the text-only experience. (p. 98)

It is suggested that as individuals gain more experience with e-mail and other forms of e-communication, they will integrate emoticons seamlessly within their text messages thereby injecting some emotional context in an otherwise affectively neutral medium.

CONCLUSION

A Simmelian approach to written communication can contribute to a better understanding of the limitations of text-based GSS. The challenge to scholars and practitioners of IS is to develop pragmatic solutions to prevent textual ambiguity in GSS messages. These solutions should include fostering increased use of emoticons, which convey emotion and feeling and thus contribute to reducing misunderstandings and distortions of the computer-mediated text (e.g., see Crystal, 2001).

It is worth noting that the emoticons can only convey emotional cues that the sender of the message intentionally chooses to reveal. Emoticons cannot convey emotions that would be unintentionally reflected in facial expressions and body movements.

KEY TERMS

Computer-Mediated Communication (CMC): A communication system that involves or is assisted by computers. Computer-mediated communication includes group support systems, e-mail, videoconferencing, chat rooms, and instant messaging.

E-Collaboration: The collaboration of two or more individuals performing a specific task over a computer network. With the growth of GSS scholarship and its openness to interdisciplinary approaches, it is anticipated that future research will treat the textual ambiguity problem with the attention that it deserves and will find new approaches to place the GSS text within its context.

Face-to-Face Communication: Real-time communication between two or more individuals in physical proximity to each other.

Group Support Systems (GSS): Interactive computer-based information systems that support and structure group interaction and facilitate group meetings.

Lean Media: A vehicle of communication having few or no verbal cues, thereby precluding the clarification and interpretation of the spoken message.

Nonverbal Communication: The conveying of information, usually of an emotional nature, by means of body movement, facial expressions, hand gestures, and voice patterns.

Rich Media: A vehicle of communication having a multiplicity of nonverbal and verbal cues, which can be used to clarify and interpret the spoken message.

ENDNOTES

1 Computer-mediated communication (CMC) is a communication system that involves or is assisted by computers. Computer-mediated communication includes group support systems, e-mail, videoconferencing, chat rooms, and instant messaging.

Virtual Communities of Practice

Chris Kimble
University of York, UK

Paul Hildreth
K-Now International Ltd., UK

INTRODUCTION

When knowledge management (KM) began to emerge in the 1990s it was seen as an innovative solution to the problems of managing knowledge in a competitive and increasingly internationalised business environment. However, in practice it was often little more than information management re-badged (Wilson, 2002). More recently, there has been recognition of the importance of more subtle, softer types of knowledge that need to be shared. This raises the question as to how this sort of knowledge might be managed. Communities of practice (CoPs) have been identified as means by which this type of knowledge can be nurtured, shared and sustained (Hildreth & Kimble, 2002). Do CoPs offer a means of managing the softer aspects of knowledge and, if they do, are they applicable to today's increasingly "virtual" world?

BACKGROUND TO COMMUNITIES OF PRACTICE

The term communities of practice (CoPs) was coined in 1991 when Jean Lave and Etienne Wenger used it in their exploration of situated learning (Lave & Wenger, 1991). Although the examples they used (non-drinking alcoholics, Goa tailors, quartermasters, butchers and Yucatan midwives) were all based on what might be broadly termed an apprenticeship model, the concept of a CoP is not restricted to this form of learning.

Lave and Wenger (1991) saw the acquisition of knowledge as a social process in which people participated in communal learning at different levels depending on their authority or seniority in the group, that is, whether they were a newcomer to the group or had been an active member for some time. The process by which a newcomer learns by being situated in the group was central to their notion of a CoP; they termed this process legitimate peripheral participation (LPP).

LPP is both complex and composite; legitimation, peripherality and participation are each indispensable in defining the other. Legitimation is concerned with power and authority relations in the community but is not necessarily formalised. Peripherality is not a physical concept or a measure of acquired knowledge, but concerned with the degree of engagement with the community. Participation is engagement in an activity where the participants have a shared understanding of what it means in their lives.

For Lave and Wenger (1991), the community and participation in it were inseparable from the practice. Being a member of a CoP implied participation in an activity where participants have a common understanding about what was being done and what it meant for their lives and their community. Thus, it would appear that CoPs with their concentration on situated learning and the exchange of understanding might be well suited to the management of the softer aspects of knowledge: but can this idea be applied to the business world?

EXTENSIONS TO THE COMMUNITY OF PRACTICE CONCEPT

Interest in CoPs continued to grow throughout the 1990s and several attempts were made to re-define Lave and Wenger's (1991) original model to encompass new areas such as communities of circumstance, communities of interest and communities of purpose. In particular, several attempts were made to re-define CoPs in a way that was more relevant to the commercial environment (e.g., Seely Brown & Duguid 1991, 1996; Stewart 1996). One of the most popular work related definitions of a CoP was offered by John Seely Brown and Estee Solomon Gray in their 1995 article called "The People Are the Company":

"At the simplest level, they are a small group of people … who've worked together over a period of time. Not a team not a task force not necessarily an authorised or identified group … they are peers in the execution of "real work". What holds them together is a common sense of purpose and a real need to know what each other knows" (Brown & Gray, 1995).

In 1998, Wenger (1998) published the results of an ethnographic study of a claims processing unit in a large

insurance company that described how employees exchanged knowledge during meetings and by the passing of handwritten notes. He proposed a view of the company not as a single community, but as a constellation of interrelated CoPs. CoPs arise out of the need to accomplish particular tasks and can provide learning avenues that exist within, between and outside organisations. CoPs are formed through mutual engagement in a joint enterprise and will share a repertoire of common resources (e.g., routines, procedures, artefacts, vocabulary) that members develop over time.

Thus, according to Wenger (1998) a CoP becomes defined in terms of:

- What it is about:

The particular area of activity/body of knowledge around which it has organized itself. It is a joint enterprise in as much as it is understood and continually renegotiated by its members.

- How it functions:

People become members of a CoP through shared practices; they are linked to each other through their involvement in certain common activities. It is this mutual engagement that binds its members together in a single social entity.

- What it produces:

The members of a CoP build up a "shared repertoire" of communal resources over time. Written files are a more explicit aspect of this, although less tangible aspects such as procedures, policies, rituals and idioms can also included.

Wenger (1998) also identified two key processes at work in CoPs: participation and reification. He described participation as:

"... the social experience of living in the world in terms of membership in social communities and active involvement in social enterprises" (Wenger, 1998, p. 55)

and reification as:

"... the process of giving form to our experience by producing objects that congeal this experience into thingness" (Wenger, 1998, p. 58)

Wenger emphasises that like LPP, participation and reification are analytically separable, but are inseparable in reality. Participation is the process through which people become active participants in the practice of a community and reification gives concrete form to the community's experience by producing artefacts. One is meaningless without the other and vice versa. In day-to-day work, people both negotiate meaning through participation in shared activities and project that meaning onto the external world through the production of artefacts.

Wenger's (1998) work with CoPs shows that the concept can be applied in a business setting. Since then, several other authors have identified the business benefits of CoPs (e.g., Fontaine & Millen, 2004: Lesser & Storck, 2001). However, almost all of the previous work on CoPs has described co-located communities. With the increasing globalisation of business and the heavy reliance on information and communication technology (ICT), the next question is "Can CoPs continue to operate in a modern business environment?"; that is, "Can a CoP be virtual?"

FUTURE TRENDS

Concerning the future of CoPs, and virtual CoPs in particular, two main issues must be considered. The first concerns the relationship between a CoP and its wider (electronic) environment; the second concerns the nature of the "work" that CoPs do; that is, do processes in a virtual CoP differ from one that is co-located?

CoPs in an Electronic Environment

Internet-based networking technologies, which can provide a single platform for groups or networks of groups to form within larger organisations, have led to the development of various forms of virtual groups and communities. Seely Brown and Duguid (2000) coined the phrase "networks of practice" (NoPs) to describe one type of virtual group. NoPs are composed of people who are geographically separate and may never even get to know each other, but who share similar work or interests. Thus, NoPs are organised more at the individual level and based on personal social networks than CoPs with their notions of mutuality and the collective social will of the community.

In a study of job seeking activity, Granovetter (1973) introduced the notion of strong and weak social ties. In terms of the previous description, CoPs are characterised by strong social ties, whereas NoPs are characterised by weak social ties. Within a wider network consisting of weak ties, an individual may act as a "local bridge" or broker that enables the network to react more quickly and provide a coordinated response. Nevertheless, within a network there is also a need for strong ties to encourage local cohesion and avoid fragmentation that would make knowledge sharing and the adoption of innovation more difficult.

CoPs can be seen in the role of hub for the wider network, providing a more tightly knit sub-network that serves as knowledge generating centres for the larger NoPs. CoPs can act as bridges drawing together different groups and

combining knowledge in new ways. They can also provide the access points for individuals to engage with the wider network and to establish a local identity within the larger organisation. Previous research has shown that the most common distributed form of a "virtual" CoP has a co-located active core (Hildreth, Kimble & Wright, 1998), which tends to support this view of distributed working.

A more recent example was provided by Lundkvist's (2004) study of customer networks as sources of innovation. This case study was generated from a long-term study of the Cisco Systems newsgroup, which identified user networks as peripheral and yet vital sites of innovation. In this case, the co-located core of the network was provided by a group of university technicians.

Work in Virtual CoPs

How might the balance between reification and participation be maintained in virtual working? This issue was addressed in an earlier paper (Kimble, Hildreth & Wright, 2000) where we described how a geographically distributed CoP managed both hard (reified) and soft (social) knowledge. In this case, the CoP was made up of four members co-located in the UK, a group of five members in the USA and one member in Japan.

In this situation, it might have been expected that sustaining participation would be more difficult and therefore reification would play a greater role. However, the findings of the case study showed that this was not necessarily the case. Shared artefacts, such as a planning document, did play an important role but the importance of social relationships remained paramount. While the group was able to sustain itself using e-media, it was still dependent on the development of relationships in the physical environment through face-to-face meetings.

It is interesting to observe how artefacts such as a planning document (reification) were used not only as ways of projecting knowledge from within the CoP but were also instrumental in the process of creating it (participation). The document stimulated discussion, problem solving, innovation and further participation. It was used both to drive meetings and as the focus of meetings. During discussions based on the document, new and innovative ideas would be triggered that could form the basis for new projects. Thus, as well as acting as a stimulus for innovation, the document acted as a catalyst leading to further participation.

A similar account can be found in Bradshaw, Powell and Terrell (2004) that describes how a team of remote workers developed into a CoP. They describe not only how the group deploys a variety of technologies to maintain contact but also the efforts that went into building commitment, ownership, engagement and focus in the group. In this case, the members of the group were all engaged in collaborative research. Writing about their work and presenting papers for peer- review was seen as a key factor in maintaining cohesion and developing the community's shared understanding of goals, development of knowledge and sense of belonging.

CONCLUSION

Reporting on a recent case study of how CoPs translate to a geographically distributed international environment, Hildreth (2003) throws further light on a number of these issues. The study examines the work of an internationally distributed CoP that spans three continents. In particular, it highlights the role that shared artefacts play in the process of creating, sharing and sustaining both types of knowledge and highlights the role that the creation of artefacts plays in enabling and sustaining participation in CoPs. Hildreth (2003) observes that the process of creating the artefact and regular (although not necessarily frequent) face-to-face contact are instrumental in maintaining the relationships that allow a CoP to function successfully in a virtual environment. Thus, paradoxically, it appears that one of the keys to a successful virtual CoP is an occasional, non-virtual, face-to-face meeting.

However, the changes that are sweeping the corporate infrastructure mean that increasingly workers find themselves forced into one or another form of virtual working. Instead of inhabiting a world of fixed roles with easy access to co-located resources, today's workers are increasingly based in a world of weak ties where resources are only obtained through personal and individual relationships. Rather than being embraced by a collective CoP, workers often find themselves functioning as individuals and building up networks, one contact at a time. Again, paradoxically, as social networks such as NoPs become more important, the fundamental unit for many examples of virtual working is not the group but the individual. This is not to say that collective groups such as CoPs and teams have ceased to exist but simply that the difficulty of building and maintaining the strong social ties needed to build a sense of community in a virtual environment should not be underestimated.

KEY TERMS

Artefact: An artefact in the context of CoPs indicates objects, articles, and "things" which have been created by the CoP to assist the members in their work and which may have some of the community's knowledge embedded in them. Artefacts do not have to be concrete – a process or procedure may be an artefact.

Communities of Circumstance: Communities of circumstance are driven by position, circumstance or life experiences. Communities of circumstance are distinguished from CoPs in that they tend to be personally focused and are often built around "life stages," such as teenagehood, university, marriage or parenthood.

Communities of Interest: Communities of interest are groups of people who share a common interest. Members exchange ideas and thoughts about the given interest, but may know little about each other outside of this area. Participation in a community of interest can be compelling and entertaining but is not focussed on learning in the same way as a CoP.

Communities of Practice: Communities of practice are groups of people who have a common goal and who are internally motivated to reach the goal. The members have some form of common background and shared language.

Communities of Purpose: Communities of purpose form around people who are to achieve a similar objective. Such communities only serve a functional purpose. Members of the community can assist each other by sharing experiences, suggesting strategies and exchanging information on the process in hand.

Hard Knowledge: Hard knowledge is unambiguous and unequivocal, can be clearly and fully expressed, can be formalised and structured, can be "owned" without being used and is both abstract and static: it is about, but not in, the world.

Knowledge Management: Knowledge management is the means whereby an organisation "manages" and leverages its knowledge resources. This can include reports, databases and patents; it also includes people – identifying experts, sharing knowledge, and helping people learn.

Legitimate Peripheral Participation: LPP is the process by which a newcomer gradually works his/her way towards full participation in the community. Lave and Wenger's (1991)

examples were based on the apprenticeship model, where a newcomer (the apprentice) was allowed to undertake basic tasks. As they became more experienced, they were given more complicated tasks until they could fully participate in the practice of the community and became old-timers.

Network of Practice: People who are not directly connected to each other but still engage in similar kinds of activities are said to belong to a network of practice (NoP). NoPs link local communities whose members have similar interests and give a minimal coherence to the network.

Soft Knowledge: Soft knowledge is implicit and unstructured, cannot be articulated, can be understood without being openly expressed, is associated with action and cannot be possessed, is about what we do and is acquired through experience.

Virtual Communities of Practice for Health Care Professionals

Elizabeth Hanlis

Merck Frosst Canada Limited, Canada

INTRODUCTION

Wenger is typically credited with the development of the metaphor of communities of practice where "learning requires an atmosphere of openness and the key is to build an atmosphere of collective inquiry" (Wenger, 1998). However, the focus of creating a sense of belonging as well as the formulation of knowledge as a social process is not as new. Rather, it can be found in the form of a learning community. Senge (1990) introduced this concept of the learning organization to explain strategies to enhance the capacity of members to consistently collaborate on mutual goals.

With the increased use of the Internet over the past decade, health professionals are examining how to effectively use this medium to support collaboration and learning, while improving patient care (Casebeer, Bennett, Kristofco, Carillo, and Center (2002).

It is therefore understandable that Continuing Medical Education (CME) on the Internet has grown exponentially over the last several years. Curran and Fleet (2005) describe that in order for physicians to be able to adapt to the demands and changes of an ever-evolving technical world, they must think about "the new dimension and innovative opportunities that the Internet affords for doctors to access CME in the 21st century" (Curran & Fleet, 2005). Online professional learning opportunities offer more flexibility than traditional face-to-face CME and are able to overcome barriers to learning like travel and irregular work hours. As a result, the Communities of Practice concept was taken to the Web and the term Virtual Communities of Practice (VCoP) appeared in the medical literature (Dube, Bourhis, & Jacob, 2006).

The first virtual communities in medicine involved patients, and focused on providing a space for mutual support, along with news on innovative treatments and helpful resources (Demiris, 2006; Nagy et al., 2006).

Virtual communities for professionals, or virtual communities of practice (VCoP), were recently generated based on similar needs (Nagy et al., 2006). According to Bates and Robert (2002), VCoP are vitally important for health care professionals and organizations, as they spread best practices and change practice (as cited in Sandars & Heller, 2006).

Unfortunately, there is limited literature that examines VCoP for health care professionals (Moule, 2006). This article will review existing literature to determine the requirements for establishing and maintaining an effective VCoP within the health care context, in support of continuing professional development. Specifically, the article will focus on the benefits of a VCoPs, the characteristics of successful VCoPs and examples of existing VCoPs with a focus on health professionals.

BACKGROUND

Communities of Practice (CoP) are groups "of people who share a concern, a set of problems, or a passion about a topic, and who deepen their knowledge and expertise in this area by interacting on an on-going basis" (Wenger, McDermott, & Snyder, 2002, p. 4). Generally, such communities seem to be an innovative way to share and manage knowledge and sustain innovation (Wenger et al., 2002).

Virtual Communities of Practice (VCoP), without excluding face-to-face meetings, rely primarily on information and communication technologies (ICT) to connect their members. A VCoP may use a large array of traditional media (phone teleconference, fax, etc.) and more or less sophisticated technological tools, such as e-mail, videoconference, newsgroups, online meeting space, or a Website Intranet to establish a common virtual collaborative space (Demiris, 2006; Dube et al., 2006).

Virtual communities in health care refer to the group of people (and the social structure they create), who communicate via ICT for the purpose of collectively conducting activities related to health care and education. Such activities may include: discussions around problems, cases, best practices, management of diseases, or treatments, collaboration around patient care or research projects, sharing of docu-

ments and resources on topics of interest, consulting with experts, or generating new ideas and innovation (Demiris, 2006; Endslay, Kirkegaar, & Linares, 2005).

Dimensions of a Community of Practice

The following three dimensions are essential to a community of practice: 1) mutual engagement, 2) joint enterprise, and 3) shared repertoire (Wenger et al., 2002).

- **Mutual engagement** involves regular interaction among participants within the community, including both informal communication (i.e., e-mail), or more formal structured communication (i.e., monthly Web meetings) (Wenger et al., 2002).
- **Joint enterprise** refers to the process that maintains the community. This includes negotiating the endeavors of the community (Wenger et al., 2002).
- **Shared repertoire** includes the ways, routines, and even language developed by the community (Wenger et al., 2002). Shared repertoire implies longevity, as such successful communities cannot flourish in a few months (Moule, 2006).

Benefits of a VCoP for Health Care Professionals

"Practitioners reflect on and learn from their practice in ways that incorporate both tacit (implicit) and explicit (codified) knowledge" (Doak & Assimakopoulos, 2007; Rynes & Bartunek, 2001 (as cited in Bartunek, Trullen, Bonet, & Sauquet, 2003)). While explicit knowledge can be found in books, journal articles, or other formal learning events, tacit (implicit) knowledge comprises a range of conceptual and sensory information and images that are difficult to articulate in words, but rather can be demonstrated or imitated (Polanyi, 1967). Tacit knowledge may therefore include intuition, perspectives, beliefs, values, and culture. As such, tacit knowledge can only be gained through individual experience and by collective participation in communities of practice (Bartunek et al., 2003). Some research indicates that tacit knowledge is better diffused within an organization whose structure and work environment promote face-to-face interaction and employee sharing at close physical proximity (Busch, 2006). Nevertheless, tacit knowledge can also be shared via a VCoP through metaphors, analogies, and stories of practice, a form of knowledge transmission that builds on contextual cues (Bartunek et al., 2003).

One of the major benefits of a VCoP is the ability of a diverse group of health care professionals to communicate and collaborate quickly across institutions and geographical locations (Demiris, 2006; Endslay et al., 2005; Robinson & Cottrell, 2005).

This exchange of knowledge within a VCoP leads to the creation of new knowledge and change in practice (Robinson & Cottrell, 2005). Nonmedical literature further supports that communities of practice can result in increased productivity and innovation (Sandars & Heller, 2006).

Characteristics of a Successful Virtual Community for Health Professionals

The literature around virtual Communities of Practice for Health Professionals was examined to determine common traits and characteristics of successful communities. As such, the following list of characteristics was developed.

Community Coordinator or Moderator

According to the literature, a high degree of structured management is critical for the success of a virtual community of practice. One way to achieve this is through online moderating of the group (Salmon, 2000) (as cited in Sandars & Heller, 2006).

The community coordinator helps the community identify important issues, focus on relevant topics, develop and maintain relationships, and develop its practice, including lessons learned and best practices. They may not be leading experts in their field as their role is not to "give all the answers" but to link people and guide members to appropriate resources (Endslay et al., 2005; Wenger et al., 2002)

Active Participants and Lurkers

Regardless of the size of the community, in order for it to be successful it needs to have both active participants and "lurkers." Active participants will ensure that there is regular interaction among members, making the community vibrant and energetic. These members provide intellectual and social leadership (Dube et al., 2006). Lurkers are members of the community who do not contribute regularly. However, lurkers may constitute up to two thirds of their community and their knowledge and resources are still important (Endslay et al., 2005; Wenger et al., 2002).

Trust and Opportunity for Socialization

Virtual communities of practice can be as effective as groups that have face-to-face meetings, provided there is the development of trust (Hildreth, Kimble, & Wright, 2000 (as cited in Sandars & Heller, 2006, p. 343)).

However, when participants cross boundaries and are from different professions and organizations, it is difficult to develop a level of trust and to buy into the idea of knowledge sharing (Wenger et al., 2002). In such cases, more effort needs to be made to break organizational silos

and promote sharing and collaboration, which takes time (Dube et al., 2006).

Building trust is also difficult when there is a wide geographical dispersion across a country, as physical distance encourages psychological distance in many cases (Dube et al., 2006; Preece, 2000). One effective strategy for building trust within virtual communities is to provide opportunities for socialization (either face-to-face or online) when launching the community (Sandars & Heller, 2006).

Clear Purpose or Goal of the Community

A VCoP can be used to support a variety of goals and endeavors. These goals and the process used to support them need to be negotiated and agreed upon by its members (Moule, 2006).

Communities of practice for health care professionals may serve one or more of the following purposes: actual delivery of health care services, staff education discussing health- and treatment-related issues and problems, sharing of documents, sustaining relationships beyond face-to-face meetings and conferences, and supporting virtual care delivery teams or research teams (Demiris, 2006).

Community Activity and Events

Regular activity and events organized for the virtual community of practice assist in "anchoring" the community at the onset, and maintaining the energy and enthusiasm of the group in the long term (Nagy et al., 2006; Wenger et al., 2002). Both structured and less structured activities are encouraged. This could range from regularly scheduled meetings, via Web conferences, teleconferences, or videoconferences, to recommending members to attend medical conferences and share lessons learned within the VCoP (Endslay et al., 2005).

Inclusion of Face-to-Face Interaction

While a VCoP relies primarily on the use of ICT, the degree of reliance on it may vary greatly. For one VCoP there may be one face-to-face meeting a year at a conference, and the remaining communication takes place via ICT. For another VCoP there may be monthly face-to-face meetings, while the remaining communication takes place online. It is widely accepted that ICT will never be a perfect substitute for face-to-face interaction and most VCoPs need some face-to-face time to be most effective (Deloitte Research, 2005).

Credibility

A VCoP needs to prove its credibility to its members. This may be accomplished by ensuring that the site remains unbiased and transparent. Some level of expert oversight also increases credibility (Nagy et al., 2006).

Ownership of Site

Participants need to be encouraged to own elements of the site. This helps to increase a feeling of ownership and belonging of participants (Nagy et al., 2006).

Educational Content

In order for a VCoP to remain vital, organizers must provide online access to a variety of educational resources and content (Nagy et al., 2006). Such resources could be interesting or problematic patient cases, Websites, or articles that are freely available on the Internet. All members should also have the opportunity to share, upload, and review resources on the site in order for a just-in-time knowledge-base to be developed (Nagy et al., 2006).

Technology and Usability

There are many communication and learning technologies that could be used to support a VCoP. Possible technologies include: e-mail, asynchronous discussion forums (or Bulletin Board), Listservs, text chat, Web conferencing, teleconferencing, wikis, blogs, and course/learning management systems.

It is important that the technology supports the essential requirements of the community, including online facilitation, and storage of tacit knowledge into explicit knowledge (Sandars & Heller, 2006). Usually a combination of tools and approaches are appropriate to meet the needs of the learner.

Regardless of the approach used, the technology should be evaluated on its ability to enhance the natural information-seeking behaviors of individual practitioners and its usability (Parboosingh, 2002). According to Preece (2000), a virtual community of practice that is usable allows members to communicate with each other, find information, and navigate the community site with ease (Demiris, 2006).

Leadership

A strong community of practice requires strong leadership. The health care organizations and its individual members need encouragement, guidance and influence to help them accept the value of communities of practice in implementing best practices and motivating change of practice (Sandars & Heller, 2006).

It is advisable to create a formal leadership structure when launching a CoP, rather then letting leadership roles and authority structures emerge on their own over time (Dube et al., 2006).

Table 1. Examples of existing VCoP for health care professionals

VCoP – Name and URL	Brief Description
Braintalk.org (*www.braintalk.org*)	An online patient support group with almost 50,000 members. ("Designing virtual communities for medical professionals",2006).
ClubPACS (http://www.clubpacs.com/)	A virtual community for picture archiving and communication system (PACS) administrators with 2,500 members (Nagy et al., 2006).
CoPosis™ (www.coposis.ca)	CoPosis™ is a Canadian online Community of Practice (CoP) for health care professionals interested in advancing discussions and understanding of issues surrounding the identification and management of fungal infections.
Emergency Care Community of Practice (http://www.nhmrc.gov.au/nics/asp/index.asp?cid=5263&gid=207&page=programs/programs_article)	The National Institute of Clinical Studies in Australia has established an emergency care CoP for health care professionals.
Health Infomatics NHS Community (http://www.informatics.nhs.uk/index.html)	Developed for UK health care professionals to support the delivery of health care and promote health (Sandars & Heller, 2006).
Healthboards.com (*www.healthboards.com)*	A collection of more than 140 discussion boards pertaining to virtually every major health topic ("Designing virtual communities for medical professionals", 2006).
Pain-Talk (*www.pain-talk.co.uk/*)	A vibrant, national community for UK health care professionals with an interest in acute, chronic, or palliative pain management ("Designing virtual communities for medical professionals", 2006).

Institutional Commitment and Recognition

Ensuring that a VCoP is recognized and supported by an institution is critical to its success (Dube et al., 2006). Institutions need to recognize participation in the VCoP as continuing professional development and allow time for members to participate (Sandars & Heller, 2006). Such recognition provides credibility to the community, which will encourage participation (Dube et al., 2006).

FUTURE TRENDS

There seems to be an abundance of literature around communities of practice in general, since the inception of the term in 1998. While VCoP share many characteristics with CoP, they have a set of distinct characteristics (Dube et al., 2006). Nevertheless, there seems to be limited literature around VCoP and even fewer studies examining the effectiveness of VCoP for health care professionals (Moule, 2006).

In order to develop evidence-based guidelines for the design and maintenance of VCoP for health care professionals, it is necessary to conduct research beyond exploratory pilot studies to clinical trials and interventions that follow an experimental design (Demiris, 2006).

To increase the broad application of findings, researchers need to document the social context, recruitment strategies, the implied and stated rules that govern the community, its utilization rate, its rate of growth, leadership roles, funding strategy, and strategies used to encourage participation (Demiris, 2006).

Most ICTs that specifically focus on workplace learning activities, such as knowledge sharing, knowledge creation and

facilitation of collaboration are recent, and studies on their effectiveness to enhance learning have not been done yet. A research agenda must be planned to assess the effectiveness of information and communication technologies that support and enhance learning in practice (Parboosingh, 2002). This research agenda needs to include a pre-post design to determine the impact of the VCoP on knowledge and skills, practice, and patient care (Demiris, 2006).

CONCLUSION

With limited time and increased costs of travel, interacting face-to-face is becoming increasingly difficult. These limitations along with the increased use of technology and the need to interact and share implicit knowledge, has led to the creation of Virtual Communities of Practice for Health Professionals.

When "a specialized profession reaches a critical mass, a virtual community of shared knowledge can become a self-sustaining and beneficial resource that grows and develops along with the needs of its participants. Such a community can be highly beneficial for the discipline (Nagy et al., 2006, p. 5).

While this article is a first attempt at determining the characteristics of successful VCoP for health care professionals, more research is needed to ensure that we are using the right technologies to support VCoP and appropriate processes to design, develop, and maintain such communities in a manner that positively influence patient outcomes and patient care.

KEY TERMS

Active Participant: An actively engaged in a virtual community. Such participants display interactive behavior which includes collaborative or positive interactive behavior or even hostile behavior (Demiris, 2006).

Asynchronous Discussion Forums (or Bulletin Board): Web-based conversations that allow users to post, view, and reply to messages (Kevin, 2006). The benefit of such a tool is that the information posted by the CoP is archived for later viewing and in most systems is key-word searchable (Nagy et al., 2006).

Communities of Practice (CoP): Groups "of people who share a concern, a set of problems, or a passion about a topic, and who deepen their knowledge and expertise in this area by interacting on an ongoing basis" (Wenger et al., 2002, p. 4).

Explicit Knowledge (or codified knowledge): A transmittable in formal systematic language expressed in symbols, words, or numbers (Rynes & Bartunek, 2001). This is the type of knowledge or information that we can easily document and obtain from books and journals.

Lurkers: Members of the community who do not contribute regularly (Endslay et al., 2005). Lurkers limit their participation to passively observing, rather than actively participating in community discussions (Demiris, 2006).

Tacit Knowledge: Personal, context-specific knowledge, rooted in action and experience that is difficult to formalize and communicate (Rynes & Bartunek, 2001). It is knowledge that is shared via stories, anecdotes, metaphors, personal reflections, and communication (Sandars & Heller, 2006).

"Virtual Communities of Practice (VCoP): Rely primarily on ICT to connect members of a CoP and may use a large array of traditional media (phone teleconference, fax, etc.) and more or less sophisticated technological tools to establish a common virtual collaborative space (Demiris, 2006; Dube et al., 2006).

Virtual Corporations

Sixto Jesús Arjonilla-Domínguez
Freescale Semiconductor, Inc., Spain

José Aurelio Medina-Garrido
Cadiz University, Spain

INTRODUCTION

At the end of the 20th century, many authors tried to predict what new structures companies would be likely to adopt in the 21st century. Now, in the 21st century a clear tendency is emerging: the virtual organization (Agrawal & Hurriyet, 2004; Alsop, 2003; Bekkers, 2003; Camarinha-Matos & Afsarmanesh, 2005; Heneman & Greenberger, 2002; Lee, Cheung, Lau, & Choy, 2003; Talukder, 2003; Vakola & Wilson, 2004). This type of organization offers the most promising response to an increasingly complex business reality. In this respect, current organization theory is beginning to change its focus to new, flexible, and virtual organizational forms.

This article is organized as follows: The background section defines different concepts of virtual organization. The first model equates the virtual corporation to a temporary network of firms that quickly comes together to exploit temporary market opportunities. The second model focuses on the manufacture of virtual products by means of stable and trusting relationships with suppliers and customers. The third model of virtual corporation tries to turn the fixed workforce costs into variable costs. The third section points out the shared characteristics of this type of organization and the role of the manufacturing function, information and information technology, the network structure, and a new type of worker. The final sections discuss future trends and our conclusions.

BACKGROUND

The term *virtual corporation* was coined by Jan Hopland, an executive at Digital Equipment Corporation at the end of the 1980s, to describe firms that can marshal more resources than they actually possess by means of both internal and external collaborations (Fitzpatrick & Burke, 2001; Weisenfeld, Fisscher, Pearson, & Brockhoff, 2001). The term can be traced to the computing concept of *virtual memory*, which describes how a computer can behave as if it had much more processing power than it really has.

The expression virtual corporation has been used in the literature to refer to concepts ranging from simply using teleworking and outsourcing intensively (Buhman, 2003; Coates, 2005; Matthews, 2004) to the wholesale restructuring of the firm. However, three approaches predominate in the literature: (1) virtual corporation as a temporary network of firms that rapidly forms to exploit temporary opportunities appearing in the market (Alsop, 2003; Beckett, 2003; Chalmeta & Grangel, 2003); (2) virtual corporation as a firm that produces virtual products, and which develops strong and stable links with its suppliers and customers (Biondi, Bonfatti, Monari, Giannini, & Monti, 2003; Lee et al., 2003; Mo & Zhou, 2003); and (3) a final model which considers that the virtual firm is an organization whose costs are essentially variable, only being generated when the firm is sure that it will recover them by selling the product or service (Matthews, 2004; Talukder, 2003).

The virtual corporation can also be defined by what it is not. The virtual corporation is not a takeover or merger between firms, nor is it a temporary employment agency, nor a "hollow" firm seeking to cut costs by closing down factories in one country and opening them up again in another one with lower labor costs.

CHARACTERISTICS OF VIRTUAL CORPORATIONS

As we mentioned in the previous section, there are three different perspectives of the concept of virtual corporation. Among the characteristics shared by these three models of virtual corporation, we would stress: excellence, technology, trust, opportunism, and absence of borders:

- **Excellence:** Since each member contributes its core competencies (Mo & Zhou, 2003), it is possible to create an organization with the best of each of them, so that every process of the virtual corporation can be the best in its class, something that no one firm could achieve on its own.
- **Technology:** Information technology—and more specifically, communications networks—will facilitate the transfer of knowledge and technologies between firms and will allow firms and workers to work together (Helling, Blim, & O'Regan, 2005; Heneman

& Greenberger, 2002; Im, Yates, & Orlikowski, 2005; Kovacs & Paganelli, 2003).

- **Trust:** This type of relationship makes firms more dependent on others, and hence requires a much greater trust than would normally be the case between firms that are just partners (Camarinha-Matos & Afsarmanesh, 2003; Clases, Bachmann, & Wehner, 2003; Gallie & Guichard, 2005).
- **Opportunism:** In the first and third model, firms will come together to exploit a very specific market opportunity, disbanding as soon as the opportunity disappears. In the second model, the opportunity to form a virtual corporation is brief. Once a firm adopts a virtual corporation structure, other firms have less chance of doing the same.
- **Absence of Organizational Borders:** The close cooperative ties established between competitors, suppliers, and customers will make it difficult to see where one firm ends and another begins (Lee et al., 2003). This organizational structure shares the knowledge and resources needed to carry out the work to be done, regardless of which firm owns or manages them.

In virtual corporations the role of the manufacturing function also changes (Martinez, Fouletier, Park, & Favrel, 2001). This type of organizational structure seeks to generate high-quality products and services rapidly in response to the demand (Offodile & Abdel-Malek, 2002; Weisenfeld et al., 2001). Generating virtual products, also known as mass-customized products (Biondi et al., 2003), requires both the customers' participation in their conception and design and the firms' implementation of time-based strategies. This implies combining the customers and suppliers in a type of highly efficient network (Lee et al., 2003), which will require information systems that support relationships at all levels (Hsieh, Lin, & Chiu 2002). Companies will focus on one, maybe two, or three core competencies, all else will be outsourced (Buhman, 2003; Erickson, 2004; Mo & Zhou, 2003; Porter, 2000). Time is regarded as a component that, like any other, can be improved by means of intelligent planning and the use of technology (Hao, Shen, & Wang, 2005; Lee et al., 2003).

Mass customization of products combines the effects of lean manufacturing processes (Guisinger & Ghorashi, 2004), zero-inventory production methods, or just-in-time, and total quality management processes. These management processes make it possible to produce the great variety of products that could once only be made by craft manufacturing, but often at a lower cost than mass production, and with excellent quality.

Moreover, incorporating the new information technology into the manufacturing processes has given rise to *flexible manufacturing systems* (FMS) and *computer-integrated manufacturing* (CIM) (Presley, Sarkis, Barnett, & Liles, 2001). Such systems help manufacturers to achieve many of the objectives of the virtual corporation, such as shorter production cycles, a smaller and more qualified labor force, smaller batches, flexibility, a better short-term response, and long-term adaptability.

In virtual corporations, the role of information and information technology is also important (Aerts, Szirbik, & Goossenaerts, 2002; Alsop, 2003; Gallie & Guichard, 2005; Heneman & Greenberger, 2002; Joukhadar & Binstock, 2000; Khalil & Wang, 2002; Kovacs & Paganelli, 2003; Stowell, 2005; Xu, Wei, & Fan, 2002). This role becomes clear in the three models described previously. The virtual corporation understood as a network of firms is also an information system where there is an exchange of the data generated by the activities or processes (internal and external) that it carries out. The success of the virtual corporation will depend on its capacity to acquire, distribute, store, analyze, and integrate this massive flow of information through its organizational elements, supported by information technology.

The model of virtual corporation defined as a generator of virtual products is characterized by the customers' intense participation in the creation of the products, and by the high information component of the latter. This growing information component of products is evident in the mass customization of products that the virtual corporation is applying.

On the other hand, the virtual corporation is organized as a *network organization structure*. Firms have gone from competing against each other to cooperating. This cooperation was initially based on more or less temporary alliances, and subsequently on connections of variable geometry. This new organizational structure of variable geometry, or dynamic network structure, considers that the main components of firms can be assembled and reassembled again and again to adapt to the changing environmental conditions (Aerts et al., 2002; Huang, Gou, Liu, Li, & Xie, 2002). This network structure is accepted by all of the authors (Camarinha-Matos & Afsarmanesh, 2003, 2005; Weisenfeld et al., 2001), although they refer to it using different analogies and names. Where there is consensus is in the idea that the dynamic network is the most flexible organizational form known. Its main characteristics are: (1) disaggregation of the firm's functions (design and development, manufacturing, marketing, and distribution), now carried out by independent organizations in a network; (2) existence of internal and external agents, responsible for linking the business functions of different firms (Aerts et al., 2002; Zarour, Boufaida, Seinturier, & Estraillier, 2005); (3) existence of market mechanisms for coordinating the functions, rather than plans and controls (Biggs, 2000); and (4) existence of freely accessible information systems for verifying each member's contribution (Zarour et al., 2005), rather than the slow processes of mutual trust building.

The virtual corporation is founded on a *new type of worker*. This organizational structure is based on the management of processes, demanding a flexible number of versatile and autonomous human resources. Thus, a radical change in corporate culture is required for the concept of virtual corporation to work. This culture will be reflected throughout the entire organization, requiring new management skills (Heneman & Greenberger, 2002; Khalil & Wang, 2002)—focusing on how to lead "persons" and manage "relationships" (Beranek & Martz, 2005)—and a new type of worker.

With regards to human resource management, the emphasis is on retaining highly qualified workers in this type of organization (Erickson, 2004), and there is significant rotation of workers between the different functions and divisions of the firm. These workers turn the firm into a learning organization.

Agile Web Inc. is an example of virtual corporation. It is made up of 20 successful small and medium-sized manufacturing enterprises in north-eastern Pennsylvania. The aim of this project was that small firms could become more competitive, more productive, and provide a greater value-added service to their customers by working together in new ways to provide totally integrated solutions. This virtual corporation has the ability to knit companies together in the right configuration to achieve each task with speed and efficiency. Agile Web Inc. acts as a single point of contact that directs all the aspects of multi-phase design and production projects, ever changing to meet the customer's needs and anticipating them. The member companies are able to communicate by e-mail and electronic data interchange (EDI) to ensure a quick response. Agile Web Inc. offers a totally integrated chain of suppliers with high flexibility by a sharing of needed information rather than within a traditional hierarchical structure. The company's mission is to provide customers with solutions at the lowest possible price, with the fastest delivery time and highest technical performance. This example of virtual corporation illustrates the above mentioned roles of the manufacturing function, information, and information technology, and the network structure.

FUTURE TRENDS

It will be many years before we see the first real virtual corporation. There is no empirical evidence that fully supports this theoretical model, but there is growing interest in the model in the literature, as well as among firms. This model never gained widespread acceptance because the technology needed to integrate companies with their suppliers and customers did not exist. Now, the technology exists and companies are beginning to revisit the virtual corporation concept (Joukhadar & Binstock, 2000). Thus, for example Hector Ruiz (personal communication, January 24, 1997), after being named executive president of Motorola's semiconductor sector, wrote in an internal memo that organizations like his were becoming increasingly virtual. This trend is recognized by the Electronics Manufacturing Service Industry (EMSI), which detects a shift towards the virtual corporation in companies as important as Apple, Cisco, Bay Networks, and HP.

From the academic perspective, important lines of research are opening up. On the one hand, researchers could investigate which of the three models of virtual corporation described previously is most likely to be adopted by firms in the future. Another line of research would be to design an approach integrating the three models. Finally, it would be interesting to analyze the virtual corporation model from the perspective of the most consolidated theories of the firm (transaction cost economics, institutional theory, agency theory, options theory, population ecology theory, resource-based view of the firm, network theory, sociological theory, etc.). Analyzing the virtual corporation phenomenon with each of these theories would allow us to increase understanding of the phenomenon, its impact on firms and society, and future trends.

CONCLUSION

The new knowledge-based economy requires flexibility, new organizational structures, and managerial processes—based more on information than on hierarchy. Firms need to encourage self-learning, adapt to and exploit rapid technological change, and use their core competencies to differentiate themselves from their competitors.

The characteristics described previously are reflected in the different models of virtual corporation discussed in this article. The first model equates the virtual corporation to a temporary network of firms that quickly comes together to exploit temporary market opportunities, using the best resources and capabilities of each firm. The second model focuses on the manufacture of virtual products—which vary according to customer needs—by means of stable and trusting relationships with suppliers and customers. The third model of virtual corporation tries to turn the fixed workforce costs into variable costs, which are only incurred when the market demands the product or service.

This article outlines both the basic characteristics that define the virtual corporation—excellence, technology, trust, opportunism, and absence of borders—and other elements that, while they are not exclusive to virtual corporations, must always be present to make them possible. This is the case of the set of technologies making up the so-called lean manufacturing, of information and information technology, of the new type of worker, and of the organizational structures of variable geometry or dynamic networks.

Nevertheless, all authors coincide in noting that we have not yet seen the pure virtual corporation defined in the

theoretical literature. At present it remains just an important trend towards which many firms are gradually orienting their management and organizational structure.

KEY TERMS

Information Component of Products: All that the buyer needs to know to obtain and use the product, and hence achieve the desired result (information about product characteristics, instructions for use, and maintenance).

Knowledge-Based Economy: An economy characterized by the recognition of knowledge as a source of competitiveness; the increasing importance of science, research, technology, and innovation in knowledge creation; and the use of computers and the Internet to generate, share, and apply knowledge.

Lean Manufacturing: "A philosophy of production that emphasizes the minimization of the amount of all the resources (including time) used in the various activities of the enterprise" (APICS Dictionary).

Strategic Network: Agreements by which firms establish a web of close, stable relationships to provide products and services in a coordinated and flexible way.

Teleworking: Professional activity that takes place in a firm and that is independent of the firm's physical location. The person who does this work at a distance—the teleworker—keeps in contact with the firm using information technology.

Variable Cost Virtual Corporation: These firms turn fixed personnel costs into variable costs. They make use of freelance teleworkers, who can be called in or sent home at the employer's convenience, and outsourcing (Coates, 2005).

Variable Geometry Structure: Dynamic network of firms whose main components can be assembled and reassembled again and again to adapt to the complex and changing environmental conditions.

Virtual Corporation as Temporary Network: Set of firms that come together quickly to exploit temporary opportunities appearing in the market, using each firm's best resources and capabilities.

Virtual Corporation that Manufactures Virtual Products: Stable and trusting relationships with suppliers and customers to manufacture products that adapt to each customer's changing needs.

Virtual Product: A product that adapts to the customer's changing needs.

Virtual Organization

Seattle University, USA

INTRODUCTION

Virtual organization has been well documented as both a tool for organizations to seek further profitability through the removal of traditional barriers, as well as a method to extend the provision of services to clientele in a manner previously achievable by only large, multinational corporations (Markus 2000). The widespread implementation of information technology and its many applications in modern business has moved the act of management towards a virtual focus, where managers are able to complete tasks through the use of teams in varying physical locations, with members that may or may not be employees of that firm, sharing a wide variety of data and information. With so many companies now employing virtual organization techniques, referring to a company as "virtual" or to its components as possessing "virtuality" lacks the clarity and specificity needed when using these firms as examples for others. The variety of methods through which a firm can achieve virtuality represents a span nearly as wide as the business community itself.

BACKGROUND

The earliest definitions of a virtual organization appeared when the concept of *virtuality* was applied to studies of management, before information technology existed in a refined state to support the theory. Giuliano (1982) saw that with the addition of telecommunications and networking technology, there was little need for work teams to assemble at the same time or even at a contiguous location. A structured concept of virtual organization was formed by Mowshowitz (1994, 2002), who defined virtual organization in previous work as a group of employees communicating and being managed electronically through *metamanagement.* This concept defines the way in which a *virtual task* is managed and further categorizes a virtual organization as a series of virtual tasks, completed by virtual teams in strategic global locations. As each team has a certain commitment to the parent organization, the similarity in purpose and communication style allows for clear distribution of work across multiple groups of organizational members.

As with Net-enabled organizations, the concept of virtual organizations has gained prominence among researchers and practitioners. As shown by the recent work of Schultze and Orlikowski (2001), virtuality can be understood through the perception of time and space. This article extends the scope of the virtual organization in terms of 'virtual space', a metaphor used in *time* and *space* (beyond the constraints of the actual location we belong to) dimensions (Allcorn, 1997). As opposed to the virtual organization, time and space dimensions are constrained in traditional or 'real' organizations. Time constraints occur in real organizations due to the operational time dimension of such organizations, while space dimension occurs due to constraints of location.

It is true that a virtual organization inherits the attributes of virtual dimensions—a newly defined concept of time and space. In other words, a virtual organization does not exist in our time and space, but rather exists only in virtual space (the perceptual world), which is only a metaphor of our consciousness and not reality. A virtual organization, in this sense, is the metaphor of our designed and structured consciousnesses that exists in virtual space to perform the intended actions of interest. However, the most important thing in a virtual organization is to identify the role of human actors who get involved in both the physical and the perceptual world (Orlikowski, 2002). I attempt to explain the relationships between the human actors, the real and virtual organizations, and our perceptions of these concepts.

DUALITY OF HUMAN MINDS

Metaphors play a very powerful role in structuring virtual organizations, because terms like 'virtual' and 'virtuality' originate from symbolic languages (Faucheux, 1997). These metaphors provide the meaning of existence, thus we can treat the organization like a real organization in virtual space. Continuous analogical processes between virtual and real organizations explain the existence of virtual organizations because there exist similarities and discrepancies in them (Ahuja & Carley, 1999). A virtual organization, operating within virtual space imagery, exists in our consciousness, while an actual organization physically exists in various

forms (more tangible or definable manner) such as culture, politics, resources, and so forth (Morgan, 1986). Although a virtual organization exists in our consciousness, it is associated with its physical counterpart in the 'real' world such as a parallel virtual organization and bureaucratic hierarchical organization counterpart (Allcorn, 1997). However, there is a possibility that a 'real' organization will exist only when its virtual counterpart exists in the human mind. Mowshowitz (1994, 2002) described this as 'a dominant paradigm' of virtual organization due to its unique advantages in the efficiency, cost, and effectiveness of goal-oriented activity. Surprisingly, human minds streamline these two opposing ideas of real and virtual worlds—thus, it becomes obvious that humans possess duality of existence in both the real and the virtual world.

This article discloses the social aspects of a virtual organization and identifies the role of human actors in a virtual organization (or 'consciousness' in Faucheux, 1997). This consciousness exists in the perceptual world that we create beyond the limits of time and space (Allcorn, 1997). However, its counterparts exist in various forms (entities) in the real world. To bridge the gaps between the consciousnesses and the entities, there exists a need for human interveners who possess dual identities in both virtual and real worlds. This research provides the meaning of virtual organization, and proceeds to explain the relationship between the consciousnesses (virtual organizations) and entities (real organizations) with human intervention (human actors).

Schultze and Orlikowski (2001) examine rhetorical oppositions between real organizations and virtual organizations, and in doing so apply metaphors to the discourse. The visions or views of two opposing elements are not divergent or dichotomous; rather, they offer substitutes for the opposition through a process referred to as dualism. As Orlikowski (1991) proposed in her earlier paper, "The Duality of Technology," this dualism is not mutually exclusive. The dualism originated from the work by Giddens (1984) in *The Constitution of Society.* Giddens's (1984) structuration theory integrated two main streams of sociology—objectivism and subjectivism. It appears that the structuration theory adopts the notion of phenomenology, as it seeks to make explicit the implicit structure and meaning in human experiences (Sanders, 1982). Phenomenology searches for the essence of what an experience *essentially is* and is the intentional analysis between objective appearance and subjective apprehension. Structuration theory (the process of structuration of an organization) seeks a complementary essence in the structure of organization science and in the process of struggles between objectivism and subjectivism. Interestingly, the conflict of objectivism and subjectivism was reflected in metaphors, as Lakoff and Johnson (1980, pp. 189) stated:

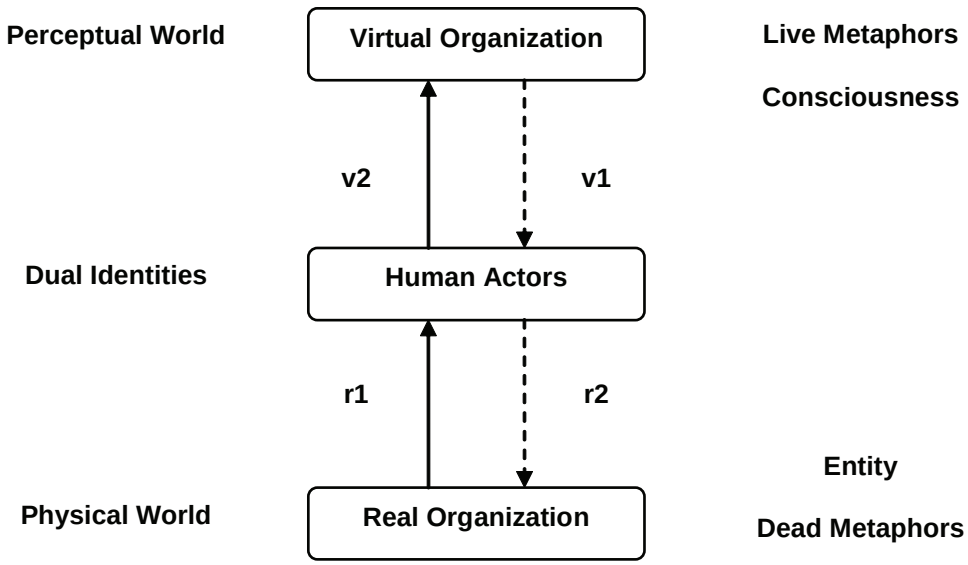
"Objectivism and subjectivism need each other in order to exist. Each defines itself in opposition to the other and sees the other as the enemy. Objectivism takes as its allies: scientific truth, rationality, precision, fairness, and impartiality. Subjectivism takes as its allies: the emotions, intuitive insight, imagination, humaneness, art, and a 'higher' truth…They coexist, but in separate domains. Each of us has a realm in his life where it is appropriate to be objective and a realm where it is appropriate to be subjective."

Human actors have very important roles in both phenomenology and metaphors due to their valuable experience. The key differentiator between objectivism and subjectivism is always human experience. Another important fact (usually overlooked by researchers) is that the use of metaphors appears in both the physical world and in the perceptual world (Harrington, 1991) because the terminology 'organization' itself results from *dead* metaphors. Tsoukas (1991) describes the process in which metaphors "have become so familiar and so habitual that we have ceased to be aware of their metaphorical nature and use them as literal terms." It implies that the metaphors of virtual organizations are *live* metaphors (Tsoukas, 1991), "knowing that these words are substitutes for literal utterances" that use dead metaphors (organization per se). Therefore, live metaphors are used to describe virtual organizations in another dimension where we can do things that are not possible in the real world because the virtual world operates without the constraints of time and space, unlike the real world.

The process of structuration involves the reciprocal interaction of human actors and institutional properties of organizations (Giddens, 1984); as Orlikowski (1991) pointed out, "The theory of structuration recognizes that human actions are enabled and constrained by structures, yet these structures are the result of previous actions." Because we live in both real and virtual worlds, we have both objective and subjective understandings of each world—dual identities. Figure 1 shows the relationship between real organizations and virtual organizations in the presence of human interveners. Both real and virtual organizations consist of rule resource sets that are implicated in their institutional articulation, thus these rule resource sets act as structures of the organizations (both virtual and real), where a structure is the medium and the outcome of organizational conduct. The structural properties do not exist outside of the actions of the organizational actors. Therefore, structural properties, related to space and time, are implicated in the production and reproduction of the organizations. In other words, both real and virtual organizations undergo structuration across the different sets of dimensions of time and space based on the perspectives of each human player.

The model in Figure 1, which is adopted from the duality of technology of Orlikowski (1991), depicts four processes that

Figure 1. Dual identities of human actors in both real and virtual organizations



operate continuously and simultaneously in the interaction between human actors and both real and virtual organizations. These processes include: (i) institutional properties, represented by arrow r1 (objective appearance of the real organization) and arrow v1 (objective appearance of the virtual organization), which are the *medium* of human actors; (ii) structures, represented by arrow r2 (subjective construction of the real organization) and arrow v2 (subjective construction of the real organization), which are the *product* of human actors; (iii) the interaction of human actors in both worlds, and the resultant influences on the social contexts of the real organization within which it is built and used (the direction of arrow r1 and v2); and (iv) how the virtual organization is built and used within particular social contexts in a real organization (the direction of arrow v1 and r2).

In Figure 1, there are two structurations from human actors, one for the real organization and the other for the virtual organization. The realms of virtual organization and real organization are objective, while the consciousness of the human player is subjective. The process of structuration (Figure 1) involves the reciprocal interaction of human actors and institutional properties of organizations (Giddens, 1984); as Orlikowski (1991) pointed out, "The theory of structuration recognizes that human actions are enabled and constrained by structures, yet these structures are the result of previous actions." We have both objective and subjective understandings of each world (dual identities) because we live in both real and virtual worlds.

The maturity phase of the real organization (with its established tradition) and the fledgling state of the virtual organization (with its newly emerging phenomena) indicate that the objective appearance of the real organization (arrow r1) and subjective construction of the real organization (arrow v2) dominate the structuration process in modern organizations. Many observations show that the knowledge and experiences accumulated in real organization enforce the formulation of the virtual organization in the abstraction process of efficient and effective goal-oriented activity (Mowshowitz, 1994). It is partly true that the creation of the virtual organization is only for the representation of the real organization in virtual space. A considerable amount of explanation arises from rethinking the basic assumptions of time and space. The real organization, whether tangible or intangible, is bound in time and space, while the virtual organization, an imaginative concept established in computer hardware and software, is free from the constraints of time and space.

Barley and Tolbert (1997) defined an institution as "shared rules and typifications that identify categories of social actors and their appropriate activities or relationships." As they explained their recursive model (institutions and actions), institutionalization involves the behavior of revision or replication of organizational abstracts (work procedures), and entails objectification and externalization of behaviors. In this sense, the successful functioning of a virtual organization is reaching institutionalization in virtual space. Through this process, the virtual organization becomes stable and helps serve as the constitution where human actors can follow their activities. Upon further inference, institutions from business processes of real organizations constrain human

actors (constitutive nature, r1), who in turn construct institutions of virtual organization (constituted role, v2) and/or vice versa (from v1 to r2).

The above arguments provide complementary insights to the social process explained by the structuration theory (Giddens 1984). In this theory, actions and institutions continuously interact, thereby determining the structure. The structuration theory lacks the explanation of how these interactions (revising and reproducing an institution or structure) are processed, although this is arguable as Giddens explains the role of reflection, interaction, and so forth. However, Barley and Tolbert (1997) clearly stated that their work, 'the aim of institutional theory', is "to develop the implications of structuration theory for the interplay between actions and institutions and to address the practical problem of how to study institutional maintenance and change in organizations."

The results of this study are compatible with the belief of Barley and Tolbert (1997) that "the institutional perspective must come to grips with institutionalization as a process if it is to fulfill its promise in organization studies." The focus of this study is the explanation of: "What is going on at a virtual organization?" The result revealed by this research is a rich description of theoretical induction. A limitation of this process is that it only reflects one part of the recursive model of institutional theory (Barley & Tolbert, 1997).

FUTURE TRENDS

Organizations today are usually faced with a turbulent environment that requires flexible and dynamic responses to changing business needs. Many organizations have responded by adopting decentralized, team-based, and distributed structures. Advances in communication technologies have enabled organizations to acquire and retain such distributed structures by supporting coordination among people working from different locations (Ahuja & Carley, 1998). Thus, virtuality comes from important roles to achieve above goals of current business environments. Conceptually, virtual organization can be seen as "emptying of organization," where emptying of information and knowledge has occurred in current communication technology (Giddens, 1984, 1990). IT (or information systems) generates and stores information that helps in the emptying (separation) of information from organizations. Knowledge, a supposedly higher format of information, is managed by knowledge management systems (KMSs), further evidence of the emptying of knowledge from organizations. Because data, information, and knowledge of organizations are emptying from their organizations (i.e., can be stored and manipulated in information systems), the separation of the organization from its four-dimensional entity **(**time factor and three location factors—latitude, longitude, altitude**)** can be achieved in the form of virtual organization (Giddens, 1984, 1990) if the rest of the components of the organization are implemented in network.

The e-business model has been widely accepted by modern business organizations. Some companies initiated this model hoping to reduce transaction costs; others are running it for its future value. Many cases show that e-business is now a necessity because Internet technology revolutionized communications. Only a few years ago many researchers and practitioners perceived e-business as an extension of conventional business practices for doing business at a lower cost. However, Internet technology changed our lifestyles and affected the way of doing business (Chudoba, Wynn, & Watson-Manheim, 2005). The e-business model is no longer a short-term strategy; it needs a thorough and systematic investigation with the foundation of virtual organization concept as discussed in Kaplan and Norton (2006).

Virtual organization incorporates all the revolutionary practices in the global network (e.g., e-business, e-commerce, virtual community, virtual company, etc.) and provides a unique opportunity for society. The foremost contribution of this study is to provide a new vision of the future organization. IT is not simply a technological product of communication networks, rather it is a vehicle whereby 'virtualization' occurs in ways to reconstruct what has been eliminated from the traditional socialization process. Virtual organization is established mainly to achieve the shared goal of participants or to take advantage of the availability of advanced IT and communication networks. When social mechanisms are developed in virtual organization, it flourishes as an entity with its own norms, culture, and SOP. As IT is integrated further into virtual organization to manage conflict and encourage cooperation, it grows into a complete organization (McKinney & Whiteside, 2006). IT becomes extended linkages among members with which they simulate frank communication and open consideration of different alternatives and opinions. The proactive members seek a productive discussion and creative thinking.

CONCLUSION

The approach of this article is that organizational transformation is "the ongoing practices of organizational actors, and emerges out of their (tacit and not so tacit) accommodations to and experiments with the everyday contingencies, breakdowns, exceptions, opportunities, and unintended consequences that they encounter" (Orlikowski, 1996). The above statement is identical to the theoretical framework of this article in that users of the system continuously interact with the system through producing, reproducing, and transforming work practices (Giddens, 1984).

The goal-oriented depiction of a virtual organization (Mowshowitz, 1997) is limited on a computer with a communication tool or computer network that increases the

efficiency and effectiveness of organization performance (Mowshowitz, 1994). This article complements the virtual organization as a social system giving the new meanings of time and space (Maznevski & Chudoba, 2000; Orlikowski & Yates, 2002). This study rethinks the philosophy of virtual organization, providing insight into the concept of duality of human identity. It is not only a lens for understanding virtual organizations, but also a socio-technical understanding of virtual organizations through structuration.

KEY TERMS

Collaborative Culture: By their nature, virtual organizations foster camaraderie between members even in the absence of face-to-face communications. Since the built-in communications tools are so easy to access and use, relationships form between members who have not even met. A corporate culture forms out of friendship that produces a highly collaborative nature, unlike traditional organizations where such extensive communicating is not required.

Complementary Core Competencies/Pooling of Resources: The ease with which two members of a virtual organization can communicate allows them to pool their resources, even with members not directly involved in a specific project. Separate entities can quickly be called upon to provide secondary service or consult on a project via virtual channels.

Customer-Based/Customized Products: A virtual organization provides the unique opportunity to provide their customers with highly specialized products as per their specific needs. This can be accomplished through outsourcing work to a separate organization or through the use of a virtually connected interorganizational node located closer to the customer. Either way, it becomes simple to add a function based on the customer's request and seamlessly integrate that function into the existing framework.

Electronic Communication: A vital concept to the virtual organization is the ability to communicate through purely electronic means, eliminating the need for physical contact and allowing the geographical dispersion of organization members. Online collaboration via e-mail, discussion boards, chat, and other methods, as well as telephone and facsimile communications, are primary contributors to the removal of time and space in this new organizational concept.

Explicit Goals: Similar to meta-management, each member of the organization is charged with an explicit task to complete as it relates to the overall function of the organization. Often times, after this single goal is completed, the link between the organization and the entity is dissolved until a further need for it is realized. At this point, the link is reestablished.

Flexibility: Virtual organizations are, by their nature, flexible. Traditional organizational structures are rooted in the physical world and rely on structures, unalterable networks, and specific locations to function properly. Because of this, when it becomes necessary to introduce change into a specific organization, a barrier is reached where further alteration requires physical, costly modifications. A virtual organization is unhindered by these problems. These structures are designed so that they can operate regardless of time or place, independent of existing physical realities.

Functional or Cultural Diversity: The nature of global diversity and the ability to locate organizational functions across the globe creates a diverse environment for the entire organization. Since members are all in different locations and charged with different tasks, diversity exists that is only found in the very largest multinational corporations.

Geographical Dispersion: The combination of virtual organization with IT allows groups of employees to make progress on one project while working in tandem with another group in a distant physical location. Because information can be shared and meetings can be held with the use of high-speed networks and computers, tasks can be carried out in the location that is most appropriate and germane to that function.

Information Technology (IT): The crucial component of a modern virtual organization. Without advances in technology, many of the realities of today's virtual companies would be merely science fiction. These components include the Internet, LAN and WAN networks for business, e-mail and online chat/bulletin boards, and real-time videoconferencing. These technologies allow smaller workgroups as part of a larger company to operate independently of each other, across a room or the globe.

Open Communication: The foundation of a virtual organization is its set of communications components that exist in absence of face-to-face exchanges. A virtual organization can only survive if its members communicate freely through the provided channels between them, be they based on the Internet or more traditional telephone technologies. The organization cannot continue to function unless it is aware of what all its members are currently completing, and often times, when communication is more closed, work that is being completed in tandem by more than one member can be hindered or brought to a halt.

Participant Equality: Each individual facet of a virtual organization is expected to contribute an equal amount of work towards a given goal, if appropriate. While the equality may not be measured best in quantity, it can be restated as effort and the successful completion of all tasks assigned to it, be they large or small. Since every task is considered to be essential as a part of the project, the equality comes in the addition of that piece to a larger puzzle.

Sharing of Knowledge: Members of a virtual organization collaborate to share their knowledge gained from individual activities performed. Since collaboration is facilitated through the communications channels that are afforded through the virtual organization, it is common to find "knowledge bases" or other database systems that contain information and documents pertaining to past experience.

Switching: The switching principle is a fundamental advantage that a virtual organization has over a traditional one. Because the links between organizational functions are largely electronic and non-physical, it is easy to replace a weak component with a stronger one. Where this activity could be considerably expensive if the item in question was a physical supply chain, it may only be a change of suppliers for the virtual organization and can be made with a phone call and database edit, as opposed to a building project.

Temporary: Virtual organizations are often formed to fill temporary needs, only extending to the end of the specific project that is charged to them. In a manufacturing project, a virtual organization may be formed between the engineers who design the project, the suppliers who provide the raw materials, and the factory who processes those into finished goods. At the end of that particular project, those alliances are dissolved, as they are no longer necessary to benefit the three independent groups.

Trust: The lack of physical interaction places a higher regard on the trust that exists between each entity involved in the organization. Since fewer "checks and balances" can be placed on appropriate departments, management and other entities trust that they will complete the appropriate work on time or be straightforward about delays or problems. If two entities working on a project together separated by thousands of miles are unwilling to trust each other, the work slows and suffers to a critical point.

Vague/Fluid/Permeable Boundaries: As a continuation of flexibility, the virtual organization is characterized by vague boundaries as to the extent of its use and purpose. Since small tweaks can easily and largely affect the overall organization, it is quite possible to extend the boundaries of an organization so that they encompass new purpose, people, or control.

A Virtual Reality System for Learning Science in a Science Center

Sharlene Anthony
Singapore Science Centre, Singapore

R. Subramaniam
Nanyang Technological University, Singapore

INTRODUCTION

Current trends in informal science learning tend to place more emphasis on science centers as tools to bridge the technological gap for their visitors (Salmi, 2003; Sandifer, 2003). In line with compelling evidence in the multimedia literature, which shows that technology-based environments do provide good instructional support for meeting learning needs (Kim, 2006; Lim, Nonis, & Hedberg, 2006), it would be useful to investigate the potential of technology-based exhibits at science centers to create new multisensory experiences for learning science topics in a way that is different from traditional methods of teaching. This can provide pointers for schools to see how such attractions can be used to assist or complement the formal science learning in schools.

The principal objective of this research is to investigate the effectiveness of technology-based exhibits in promoting affective learning outcomes among students of mixed ability visiting a science centre. The chosen exhibit is the CAVE (cave automated virtual environment), a supercomputer-based multimedia system.

BACKGROUND

The CAVE is basically a virtual reality system. Its genesis can be traced to the need to develop compact virtual reality systems that can overcome the inconvenience of using head-mounted display sets and the limitations of single-user interaction at a time, both of which have plagued earlier versions. The ideas of Thomas DeFanti and Don Sandin of the Electronic Visualization Laboratory at the University of Chicago, in 1991, provided the basis for the development of the first working model of the CAVE by Carolina Cruz-Neir in 1992 (Cruz-Neir, Sandin, DeFanti, Kenyon, & Hart, 1992; Defanti, Sandin, & Cruz-Neira, 1993).

Relying on the use of computer-generated graphics and multisensory digital data, the CAVE provided, for the first time, the relishing of virtual reality as immersive and interactive experiences for a group of people in a specialized setting. Soon, the scope for using the CAVE as a platform to simulate complex scientific phenomena, as well as for generating walkthroughs in a range of virtual environments, was recognized. Over the years, several applications have been modelled to exploit the unique features of the CAVE. Some of these include

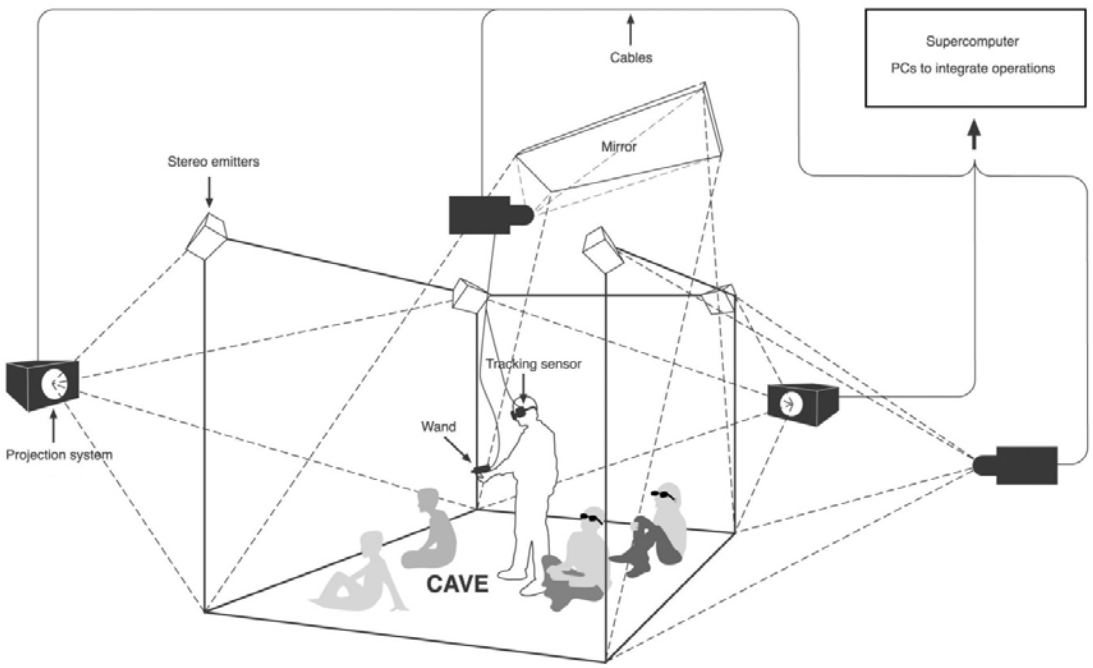
a. Exploration of a sprawling virtual plains inhabited by diverse vegetation (Moher, Johnsoon, Yongjoo, & Ya-Ju, 1999)
b. Collaborative construction, cultivation, and tending of a healthy virtual garden by young children (Roussos, Johnson, Leigh, Vaslakis, Barnes, & Moher, 1997)
c. In-depth probing of an ant, the inside of the Earth, an iceberg, a volcano, the solar system, and the human heart (Johnson, Moher, Ohlsson, & Gillingham, 1999)

The CAVE

This study focuses on the CAVE (Tan, Subramaniam, & Anthony, 2005) at the Singapore Science Centre. It is of interest to note that the only other CAVE to be set up outside a research laboratory in the world is the one at the National Museum of Emerging Science and Innovation in Miraikan, Japan.

Modelled as a cube of area 27 m^3, the CAVE comprises display screens mounted at right angles to the plane of image projection, acoustic speakers placed at the upper vertices to produce sonic effects, stereo emitters situated at the edges to ensure proper mapping between the frame rate and the configuration of the stereo glasses used by participants, tracking sensors on the stereo glasses used by the lead user to ensure that what the lead user sees is also what the participants wearing stereo glasses see, and a supercomputer (Silicon Graphics Onyx 2 Reality engine) to coordinate the overall operations. Navigating through the virtual environment is facilitated by the joystick on the wand held by the lead user,

Figure 1. Architectural elements of the CAVE



while the three buttons on the wand can be used to set off various acts of interactivity The stereo glasses used by the participants produce the 3-D effect, and this allows them to be immersed interactively in the virtual environment.

Figure 1 shows the principal elements of the CAVE.

CAVE Program on Water

The program that is the focus of this study is on the molecular structure of water. Appreciation of the following 3-D scenarios is made possible in the CAVE with this program:

- Coupling of two hydrogen atoms and one oxygen atom via covalent bonds to form a molecule of water; this exists as a 3-D structure in the space of the CAVE and can be "touched"!
- Motion of electrons going around the nucleus of the hydrogen and oxygen atoms; it is possible for participants to walk through into the interior of these atomic configurations and get a nuanced view from any perspective!
- Excursion into the interior of the crystal structure of ice.
- Clustering of H_2O molecules in various packing densities to form the three states of matter: ice, water, and vapour.

To enhance the reality of the immersive and interactive experience, suitable sound effects are produced when various modes of interactivity are triggered, and participants are also able to "touch" the 3-D images in the CAVE.

Samples for this Study

In the present study, all participants were from the Primary five level (Grade 5). One group was a class of 35 students (16 males and 19 females) from the EM1 stream. The second group comprised a class of 33 students (16 males and 17 females) from the EM2 stream, while the last group comprised 34 students (16 males and 18 females) from the EM3 stream. All three groups were from different schools,

and they were exposed to the CAVE experience on separate days. In terms of academic ability, EM1 > EM2 > EM3. The CAVE can accomodate about 10 persons at a time

EVALUATION INSTRUMENTATION

In order to test the efficacy of the CAVE programme offered on water, an evaluation instrument was developed, validated, and piloted. Based on a five-point Likert-type scale, ranging from Strongly Agree (SA) to Strongly Disagree (SD), the final version of this instrument was used to measure the affective outcomes of the students' experience. The instrument took about 5 minutes for completion by the students.

RESULTS

Internal consistency of the evaluation instrument was obtained by extracting the Cronbach Alpha coefficient; the value of 0.91 is well above the recommended norm of 0.70, and thus indicates good reliability of the instrument developed. The Cronbach Alpha coefficients for the subscales are as follows: 0.86 for Educational Potential sub-scale, 0.77 for the Effectiveness of Learning subscale, and 0.70 for Learning Climate sub-scale. The overall means for the individual statements are presented in Table 1.

The highest overall mean score for the entire survey was found among the EM3 males ($\underline{M}$ = 67.87, $\underline{SD}$ = 4.69), while the lowest mean score was found among the EM1 males ($\underline{M}$ = 59.75, $\underline{SD}$ = 14.67). The relevant descriptive statistics are shown in Table 2.

A one-way between groups analysis of variance was conducted to explore the impact of stream on the affective survey instrument. Equal variance was assumed (Levene's test $p>.05$). There was no significant difference found between the streams at the $p<.05$ level [$F(2, 99) = 1.57$, $p=.21$].

An independent-samples t-test was conducted to compare the affective survey scores for males and females. Equal variance was assumed (Levene's test $p>.05$). There was no significant difference in scores for males ($\underline{M}$ = 63.71, $\underline{SD}$ = 10.19) and females [($\underline{M}$ = 62.72, $\underline{SD}$ = 11.65); $t(100)=0.45$, $p=0.65$]. The magnitude of the differences in the means was very small (eta squared = 0.002).

The mean scores for each individual statement were compared using an independent-samples t-test to investigate the effect of gender. Equal variance was again assumed (Levene's test $p>.05$) for all statements except for Statement 10 (*The guide who led the CAVE presentation facilitated effectively my learning*). There was no statistically significant difference found between the mean scores of the individual statements in the affective survey for males and females.

DISCUSSION

This study builds on the notion that technology, used appropriately, can enhance learning and be a vital element for the education system (Cohen, 2001). Specifically, the use of technology-based exhibits in science centers can provide instructional support to enhance students' visual-spatial thinking, a key component that is much neglected in boosting scientific creativity and communication in science education (Mathewson, 1996), especially in the formal school environment. It further builds on growing evidence that science centers, by their very nature, can provide an environment conducive for inculcating an interest in science and providing the formal learning system with a much needed avenue to broaden and spark interest in science among their students through the use of technology-rich environments.

The CAVE uses high quality visualizations, immersive experiences, interactivity, and stereoscopic imagery to provide a unique virtual environment that is conducive for learning. This contrasts sharply from the first few attempts at virtual reality systems, which were fragile and required the use of head-mounted display sets to showcase the visualization of learning scenarios (Teitel, 1990) and that allowed only single users at any one time. The CAVE afforded, for the first time, a generational advance in immersive and participatory experiences for a group of people at the same time. The more rugged and robust CAVE provides a quantum leap in virtual reality technology (Cruz-Neira, et al., 1992; DeFanti, et al., 1993).

Virtual reality technology has been noted to provide a plethora of benefits. Pantelidis (1997) (as cited in Bakas & Mikropoulos, 2003) highlights that virtual reality can be motivating, has the capacity to depict various processes more accurately, allows objects to be appreciated via multidimensional perspectives spanning the micro to the macro domains, provides instructional support for topics that are rather risky or time-consuming to teach, and promotes active participation.

However there remain many obstacles in the implementation of such advanced technologies in schools. Johnson et al. (Johnson, Moher, Cho, Lin, Hass, & Kim, 2002), list a few of such factors: "insufficient resources to support teaching practices constrained by conventional school organization; lack of alignment between technology-based materials and school curriculum/performance goals; lack of authentically motivated teacher preparation and training offered; lack of time for teachers to pursue additional training; insufficient technical support both for maintaining and upgrading hardware and software systems and for providing assistance on the operation and capabilities of applications software; and failure to provide specific mechanisms for assessing the pace

Table 1. Overall means and standard deviations for the statements in the evaluation instrument

S/n	Statement	Overall Mean (SD)
	Learning Climate	
1	The CAVE makes learning fun and interesting	4.42 (0.88)
2	The design of the CAVE is appropriate for learning	4.08 (1.13)
3	The amount of material used in the multimedia presentation in the CAVE was just right	4.60 (0.80)
4	The sequence of material shown in the multimedia presentation in the CAVE was logical and systematic	4.44 (1.0)
5	I liked the immersive environment in which the topic was taught	3.93 (1.16)
	Effectiveness of Learning	
6	The use of multimedia technology in the CAVE helped to illustrate concepts in a way that facilitated my understanding	4.13 (1.19)
7	I learnt more about the structure of water from the CAVE than from my text book	3.87 (1.20)
8	The CAVE builds on my knowledge of water learnt from text books and in the classroom	4.44 (0.79)
9	The interactive environment in which the topic of water was explored in the CAVE contributed to greater learning	3.98 (1.22)
10	The guide who led the CAVE presentation facilitated effectively my learning	4.05 (1.22)
	Educational Potential	4.41 (1.12)
11	The CAVE is a good teaching tool to learn science	
12	I would like to learn other science topics through the CAVE	4.29 (1.22)
13	The CAVE is an exciting media for learning	4.11 (1.27)
14	The use of technology in the CAVE increased my motivation to learn	4.10 (1.17)
15	Because of the way information is presented in the CAVE, I understand the topic of water better	4.32 (0.83)

Table 2. Overall means and standard deviations of the evaluation instrument by stream and gender

Groups	Total Mean (SD)
EM1 Males (N=16)	59.75 (14.67)
EM1 Females (N=19)	61.53 (11.39)
All EM1 (N=35)	60.71 (12.82)
EM2 Males (N=16)	63.50 (7.27)
EM2 Females (N=17)	63.76 (8.36)
All EM2 (N=33)	63.64 (7.73)
EM3 Males (N=16)	67.87 (4.69)
EM3 Females (N=18)	63.00 (14.74)
All EM3 (N=34)	65.29 (11.31)
All Males (N=48)	63.71 (10.19)
All Females (N=54	62.72 (11.65)
Overall (N=102)	63.19 (10.95)

and effectiveness of technology integration with respect to student learning and school climate."

The siting of the CAVE in a public access setting, such as a science centre, can help to realize the educational benefits of virtual reality technology by reaching out to a large student population through field trips that complement the school science syllabus and thus, providing a novel and exciting medium for students to learn..

Gender

Although evidence exists in support for and against the existence of the so-called gender gap in science between males and females, the difference seems to be mainly in attitudes towards science (Martin, Mullis, Gonzalez, Gregory, Smith, et al., 1999; Weinburgh, 1995), and not so apparent in achievement in science (Kotte, 1992). This trend follows through in Singapore, as reported in the Third International Mathematics and Science Study (TMSS) report. For Singapore, the results indicated that gender differences are less prominent in terms of achievement in science, but are more apparent in the attitude realm. In the 1995 and 1999 tests, Singapore was ranked third and second respectively among 14 countries (that teach science as a single subject). A very apparent point from the TMSS results was the existence of a wide gender gap in attitudes towards science, with males showing more positive attitudes towards science than females (Martin et al., 1999, p. 152).

Analysis of the effect of the CAVE experience, with respect to gender, showed no statistical difference in scores between males and females. However, the mean scores for males ($\underline{M}$ = 63.71, $\underline{SD}$ = 10.19), although not significant, were higher compared to the females ($\underline{M}$ = 62.72, $\underline{SD}$ = 11.65). There is a strong expression of interest by both groups of students in wanting to learn about other science topics through the CAVE; mean for Statement 12 in respect of this is 4.29. The CAVE is thus an exhibit that provides favourable affective outcomes for both males and females, and puts them on equal learning terms. Overall, the feedback was very positive on the use of the CAVE as a teaching tool, regardless of gender.

Academic Ability

A review of the literature has shown that academic ability (as determined by intelligence quotient, achievement test scores, academic performance, and teacher feedback) correlates significantly with science achievement (Neathery, 1997). In Singapore, a similar effect was observed among Secondary Three (Grade 9) students, with the above-average students outperforming the lower academic ability students in science achievement tests (Lim, 1986). The same study also found that academic ability was linked with attitudes towards science. Here, the higher ability students reported greater enjoyment in science, and placed the subject in a favourable position in society, as compared to those in the EM3 stream (Lim, 1986). According to Weinburgh (1995), there exists an interaction effect between academic ability and gender. The low to moderate ability males showed higher positive attitudes towards science than their female counterparts, while the high ability girls had more positive

attitudes than high-ability boys. On the other hand, females of both high and low abilities reported higher correlation between attitude and achievement than the males.

In the present study, there was no significant difference found between the various academic streams at the $p<.05$ level [$F(2, 99) = 1.57$, $p=.21$]. Although not statistically significant, the results actually showed that the lowest ability students EM3 ($\underline{M} = 65.29$, $\underline{SD} = 11.31$) had the highest total mean score in the affective survey, followed by the EM2 ($M = 63.64$, $SD = 7.73$), and finally the EM1 ($M = 60.72$, SD, 12.82) students. Perhaps this could be due to the higher ability students' (in this case, the EM1 students) preference for receiving information in a more traditional manner. No interaction effect between stream and gender was observed.

Overall, the experience was well received by the students. The use of high-resolution graphics, wide field view contributing to an enveloping experience, 3-D imagery, and special sound effects have proved to be a powerful combination for promoting learning. Whilst not their first experience with virtual reality, since virtual reality arcades and home PC-based virtual reality games are common in Singapore, the feeling of immersion is powerful, as is also the stereoscopic reality of the imagery. The virtual reality environment managed to generate a good deal of interest and excitement. The guided experience and ability to pause and take questions as they arise also puts the CAVE in a positive light.

All these provide the scaffolding necessary to entrench the concepts in the cognitive psyche of students to a reasonable extent. More importantly, the shared learning experience in the communal setting of the CAVE is a factor that has found support among students coming for such experiences. Teachers have also commented favourably on the realistic portrayal of the various processes and structures. Coupled with the visible interest and enthusiasm generated by their students during the CAVE session, the quantitative data collected on the CAVE, in this study, provides the necessary indication of its potential as an educational tool, and makes it easier to convince teachers of the direct and indirect benefits of an out-of-school trip to experience technology-based exhibits at a science center The role of the teacher in exposing students to new learning environments in order to make learning enjoyable is thus, of paramount significance (Barry & King, 1993; Lucas, 2000). In Singapore, it is the teacher who makes the decision on what out-of-school learning experiences their students are exposed to.

Clearly, the learning climate, the effectiveness of learning, and the educational potential of the CAVE are rated positively by the students in this study. This is not surprising, as the CAVE program on water was specifically developed as an application to complement this topic in the science curricula in schools in Singapore.

FUTURE TRENDS

The advent of the CAVE has made virtual reality applications in 3-D to be enjoyed by a good number of people at the same time, unlike the days of head mounted displays, when only one person can use it at a time. Since the CAVE uses a supercomputer, it is likely that it will be used mainly for high-end applications in universities, research institutes, and public access settings, such as museums and science centres. The wide field presentation permits scaling up of processes and phenomena, as well as navigation through these environments, to an extent hitherto not thought possible.

CONCLUSION

Science centers provide resources in the form of tools and facilities for teachers to make use of to engage their students. Teachers who turn to participatory science museums as a resource to supplement classroom learning will, no doubt, find that some learning does take place on the school trip (Falk, Koran, Jr., & Dierking, 1986; Wellington, 1990). In the case of attractions like the CAVE, which provide a novel learning environment in the form of 3-D, teachers can be assured that besides the fun and entertaining elements that are usually associated with such visits (Hofstein & Rosenfeld, 1996), some content learning is also transferred. The experience of the CAVE, if integrated with the classroom learning, can provide a holistic learning experience for students.

The results of this study provide further support for the successful use of virtual reality in science centres (Bell & Rabkin, 2002), and indicate that schools can capitalize on such technology-based attractions to promote learning for their students, since it permits realistic visualizations of complex phenomena on a variety of topics.

On the downside, often these attractions are expensive and beyond the reach of schools to own. In addition, the equipment requires regular maintenance and a dedicated technician to operate and troubleshoot.

As can be seen from this study, teachers can take advantage of the informal learning environment of a science center, where they are presented with more opportunities to build on their mutual relationship with students. Students, on the other hand, have an opportunity to gather information from sources other than their teachers, and in an environment that is novel. Science centres, on the other hand, would have played their part in promoting science, while stimulating interest in learning science concepts in a manner that is exciting.

KEY TERMS

3-D: An abbreviation for three dimensions.

CAVE: An abbreviation for **c**ave **a**utomated **v**irtual **e**nvironment.

Edutainment: A term formed by the fusion of education and entertainment, and used to denote experiences that are both educational and entertaining.

Multimedia: A term used to denote the combination of image, sound, and graphics.

Science Center: An institution for the popularization of science and technology.

Stereo Glasses: A kind of goggles that is necessary to see images on a screen in 3-D.

Supercomputer: A very powerful computer that can process large amounts of data at enormous speeds

Virtual Reality: A technology for creating interactive and immersive experiences in cyberspace.

Virtual Teams

Robert M. Verburg
Delft University of Technology, The Netherlands

INTRODUCTION

Global market developments and the large-scale use of diverse applications in the area of information and communication technology have been key factors in the emergence of distributed teams. Such teams are often referred to as virtual teams. Virtual teams enable collaboration between people across traditional boundaries and offer tremendous opportunities for various achievements. Businesses are no longer tied to a single time zone and are, for example, able to develop software around the 24-hour clock. The Internet as the almost universal medium for interaction across boundaries has created an infrastructure that enables many organizations to launch virtual teams. Hardly any technical obstacle for communication and collaboration across geographic boundaries remain as these processes are supported by high tech collaboration solutions, such as groupware and other collaborative applications (e.g., videoconferencing, electronic blackboards). Virtual teams have a number of opportunities that are not found with colocated teams, such as involving rare expertise.

For example, a group of eight scientists from different organizations rapidly developed a revolutionary rocket engine design by working under geographically dispersed conditions and without prior work relationships (Majchrzak, Rice, Malhotra, King & Ba, 2000). The complex and innovative design could not have been developed without the expertise of the eight highly specialized scientists. However, the design was not only a result from a careful combination of expertise but required a number of interdependent iterative "virtual" brainstorming sessions among the team of rocket scientists. All these activities were performed through a collaboration tool called "the Internet notebook" whereby the specialists spend no more than 15% of their time on the project.

As the example illustrates, virtual teams have the advantage of bringing people together without the obvious constraints with regard to travel time, workspace, and socialization. Virtual teams perform a variety of tasks and are also defined in various ways. Martins, Gilson, and Maynard (2004) have defined virtual teams as teams whose members use technology to varying degrees in working across locational, temporal, and relational boundaries to accomplish an interdependent task. Earlier definitions were focused more on making a distinction between virtual teams and conventional colocated teams, mostly based on geographic distribution and mediated communication. Virtual team research is focusing increasingly on real world virtual teams, which often have some virtualness characteristics, but only seldom resemble "pure forms". Therefore virtualness is now widely accepted as being dimensional in nature. More attention is also given to the fact that virtual teams are first and foremost teams, who are carrying out interdependent tasks under difficult circumstances.

BACKGROUND

Being virtual is a matter of degree and refers, according to various authors, to dimensions such as spatial distance, time, cultural diversity, temporality, organizational contract, and mode of interaction (DeSanctis, Staudenmayer & Wong, 1999; Jarvenpaa & Leidner, 1998; Mowshowitz, 1997). Mediated communication is an important dimension. Some teams meet regularly face-to-face, but may have also some e-mail-based interaction, while other teams interact intensively and almost exclusively via various media and sophisticated groupware tools. Geographic distance and different timeframes may obviously be important reasons for groups to communicate electronically.

"Virtuality" refers to the extent to which a group is geographically distributed (Bell & Kozlowski, 2002), and to the extent that team members rely on ICT mediated communication (Dubé & Paré, 2004). Proposed indicators or measures of virtuality are therefore the relation of face-to-face to non face-to-face communication, the average distance between the members, but also the number of working sites represented in the team together with the number of members at each site (see also Kirkman, Rosen, Tesluk & Gibson, 2004; O'Leary & Cummings, 2002). Teams that span large geographic distances between members, will likely encounter additional complicating factors such as cultural diversity, different organizational affiliation, and distribution of members over different time zones. Apart from the above factors, virtual teams are also often associated with shorter life cycles and low member stability.

A useful definition of a team (or work group) is a collection of individuals who see themselves and who are seen by others as a social entity, who are interdependent because of the tasks they perform as members of a group, who are embedded in one or more larger social systems (e.g., community, organization) and who perform tasks that affect others (Guzzo & Dickson, 1996). Although often not defined,

a number of implicit characteristics of conventional teams seem to include that members are often permanent employees of one organization, are often colocated and the main form of interaction consists of face-to-face contact.

Virtual teams may not seem to be crucially different from colocated teams. There are comparable levels of responsibility for adequately performing basic processes of groups, such as information sharing, cooperation, coordination and team building. Virtual teams do also have to mobilize the necessary resources, and need to develop a cohesive team with clear goals. However, virtual teams have to care for these processes under conditions of geographic distribution, which has been found to be significantly and negatively related to work processes and team effectiveness (Cramton, 2005). Inadequate ICT tools or infrastructures and the incompatibility of technology will also result in barriers for cooperation. But with sufficient attention to team building and adequate ICT tools these problems may be overcome. The process of team building can be difficult in the virtual context, specifically when the "life cycle" of a team is short, the stability of membership is limited and face-to-face meetings are scarce. *Global* virtual teams have to deal with the additional issues of communicating across different time zones, languages, and cultures (Montoya-Weiss, 2001).

Other problems may include missing nonverbal cues in communication and a lack of unplanned social encounters, resulting in problems with awareness of availability and state of others, of progress of the work or of the setting in which others work (see e.g., Steinfield, 2002). These barriers may result in a lack of trust and cohesion, which often may lead to lower performance levels. Jarvenpaa and Leidner (1998) confirmed that global virtual teams might start with a form of swift trust (Meyerson, Weick & Kramer, 1996), but that such trust appears to be fragile and temporal. Cramton (1997) illustrates, for instance, the multiple interpretations members of virtual teams may give to the meaning of silence of their distant team members. Additionally, virtual team membership can be highly fluid, demanding for continuous adaptation processes between the existing team and new members, who bring their own beliefs and frame of reference. It is this system of views and beliefs people hold that is often considered very important for team functioning. This system is often referred to as a mental model, which can reflect knowledge and belief systems about members in the team, the teams' task, team interaction processes, and the technology used in the team (Cannon-Bowers, 1993). A high degree of sharedness of mental models has been suggested to lead to more effective teams. However, the distributed nature of, and ICT mediated communication in virtual teams hamper efficient development of shared mental models. Member diversity in organizational affiliation, professional background, and national cultures can complicate matters further.

TEAM PERFORMANCE

A crucial difference between colocated and virtual teams is the fact that virtual teams have the opportunity to combine and integrate both colocated and distributed interaction. Virtual teams may combine the better of two worlds and may therefore have an advantage over conventional teams. Virtual teams require certain tools in the area of information and communication technology (ICT) to support interaction. Some modern tools have sophisticated functionalities that provide such teams with opportunities that conventional teams do not have. One of the major effects of the introduction of collaboration technology has been that certain types of meetings can now be held with a large number of participants. Moreover, some tools allow for easy storage and retrieval of information and for collaborative editing of documents. Research results on the performance of virtual teams, relative to face-to-face teams have been mixed. Virtual teams have been generally found to take more time to complete tasks. However, virtual teams have been found to outperform face-to-face teams on idea generation tasks. In general research results in the area of team performance, and quality of work have been mixed and often contradictory (Martins et al., 2004).

So far, the development of virtual teams has mostly been technology-driven, almost neglecting other aspects of work, such as knowledge sharing, combining expertise, and dividing tasks.

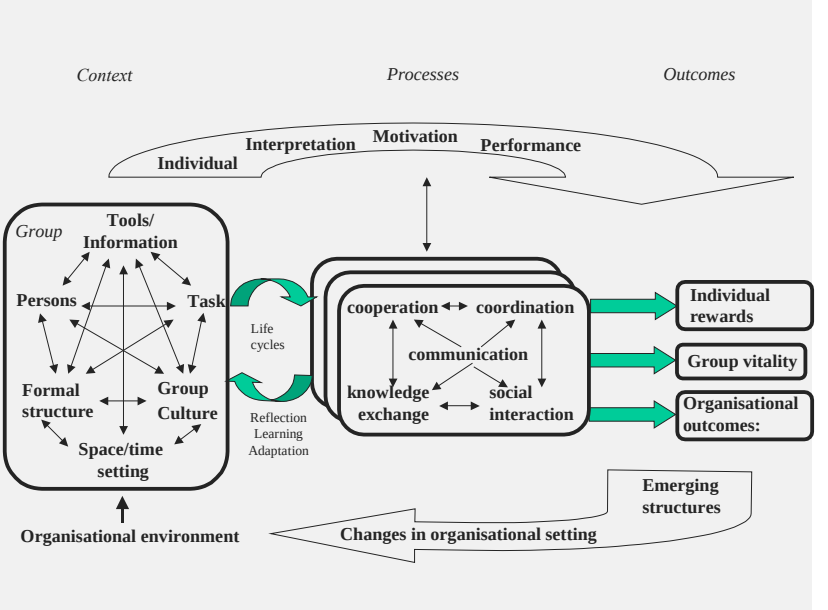
In order to reach an optimal level of functioning, these new types of collaboration require new ways of organizing and managing. Major challenges for both managers and employees are the consequences of dealing with virtual teams. Systematic insight in the design and performance of effective (global) virtual teams is therefore an important prerequisite. It is clear that virtual teams may face substantial barriers for effective cooperation and that the probability of failure is ever present. The next section presents a model for analyzing the reasons for failure and can support the design of virtual groups.

Analyzing Virtual Teams: A Model

The model is based on a general model of group functioning, called the Dynamic Group Interaction model (DGIn-model), which is applied in several case studies (Andriessen, 2002; Andriessen & Verburg, 2004). The purpose of this model is not to limit the analysis of collaborative activities to specific aspects, but to structure the analysis by providing ideas and insights that have proven their value in other contexts.

In this model, elements of several theories are brought together. Three levels of behavior are taken into account, that

Figure 1. Adapted from the Dynamic Group Interaction Model (DGIn -model) (Andriessen, 2002)



is, individual goal directed behavior and cognitive processes (based on Action Theory, Activity Theory, Media Richness Theory), interpersonal and group processes (Activity Theory, Adaptive Structuration Theory, Social Information theory, Coordination theory) and a macrosocial perspective (Structuration Theory). The various notions are brought together in a heuristic model concerning group processes, related to traditional 'input-process-output' schemas (see e.g., Hackman, 1987; Kraemer & Pinsonneault, 1990; McGrath, 1984; McGrath & Hollingshead, 1994). However, they are enriched with interpretative and structurational notions and feedback cycles (see Figure 1).

The DGIn-model has the following four basic principles that can be applied to virtual teams.

Effectiveness

Some virtual groups cooperate only once, so in those cases vitality and continuity of the group as outcomes may not be that interesting for the members. In case of real (project) teams, however, it is not enough to come up with clear results, and with rewards for their members. They also need to cater for trust, group vitality, and continuity in order to be effective. Virtual teams do not differ from conventional teams in this respect. However, developing vitality is more difficult than in colocated groups. High performing teams have been found to be able to maintain high levels of trust throughout the team's life (Kanawattanachai & Yoo, 2002).

The Quality of Group Processes

Six basic group processes were distinguished: communication, and the five other processes that can only exist on the basis of communication (cooperation, coordination, learning, reflection, and team building). These processes need to be aligned.

The type of *communication*–mediated to a smaller or larger extent–constitutes the core dimension for the concept of virtuality. In case of virtual groups, the model implies that collaboration, coordination, knowledge exchange, social interaction and reflection need to be adjusted to the degree of mediation of communication. This is reflected, amongst other things, in the fact that both remote *cooperation* and *social interaction* in mediated meetings need to be much more explicitly structured than face-to-face meetings in order to be effective. The already mentioned lack of non-verbal cues in communication, resulting in problems with awareness of availability and state of others, makes it difficult to interact. Overall, face-to-face meetings allow for more flexibility during meetings and do not need to be as structured as mediated meetings. It is important to provide minutes of virtual meetings as these help to assure that all members understand the same conclusions. In case of virtual student teams, Cramton (1997) showed that team members have difficulty in extracting information about the context in which their distant partners operate, while members themselves often fail to provide important information about their own context.

Globally distributed teams should give sufficient time and attention to group members who are less assertive than most members from a number of Western countries. *Leadership and coordination* of virtual teams play therefore a critical role in facilitating the work and organization of virtual teams (Bell & Kozlowski, 2002). In general the activities of virtual teams appear to need much more preparation and explicit coordination than colocated teams. The role of coordinators is, therefore, vital for the performance of virtual teams (Connaughton & Daly, 2004).

The Quality and Match of the "Context" Characteristics

The quality of group processes depends on characteristics of the "context". Six groups of characteristics are distinguished: the task of the team, tools, member characteristics (knowledge, skills, attitudes), team structure (such as role division and meeting type), culture (norms, trust, cohesion, cognitive distance), and time-space setting (e.g., geographical distribution). The context characteristics need to match each other in order to optimally support the group processes.

ICT support. The technical tools and their usage should be adjusted to the virtuality of the group. The following suggestions can be made:

- Virtual groups require information storage and exchange tools.
- Virtual groups may benefit from a database with information on background and expertise of the group members (*yellow pages*).
- Virtual groups with intensive and nonroutine interaction may benefit from tools for synchronous communication: chat features, where possible video links.
- Virtual groups with complex and time sensitive tasks require workflow management tools for providing information regarding the progress of the project and activities of group members.
- The tools have to be easy to use and equally accessible to all members.
- Group members should be sufficiently trained in remote interaction and in using the technology.
- Global virtual teams should be careful in choosing and using the right tools. Research suggests that people from some cultures prefer direct expression of ideas whereas others may be more sensitive to nonverbal cues and group relations (see for instance Trompenaars, 1993, for examples). The first group of people would probably prefer a collaboration tool that enables synchronous communication, such as telephone, video and chat. People from the other group would be happy with an asynchronous communication tool enabling them to express themselves more carefully. The choice for a suitable collaboration tool to facilitate both groups is, therefore, complicated.

Storage of information. Special attention should be given to information (document) exchange and storage. Effective virtual teams rely heavily on information exchange. Systems and procedures that allow for swift information exchange are therefore a prerequisite. Such systems need to be usable and accepted by all members of the team. In multi-cultural teams such systems are not always easy to obtain. Differences in preferred practices of communication and storing information will limit the choice of an equally useable tool.

Cultural diversity may be large in virtual teams. In order to avoid conflicts and facilitate a smooth work process, group members should be trained to understand the potentially disturbing effect of diversity in national, organizational and professional cultures (Dubé & Paré, 2004). The next step is to learn about each other's background so that differences in solving problems and ways of working will not form a source of major misunderstandings. As soon as members respect and trust distant team members, virtual teams will be able to benefit from the diversity of their members.

Development and Adaptation: Team Building

Groups develop and tools are adopted and adapted, through interpretation, interaction processes and feedback. One of the processes through which this development and adaptation can be explicitly structured is team building. Team building proves to be a critical aspect of team performance and acts as the foundation for the development of necessary levels of trust, cohesion and cognitive closeness among team members. In many cases, team building in virtual teams can benefit strongly from a face-to-face kick off meeting (see Maznevski & Chudoba, 2001, for an overview). Coordinators should be alert to organize such meetings whenever needed or possible.

FUTURE TRENDS

As more and more organizations will explore the opportunities of working across boundaries, the number of virtual teams will increase in the coming years. These teams will experience the complexity of coordination of cross-border work activities. Future research in the area of virtual team analysis will highlight the relationship between virtuality and team effectiveness more closely. Especially, research with regard to the coordination and management of virtual teams will get more attention. So far, research into coordination of virtual teams has primarily focused on the role of leaders of virtual teams (e.g., Cascio & Shurygailo, 2003). Other

possible ways of coordination in virtual contexts, such as the successful use of groupware tools and the role of substitutes for leadership, did not receive much attention yet but will be trends for research in the coming years.

CONCLUSION

Virtual teams offer great opportunities for collaboration across boundaries, which have encouraged many companies to form such teams. However, virtual teams also face challenges, particularly in the areas of communication and coordination. We have presented the DGIn model for team analysis. On the basis of our analysis we recommend that virtual teams should more explicitly pay attention to issues of team building, awareness, preparation, and information storage in order to work and collaborate effectively. Virtual teams should also benefit from the use of specialized groupware tools if applied properly.

ACKNOWLEDGMENT

This enhanced chapter is based on an article authored by Robert Verburg, Erik Andriessen, and Joris De Rooij previously published in the *Encyclopedia of Information Science and Technology*.

KEY TERMS

V

Action Theory: Perspective on action facilitation that makes a distinction between acts, actions, and operations in performing a task. A basic principle of the theory is that the tools used should provide sufficient feedback to allow for adaptation of task execution.

Group Dynamics: Field of inquiry dedicated to advancing knowledge about the nature of groups.

Groupware: ICT applications that support communication, coordination, cooperation, learning and/or social encounters through facilities such as information exchange, shared repositories, discussion forums, and messaging**.**

Media Richness Theory: Theory on mediated communication that highlights the extent to which a medium is capable of sending rich information (i.e., text, smell, pictures, noise, etc.) as well as the proposition that media use is most adequate if the medium is matched with the complexity of the task at hand.

Dynamic Group Interaction (DGIn) Model: In this model elements of several theories with regard to group performance are brought together. Three levels of behavior are taken into account, that is, individual goal directed behavior, group processes and a macrosocial perspective. The various notions are brought together in a heuristic model concerning group processes. They are related to traditional input-process-output schemas.

Structuration Theory: A theory of societal processes on a high abstraction level. Adaptive Structuration Theory (AST) focuses on the analysis of the way existing technologies are taken up by groups and evolve in their role during the appropriation process (i.e., the process of adaptation to new technical tools, which changes the original situation).

Team: A collection of individuals who see themselves and who are seen by others as a social entity, who are interdependent because of the tasks they perform as members of a group, who are embedded in one or more larger social systems (e.g., community, organization) and who perform tasks that affect others.

Virtuality: The extent to which a group is geographically distributed, is organizationally and culturally divers, has different time frames for work, communicates electronically and whose members are freelance or have fixed contracts with an organization.

Virtual Work Research Agenda

France Bélanger
Virginia Polytechnic Institute and State University, USA

INTRODUCTION

The paper by Bélanger, Watson-Manheim, and Jordan (2002) addresses the gap between research conducted and practitioner concerns in virtual work. One of the key difficulties in conducting research in this area is the overlap between terms used (McCloskey & Igbaria, 1998; Pinsonneault & Boisvert, 2001). While there are other distributed work arrangements such as hotelling, neighborhood work centers and flextime, most of the previous literature has focused on telecommuting (telework) and virtual teams/organizations. In this article, the term virtual work represents work environments where individuals spend some time working in a non-face-to-face (FTF) mode, using information and communication technologies to perform work activities.

Virtual work environments are increasingly employed by organizations. While there is increased complexity and potential for problems, virtual work strategies allow organizations a great deal of flexibility to compete in a rapidly changing business environment. While existing research provides insights into such environments, it does not clearly deal with major concerns faced by managers (referred to as the "gap" between research and practice). One of the potential reasons for this gap is that practicing managers are concerned with current challenges in their own work setting while academics are concerned with developing more generalizable rules and understanding.

This article addresses these issues, with three particular objectives:

1. examine the gap between research and practice in virtual work;
2. investigate factors leading to the gap; and,
3. identify a research agenda that addresses emerging issues and concerns relevant to practice in virtual work.

BACKGROUND

To explore the gap between virtual work research and practice, the authors first review previous literature, which they then compare to concerns raised by practitioners in two organizations. To identify relevant academic research, the authors searched for articles in mainstream IS journals. They then used the "snowball" technique, mining citations in articles for further references. They did not include the large number of conference papers and studies of homeworkers, entrepreneurs, or supplemental work at home. They focused on empirical and/or theoretically grounded studies.

Literature Review

Their review of recent literature (1998 to 2001) revealed six literature reviews and 35 empirical studies. In the original paper, a table including methodology details and key concepts was provided but is not included here for brevity, although sample references are provided. Overall, literature addresses the following questions:

- Who are the virtual workers? There are two types of studies that discuss who virtual workers are. The first type is descriptive, usually presenting demographics and other characteristics of virtual workers based on general surveys or public records (e.g., Johnson, 2001). The second type investigates characteristics of telecommuters (e.g., Bélanger, 1999b).
- How is communication influenced by virtual work? This area has been the most researched in recent years. The published work comprises studies of communication patterns (e.g., Bélanger, 1999a) and studies of choices of communication modes (e.g., Wiesenfeld, Raghuram, & Garud, 1999).
- What technologies are used and how do they influence virtual work outcomes? There were few studies prior to 1998 focusing on technologies in virtual work.

Recent studies look at computer-mediated communication systems, the Web, the role of technologies in affecting productivity of teleworkers (e.g., Bélanger, Collins, & Cheney, 2001), and usage patterns of technology in virtual teams (e.g., Majchrzak, Rice, Malhotra, King, & Ba, 2000).

- What is the nature of the work-family conflict in virtual work? There are some recent studies looking at stress but most studies were published prior to 1998 (e.g., Duxbury, Higgins, & Mills, 1998), or in non-IS mainstream journals.
- What are the outcomes of virtual work environments? Most hypothesis-driven studies used outcomes of virtual work, such as productivity, satisfaction, or level of communication, as dependent measures (e.g., McCloskey, 2001). Potential outcomes were also discussed extensively in pre-1998 literature.
- What happens in virtual group work? Studies investigate trust, development processes, and performance in virtual teams, and perceptions in virtual groups (e.g., Maznevski & Chudoba, 2000).
- What are the key issues in managing remote group workers? Studies typically look at issues with managing teleworkers (e.g., Staples, 2001).

Overall, the review showed that a number of barriers, enablers, and outcomes of virtual work have been studied. The samples have often been limited, for example, one organization, which can limit the generalizability of the findings. However, sample size has increased in recent years. In general, given the complexity of organizations, the current research still seems to be narrowly focused.

Case Narratives

To investigate the gap, interviews were conducted in two organizations with distributed workers but with quite different levels of worker distribution. The first organization is Booz Allen Hamilton. It is a global management and technology consulting firm. For their IT practice of the Worldwide Technology Business (WTB), they rely on distributed teams comprised of geographically dispersed employees. The teams are classified as functional, delivery, development, and external teams. Their flexible matrix allows members to participate on multiple teams.

The organization has had success using technology support for team communication. The technologies available include project management, collaboration, and knowledge management tools. Management challenges, however, do occur with practical issues such as the needs for breadth of multi-disciplinary domains, collaboration tools, and training. In managing the breadth of multi-disciplinary domain, identifying the right "mix" of team members with requisite skill sets is a challenge. While electronic collaboration tools are available, managers are not sure whether and how using particular tools makes positive outcomes more likely. Computer and collaboration technology training is left up to each consultant. Management wonders whether project managers are effective because of interpersonal qualities or because of automated tools usage.

The second case is a Fortune 100 telecommunications company headquartered in Southeast USA. It services residential and business telephone customers in nine states. The narrative focused on the management of 700 network service technicians responsible for installation and repair of telephone services within one district. Technicians complete four to five work orders per day assigned by a centralized provisioning center. They are evaluated based on efficiency in completing orders and quality of the work performed. Some teams are staffed in shifts 24 hours/day, seven days/week, while others have eight-hour days with frequent overtime.

Technicians and supervisors use information and communication technologies extensively, including cell phones, pagers, and wireless laptops. The first work order is loaded on the technician's laptop before the work day begins. Technicians update the work order, and completed orders are updated in the system as soon as a worker establishes a connection. A new work order is then assigned. Such a system allows dynamic assignment of work orders based on changing priorities throughout the day.

Managers are responsible for overseeing eight to 15 technicians, including visiting and inspecting the site where work was completed. Supervisory duties also include providing training for technicians (formal and informal). They must respond to individual questions which arise due to unique field conditions or changes in technology. In addition, they must conduct performance evaluations, counsel technicians on career development, and mentor technicians new to the job.

Such responsibilities pose challenges for managers. Management challenges include work activity coordination, measurement tools, training, and information sharing for team building. Coordinating activities of distributed field workers who face process changes, often due to field conditions, is challenging. Supervisors are not able to

Table 1. Gaps and overlap in virtual work research and practice

Practitioner Issues	Examples of questions of interest	Overlap*	Examples of questions/areas researched	Research in Virtual Work
Team building	What factors are critical for building and maintaining a solid team culture and effective communications process in distributed environments?		What is the effect of virtual work on communication patterns and structures in teams and work groups?	How is communication influenced by virtual work?
	What communication structures and mechanisms can be used to distribute information and coordinate tasks among team members in timely manner?		What effects does telework have on group communication structures?	How is communication influenced by virtual work?
Organizational/ management structure	Does management role change in distributed environments?		What factors lead to more successful management of remote workers?	What are key issues in managing remote workers?
	What role does distance play in determining organizational structure and job design?			
	How are resources best allocated in distributed environments?			
Information sharing & distribution	How can information sharing be facilitated in distributed environments?		How is communication and coordination performed in virtual work?	How is communication influenced by virtual work?
	How is time-sensitive information best distributed?			
	What are effective interpersonal networking techniques used by successful distributed workers?		How is communication in teams affected by virtual work?	How is communication influenced by virtual work?
Employee assessment & development	What are the best methods and metrics for employee assessment in virtual work?		Are demographics of teleworkers linked to success or other outcomes?	Who are the virtual workers**?**
	What is the role and appropriateness of employee monitoring in this environment?			
	How is the critical management function of employee development best performed in distributed work?			
	In distributed work teams that do not meet daily, are there differences between the factors considered in team members' evaluations and those of co-located teams?		How can trust be developed between distributed team members?	What happens in virtual group work?
	Should some performance evaluation factors be weighted more heavily than others in virtual work? Which?			
Work process training	What skills need to be developed for different types of virtual work environments?		What are the characteristics of individuals performing virtual work, including skills?	Who are the virtual workers?
	How can we train distributed workers for optimum job knowledge sharing and work in virtual teams?			
IT training and readiness	What IT training is needed and how is it most effectively employed in distributed work?			
	At what stage are employees (and org.) in their acceptance of and readiness to use information and communication tools?			
Communication tools & technology choice	How does management assess the appropriateness of available communication technologies and applications?		Which communication tools lead to greater success in telework?	What technologies are used and how do they influence virtual work outcomes?
	What tools are available, and which are best to support collaborative distributed work?		Which communications tools are available and used in virtual work?	What technologies are used and how do they influence outcomes?
	How does management assess the effectiveness of collaborative tools, where they are successful, and under what conditions?			
				What is the nature of work-family conflicts in virtual work?
				What are outcomes of virtual work?

* Filled cells indicate overlap. White cells indicate limited or no overlap.

observe the work performed, which causes difficulty in providing feedback to technicians on the quality of their work. Training in a timely and consistent manner is difficult with staggered schedules of field workers. In addition, it is difficult for distributed workers to develop relationships with team members. Thus, inability to share information with team members, especially for newer people, poses a challenge for managers.

MAIN TRUST OF THE ARTICLE

A number of managerial themes emerged from the interviews. The themes are summarized in Table 1, and only a few sample questions are provided in the following text for each theme. Please refer to Table 1 for further research questions.

Team building is an issue due to the complexity of lateral communication among team members in virtual work environments. The lack of physical interaction causes difficulty in creating relationships. An example of a question practitioners need answered is: What factors are critical for building and maintaining a solid team culture and effective communication process in distributed work?

Hierarchical communication between employees and managers also becomes more complex in virtual work. Coordination of unpredictable tasks is difficult for supervisors. In relation to organizational management structure, practitioners need answers to issues like: How are resources best allocated in the distributed environment?

Communicating organizational information in a timely manner is a challenge. Information sharing among team members may be difficult since work teams are physically distributed. Timely updates are difficult without methods for sharing information such as posting system messages and alerts for fellow workers. A sample question of interest to practitioners could be: What are effective interpersonal

networking techniques used by the most successful teleworkers?

Measuring and monitoring employees' work is complex in distributed work. Better measurement criteria on work patterns or processes would enable management to more fairly assess and provide effective feedback to employees. This leads to questions like: What are the best methods and metrics for employee assessment in virtual work?

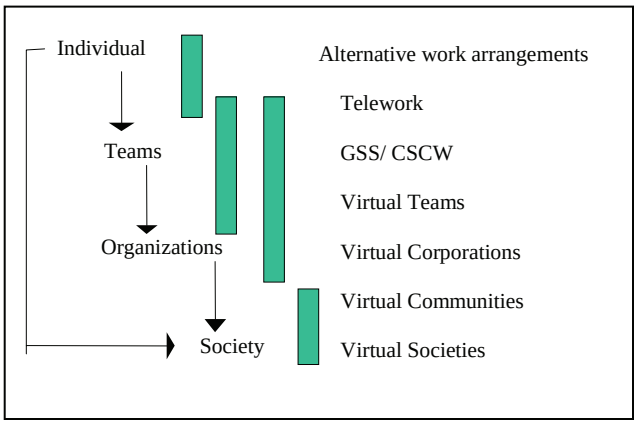
Development and training of employees for future assignments can be difficult, particularly for new employees in distributed settings. A sample question that needs further investigation is: How are the critical management functions of employee development best performed in the distributed environment?

Ensuring that employees are performing work activities most effectively is difficult in distributed work. Tension occurs between organizational consistency and employee independence. This area has just started to be researched by academics (Cooper & Kurland, 2002; Kurland & Cooper, 2002). A sample question needing further investigation in this area is: How can we train distributed workers for optimum job knowledge sharing and work in virtual teams?

The use of information and communication technologies is critical to effective performance in distributed settings. However, the complexity and rapid change of technologies adds to the challenge of providing training at a distance. An example of a question of interest is: How is necessary IT training most effectively conducted in distributed settings?

Choosing the best communication technology is critical. Management in both organizations interviewed, however, had little guidance in how to make the choice. A typical question of interest could be: What tools are available, and which are best to support collaborative work in distributed settings?

Figure 1. Proposed virtual work units of analysis



FUTURE TRENDS

A summary of the issues raised in the case narratives as compared to the literature is presented in Table 1. It provides a high level view of potential gaps between virtual work research and practice. In general, the literature does not always adequately capture the complexity of virtual work environments, which creates a gap between managerial concerns and academic research. In addition, topics addressed by research are not always addressed in as much depth as what is needed by practitioners. For example, researchers look at coordination and communication in general while practitioners are interested in how communication within virtual work can be better used for information sharing, information distribution, performance feedback and/or relationship development. Some gaps, however, may be justifiable. For example, work-family conflict issues should be studied by researchers, but do not seem to be major concerns of practitioners. The need to address longer-term issues about societal effects of virtual work may justify research in this area. One overlap is team building where issues of trust and communication in virtual teams are researched and are seen as practical concerns by managers. Another overlap is evaluation of tools and technologies for virtual work. Research has focused on e-mail and the Web, also important to managers. In addition, managers are interested in groupware and knowledge management tools.

While exploring the gap, several factors that might cause a disparity between research on virtual work and concerns of practitioners became apparent. Possible reasons for the gap include multidisciplinary nature of managerial concerns, time-intensive requirements for research methodologies, and lack of proper definition of the unit of analysis.

Virtual work research is fragmented by areas while problems faced by managers are multi-disciplinary in nature. Business organizations require a more systemic and holistic approach to studying virtual work. For example, issues of technology and organizational communication cannot be separated in virtual work. Understanding interpersonal relations is critical to understand how relationships are formed and maintained in an environment where cooperating individuals are working in different contexts with different technologies.

Longitudinal case studies or multiple case studies are the most appropriate research methodologies to study virtual work. The type of research needed requires substantial

time investments from the researchers' perspective. It is, therefore, more difficult to accomplish this research and get the appropriate rewards of timely publications.

The unit of analysis needs to be appropriate to the research question, and the research question should be relevant to the "unit" being studied. A proposed view of the appropriate unit of analysis in virtual work research adapted from Agres, Edberg, and Igbaria (1998) is shown in Figure 1. For example, the organizational level unit of analysis could include studies of telecommuting, GSS/CSCW, virtual teams or virtual corporations.

CONCLUSION

Through an in-depth review of virtual work literature and insights from two organizations, a gap between research and practice was identified since practitioners are faced with issues and challenges in virtual work environments for which research does not always capture the complexity. Although possible reasons provided for a gap between research and practice is not exhaustive, it is apparent that a need exists to have better communication between practitioners and researchers on issues of importance and on how each can benefit from one another's work. As academics, we should consider these as opportunities to perform research of importance to both the academe and practitioners.

KEY TERMS

Computer Supported Collaborative Work (CSCW): Research area that focuses on investigations and development of technologies that can be used for collaborative work in distributed settings.

Group Support Systems (GSS): A set of technologies used to help groups in their decision making processes.

Hotelling (Neighborhood Work Center): Organizational facility for employees to work at but where they do not have a permanently assigned desk. They must "check-in" every time they come to work there.

Longitudinal Case Studies: Research method that involves looking at particular cases over a longer period of time, with repeated measures to observe a phenomenon as it evolves.

Telecommuting (Telework): Work arrangement that allows employees to work at home during regular work hours.

Virtual Teams/Organizations: Teams and/or organizations where some or all of the members work from different physical locations.

Virtual Work: Work environments where individuals spend some time working in a non-face-to-face (FTF) mode, using information and communication technologies to perform work activities.

Virtual Work, Trust and Rationality

Peter Murphy
Monash University, Australia

INTRODUCTION

Since the development of the Internet—and the emergence of computer networking as a mass medium in the mid-1990s—many organizations and institutions have experimented with Internet protocol (IP)-based communications to coordinate work and activities across geographical distance. This has been in response to growing needs to coordinate business and projects between different offices, firms, regions, and states. Rather than organizations flying people to meet face-to-face, network technology presents opportunities for persons located apart to work together. It offers the potential for cheap and efficient collaborations across distance. Yet, while economic pragmatics drive organizations to adopt virtual work methods, virtual working is difficult to implement. This is because it strains many conventional assumptions about work behaviour and the cognitive and emotional foundations of collaboration.

BACKGROUND

Since the 1970s, there has been a general trend worldwide for organizations to move from being closed systems to open systems. This has involved growing pressures on organizations to interact with their environment rather than trying to internalize their environment. The most visible consequences of this have been the escalating tendency of organizations to contract out functions, to relocate parts of their operations across the world, and to grow the number of strategic collaborations with other organizations. The result is more and more organizational actors working with persons—often persons they do not know—in other locations. Working with people at a distance means working virtually (Duarte & Snyder, 1999; Franke, 2002; Igbaria & Tan, 1998; Jackson, 1999; Kisielnicki, 2002; Lipnack & Stamps, 2000; Mowshowitz, 2002; O'Hara-Devereaux & Eccles, 1994). Virtual collaborators (teams and partners) have no shared physical presence. Collaborators may see one another only rarely if at all.

The technologies of virtual collaboration are relatively straightforward: e-mail, ftp, collaborative groupware, and audio-video conferencing. Groupware and IP-based conferencing is still relatively under-utilized. Third-party hosted groupware offers solutions to high-level collaboration across firewalls. IP-based conferencing provides opportunities to enrich interactions with sound and visuals. Groupware to date, however, does little more than make conventional file storage and threaded discussion available to persons working in multiple locations across organizational boundaries. Conferencing software is only beginning to be able to deliver quality audio across low bandwidth connections. Typically, high-quality video and the sharing of complex software applications still require high network bandwidth, and are often unavailable from roaming and non-institutional locations.

While technology shapes the possibilities of virtual interactions, psychology is a more powerful factor in determining the viability of such interactions. A basic condition of virtual collaboration is the ability to work with others without seeing them, knowing them, or meeting them in person. While technology can enable such work, to effectively leverage these technological possibilities, organizations have to adapt themselves to different ways of working, and in some cases they have to re-invent themselves. Working virtually at the micro-level of teams, groups, and pairs is only effective where the larger organizational environment lends itself to virtual interaction.

There are three basic types of organization: social, procedural, and the virtual or self-organizing (Miller, 2002). Social organizations are the most common type. These are based on face-to-face interactions and on character norms such as loyalty, dedicated service, and "keeping your word". Procedural organizations are built on impersonal roles and rules. Virtual organizations are structured around more abstract patterns and forms. The family firm and the relationship-driven Japanese corporation are examples of the social organization (Fukuyama, 1995). The Fordist-type American corporation typifies the procedural kind (Chandler, 1977). In contrast, production and distribution reliant on intangible or intellectual capital, such as licensing, patents, or correspondence, encourages forms of virtual collaboration based on high degrees on self-organization (Barley, Freeman & Hybels, 1992).

In order to be effective, any organized human activity must be rational. Rationality is another word for continuity, identity, and stability of expectation. Organizational behaviours deteriorate or collapse if the members of an organization cannot see that these behaviours are for the most part rational. The emotional correlate of rationality is trust. What is felt to be reliable, and worthy of trust, is

also that which is recognized to be rational. Any organization where people trust one other is more effective than an organization where persons are suspicious of each other (Kramer & Tyler, 1996).

In social organizations, people "with character" are generally recognized as rational actors. These might be persons who are dependable, loyal, and unwavering in their treatment of each other. Through demonstrating that they are good at following social norms, such agents generate trust (Fukuyama, 1995; Handy, 1995). With the development of equity corporations and modern management in the late nineteenth century, social organizations in many places were replaced at least in part by procedural or bureaucratic organizations (Chandler, 1977; Yates, 1989). These developed around rules, roles defined by rules, procedures, work demarcations, impersonal written communication, and file management. Knowledge of rules rather than of people provided organizational continuity, identity, and stability. Thus persons who were consistent at following and applying rules acquired reputations for trustworthiness. Predictability in decision-making and task execution became the primary source of trust in bureaucratic organizations—complementing and often superseding the loyalty and patronage work cultures of social organizations.

Virtual work does not follow the logics of either social or procedural organizations. Without face-to-face interaction, character norms cannot be the basis of organized action. At the same time, procedural rules are difficult to agree on, to follow, or to enforce because virtual collaborators do not share the same office, organization, or manager. Virtual actors have to deal with multiple rule sets across diverse institutions, geographies, and cultures. Under these conditions, rules become ambiguous, conflicted, and uncertain. One party's rationality becomes another's irrationality. Such conflicting expectations breed distrust. Thus, under virtual conditions, rationality and trust have to be generated by other means (Murphy, 2003).

CRITICAL ISSUES

Because there is not the same history of working virtually as there is of working socially or working procedurally, identification of the means by which virtual partners and teams generate rationality and trust is less developed. If virtual collaborators cannot rely on personal moral character or on impersonal "rules and roles" to facilitate their interaction, then what can they rely on? The simplest answer is that, in the absence of social cues or clear-cut procedural direction, persons working have to be self-organizing. The key to successful self-organization is the sense of pattern or designing intelligence. Where self-directed activity (Ray & Bronstein, 1995) dominates cooperative and peer interaction, design intelligence and pattern rationality function as the coordinating medium of organized activity and group behaviour. If not, collective cohesion readily collapses.

Human beings have a strong design sense. They pick up exceptionally quickly on design characteristics such as rhythm, harmony, and proportion. Pattern recognition is central to brain processing (Davies, 1992). For instance, we use our pattern sense to make judgments about regular sentences, trustworthy buildings, and reliable machines (Alexander, 1977; Fodor & Pylyshyn, 1988; Gelernter, 1998). Such pattern rationality is also conducive to building trust. Patterns generate feelings of surety, satisfaction, and reliability. This applies as much to work environments as to cities, machines, or sentences. To create patterns, organizations employ tacit forms of aesthetic cognition (Calas & Smircich, 1996). Aesthetic cognition uses beauty, elegance and economy rather than rules or roles to achieve its ends.

Successful virtual work is conducted like a design process (Murphy, 2003). It relies less on the passing around of overt messages, and more on the ability of collaborators to understand through the exercise of imagination where their part "fits" into the overall design of the workflow. "Fit" is achieved by thinking in aesthetic terms of proportionality, rhythm, and harmony rather than in terms of rules or roles. The rationality of a virtual organization is not the rationality of character or procedure but of design. Much of this "acting by design" is intuitive or unspoken. It rests on imaginative cognition. Persons who work virtually by necessity cannot talk a lot or interact a lot with each other—so they need to imagine a lot. They need to be good at projective or anticipatory thinking. This projective thinking is not the same as the anticipatory thinking involved in either relationship empathy or in Gantt chart style project management. Rather, it is much more figurative in nature. The virtual collaborator who uses imagination is good at "seeing the shape of things" in lieu of dense social relationships or strong procedural guidance.

Virtual team or partnership work relies heavily on imaginative visualization and intuition. This is a kind of tacit knowledge. It is tacit in the sense that it involves picture thinking and pattern cognition rather than verbalization. It requires the cognitive-psychological capacity to "figure" things out (Mintzberg & Westley, 2001). Such cognitive figurative methods are closer in kind to processes of creative design than they are to processes of social recognition. In this context tacit does not mean the implicit understanding we derive from the warm handshake or the disapproving stare of another person. The tacit nature of figurative work methods thus are different in nature from the tacit knowledge that we draw from the bodily presence of collocated work partners. In the case of the imagination, tacit refers to high levels of picture-like abstraction. At the same time, however, because many aspects of this design intelligence operate non-discursively, the imaginative abstraction that is required in virtual working is quite unlike the explicit rules

of procedural organizations or the rule-driven inferential reasoning typical of procedural rationality.

Virtual work elides socio-emotive contents and makes conventional discursive (mile-stone) office planning difficult to implement. For virtual work to be successful, even on a micro-scale, it must draw heavily on the faculty of imaginative and figurative thinking. To be proficient at cooperation and interaction, virtual workers must be able to picture what is absent and organize that picture "aesthetically".

In virtual collaborations, designing intelligence generates shared integrative schemas—such as asynchronous rhythms of interaction or proportionate distributions of task load. Where virtual teams and collaborators "find their rhythm," they will—more likely than not—produce good work. Correspondingly, it is the act of producing good work that builds trust amongst virtual collaborators. Trust arises where collaborators know that each will "do their part". "Doing their part" does not mean sending lots of social messages, nor does it mean showing procedural fluency. Virtual trust is generated not through relationships or procedures but rather through the aura of reliability that arises from the visible effects of the "invisible" qualities of beauty, elegance and economy that virtual actors employ when they cooperate at a distance to produce things in imaginative ways. This means producing well-designed objects—be they physical goods, processes, systems, or learning objects—in a "choreographed" manner. The choreography of the virtual team rests not on social gestures or on rules but on a good sense of rhythmic or harmonic "fit". The sense of satisfaction and surety derived from such "fit" provides the emotional trust that is the counterpart of aesthetic rationality.

FUTURE TRENDS/CONCLUSION

As business and government are pressed to operate over increasingly large scales and long distances, and as inter-organizational, inter-agency, and inter-state activity becomes more common, the need for distance communications and virtual teams is growing and a class of virtual workers is gradually emerging.

All the while, established paradigms of work remain entrenched, meaning that there is a latent propensity to try and build virtual teams and partnerships around social communication and procedural norms. This creates conflict between the intrinsic nature of virtual cooperation and the extrinsic goal extending the reach of traditional organizational structures. As organizations at the micro-level of team and peer relations continue to expand their geographical scope, and as the boundaries of organizations become increasingly fluid as a result, a major challenge for the future will be increasing the understanding of the role of aesthetic rationality and designing trust in the formation of productive relations between actors who are separated by distance and time.

KEY TERMS

Design: The structured composition of an object, process or activity.

Distance Communication: Communication under conditions of geographic separation that minimize the possibility of face-to-face and synchronous interactions.

IP-Based: Network technologies based on Internet protocols.

Open System: Any system without strong boundaries, where information and other goods flow to and from the system's environment.

Organization: The deliberate integration of persons in order to achieve a goal or outcome.

Procedure: A rule that governs a formal organizational process.

Rationality: The ability to infer with relative certainty from existing or past behaviour and statements future behaviour and statements.

Trust: Confidence that an object, process, institution, or another person's actions can be relied upon to produce some good.

Virtual Interaction: Computer-mediated interaction between persons who do not occupy the same physical space.

Virtualization and Its Role in Business

Jerzy A. Kisielnicki
Warsaw University, Poland

INTRODUCTION

A new management trend of the global information technology (IT) application—virtualization—has appeared in the contemporary management. Virtualization is a process of enterprise transformation (using IT) that allows breaking through various limitations of organizational constraints. Virtualization changes dramatically the image of business, especially of small and medium enterprises (SMEs); by adopting the concept of virtualization, they can become fully competitive and may effectively operate in the global market. Barriers of the scale between SMEs and large organizations disappear. This new type of organizations is often called in literature *modern organization* or *virtual organization*. Organizations of this type have an effective decision-making process, and function based on economic criteria. Consequently, their opportunities to grow and to compete in the global market are greater than for traditional SMEs. Hence the thesis that virtualization allows individual organizations to enter strategic co-operative alliances with other similar businesses. Such of virtual organizations have a competitive position in the global market.

In the literature, there are many terms used to define virtual organization: "network organizations" (Drucker, 1988, p. 9), "organizations after re-engineering" (Hammer & Champy, 1993, pp. 77-79), "crazy organization," "crazy time for crazy organization" (Peters, 1994, pp. 5-7), and "intelligent enterprise" (Quinn, 1992, p. 3).

BACKGROUND

Virtualization, defined as a process of continuous transformation, is a herald of a new direction in the science of organization management. In the context of this analysis, this process may assume such form that will allow them to become competitive in the global market. The process of transformation consists of quick adjustments of the enterprise to new requirements (Hendberg, Dahlgren, Hansson, & Olive, 2000). This is done through changes in the organizational structure as well as in the portfolio of products and services. These changes are possible due to development in the IT sector, particularly Internet applications (Kenny & Marshall, 2000).

From the theoretical perspective, we can separate the following forms of virtualization:

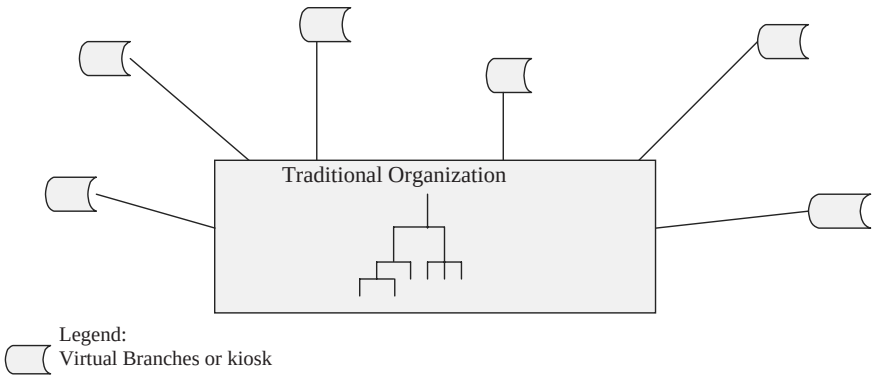
1. Functional extension (i.e., a vertical development). This occurs when the enterprise either wishes be closer to the customer and it does not have adequate resources or when the establishment of a traditional branch is not profitable. The enterprise creates for this purpose virtual branches or *kiosks*. Sometimes it enables their customers to use its services via computer or mobile phone. Examples are Internet banks, bookshops (best known is amazon.com), department stores, and travel agencies. Large companies also commonly extend their scope through such vertical development. It ensures increased competitiveness with a simultaneous control over the whole organization. SMEs apply such a strategy to a limited extent, most often for the purpose of marketing their presence in the Internet.
2. Creation of the virtual organization, or the horizontal development. Such a development occurs through a virtual incorporation of other organizations. The literature lacks a unanimous definition of this concept (Hendberg et al., 2000; Kisielnicki, 1998; Quinn, 1992; Scholzch, 1996).
3. Specialist structures being created in order to collaborate. In physical terms this is a computer or a network of computers equipped with specialist software. This form of virtualization is used for raising qualifications of the personnel by both SMEs and large enterprises (Fong, 2005).

For the purpose of this analysis, we assume that:

Virtual organization is created when its members voluntarily enter in relations of various types to achieve their common goal. Every member who creates this organization defines duration of the relation. The member who first admits that the existence of that relation is unfavorable, makes the decision on its liquidation, and withdraws. The virtual organization operates in the *cyberspace* and requires existence of the Internet and global IT infrastructure.

LSEs use IT to strengthen their competitive position in relation to other enterprises. As Hammer and Stanton (1999) rightfully notice, IT becomes—for a certain class of organizations—a "wall" that divides them from other enterprises. Large enterprises are described as "castles" (Hammer & Stanton, 1999). LSEs build these "castles" to protect themselves from competition. SMEs do not have such a sheath. They are more flexible than LSEs at a price: they are more prone to infiltration. In general, however, the

Figure 1. Virtual organization based off traditional structure



more experienced and knowledgeable the SMEs are, the more attractive they are to other enterprises seeking their share in the virtual enterprise.

MAIN THRUST OF THE ARTICLE

Virtualization in Traditional Organizations

Virtualization allows for organizational development at much lower cost than through the traditional process. The following diagram presents a virtual organization based off a traditional structure and connected with its virtual elements. These elements are flexible, allowing the organization quick adjustment to changing environments.

The virtualization may be developed as follows:

- The organization creates virtual kiosks or shops. For example, an organization that sells furniture using the Internet may present its products on a computer screen. It may also receive orders from customers located outside their traditional market. Other organizations (tourist, real estate, bookshops, stock exchange, etc.) may operate in the same manner.
- An organization places information about its activity on the Internet (Porter, 2001). It is available to its clients 24 hours a day, seven days a week, rather than being limited to office hours. Internet banking services are a good example. In addition, the expenses connected with the services of an organization are shifted to the client (the client pays for the terminal, access to the Internet, etc.). The organization covers the cost of the development and maintenance of an application.
- The organization creates a possibility of working from home (called Tele-work). It is a good way of increasing professional activity in those regions where it is difficult to find "traditional" employment. Also, through a Tele-work, a local organization may become a global one.

Virtualization allows traditional organizations to have a wider range of influence. Society is better informed of the organization's activities both by the organization itself and by its clients. The restrictions on this development are varied. The most common include available financial resources for IT infrastructure, language, and a necessity to have global, reliable computer networks. It should also be stressed that, unfortunately, virtualization enables organizations that are socially unaccepted (pornography, terrorism) to operate freely.

Based on the analysis of organizations that use virtualization, it is estimated that their operations require five times lower investment outlays. Generally, minimum savings obtained as a result of virtualization exceeded 60%. Only in a few cases, this proportion was less favorable.

In the organizations using Tele-work, the proportions are difficult to calculate. The analysis of organizations using Tele-work for outsourcing their services to developing countries confirms the effectiveness of virtualization. A good example is software development. The companies from highly developed countries (U.S., Great Britain, etc.) employ programmers from India, China, or Pakistan. This situation is beneficial for both the company and the countries providing resources.

A different situation occurs when Tele-work is connected with professional activation of the disabled or unemployed. Direct costs are higher as we deal with the poorer part of the society. Thus additional costs have to be incurred for training, hardware, and software. Unfortunately, there is no data available to make a precise estimate. In many countries, the cost of training and equipment is covered by special social programs. It is also difficult to estimate advantages. It may be said that social effect (i.e., decreased unemployment)

and—in case of the disabled—the ability to live a normal life is the most important one. This is possible only through virtualization.

Generally, Tele-work reduces the operating costs (parking space, office space) and provides timesaving (i.e., no travelling to work) to employees.

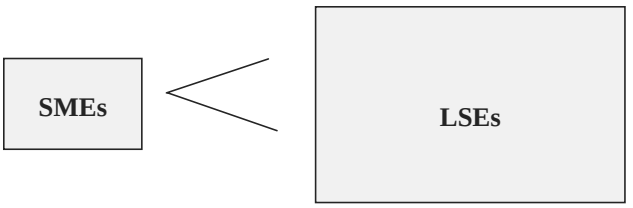
VIRTUAL ORGANIZATION AS A CHANCE FOR SMEs

Virtualization allows more and more SMEs to leave local markets and become global enterprises. Thus, the global market, for many years available only for LSE, opens up to a wide range of enterprises. As Yip (2004, p. 27) states, "the skill of defining and implementation a global strategy is a true test of leadership and management skills." The contemporary global market most often exists as e-market as well as e-business (Turban, King, Lee, Warkenting, & Chung, 2002). The enterprise, irrespective of its size, that wants to make its existence in the global market, should meet a number of conditions, such as:

1. Possessing a well-known and reputable brand
2. Built-up distribution and service network
3. Product or services that are unique and in demand
4. Management team able to support the global enterprise

To meet these conditions, the enterprise must have at its disposal adequate funds as well as material and human resources. Comparing SMEs with LSEs, the first are in a very difficult situation. The enterprise, to make its appearance in the global market, must incur definite outlay (a break-even point) to enter the global market. This break-even point is determined by:

Figure 2. Comparison of individual SMEs and LSEs (LSEs have a competitive advantage over individual SMEs)

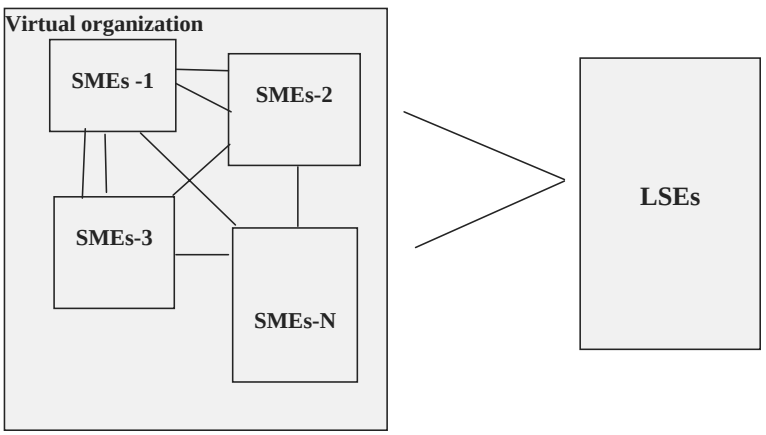


1. Advertising and promotional campaign
2. Volume of production or services, allowing for selling price below the current market price
3. Quality of product or service meeting international standards, such as ISO
4. Access to the distribution channels
5. Formal barriers (legal, duties, taxation, etc.)

Operating in the global market is much more difficult than in local markets, as it demands application of advanced IT solutions, access to the international data warehouses, and so forth. Only with the use of IT and access to information, a global company can reduce the risk of failure.

Operational costs of the enterprise are still larger if it operates in the global e-market (Elstrom, 2001). Surveys (Reichheld, 2001; Reichheld & Schefter, 2000) have shown that the cost of gaining a customer in this market is significantly higher than in the traditional market. For example, in the fashion industry, the cost of gaining a customer in the e-market is up to 40% higher. The profits following years, however, grow much faster. In the near future, organizations that cannot succeed in this market will not be able to succeed at all.

Figure 3. Comparison of a virtual organization and LSEs (A virtual organization as a set of SMEs is more competitive than LSEs)



Identification of the break-even point requires empirical surveys. It depends on the industry and the degree of globalization of the enterprise (there are not many enterprises that have been operating on all continents). To identify the break-even point, we may apply the methods of the strategic analysis, and especially the analysis of Porter's five forces. For example, the break-even point may be identified by the investment required to realize 2% of revenue from the global market. Sometimes, we can consider as an organization of such a type the one that has more than 50% of revenue from the global market. Because single SMEs do not have such resources to surpass the break-even point, they create strategic alliances in the form of virtual enterprise.

Theoretically, development of the virtual organization may be significant. Practically, a degree of its development is connected with technical barriers and with the necessity to achieve the goals set up for the virtual SMEs. Modification of the goal causes a fast modification of the enterprise.

Modern companies use such development strategies, which allow them to have a competitive position on both home and world markets. In different organizations, nowadays, it is connected with possibilities that are provided by virtualization and the Internet in particular. Among others, this fact is pointed out by Champy (2002) who presented foundations of the X re-engineering.

FUTURE TRENDS

My research suggests that a significant number of students feel the need to learn business administration (Kisielnicki, 2001). At the same time, learning should be as close to the reality as possible. Virtualization is the discipline of studies, which may cause the distance between the theory and practice to diminish. One may even risk a statement that it is the exact direction of the virtualization, which, in the nearest future, shall have the most significant impact on the society. Virtualization increases the effectiveness of the teaching process in the widest possible sense by supporting traditional teaching methods. Virtualization may be applied in such areas as lowering the cost and decreasing time of training jet pilots and also in improvement of military command, operating on the stock exchange, or cognitive analysis of genetic processes. In science, there are many examples of big discoveries, which were first tried on computer-simulated models. It is virtualization that allows for business simulation of both the decision-making process and the analysis of complex technical or sociological processes. In virtualization of teaching, there are two basic directions:

The first one is the direction of common education where everybody can, using the IT, gain a given knowledge. A classic example is a virtual stock exchange. In many countries, a lot of people want to learn how to operate on the stock exchange before they actually start using it to make money. They can get the necessary experience using appropriate software. They can acquire necessary skills in the virtual world. There are also numerous games available through the Internet. These games not only provide pleasant time spent on playing, but also teach foreign languages or how to drive a car.

Another direction is dedicated teaching. There are the following activities where virtualization can help:

- **Self-Evaluation:** Using special software to assess the level of language knowledge.
- **Learning Assistance:** Includes, amongst others, enterprise laboratories, business games, and special simulators that teach how to use a specific technical equipment, for example, flying simulators.
- **Distant Learning:** A student who has a proper terminal and software may participate in classes from a distance. This direction of virtualization is similar to the previously presented distance work.

The researches that I have conducted until now have shown that strategies connected with using only the virtual organization do not always provide positive results and meet people's expectations. It is due to a number of factors, concerning ethics and trust toward the virtualization issues (these matters were considered by Sutherland, 2004, and Kisielnicki, 2002). Therefore, obtaining a better position on a competitive market requires applying more of the convergence strategy. The convergence strategy combines traditional strategy with the use of virtualization (Kisielnicki, 2006; Thomenendal, 2006).

CONCLUSION

Virtual organization operates as a *transparent organization* in a sense that all its initiatives are known to the competition. This enforces responsibility. The image of a virtual organization is influenced by activities of its individual participants. Virtual organizations do not have common administration, offices, and real estate. In addition, virtual organizations do not have a joint executive team, middle management, or coordinators. Since the influence of each individual virtual organization is limited, the key success factor is a mutual trust.

Virtual organizations give a new insight into business management. They may trigger increased entrepreneurship and competitiveness. They also introduce new management methods different than traditional ones. Virtual organizations are an interesting alternative for current organizations. They are especially attractive for developing countries that want to operate in the international environment. It is fascinating how virtual organizations—without a formal reporting structure and control—can achieve high operational per-

formance and thus have a competitive advantage over their traditional counterparts.

Regardless of speculation on future solutions, we can now safely define the areas where virtual organizations can easily out-perform traditional organizations. They are trade, tourism, and services. In these areas, the benefits of virtual organizations are as follows:

1. Operational flexibility is much higher, especially when a quick reaction to the emerging market niche is required.
2. A transaction lifecycle is much shorter (especially the closure).
3. Use of cyberspace to close some transactions (despite legal and organizational barriers).
4. Lower operational costs.
5. Lower start-up costs.
6. Ability to cooperate with organizations that LSEs cannot accept (for political, geographical, racial, religious reasons).

Depending on each individual opportunity, virtual organizations can be successful in other industries as well. Very rarely, traditional organizations can outperform the virtual ones.

The economic metrics supporting the benefits of virtual organizations are generally available for individual cases. However, for illustration purposes, I include the results of research recently carried out in Poland:

1. Virtual travel agencies achieved 20% higher profit per transaction than traditional organizations.
2. Transaction life cycle was 100% faster in the Internet bank than in a brick-and-mortar bank.
3. The average transaction cost on the Internet bank was $0.10-0.15 compared to $1.10 in the brick-and-mortar bank.

We can put forward a hypothesis that progress in IT will create a snowball of virtual organizations. Tapscott (1998), introducing the 12 rules of the new economic deal, writes that they lead toward "virtual reality." Future strategy of business wills strategy convergence strategy.

KEY TERMS

Cyberspace: Defined by the Miriam Webster Online dictionary as an "online world of computer networks." This definition can be augmented by the following characteristics: the network consists of various, globally distributed computers that can send and receive information using common protocols. In addition, this network does not have physically defined measured boundaries. The examples of the network types are electronic mail (e-mail), World Wide Web (WWW), electronic data interchange (EDI), business to business (B2B) applications, business to customer (B2C) applications, and peer-to-peer (P2P) applications.

Virtual Organization: (a) Virtual organization (Kisielnicki, 2002, p. 102) is created voluntarily; its members create this organization to accomplish a certain goal. Virtual organization is created anytime a manger realizes that he or she needs the cooperation of other organizations to accomplish its goal. The duration of a virtual organization is defined by each of its members; virtual organization operates in the cyberspace, which means that its duration can be very short, so short in fact, that it would be impossible to cooperate with other organizations using the traditional methods. The decision to restructure or fold the organization can be made anytime by any of its members. Virtual organization does not have one president or general manager. The virtualization process is a process of transformation from traditional organization into virtual using informational technology. This process can result in two forms of virtual organization: traditional organization with virtual divisions, or an association of many organizations, as depicted in Figure 3. (b) Artificial organizational structure where individual organizations provide base competencies. The integration and coordination of these base competencies allows for effective execution of chain process to deliver a product and satisfy a customer. This integration and coordination does not incur additional costs and maintains the customer focus (Scholzch, 1996). (c) Temporary network of independent enterprises—suppliers, customers, even former competitors—linked through the IT and working together to share their knowledge and costs to enter a new market (Byrne & Brandt, 1993).

INTRODUCTION

Images have constituted an essential data source in medicine in the last decades. Medical images derived from diagnostic technologies (e.g., X-ray, ultrasound, computed tomography, magnetic resonance, nuclear imaging) are used to improve the existing diagnostic systems for clinical purposes, but also to facilitate medical research. Hence, medical image processing techniques are constantly investigated and evolved.

Medical image segmentation is the primary stage to the visualization and clinical analysis of human tissues. It refers to the segmentation of known anatomic structures from medical images. Structures of interest include organs or parts thereof, such as cardiac ventricles or kidneys, abnormalities such as tumors and cysts, as well as other structures such as bones, vessels, brain structures and so forth. The overall objective of such methods is referred to as computer-aided diagnosis; in other words, they are used for assisting doctors in evaluating medical imagery or in recognizing abnormal findings in a medical image.

In contrast to generic segmentation methods, techniques used for medical image segmentation are often application-specific; as such, they can make use of prior knowledge for the particular objects of interest and other expected or possible structures in the image. This has led to the development of a wide range of segmentation methods addressing specific problems in medical applications. In the sequel of this article, the analysis of medical visual information generated by three different medical imaging processes will be discussed in detail: Magnetic Resonance Imaging (MRI), Mammography, and Intravascular Ultrasound (IVUS). Clearly, in addition to the aforementioned imaging processes and the techniques for their analysis that are discussed in the sequel, numerous other algorithms for applications of segmentation to specialized medical imagery interpretation exist.

BACKGROUND

Magnetic Resonance Imaging

Magnetic Resonance Imaging (MRI) is an important diagnostic imaging technique attending to the early detection of the abnormal conditions in tissues and organs because it is able to reliably identify anatomical areas of interest. In particular for brain imaging, several techniques which perform segmentation of the brain structures from MRIs are applied to the study of many disorders, such as multiple sclerosis, schizophrenia, epilepsy, Parkinson's disease, Alzheimer's disease, and so forth. MRI is particularly suitable for brain studies because it is virtually noninvasive, and it achieves a high spatial resolution and high contrast of soft tissues. To achieve the 3D reconstruction of the brain morphology, several of the existing approaches perform segmentation on sequential MR images. The overall process usually includes noise filtering of the images and edge detection for the identification of the brain contour. Following, perceptual grouping of the edge points is applied in order to recover the noncontinuous edges. In many cases, the next step is the recognition of the various connective components among the set of edge points, rejection of the components that consist of the smallest number of points, and use of the finally acquired points for reconstructing the 3D silhouette of the brain, as will be discussed in more detail in the sequel.

Mammography

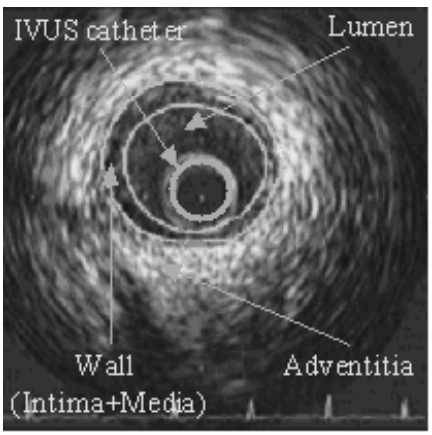
Mammography is considered to be the most effective diagnostic technique for detecting abnormal tissue conditions on women's breast. Being used both for prevention and for diagnostic purposes, it is a very commonly used technique that produces mammographic images by administering a low-dose of x-ray radiation to the tissue under examination. The analysis of the resulting images aims at the detection of any abnormal structures and the quantification of their characteristics, such as size and shape, often after detecting the pectoral muscle and excluding it from the further processing. Methods for the analysis of mammographic images are presented in the sequel.

Intravascular Ultrasound

IVUS is a catheter-based technique that renders two-dimensional images of coronary arteries and therefore provides valuable information concerning luminal and wall area, plaque morphology and wall composition. An example IVUS image, with tags explaining the most important parts of the vessel structure depicted on it, is shown in Figure 1. However, due to their tomographic nature, isolated IVUS images provide limited information regarding the burden of atherosclerosis. This limitation can be overcome through 3D reconstruction techniques in order to stack the sequential 2D images in space, using single-plane or biplane angiography for recovering the vessel curvature (Giannoglou et al., 2006; Sherknies, Meunier, Mongrain, & Tardif, 2005; Wahle, Prause, DeJong, & Sonka, 1999).

The analysis of IVUS images constitutes an essential step toward the accurate morphometric analysis of coronary plaque. To this end, the processing of IVUS images is necessary so that the regions of interest can be detected. The coronary artery wall mainly consists of three layers: intima, media and adventitia, while three regions are supposed to be visualized as distinguished fields in an IVUS image, namely the lumen, the vessel wall (made of the intima and the media layers) and the adventitia plus surroundings. The above regions are separated by two closed contours: the inner border, which corresponds to the lumen-wall interface, and the outer border representing the boundary between media and adventitia. A reliable and quick detection of these two borders in sequential IVUS images constitutes the basic step towards plaque morphometric analysis and 3D reconstruction of the coronary arteries.

Figure 1. Example IVUS image with tags explaining the most important parts of the vessel structure depicted on it



VISUAL MEDICAL INFORMATION ANALYSIS TECHNIQUES

Magnetic Resonance Imaging Analysis

Several techniques have been proposed for the analysis of MR images. In Grau, Mewes, Alcaniz, Kikinis, and Warfield (2004), a modification of a generic segmentation technique, the watershed transform, is proposed for knee cartilage and gray matter/white matter segmentation in MR images. This introduces prior information in the watershed method via the use of a previous probability calculation for the classes present in the image and via the combination of the watershed transform with atlas registration for the automatic generation of markers. As opposed to Grau et al. (2004), other methods are more application specific; in Woolrich, Behrens, Beckmann and Smith (2005), for example, segmentation tools are developed for the study of the function of the brain, that is, for the classification of brain areas as activating, deactivating, or not activating, using functional magnetic resonance imaging (FMRI) data. This method performs segmentation based on intensity histogram information, augmented with adaptive spatial regularization using Markov random fields. The latter contributes to improved segmentation as compared to nonspatial mixture models, while not requiring the heuristic fine-tuning that is necessary for nonadaptive spatial regularization previously proposed.

Because MR images contain a significant amount of noise caused by operator performance, equipment, or even the environment, the segmentation on them can lead to several inaccuracies. In order to overcome the effects of noise, Shen, Sandham, Granat and Sterr (2005) propose a segmentation technique based on an extension to the traditional fuzzy c-means (FCM) clustering algorithm. The segmentation performance is improved using neighborhood attraction, which depends on the relative location and features of neighboring pixels. The degree of attraction is optimized by applying a neural network model. Greenspan, Ruf and

Goldberger (2006) have also developed an algorithm for the automated brain tissue segmentation on noisy, low-contrast (MR) images. Under their approach, the brain image is represented by a model that is composed of a large number of Gaussians. For the algorithm's initialization an atlas or parameter learning are not required. Finally, segmentation of the brain image is achieved by affiliating each voxel to the component of the model that maximizes an a posteriori probability. In Valdes-Cristerna, Medina-Banuelos and Yanez-Suarez (2004) a hybrid model for the segmentation of brain MRI has been investigated. The model includes a radial basis network and an active contour model. The radial basis network algorithm generates an initial contour, which is following used by the active contour model to achieve the final segmentation of the brain.

Mammography Image Analysis

Several applications have been proposed, which process the mammographic images in order to assist the clinicians in their diagnostic procedure. In Székely, Toth and Pataki (2006) the mammographic images are analyzed using segmentation in order to identify regions of interest. The applied segmentation technique includes texture features, decision trees, and a Markov random field model. The extracted features which refer to the object's shape and texture parameters are linearly combined to lead to the final decision. Because the pectoral muscle should be excluded from processing on a mammogram intended for the breast tissue, its identification is important. Kwok, Chandrasekhar, Attikiouzel and Rickard (2004) have developed an adaptive segmentation technique for the extraction of the pectoral muscle on digitized mammograms. The method uses knowledge about the position and shape of the pectoral muscle. Other approaches, such as Cascio, Fauci, Magro, Raso, Bellotti, De Carlo et al. (2006) use supervised neural networks for detecting pathological masses in mammograms. A segmentation process provides features of geometrical information, or shape parameters which constitute the input to the neural network that computes the probability of the lesion existence.

IVUS Image and Image Sequence Analysis

Traditionally, the segmentation of IVUS images is performed manually, which is a time consuming procedure with results affected by the high inter- and intra-user's variability. To overcome these limitations, several approaches for semi-automated segmentation have been proposed in the literature. In Herrington, Johnson, Santago and Snyder (1992) after the manual indication of the general location of the boundary of interest by the user, an edge detection filter is applied to find potential edge points within the pointed neighborhood. The extracted image data are used for the estimation of the closed smooth final contour. Sonka, Zhang, Siebes, Bissing, DeJong, Collins et al. (1995) implemented a knowledge-based graph searching method incorporating a priori knowledge on coronary artery anatomy and a selected region of interest prior to the automatic border detection. Quite a few variations of active contour model have been investigated, including the approach of Parissi et al. (2006), where a user interaction is required, by drawing an initial contour as close as possible to its final position. Thus, the active contour is initialized and tends to approximate the final desired border.

The active contour or deformable models principles have been used to allow the extraction of the luminal and medial-adventitial borders in three dimensions after setting an initial contour in Kovalski, Beyar, Shofti and Azhari (2000). However, the contour detection fails for low contrast interface regions such as the luminal border where the blood-wall interface in most images corresponds to weak pixel intensity variation. In order to improve the included active surface segmentation algorithm for plaque characterization, Klingensmith, Nair, Kuban and Vince (2004) use the frequency information after acquiring the radiofrequency (RF) IVUS data through an electrocardiogram scheme. Radio frequency data are also used in Perrey et al. (2004), after in vivo acquisition for the segmentation of the luminal boundary in IVUS images. According to this approach, tissue describing parameters are directly estimated from RF data. Subsequently, a neuro-fuzzy inference system trained to several parameters is used to distinguish blood from tissue regions.

For clinical practice the most attractive approaches are the fully automatic ones. A limited number of them has been developed so far, such as the segmentation based on edge contrast (Zhu, Liang, & Friedman, 2002); the latter is shown to be an efficient feature for IVUS image analysis, in combination with the gray level distribution. Specific automated approaches which utilize the deformable models principles in combination with other various techniques and features reported in the related literature have been investigated. Brusseau, de Korte, Mastik, Schaar and van der Steen (2004) exploited an automatic method for detecting the endoluminal border based on an active contour that evolves until it optimally separates regions with different statistical properties without using a preselected region of interest or initialization of the contour close to its final position. Another automated approach based on deformable models has been reported by Plissiti, Fotiadis, Michalis and Bozios (2004), who employed a Hopfield neural network for the modification and minimization of an energy function as well as a priori vessel geometry knowledge. An automated approach for segmentation of IVUS images based on a variation of an active contour model is presented in Giannoglou et al. (2007). This technique is in vivo evaluated in images originated from human coronary arteries. The initialization of

the contours in each IVUS frame is automatically performed using an algorithm, which is based on the intensity features of the image. The initially extracted boundaries constitute the input to the active contour model, which then deforms the contours appropriately, identifying their correct location on the IVUS frame.

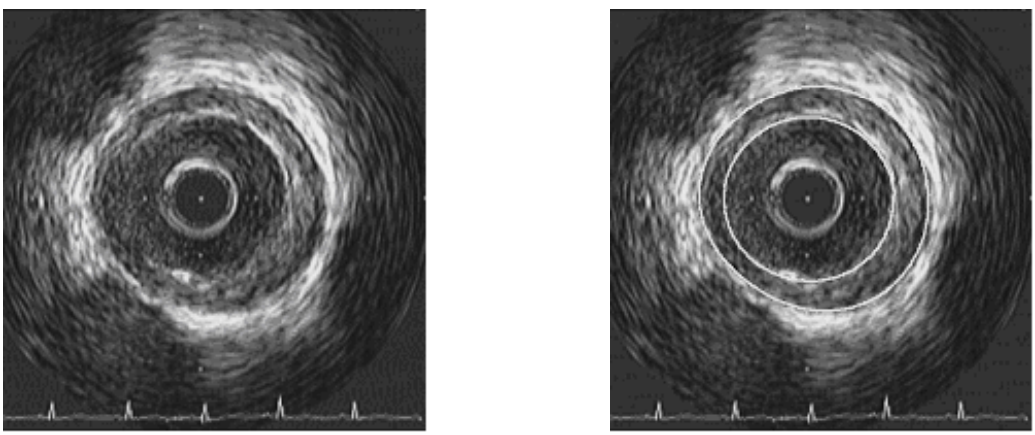
A fuzzy clustering algorithm for adaptive segmentation in IVUS images is investigated by Filho, Yoshizawa, Tanaka, Saijo and Iwamoto (2005). Cardinal et al. (2006) present a 3D IVUS segmentation applying Rayleigh probability density functions (PDFs) for modeling the pixel gray value distribution of the vessel wall structures. Other approaches are based on the calculation of the image's energy. In Luo, Wang and Wang (2003) the lumen area of the coronary artery is estimated using the internal energy, which describes the smoothness of the arterial wall and the external energy which represents the grayscale variation of images that constitute an IVUS video. The minimal energy which defines the contour is obtained using circular dynamic programming. Other methods include statistical analysis, such as Gil, Hernandez, Rodriguez, Mauri and Radeva's (2006), where the presented approach uses statistical classification techniques for the IVUS border detection.

In Papadogiorgaki, Mezaris, Chatzizisis, Kompatsiaris and Giannoglou (2006), a fully automated method for the segmentation of IVUS images and specifically for the detection of luminal and medial-adventitial boundaries is presented. This technique is based on the use of the results of texture analysis, performed by means of a multilevel Discrete Wavelet Frames decomposition. Following image preprocessing, to remove catheter-induced artifacts, a two-step process is employed for the detection of the boundaries of interest. Objective of the first step, termed contour initialization, is the detection of pixels that are likely to belong to the lumen and media-adventitia boundaries, taking into consideration the previously extracted texture features. As a result of this step, initial contours are generated; however, these are not smooth and are characterized by discontinuities, as opposed to the true lumen and media-adventitia boundaries. Thus, at the second step, a filtering or approximation procedure is applied to the initial contour functions, so as to result in the generation of smooth contours that are in good agreement with the true lumen and media-adventitia boundaries. This approach does not require manual initialization of the contours and demonstrates the importance of texture features in IVUS image analysis. A sample IVUS image and the corresponding analysis result of this approach are illustrated in Figure 2.

FUTURE TRENDS

With the number of medical imaging techniques used in everyday practice constantly rising and the quality of the results of such imaging techniques constantly increasing, to the benefit of the patients, it is clear that the need for accurate and automated to the widest possible extent analysis of medical images is a key element in supporting the diagnosis and treatment process for a wide range of medical conditions. To this end, future research will continue to concentrate on the development of analysis methods that are automated, robust and reliable. In addition to that, particular emphasis is expected to be put on the coupling of the results of automated analysis with techniques for the formal representation of them.

Figure 2. Sample IVUS image (left) and the corresponding analysis result of a texture-based approach to the detection of luminal and medial-adventitial boundaries (right)



Examples of early systems for the formal representation of knowledge extracted from medical images, though not in an automated manner, include those discussed in Dasmahapatra et al. (2006), Hu, Dasmahapatra, Lewis and Shadbolt (2003). These are concerned with the annotation of medical images used for the diagnosis and management of breast cancer, such as those generated by mammography and MRI, by expressing all the extracted features and regions of interest using domain knowledge and assigning them to specific concepts of a knowledge structure. In an analogous approach, in Gedzelman, Simonet, Bernhard, Diallo and Palmer (2005) a knowledge structure of cardiovascular diseases is constructed in order to be used for the representation of the findings of the relevant imaging techniques, so as to support concept-based information retrieval.

Combining automated analysis results with techniques such as those briefly discussed above for the formal representation of them will empower new possibilities in the areas of retrieval in extensive medical databases and reasoning over the results of analysis, consequently providing the physicians not only with the analysis results themselves but also with hints on their meaning, minimizing the risk of misinterpretation.

CONCLUSION

In this article, visual medical information analysis was discussed, starting with an introduction on the current use of medical imaging and the needs for its analysis. The current article then focused on three important medical imaging techniques, namely Magnetic Resonance Imaging (MRI), Mammography, and Intravascular Ultrasound (IVUS), for which a detailed presentation of the goals of analysis and the methods presented in the literature for reaching these goals was given. The future trends identified in the relevant section provide insights on how the algorithms outlined in this article can be further evolved, so as to more efficiently address the problem of medical image analysis and consequently pave the way for the development of innovative doctor decision support applications that will make the most out of the available image data.

KEY TERMS

Active Contour Model: Energy-minimizing parametric curve that is the basis of several medical image analysis techniques.

Computer-Aided Diagnosis: The process of using computer-generated analysis results for assisting doctors in evaluating medical data.

Coronary Angiography: X-ray diagnostic process for obtaining an image of the coronary arteries.

Intravascular Ultrasound (IVUS): Diagnostic catheter-based technique that renders two-dimensional images of coronary arteries.

Magnetic Resonance Imaging (MRI): Imaging technique that uses a magnetic field to provide two-dimensional images of internal body structures.

Mammography: Diagnostic X-ray technique which produces breast images and is used to detect breast tissue abnormalities.

Medical Image Segmentation: The localization of known anatomic structures in medical images.

Web Access by Older Adult Users

Shirley Ann Becker
Florida Institute of Technology, USA

INTRODUCTION

The older adult population in the U.S. continues to increase at a rapid pace due to aging baby boomers and increased life expectancy. Older Americans, 60 years and older, will comprise about 20% of the total population by 2030, which is more than twice the number of aging adults than in 2000 (Administration on Aging, 2002).

The Web offers an unprecedented opportunity for older adults to access a wealth of online resources. Increasingly, older adults are using the Web for information on self-diagnosis, treatment, and prevention of health problems (Preidt, 2003). They are taking advantage of electronic government resources to vote, file taxes, obtain social services, voice their opinions to officials, and search historical records. Older adults are also using the Web to stay socially active in terms of communicating with other users via lists and chat rooms (Czaja, Guerrier, Nair & Landauer, 1993; Kerschner & Hart, 1984).

Older adults are getting online by an estimated growth rate of 15% per year (Coulson, 2000). They log over eight hours of online time per week and visit more Web sites than persons in younger age groups when they are online (Morrell, Dailey, Feldman, Holt, Mayhorn & Echt, 2002). Their use of the Internet is predicted to increase as much as 358%, from 3.7 million users in 2001 to 17.3 million in 2005 (Scanlon, 2001).

Unfortunately, older adults may have trouble accessing a Web site because of design issues that impede its use. Barriers may be encountered due to a site's color scheme, font size and type, navigation, vertical screen length, image mouseovers, and sentence complexity, among others. In this information-rich society, many older adults will remain "information have-nots" unless these barriers are removed.

BACKGROUND

In the U.S., the Internet has emerged as a major communications medium with the potential to disseminate information to all citizens including older adults. Yet, there is an ongoing concern that the opportunities associated with Internet access may not be readily available to all citizens. This concern has been expressed in a recent Pew Foundation study (Lenhart, Horrigan, Rainie, Allen, Boyce, Madden & O'Grady, 2003, p. 6):

"Internet non-users will have less power as consumers and fewer economic opportunities, less access to high-quality health information, fewer options for dealing with government agencies, no chance to learn about their world from the millions of organizations and learning centers that have posted their material on the Web, and less opportunity to interact with others through email and instant messaging."

Older adults in particular may encounter Web accessibility barriers due to vision, cognition, and physical changes that are associated with the normal aging process. Reading complexity may also become a barrier when literacy skills of older adults are not taken into account in the design of Web content.

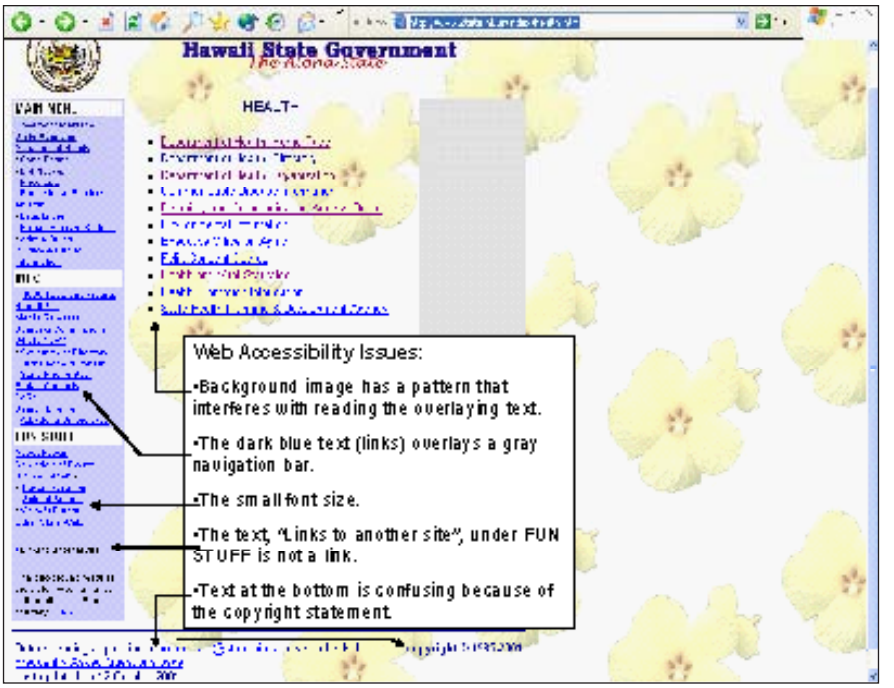
Vision

The aging eye has a reduced ability to focus on close objects due to a reduction in the elasticity in the lens. Other vision changes due to the normal aging process include: a decline in visual acuity, impacting the ability to see objects clearly, yellowing and thickening of the lens, impacting color perception, decreased light sensitivity, impacting adaptation to changes in light levels, increased sensitivity to glare from light reflecting or shining into the eye, and reduced depth perception, making it more difficult to judge the distance of an object (American Foundation for the Blind, 1999). These vision changes impact the use of the Web in terms of the legibility of written content on the page. They also impact searches, navigation, and reading speed and comprehension (Echt, 2002).

Figure 1 illustrates readability issues associated with a state government Web page when taking into account aging vision. The patterned background image may negatively impact readability, especially given the small size of the foreground text[1]. The format of the text at the bottom of the page also impacts readability given that the sentence "Before sending a question to <webmaster>, please check the Frequently Asked Questions page" breaks to accommodate the copyright statement appearing on the right.

The use of color can also impact the readability of information content on a Web page due to aging vision (refer to Becker, 2004a for a discussion on color and Web accessibility for older adults). For many older adults, foreground and background color combinations may render a Web page visually inaccessible. In Figure 1, the contrast between the text and background colors in the navigation bar may be

Figure 1. Illustration of Web barriers and aging vision (http://www.state.hi.us/index/health.htm)



insufficient for older adult readers. Figure 2 shows the New Mexico state government homepage with saturated colors for both the foreground and background. The edges of the text tend to blur when bright or neon colors are used in combination with saturated colors (e.g., bright yellow text displayed on a red background), thus reducing legibility of the text for many older adult users.

Cognition

Studies show that an older adult's working and spatial memory task performance declines with age (Holt & Morrell, 2002). As a result, an older adult may not be able to discern details in the presence of distracting information. In addition, complex navigational schemes, nonintuitive searches and cluttered pages may impede use of a Web site because of declines in working and spatial memory.

Of 40 U.S. state government sites assessed, over 60% required traversing three or more screen pages to navigate directly to resources for older adults (Becker, 2004b). Less than 8% of these sites had a descriptive link on the homepage linking to senior resources. Those Web sites having nondescript links required trial and error searches for senior resources. This type of navigational complexity impedes the use of electronic government by many older adult users.

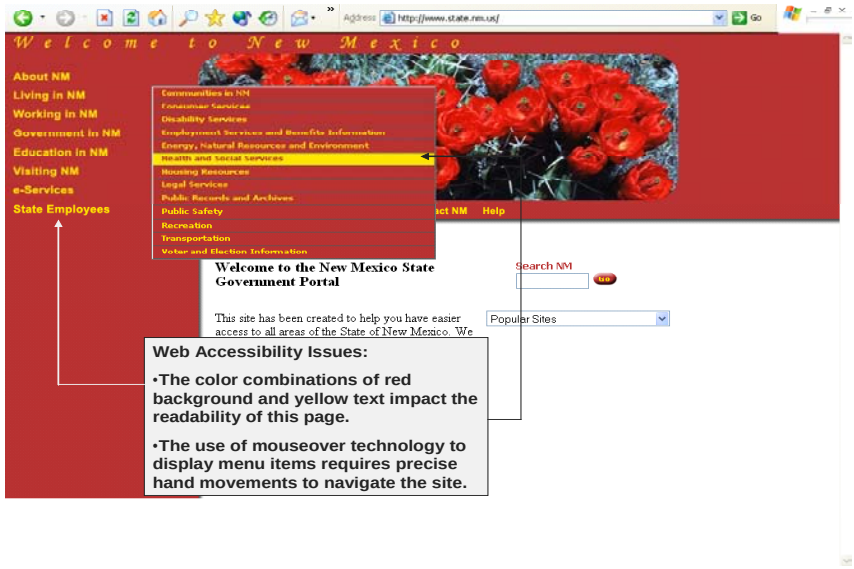
Physical Impairments

Older adults experience a decrease in motor coordination, and as such, may have difficulty with cursor positioning, precise mouse movement, and clicking on links (Chaparro, Bohan, Fernandez, Choi & Kattel, 1999; Ellis & Kurniawan, 2000; Hawthorne, 2000). Figure 2 shows a Web page that requires the precise use of mouseover technology in order to navigate the Web site. This site becomes virtually inaccessible to those users who cannot precisely click on a link and move the mouse to the pop-up menu.

Literacy

The Joint Committee on National Health Education Standards (1995) defines health literacy as the capacity of an individual to obtain, interpret, and understand basic health information and services and the competence to use such information and services in ways that are health-enhancing. This includes the ability to understand instructions on prescription drug bottles, appointment slips, medical education brochures, doctor's directions and consent forms, and the ability to negotiate complex health care systems. In today's wired world, health literacy is expanded to include the comprehension of online health information.

Figure 2. Illustration of Web barriers due to color and mouseovers (http://www.state.nm.us)



The Web is transforming health care by providing online health information to patients, clinicians, caregivers, and family members. There are hundreds of health-related Web sites offering access to unprecedented amounts of health information. Because of their heavy use of health services, older adults could be among the major beneficiaries of Web-accessible health information. But, when the literacy requirements of these pages are misaligned with the literacy skills of older adults, the results could be devastating.

The Web offers an extraordinary opportunity to disseminate timely and much needed health care information to older adults. This opportunity is expanding further with technological advances in wireless communication and increasing availability of community computing resources through institutions such as nursing homes, schools, and libraries.

Older adults in general have a lower education level than younger adults according to the U.S. Census (www.census.gov). The National Adult Literacy Survey found that 71% of older adults performed in the lowest two levels of literacy defined in the survey (Kirsch, Yamamato, Norris, Rock, Jungeblut & O'Reilly, 2001). Approximately 67% of older adults appeared to have difficulty with finding and processing quantitative information when compared to younger adults (Brown, Prisuta, Jacobs & Campbell, 1996).

The reading complexity of content targeting older adults is illustrated by the following sentence appearing on the Alabama state Web site (http://www.adss.state.al.us/seniorrx.htm):

"In case you're not familiar with the program, SenioRx is a partnership of state agencies and community organizations designed to assist senior citizens (ages 60 and older) with chronic medical conditions who have no prescription insurance coverage and limited financial means (living below 200% of the poverty level) with applying for drug assistance programs provided by pharmaceutical manufacturers."

The reading grade level associated with this sentence is far beyond a 12th grade level because it is composed of 58 words. In addition, about 33% of the sentence is composed of three or more syllable words, adding to its complexity. Though there is only one sentence in this sample, it illustrates the reading comprehension barriers that older adults may encounter while surfing the Web.

WEB ACCESSIBILITY INITIATIVES

The National Institute on Aging in conjunction with the National Library of Medicine has developed Web accessibility guidelines for making sites senior-friendly (NIA & NLM, 2001). These guidelines are based on scientific findings from research in aging and cognition and human factors (Morrell et al., 2002). They provide information on how to improve the design, navigation, and information content of Web sites to remove accessibility barriers for older adult users. Table 1 lists several of these guidelines for promoting the development of accessible Web sites. Note that several

Table 1. NIA/NLM guidelines for making senior-friendly Web sites

Guideline	**Description**
Sans serif typeface	Sans serif font types should be used to display information content because they are not condensed.
12 point or greater font size	The use of a large font size improves legibility of information content such that text body, buttons, links, images, and other textual objects are readily seen by an older adult.
Mixed case letters in text body	The text body should be in mixed case text to improve readability. Upper case text should be reserved for headlines on a page.
Left justification	Text should be left justified because spacing between letters is consistently the same.
Plain background images	Patterned background images should be removed from a Web page because they reduce the legibility of text overlaying them.
Text effects only in headlines	Text effects including underlining, italics, bold, or strikethrough should not be used in the body of the text.

of these guidelines, font size, and patterned background images were not followed in the design of the government Web page previously shown in Figure 1.

Another initiative is the National Cancer Society's usability.gov Web site, which provides information about making Web content more usable, accessible, and useful (*www.usability.gov*). It provides research and practitioner-based guidelines on design layout, navigation, information content, and other usability aspects of Web design targeting the general population of computer users. Though it does not specifically target the usability needs of older adults, many of these resources will improve Web site usability for this user group.

Nonprofit groups, including the SPRY foundation (*www.spry.org*), Seniornet (*www.seniornet.org*), and AARP (*www.aarp.org*), provide online resources and support research in Web accessibility for older adults, health literacy, and related areas. Much of the research conducted by these groups provides feedback on the digital divide, health literacy issues, community resources, and the status of older adults getting and staying online.

From a broader user perspective, there have been initiatives in promoting Web accessibility for those with disabilities. Microsoft, IBM, Apple, Watchfire and other corporations have provided resources, tools, and techniques for improved accessibility of Web designs. The Trace Research and Development Center at the University of Wisconsin (*www.trace-center.org*) is one of several centers that focus on universal usability in order to make technology accessible to anyone, anytime, and anyplace. The ACM SIGCAPH (Special Interest Group on Computers and the Physically Handicapped) Web site provides a full listing of Web accessibility resources (*http://www.hcibib.org/accessibility/#ORGANIZATIONS*).

Section 508, an amendment to the 1973 Rehabilitation Act, was enacted by the U.S. government in order to eliminate information barriers for those persons with disabilities. It requires that individuals with or without disabilities have equal access to information provided by federal agencies (www.Section508.gov). Web content guidelines have been put forth by the World Wide Web Consortium (www.w3c.org/WAI/) in order to eliminate accessibility barriers. Though Section 508 does not specifically address the barriers to Web use due to the normal aging process, many guidelines on design layout, information content, navigation, and design consistency improve usability from an older adult perspective.

CONCLUSION

Though significant strides have been made to promote Web accessibility for older adults, there are still barriers to overcome. Web accessibility and online literacy research requires further study in determining an optimal presentation of content to meet the literacy needs of older adult users. The NIA/NLM guidelines recommend active versus passive voice sentence structures, short sentences, and appropriate reading grade levels. Because these guidelines are rather vague, it may be difficult to enforce them during the design of Web content. For example, what is a sufficiently "short" sentence in terms of word count and syllable complexity? Cultural diversity and English proficiency of the older adult population also require further study in terms of potential barriers to Web use.

KEY TERMS

Digital Divide: The digital divide is a term used to describe the disparity between persons who have access to information and computing technology and those who do not. Often, it is used to describe the lack of Internet accessibility to those living in rural or remote areas or who lack computing knowledge and skills.

Electronic Government: Electronic government (e-government) refers to the use of information and computing technologies by government agencies to deliver services, information, and resources to citizens, businesses, and other organizations.

Health Literacy: Health literacy is the capacity of an individual to obtain, interpret, and understand basic health information and services and the competence to use such

information and services in ways that are health-enhancing (refer to text box 1).

Older Adults: An older adult is defined as a person who is 60 years or older in the National Institute on Aging's guidelines on making senior-friendly sites.

Visual Aging: Visual aging takes into account age-related changes in vision that have consequences on daily activities. In this article, the consequences are related to using the Web.

Web Accessibility: Web accessibility means that any person, regardless of disabilities, is able to use Web technology without encountering any barriers.

Web Usability: Web usability refers to the user satisfaction associated with a Web site. It typically includes the effectiveness of the site in meeting the needs of the user. It also includes the site's performance, reliability, and overall efficiency in supporting specified user goals.

ENDNOTES

[1] The impact on readability is minimized when displaying in black and white the patterned background image and its overlaying text and foreground and background color combinations.

Web Accessibility and Compliance Issues

Shirley Ann Becker
Florida Institute of Technology, USA

INTRODUCTION

The impetus for accessible electronic and information technology was driven by federal initiatives with the objective of "bridging the digital divide" (U. S. Department of Commerce, National Telecommunications and Information Administration, 2000). This initiative focused on improving quality and longevity of life, addressing social disparities, promoting small businesses, and providing educational opportunities, among others. As an outgrowth of this initiative, the concept of building an "information society for all" was promoted in the form of universal usability of all electronic and information technology. The long-term goal was to ensure that no one was left behind in terms of inaccessible electronic and information technology.

In 1998, congress amended the Rehabilitation Act of 1973[1] with section 508 to require federal agencies to make electronic and information technology accessible to people with disabilities. Section 508 was enacted to eliminate barriers in electronic and information technology, make available new opportunities for people with disabilities, and encourage the development of technologies that will help achieve these goals (www.section508.gov). The law applies to all federal agencies when they develop, procure, maintain, or use electronic and information technology. Under section 508, agencies must give disabled federal government employees and citizens access to information that is comparable to the access available to others without disabilities.

The Internet and supporting technological advances opened doors for government employees and citizens to access electronic information that in the past were not readily available. However, those with disabilities or normal aging considerations found it difficult if not impossible to use basic technology that nondisabled individuals could use freely (McLawhorn, 2001). This disparity of access to electronic data and information was addressed by congress when it amended the Rehabilitation Act (1973) with section 508. Congress recognized that the federal government is the largest technology consumer in the U.S.; and as such, it can influence the design and manufacture of accessible technologies and supporting products.

BACKGROUND

Section 508, which went into effect in June 2001, requires all federal agencies to comply with accessibility standards administered by the Architectural and Transportation Barriers Compliance Board (referred to as the Access Board).[2] These standards ensure that electronic and information technology is accessible to disabled persons to the extent it does not pose an undue burden on an agency. When section 508 went into effect, federal agencies could no longer procure noncompliant electronic and information technology (Charles, 2001). This meant that vendors, who supply hardware, software, Web, telecommunications, and other information technologies, must ensure compliance with section 508 accessibility in order to obtain government contracts.

The Access Board put together the Electronic and Information Technology Access Advisory Committee (EITAAC) in order to develop section 508 standards. The EITAAC is comprised of industry, government, academic, and disability advocacy organizations. The EITAAC (1999) developed generic standards that were organized into three areas including: (1) accessibility of operation and information, (2) compatibility with peripheral devices, and (3) documentation and services associated with electronic and information technology. The committee made recommendations for implementation of section 508, formalized a definition of electronic and information technology for interpreting the statute, and developed recommendations for procurement processes.

The Access Board defines electronic and information technology as, "information technology and any equipment or interconnected system or subsystem of equipment used in the creation, conversion, or duplication of data or information" (U.S. Access Board, 1999). This definition encapsulates telecommunications, information kiosks, transaction machines, Web sites, copiers, faxes, and other multimedia office equipment. It does not include embedded information technology; back office equipment used only by service personnel for maintenance, repair, or similar purposes; or computer hardware and software, equipment, services, and other resources that automatically manipulate, acquire, store, manage, move, control, display, switch, interchange, or transmit data or information (McLawhorn, 2001).

Table 1. Section 508 technology standards (Federal Register, 2000)

Technical Categories	Subsection
Software applications and operating systems. The criteria primarily focuses on software specifications related to vision disabilities including navigation, animated displays, color and contrast settings, flash technology, electronic forms and others.	1194.21
Web-based information or applications. The criteria used is based on the access guidelines put forth by the World Wide Web Consortium (W3C). The focus of these standards is on accessible, federal government Web sites and private sector Web sites under contract to a federal agency.	1194.22
Telecommunications products. The criteria is designed primarily to ensure access for deaf or hard of hearing persons. The standards require technology that is compatible with hearing aids, implants, and devices for communicating over a telephone, among others.	1194.23
Video or multimedia products. The criteria focuses on video programs, computer generated presentations, and other products that use more than one media. The standards require alternate presentations (user-selectable) for training and informational multimedia productions developed or procured by federal agencies.	1194.24
Self-contained, closed products. The criteria focus primarily on products that have embedded software that cannot readily support assistive technology such as kiosks, copiers, printers, and faxes. As such, assistive technology must be built into the product with requiring assistive technology devices.	1194.25
Personal computers and portable computers. The criteria focus on keyboards and other mechanically operated controls, touch screens, ports, and connectors, among others.	1194.26

Table 2. Statutes and laws related to section 508 of the Rehabilitation Act (1973)

Statute or Law	Description
American with Disabilities Act (ADA) of 1990	American with Disabilities Act (1990) prohibits discrimination and ensures equal opportunity for persons with disabilities in employment, state and local government services, public accommodations, commercial facilities, and transportation (http://www.usdoj.gov/crt/ada/pubs/ada.txt).
Assistive Technology Act of 1998	The Assistive Technology Act (1998) establishes a grant program, administered by the U.S. Department of Education, to provide federal funds to support state programs addressing assistive technology needs of individuals with disabilities (http://www.section508.gov/docs/AT1998.html).
Section 501 of the Rehabilitation Act	Section 501 prohibits discrimination on the basis of disability in federal employment and requires federal agencies to establish affirmative action plans for the hiring, placement, and advancement of people with disabilities in federal employment (www.section508.gov/index.cfm?FuseAction=Content&ID=17).
Section 504 of the Rehabilitation Act	Section 504 prohibits discrimination based on disability in federally funded and federally conducted programs or activities in the U.S. including employment programs (www.section508.gov/index.cfm?FuseAction=Content&ID=15).
Section 505 of the Rehabilitation Act	Section 505 establishes enforcement procedures for title V of the Rehabilitation Act. Section 505 (a) (1) specifies that procedures and rights set forth in section 717 of the Civil Rights Act of 1964 shall be available with respect to any complaint under section 501. Section 505 (a) (2) specifies that remedies, rights and procedures set forth in title VI of the Civil Rights Act of 1964 shall be available to any person alleging a violation of section 504. Section 508 is also enforced through the procedures established in section 505 (a)(2) (http://www.section508.gov/index.cfm?FuseAction=Content&ID=18).
Section 255 of the Telecom-munications Act of 1996	Section 255 of the Telecommunications Act (1996) requires manufacturers of telecommunications equipment and providers of telecommunications services to ensure that equipment and services are accessible to persons with disabilities, if readily achievable (www.fcc.gov/telecom.html).

Table 1 summarizes each section of the technology standards put forth by the board and as recommended by the EITAAC. The technical categories in the table focus on the functional capabilities covered under section 508. These standards focus on assistive technologies (e.g., screen reader devices) and alternative technologies (e.g., keyboard navigation instead of mouse navigation) that allow access to those with disabilities. Though not specifically described in the table, each standard outlines the technical and information dissemination requirements for the use of electronic and information technologies.

Though section 508's enforcement mechanisms apply only to procurement, both sections 501 and 504 of the Rehabilitation Act (1973) require accommodations for individuals with disabilities. (Table 2 provides definitions of sections 501 and 504 along with other related statutes and laws.) As such, federal agencies cannot use section 508 to avoid accessibility requirements and must provide alternative means of access to information for federal employees and individuals with disabilities. If an undue burden claim prevents procurement of accessible electronic and information technology, then a federal agency must provide alternative means of access (www.section508.gov)

SECTION 508 AND WEB ACCESSIBILITY

The W3C, as the standards setting body for the Web, has provided support to the Web Accessibility Initiative (WAI) in the development of Web Content Accessibility Guidelines (WCAG) (Chisolm, Vanderheiden, & Jacobs, 2001). These guidelines enforce the section 508 Web accessibility standard (refer to www.w3.org/TR/WCAG10/ for more information). They continue to play an integral role in the implementation of section 508 by federal government and contracting vendors as mandated by law. They are also used by commercial, education, nonprofit, and other government sectors in voluntarily promoting Web accessibility for all users.

Web Accessibility Guidelines

The WAI guidelines for Web content accessibility focus on making online information accessible to those with disabilities. This includes text, images, links, audio, and other elements that compose a Web page or application. These guidelines are briefly described.

1194.22 (a) A text equivalent for every non-text element shall be provided. Pictures, graphs, and other elements on a Web page not in electronically readable form are supplemented with a text description to be read by screen reader software and Braille displays.

1194.22 (b) Equivalent alternatives for any multimedia presentation shall be synchronized with the presentation. Captioning provided for audio information as well as audio descriptions of visual information are examples of equivalent alternatives that must be synchronized for accessible Web content.

1194.22 (c) Web pages shall be designed so that all information conveyed with color is also available without color. Color alone cannot be used to convey information as it may render the Web site inaccessible to a user with color deficient vision.

1194.22 (d) Documents shall be organized so they are readable without requiring an associated style sheet. A style sheet is a file that contains instructions on how information is to be presented to the user. It is important to design style sheets such that specialized software can provide access to information by a disabled user.

1194.22 (e) Redundant text links shall be provided for each active region of a server-side image map. A server-side image map sends coordinates of the image map to a computer server that then identifies the URL (link) being selected. For those who cannot accurately click on a specific region, it would be important to provide redundant links on the map.

1194.22 (f) Client-side image maps shall be provided instead of server-side image maps except where the regions cannot be defined with an available geometric shape. A client-side image map associates a link with a particular image map region. It would be important to use client-side instead of server-side image maps whenever possible for improved accessibility.

1194.22 (g) Row and column headers shall be identified for data tables.

1194.22(h) Markup shall be used to associate data cells and header cells for data tables that have two or more logical levels of row or column headers. Descriptive identifiers for each row and column header allow a screen reader device to read table data in a meaningful format.

1194.22 (i) Frames shall be titled with text that facilitates frame identification and navigation. For those sites using frames, it is important to label each frame with descriptive information for accessible navigation.

1194.22 (j) Pages shall be designed to avoid causing the screen to flicker with a frequency greater than 2 Hz and lower than 55 Hz. Objects that flicker on a Web page may be a problem for users with photosensitive epilepsy, as there is the potential for triggering a seizure when flickering in the 4 to 59 flashes per second (Hertz) range.

1194.22 (k) A text-only page, with equivalent information or functionality, shall be provided to make a Web site comply with the provisions of this part, when compliance cannot be accomplished in any other way. The content of the text-only page shall be updated whenever the primary page changes. For those Web pages that cannot be designed to be compliant with the standards put forth by section 508, a text-only page can be provided.

1924.22 (l) When pages utilize scripting languages to display content, or to create interface elements, the information provided by the script shall be identified with functional text that can be read by assistive technology. Some Web sites use scripting language to customize a page with the display of dynamic content. It is important that text is associated with these elements to ensure that a visually impaired user is provided meaningful information.

1924.22 (m) When a web page requires that an applet, plug-in or other application be present on the client system to interpret page content, the page must provide a link to a plug-in or applet that complies with §1194.21(a) through (l). For example, PDF files require the downloading of Adobe Acrobat Reader software. As such, a download link would be provided adjacent to the PDF file.

1194.22 (n) When electronic forms are designed to be completed online, the form shall allow people using assistive technology to access the information, field

elements, and functionality required for completion and submission of the form, including all directions and cues. A Web form requires a label (e.g., "Last Name") adjacent to each element in order for the screen reader to present meaningful information to the user.

1194.22 (o) A method shall be provided that permits users to skip repetitive navigation links. Most Web sites have repetitive links on the top, side navigation bars, and bottom of a page. This design method allows repetitive links to be ignored by a screen reader device.

1924.22 (p) When a timed response is required, the user shall be alerted and given sufficient time to indicate more time is required. Web pages may time out when a response is not received within a specified time period rending the site inaccessible. An alert feature would warn a user of the impending time out.

Web Accessibility Compliance

According to Reed (2003), Matthews (2002), and others, federal agencies were initially slow to adopt compliance practices aggressively. This is reflected in early studies in section 508 Web accessibility compliance. Stowers (2002) conducted a study on 148 federal Web sites and found that only 13.5% of the sites met the accessibility standards of section 508. Additional studies were carried out by the World Markets Research Center and Brown University (2001) and West (2002) in assessing accessibility features of government sites. These studies also uncovered the lack of full compliance with the section 508 Web accessibility standard.

Since these early studies, most federal sites have made great strides in complying with section 508 through the use of automated support, such as provided by Watchfire Bobby™ 5.0, Microsoft FrontPage®, and Macromedia's Dreamweaver®. These tools provide feedback on noncompliance errors associated with the Web content accessibility guidelines. Unfortunately, there are still accessibility barriers even when automated tools report no compliance errors. A study by Becker (2005), for example, found that 60% of sampled federal Web sites had nondescript labels on navigational links. Though these would not be flagged as noncompliance errors by automated tools, they pose accessibility barriers when using assistive technology given that they provide insufficient information for navigating the site.

An illustration of this type of accessibility barrier is the text equivalent message "Americans with Disabilities" associated with an icon on the U.S. Small Business Administration Web site (http://www.sbaonline.sba.gov/). Though this message is in compliance with *1194.22 (a) A text equivalent for every non-text element shall be provided*, a user relying on a screen reader device would be unaware that the icon links to the Americans with Disabilities Act Web page. In contrast, the U.S. Treasury Department Web site (www.ustreas.gov) has a meaningful text equivalent message associated with its graphic. The message, "Social Security Banner that links to http://www.strengthening socialsecurity.gov," when read aloud by assistive technology relays information about the graphic as well as the navigational link associated with it.

FUTURE TRENDS

Government, nonprofit organizations, academic institutions, and commercial vendors continue to provide information, resources, and tools to assist in both mandatory and voluntary compliance with section 508. The WAI guidelines continue to provide important information about each accessibility barrier and potential solutions to it. The University of Wisconsin's Trace Center (2004) has recently collated the Access Board's 508 final rule and guidelines. John Hopkins University offers an updated list of Web accessibility resources and tools (Reinzi, 2005).

However, more needs to be done in promoting Web accessibility beyond a strict interpretation and adherence to standards. Though compliant with section 508, the lack of a meaningful text equivalent description for a graphic or image is an accessibility issue that needs to be addressed. For those with unsteady hands, arthritis, or other motor skill disabilities, mouseover technology may pose an impediment to navigating a site. For users with vision impairments, insufficient contrast between foreground and background colors may impede readability of Web contents. A Spanish version of a federal Web site that has nontranslated components becomes inaccessible when read aloud by assistive technology to a user with low or no English proficiency.

Jaeger (2003) recommends a rating system for no, partial, or full compliance; as well as, an identification component for whom the site is accessible. Future research is needed to explore the potential for this type of rating that could expand voluntary compliance with section 508 by nongovernmental entities.

CONCLUSION

Section 508 has made a significant impact on bridging the digital divide especially for those with disabilities. It has provided the impetus for building e-government sites that are universally accessible to all citizens. However, universal Web accessibility cannot be achieved through the sole use of automated technologies or strict adherence to section 508 guidelines (Brewer, 2004). Automated technologies can only guide the developer through an accessibility assessment and may not uncover barriers related to meaningful information content. Full compliance with section 508 will require inspection of Web elements including the good use of color,

meaningful labels on graphics and links, and full translation of content, among others.

KEY TERMS

Assistive Technology: Equipment, device, or other product that assists a disabled user in performing tasks that otherwise would be difficult or not possible to accomplish.

Color Deficiency: Color deficient vision results in an inability to distinguish certain colors and shades when compared to normal vision.

Digital Divide: The digital divide is the gap between those who have access to electronic and information technology and those who do not.

Electronic and Information Technology: Information technology and any equipment or interconnected system or subsystem of equipment used in the creation, conversion, or duplication of data or information (www.access-board.gov).

Motor Disabilities: Physical impairments that can impede movement, coordination, or sensation. They can include weakness and lack of muscle control.

Screen Reader: Speech synthesis software used by a vision-impaired person to read aloud what is displayed on a computer screen.

Section 508: Amendment to the 1973 Rehabilitation Act requiring federal agencies to make electronic and information technology accessible to people with disabilities.

Web Accessibility: Web accessibility means that a person, regardless of disabilities, is able to use Web technology without encountering any barriers.

ENDNOTES

1 Rehabilitation Act of 1973, *as amended by* § 508, 29 U.S.C. § 794(d) (1998).

2 Architectural and Transportation Barriers Compliance Board is an independent federal agency, established by Section 502 of the 1973 Rehabilitation Act. Its primary function is to promote accessibility for individuals with disabilities.

Web-Based GIS

Anselmo Cardoso de Paiva
University of Maranhão, Brazil

Cláudio de Souza Baptista
University of Campina Grande, Brazil

INTRODUCTION

Currently, the Internet is becoming the main vehicle for publishing geographical information, which enables data interchange, analysis, and geographical data visualization. The rapid evolution of Web technology has lead to an improvement of the geographical information utilization and availability.

The rise of the Internet has created an infrastructure ideally suited to the widespread distribution and dissemination of geographical information. By using Internet GIS applications, users may view, query, analyze, and download spatial information from anywhere at anytime. While this improvement provides new opportunities for public domain as well as commercial use of spatial datasets, new problems arise. One of them is the problem of transferring data efficiently from server to client. Geographical datasets are generally very large, and this process may demand too much time.

The Internet has created an interesting environment for geospatial data sharing, in which data providers make their databases available through the Web, and users may transfer, visualize, manipulate, and interact with them (Bertolotto & Egenhofer, 1999). This environment introduces new problems that must be addressed to make possible an efficient and effective use of these datasets. One such problem is related to the availability of huge geospatial data amounts in repositories with limited connection bandwidth (Flewelling & Egenhofer, 1999).

One of the main concerns on Web-based geographical information systems (Web GIS) is related to performance issues, as these datasets need to migrate, as fast as possible, from server to client tiers (Peng & Tsou, 2003). This is the problem of generation and transmission of the digital maps, which are suitable for user needs. Another important issue is to enable fast and easy Internet GIS application deployment.

In this chapter, we discuss solutions proposed for Web GIS based on the vector format, particularly the iGIS framework (Baptista, Leite Jr., Silva, & Paiva, 2004). The iGIS is a Web GIS that renders maps using multiresolution techniques, and enables user interaction them, using the W3C SVG specification. The chapter also addresses the issues that affect Web GIS performance, presenting an overview of the techniques that increase Web GIS performance and the results obtained by using the iGIS framework.

BACKGROUND

Web GIS applications evolved from the delivery of static maps conveyed in raster formats (e.g., JPEG, GIF, PNG) to an actual stage in which users may choose the window, the scale, and possibly also the data layers to be displayed, and the map is generated dynamically from a database and transmitted in the vector format. Web mapping deals at least with two basic problems: map generation, and map transmission.

Regarding map generation, there are, basically, two approaches. The first one is based on the use of a database that stores geometry information at the most precise scale, and each visualization at less precise scales are automatically derived from that, mainly through cartographic generalization (Müller, Lagrange, Weibel, & Salgé, 1995; Weibel & Dutton, 1999). This implies the execution of map generalization procedures on the fly (Harrie, Sarjakoski, & Lehto, 2002; Lehto & Kilpelainem, 2001). The second approach utilizes a multiresolution database in which spatial objects may be associated to a variety of geometric representations that are scale dependant (Zhou, Prasher, & Kitsuregawa, 2001). In this case, it is necessary to process an off-line computation of a multiscale database containing several independent levels of detail.

Associated with the map generation problem, there is also the problem of vector map transmission. A possible solution is the use of progressive data transmission that is well known and successfully applied to raster images, in which coarser versions of the data are displayed before the complete image is downloaded.

One of the first works on progressive vector data transmission on the Internet has been proposed by Buttenfield (1999, 2002). His work focuses on the hierarchical subdivision of vector data by using tree structures based on the Douglas-Peucker generalization algorithm (Douglas & Peucker, 1973) similarly to the BLG tree by (Oosterom & Schenkelaars, 1995).

Bertolloto and Engenhofer (2001) did a work based on progressive transmission of vector data in conjunction with on-the-fly mapping over the Internet. They proposed the creation of multiple dataset representations corresponding to different levels of details. These levels of details are then sequentially transmitted and added to the currently displayed representation. Although the proposal is very interesting, it remains an open issue; the integration of two different levels of details dataset on the client side in a way that maintains the visualization completely and correctly at each step.

WEB-BASED GIS: DEVELOPMENT TOOLS AND PERFORMANCE ANALYSIS

The iGIS framework makes it possible and easy to build a GIS application in few minutes. By configuring an XML file using the deployment tool, a user can put any application online. Firstly, it is necessary to populate the database. Then, the user sets data location by providing the parameters: login, password, and database URL; the layers to be displayed; the colors that are going to be used; and other parameters.

The iGIS architecture is based on three tiers: presentation, application, and database. In the presentation layer, Java Server Pages, JSP, are used for implementing dynamic pages. Scalar vector graphics (SVG) format and JavaScript are used for map drawings and graphical tools. SVG was chosen due to many reasons including the fact of being a W3C recommendation; the ability of using vector maps with client manipulation operations such as zooming and panning; and map data compression.

The application layer is responsible for the business logic, and it is composed of the following modules:

- Data loader, which is responsible for loading data from different data sources, configured in XML. To add a new data source, it is necessary to extend some classes from this package;
- Application data model, which uses the OpenGeo-Spatial Simple Features standard for implementing the system logic classes;
- Data formatter, which formats data according to the rendering type chosen. This module is extensible and is configured using XML. Currently, the iGIS uses SVG for rendering; and
- Static maps, which loads and stores SVG maps, improving system performance.

Finally, the data layer contains different data sources. Currently, there are drivers for Oracle, IBM DB2, and Postgresql database servers, and spatial data in ESRI shapefile format. Again, this module can be extended to support other data source types.

iGIS copes with spatial and nonspatial data in an integrated way: both data types are stored in the database server and manipulated via data manipulation language and data definition language statements. For example, information about a hospital would include name, address, number of rooms, physicians, equipment, and its latitude and longitude coordinates. Fortunately, there are several database servers with support to spatial dimension, such as Oracle, IBM DB2, Postgresql, MySQL, and, more recently, the Microsoft SQL Server. Therefore, by using SQL statements, users may submit spatial queries together with nonspatial ones.

iGIS works with different measure units that facilitate internationalization. Moreover, iGIS implements multiresolution by enabling users to navigate through several levels of detail in a map. For example, an application initially presents information at country level of detail. Then, after some operations of zooming in, it can present information at state level of detail, then at city level, and so on. In order to achieve that, iGIS deals with static and dynamic map generation.

On the other side, it is also important to address the aspects that affect the Web GIS performance once it is required to a Web-based GIS an efficient data transmission for the publication of spatial information. Furthermore, the provision of adapted data to heterogeneous clients, which may range from mobile to desktop ones, is another important requirement. Thus, the use of optimization techniques in order to obtain both data reduction and just-in-time delivery mechanism are also relevant to reach high performance. Some of these techniques, as pointed out by Baptista, Nunes, Sousa, Silva, Leite Jr., and Paiva (2005), are data simplification, relative coordinates, static maps, multiresolution, compression, on-demand loading, and progressive transmission.

Data simplification is one of the most used techniques for Web GIS optimization. Depending on user needs, a more detailed view may be required in map rendering. However, for some users, it is enough to have a broader view of map contents and some details in few zoom levels. Hence, map rendering can be done according to the details required by users. Moreover, maps are rendered for clients using their specific resolution, which may also introduce information loss.

Data simplification is a process that identifies, a priori, the map information that can be omitted, and removes it before map transmission.The amount of transmitted data without loss in visual quality is reduced. Map coordinates are generally set with high precision; consequently, the number of points is too large. The simplification process will reduce the number of transmitted points.

In general, vector graphics languages accept the representation of polygonal in two ways: using either absolute

or relative coordinates. Absolute coordinates specify each point position based on a fixed coordinate system. Relative coordinates express each point position in either a polyline or a polygon based on the previous point position.

A point expressed using relative coordinates represents the translation of the absolute coordinate point relative to the previous point in either polyline or polygon description. The initial point is always expressed using absolute coordinates.

A Web GIS usually stores its maps in a spatial database system. Hence, each user session needs both to establish a connection to the database system and to load the data. This loading process is time consuming, as a spatial query is executed and the resulting set must be transformed according to the GIS output format, such as SVG, Flash, WebCGM, and so on. As most Web GIS applications are read-only, it is worthy to load these maps statically as soon as they are needed. Thus, the first access to the required map will take more time to be rendered then next access, as the spatial query will be executed, and the transformation for the specific output format will be done. Nonetheless, next accesses to this map will be fast, as it is already formatted in an appropriate transmission format.

Let us consider a map that contains country, city, street, and quarter layers. A better performance can be achieved if maps are presented in different levels of detail. This is the purpose of multiresolution procedure.

Multiresolution divides the maps into cells, forming a hierarchy. Hence, detailed maps are presented progressively (such as streets) as the user zooms in. Each multiresolution level in the hierarchy has a number of zoom levels, and when the last one is reached, the next zooming operation points to another level. The first level is divided into nine subregions, called cells; each of these is represented in a file. The overlapping of cells is necessary to enable the implementation on the client-side of the pan visualization operation.

Each cell adopts the same procedure, that is, it has a number of zoom levels, and then it is subdivided into nine cells, and so on. This subdivision is done recursively, until the last level of multiresolution is reached. A cell is sent to a client only when it reaches the map representing it. This procedure tends to reduce data transmission. Paiva, Silva, Leite Jr., and Baptista (2004) explain this procedure with more detail.

On-demand map loading is another alternative to increase the availability of maps to Web GIS. It has been defined as the creation of a map upon user request, with the following features: appropriated scale; addressing the chosen area of interest; and focus on the required purpose.

Thus, the map geometries are transmitted to the client on the fly, through either a zooming or panning operation. This approach is based on two main concepts: layer visibility and map window.

The layer visibility concept defines that each map layer has a range of scales in which it is visible. This is a common organization task in map generation to avoid the map pollution confounding the user. Thus, at a given scale, some layers may be invisible, and this contributes to the map understanding.

The map window concept defines a region of interest from all geographical databases in which the user is interested; this defines a rectangle area that must be used to clip all the features that do not need to be integrated into the map because they will not be visualized. When a user requests a map, the client sends to the map server a window, and this window is used to locate all the geographic features in the database that intercept it.

As the user requests a change in the interest area (e.g., a pan operation) or in the current map scale (e.g., a zoom operation), the map server will generate a new map appropriated to user request, and will send it to the client side. Apparently, this process may seem slow, but for some class of maps with a large amount of geographical data, this process may improve map visualization performance.

Finally, another important aspect that must be used to improve the performance of Web GIS is the progressive transmission. In the progressive transmission, the map server divides the map into a low-resolution version and a set of incremental versions that, when incorporated to a certain map version, will generate a more detailed map version. The client is responsible for receiving a map detail increment at some level n, and for integrating it into the current map version, which generates a map version at level $n+1$.

Other approaches to this problem explore device restrictions, like visualization resolution. This can determine the level of detail that can be visualized in a specific device. In general, the device can represent less detailed information than the amount that is sent by the map server. The level of detail that cannot be visualized increases the transmission cost, and does not improve the quality of the map visualized by the client. Thus, the elimination of such information reduces response time at the client side without compromising map quality.

Baptista et al. (2005) present an evaluation of the impact of some of these techniques, and we may see that with a combination of these techniques, we may obtain about 63% in the improvement of performance. This was achieved using GZIP filter, simplification with precision value three, and relative coordinate techniques.

Additionally, Costa, Paiva, Teixeira, Baptista, and Silva (2006) present a progressive transmission scheme for the iGIS Web mapping framework. The proposed scheme enables the Internet GIS developer to plan a scale discretization for multiple levels of detail in offline maps. This approach provides, to the user application, a more efficient environment to visualize and interact with geographic data, especially when considering low bandwidth networks.

The proposed scheme is based on the visualization device resolution. The map features are simplified and a compact map representation is generated, aiming to improve response time. To evaluate the impact of our proposed scheme in the visualization task, several experiments were performed. The experimental results have demonstrated that the amount of information transmitted is significantly less in our proposed scheme, being, therefore, very effective for Web-mapping systems.

FUTURE TRENDS

We also expect that soon, we will make the transition from the historical 2-D planimetric maps to the 3-D view of the terrain, completely integrated with a set of multimedia information.

Finally, a major challenge is the integration of current technologies to generate the 4-D GIS (XYZ and time). This will open the way for integration with predictive modeling, to introduce a look into the future, or more traditionally, study the dynamics of various phenomena.

CONCLUSION

This chapter focused on the theme of Web-based GIS. Web GIS is becoming very popular, especially due to the high variety of open source solutions, such as Degree, GeoTools, GeoServer, Mapserver, and others, which makes this complex technological solution more affordable.

We conclude that, most of the time, the proposed optimal solutions, which maximize performance and accuracy of spatial data, may be employed. These solutions are very useful when there are constraints on both network bandwidth and device memory and screen sizes, as it is the case of mobile phones.

KEY TERMS

Framework: A set of software components that provides a foundation structure for an application. Frameworks maximize developer productivity and produce more reliable code, as there is reuse of already tested code, which enables not writing an application from scratch.

GIS: Geographical information system is a system of hardware and software used for storage, retrieval, mapping, and analysis of geographic data.

Map Simplification: A set of algorithms to find simpler representations for each map object.

Multiresolution: A strategy to construct different representations of vector maps in different scales based on the construction of the map objects simplification.

On-Demand Map Loading: A scheme for map transmission that sends, to the client, just the map portion that is being visualized.

Progressive Transmission: Map transmission scheme in which the map server divides the map into a low-resolution version and a set of incremental versions that, once incorporated to a certain map version, will generate a more detailed map version.

Spatial Operators: Set of SQL operators to deal with the spatial dimension of the data, and making possible the definition of spatial queries.

SVG: Scalar vector graphics, is an XML specification of the W3C to deal with vectors graphics in the web.

Web Caching

Antonios Danalis
University of Delaware, USA

INTRODUCTION

The popularity of the World Wide Web has led to an exponential increase of the traffic generated by its users for over a decade. Such a growth, over such a long period of time, would have saturated both the content providers and the network links had Web caching not been efficiently deployed. Web caching can improve the overall performance of the World Wide Web in several ways, depending on the decisions made regarding the deployment of the corresponding caches. By placing caches in strategic positions, the core network traffic can be reduced, the load of a content provider can be scaled down, and the quality of service, as the users perceive it, can be improved. In this article we present an overview of the major design and implementation challenges in Web caching, as well as their solutions.

BACKGROUND

A Web cache can be placed at different positions on the Web and yield different benefits. Namely, it can be placed next to a content provider, in strategic positions inside the network, at the boundaries of local area networks, or inside the host that runs the requesting browser.

Most users tend to access particular pages quite often. An example could be the "home page" that has been set on their browser, or Web sites that contain documentation they are interested in. Furthermore, during browsing, many users visit the same pages multiple times in short periods of time, by using the history of their browsers. To exploit these access patterns, most browsers keep local copies of the frequently or recently accessed pages. This way, the user is served in near zero time, and the network traffic is reduced. Although this technique can have a positive effect on the browsing experience of a single user, it has a minimal effect on the network traffic. This is mostly due to the small disk space used by this type of caching and the lack of sharing between different user caches.

To yield significant results, dedicated computer systems, called proxies, are installed at the edges of local or wide area networks. These systems can achieve significant reduction in the network traffic and improvement in the user perceived quality of service, by filtering and serving the Web requests generated inside the entire network they serve. If a user has defined in the browser's settings a particular proxy to be used, every time he or she requests a Web page the browser will send this request to the proxy. If the proxy happens to have the page, the user will be served promptly without the original content provider being contacted. If the proxy cannot serve the request, it will fetch the appropriate Web objects (such as the text documents, images, applets) from the original server, and possibly keep a copy for later use. Transparent proxies are a special kind of proxy that end users do not explicitly specify in their browser's settings. Rather, the gateway of the network identifies Web requests and forwards them to the proxy. This model is more efficient, and easier to administrate, since all the users of the local network will be using the proxy, and they need not know about possible changes concerning the proxy.

To improve the performance of a content provider, a cache can be deployed on the server side. These caches, also called server accelerators, or reverse proxies, are usually deployed in front of clusters of Web servers (Challenger, Iyengar & Dantzig, 1999) and cache the most popular documents in their main memory. Since a few highly popular documents are in most cases responsible for a large percentage of requests, by using a server-side cache, a Web server can decrease its disk I/O load (Abrams et al., 1995; Markatos, 1996; Tatarinov, Rousskov & Soloviev, 1997) and significantly improve the request serving quality of service. Nevertheless, a reverse proxy benefits only a particular content provider and does not reduce the network traffic.

In addition to client and server-side caching, there exists the approach of adaptive caching (Michel et al., 1998). In this scheme caches can exist at different points inside the network, and be configured to cooperate with one another, in order to improve the overall performance and balance the load. In this model, different caches, potentially belonging to different organizations, are organized into dynamic groups, which each one can join or leave depending on content demand. The communication needed for a group to form and for documents to be located is done through the Cache Group Management Protocol (CGMP) and the Content Routing Protocol (CRP), respectively. Adaptive caching can deal very well with request surges, occurring when some documents become highly popular in a short period of time (usually articles in online newspapers), but assumes that cooperation across administrative boundaries is not an issue.

CRITICAL ISSUES OF WEB CACHING

To improve their effectiveness, caches can be combined in groups to serve requests cooperatively. Such groups may be organized in meshes, as in the case of adaptive caching, or in hierarchical formations, as in the case of the Harvest Cache project (Chankhunthod et al., 1996). In hierarchical designs, caches are usually organized in tree-like structures, and are configured such that child nodes can query their parents and their siblings, but never their children. Although grouping several caches can improve the scalability of the caching system, control messages between a large number of nodes could saturate the parent nodes and the network links (Baentsch, 1997). To make the communication between the caches efficient, several special purpose protocols have been introduced.

The most popular inter-cache communication protocols are ICP, CRP, CARP, cache digest, and WCCP (Melve, 1999). The Internet Cache Protocol (ICP) was developed for the communication of the caches in the Harvest project and was refined within Squid (SQUID). It is a lightweight message format, used by the caches for issuing queries and replies, to exchange information among one another regarding the optimal location from where a certain object can be retrieved. The large number of messages exchanged in ICP, when the number of caches is high, has been shown to impede scalability (Baentsch, 1997; Fan et al., 2000). To avoid similar effects, the Content Routing Protocol (CRP) uses multicast to query cache meshes. CRP exploits the overlapping that exists in cache group formations to propagate queries or popular objects between the groups. To further improve on the performance of the inter-cache communication protocol, cache digests can be used (Fan et al., 2000; Rousskov & Wessels, 1998). Cache digests compact (using a lossy algorithm) the information about the contents of a cache, and make it available to its neighbors. By checking the digests of its neighbors, a cache can identify, with some uncertainty, which neighbors are likely to have a given document. In addition to these protocols, there exist two proprietary ones, CARP and WCCP, designed by Microsoft and Cisco respectively. Unlike the protocols mentioned before, the Cache Array Routing Protocol (CARP) implements routing in a deterministic way. In particular, it uses hashing to identify which member of the proxy array has the requested document. This way it avoids the scalability problems that appear in ICP due to the large number of control messages. The Web Cache Communication Protocol (WCCP) is designed to support transparent caching. The idea is that a router (such as Cisco Cache Engine) that can recognize Web traffic will intercept user requests and redirect them to a cache.

The protocol used for the communication between the Web clients, proxies, and servers is the Hyper-Text Transfer Protocol (HTTP). HTTP runs on top of TCP/IP, which is the most common protocol used in the Internet for reliable transfers, flow control and congestion avoidance. To initialize a connection, TCP sends a special packet (SYN) from the client to the server, and the server responds with an acknowledgment. After initializing the connection, in order to request a page, the client has to send an additional message to the server, and wait for the reply. In the first version of HTTP, this four-step procedure had to take place for all individual objects of a page, such as images, or applets, separately. To reduce the number of round-trips needed, persistent connections, that is, connections that remain open after the retrieval of a file, were proposed (Caceres et al., 1998; Heidemann, Obraczka & Touch, 1997; Mogul, 1995). Persistent connections allow a client to fetch all the components of a Web page by facing the connection startup latency only once. In addition to the multiple steps handshake, slow-start is another feature of TCP that has negative effects in the context of Web transfers. As the name implies, slow starts demand that newly created TCP connections transmit data very slowly and they increase the throughput as they transmit more and more. In the general case, where flow control and congestion avoidance is necessary, this technique is very efficient. In the case of Web transfers though, where the majority is short-lived since most documents are a few kilobytes long (Arlitt & Williamson, 1996; Cunha, Bestavros & Crovella, 1995; Shriver et al., 2001), slow start translates to slow transfer. In order to deal with these issues, HTTP/1.1 (Fielding et al., 1997) was introduced. This new version, among other improvements, supports persistent connections and has been shown to dramatically outperform its predecessor (Nielsen et al., 1997).

In heavily loaded Web caching systems, disk I/O can become a significant bottleneck (Markatos et al., 1999; Mogul, 1999; Rousskov & Soloviev, 1998), because disks are significantly slower than the main memory, and traditional file systems are not optimized to handle Web traffic. To reduce this overhead, Gabber and Shriver (2000) proposed the use of a special purpose file system and Markatos et al. (1999) and Maltzahn, Richardson and Grunwald (1999) proposed the use of special purpose storing policies that reduce the overhead of file creation, deletion, and access. Such policies take into account Web access patterns when they make decisions regarding file placement. For example, in most cases, the HTML text of a Web page and the embedded objects (such as images) of the page will be requested one after the other. By placing these objects in files located close to each other on the disk (Maltzahn, Richardson & Grunwald, 1999), or in neighboring locations within the same file (Markatos et al., 1999), both reading and writing will access almost sequential disk blocks, yielding a significant performance improvement. Additionally, a specialized file system (Gabber & Shriver, 2000) could avoid keeping metadata to improve performance, or could use in-memory data structures to quickly identify cached objects without performing any disk I/O (Tomlinson, Major & Lee, 1999).

Regardless of the method used to access the disk, and no matter how large the storage space is, it is not possible to store the whole Internet. Therefore, there must exist some techniques to decide which documents to keep in the cache and which to replace when the cache fills up. Several algorithms have been proposed, each trying to keep the most valuable documents in the cache. To assign a value to a document, most algorithms take into account one or more parameters such as recency of access, frequency of access, document size, and fetching latency, and try to evict the documents with the lowest value. The effectiveness of a replacement policy is measured by Hit Rate (HR) and Byte Hit Rate (BHR). HR is the percentage of requests that are served from the proxy, and BHR is the percentage of bytes served from the cache. The Least Recently Used (*LRU*) algorithm is a replacement policy already known and used in virtual memory paging systems. Based on the fact that the possibility of a file to be requested again drops dramatically as the time since the previous request increases (Cao & Irano, 1997; Rizzo & Vicisano, 2000), it tries to replace the least recently used document, when space is needed for a new one. The *SIZE* algorithm (Rizzo & Vicisano, 2000) considers the large files to be the least valuable, and thus removes the largest document to make room for several smaller. Due to the high popularity of small files (Shriver et al., 2001), *SIZE* is among the best replacement algorithms. Capitalizing on frequency of use, the Least Frequently Used (LFU) algorithm evicts the documents that have been used the least amount of times. Although this algorithm can perform similarly to LRU for many access patterns, its main disadvantage is that it does not evict documents that were popular once, but not any more (such as old newspaper articles). To deal with this issue, Arlitt et al. (1999) presented LFU-DA, which is LFU with Dynamic Aging. Their variation takes into account the age of a document and thus manages to perform better than most existing algorithms in terms of both HR and BHR. To achieve even higher efficiency, researchers have introduced algorithms that combine the different dimensions. Lowest Relative Value (LRV) (Rizzo & Vicisano, 2000), for example, assigns a value to each document, calculated based on its age, popularity and size, and replaces the one with the lowest value. Hybrid (Wooster & Abrams, 1997) takes into account even more parameters, such as bandwidth to the content provider, and time to connect, for calculating the value of a document, and has been shown to outperform most traditional algorithms in terms of both HR and latency reduction. Finally, Cao and Irani (1997) proposed GreedyDual-Size, which consists of a family of replacement policies, all working under the same basic idea, but optimized for different goals. Therefore, depending on the goals a cache wants to achieve, GreedyDual-Size can be configured to maximize the HR, or minimize the average download latency, or reduce the network traffic.

Besides evicting documents when space needs to be made for new ones, a proxy needs to delete documents that are not valid any more, to preserve the consistency of its cache. The most common cache consistency mechanisms are time-to-live (TTL) fields, client polling, and invalidation protocols (Gwertzman & Seltzer, 1996). TTL is actually an estimation of how long the current copy of a document will be valid for. Although this approach can be very useful in cases where this information is known, as in the case of periodically changing news articles, it can lead to waste of bandwidth if the estimation is too conservative, or cache inconsistency if the value of TTL is too large. Adaptive TTL tries to find a better estimation by taking into account the document's age (Gwertzman & Seltzer, 1996). In client polling, every time a document is requested, the cache sends an if-modified-since (IMS) request to the original server. According to the result, the file is either proven valid and served by the cache, or the new version is fetched. This approach generates a large number of control messages, since an IMS is sent to the server for every document requested. To gain the benefits of both techniques, squid (SQUID) uses an adaptive TTL policy to decide when to send an IMS validation request to the server. Invalidation callbacks are an approach where the original server keeps track of the proxies that have a copy of its documents, and contacts them when the documents change. Callbacks provide strong consistency without saturating the network with control messages (Cao & Liu, 1998), but raise privacy and security concerns.

Dynamic pages, either created according to the preferences of each individual user, or updated dynamically to meet real-time changing data, such as the stock market or sports scores, raise important issues in regard to cache consistency. If a dynamic document is cached and served by a traditional proxy, it is very likely to be invalid even before the very next request. On the other hand, if a proxy decides not to cache dynamic objects, it will lose an important percentage of Web traffic (Caceres et al., 1998; Wolman et al., 1999). Markatos (2001) suggests caching of search engine results for hours or days, based on the fact that query results are already several days old. Several approaches deal with dynamic pages by caching static, sub-document objects (Douglis, Haro & Rabinovich, 1997; Meira et al., 1999; Shi et al., 2003).Furthermore, Mohapatra and Chen (2002) and Challenger et al. (1999) construct a graph of the objects that constitute a Web page and upon a change, graph traversal reveals the objects that need to be updated for the page to be reconstructed. The transfer of "deltas", that is, the differences between the cached and the original document, is another technique shown to work well (Mogul et al., 1997; Savant & Suel, 2003). Finally Cao, Zhang and Beach (1998) suggested an approach where proxies can fetch from the server a special purpose program (a CacheApplet) attached to the data, to deal with reconstructing or refetching the page the way the original content provider wishes.

CONCLUSION AND FUTURE TRENDS

Web caching has been extensively deployed during the last years to support the needs of the exponentially growing World Wide Web. Depending on their placement, Web caches can accelerate the performance of a content provider, improve content availability, reduce network traffic and download latency, and improve the overall user experience of the Web. In this article we have presented the most important design and implementation issues concerning Web caches, as well as their solutions. Some issues, such as dynamic document handling, remain open and new ideas are still being proposed. In particular, the issues of caching dynamic documents (Rhea, Liang & Brewer, 2003; Yuan, Chen & Zhang, 2003; Yuan, Hua & Zhang, 2003) and ensuring cache consistency (Mikhailov & Wills, 2003; Pandey, Ramamritham & Chakrabarti, 2003) in the presence of changing, non-static Web pages, are expected to attract considerable scientific interest in the near future. Regardless of the final decisions to prevail though, it is most likely that in the following years, caching will keep being a key solution for the performance of the World Wide Web.

KEY TERMS

Byte Hit Rate: The ratio of bytes served by the cache over the total number of bytes requested by the clients. BHR can be significantly different from HR in a case where only few, but large files are being served by the cache.

Hit Rate: The ratio of requests served by the cache (hits) over the total number of requests made by the clients.

HTTP: Hyper-Text Transfer Protocol. The protocol used for most of the communication on the Web, between the clients, the proxies, and the servers.

Layer 4 Switch: A switch that can retrieve from the network packets information about the port number they are using, and thus the application that generated them.

Proxy Cache: A machine dedicated to serving client requests for Web documents. Usually it is installed at the edge of local or wide area networks to provide fast responses to the users and reduce the traffic exiting the network.

Server Accelerator: A machine dedicated to improving the performance of a Web server by caching popular Web objects. Usually it is installed in front of a single or a farm of Web servers in order to improve their performance and load the balance among them.

Transparent Proxy: A proxy that closely cooperates with either a router or a Layer 4 switch, to intercept Web requests while invisible to the users. Other than being invisible it works as a regular proxy cache.

This work was previously published in Encyclopedia of Information Science and Technology, edited by M. Khosrow-Pour, pp. 3048-3053, copyright 2005 by Information Science Reference, formerly known as Idea Group Reference (an imprint of IGI Global).

Web Portal Research Issues

Arthur Tatnall
Victoria University, Australia

INTRODUCTION

In general terms, a portal can be seen as "a door, gate or entrance" (Macquarie Library, 1981), and in its simplest form the word just means a gateway; however, it is often a gateway to somewhere other than just to the next room or street. *The Oxford Reference Dictionary* defines a portal as "a doorway or gate etc, especially a large and elaborate one" (Pearsall & Trumble, 1996). In the context of this article, a Web portal is considered to be a special Internet (or intranet) site designed to act as a gateway to give access to other specific sites.

A Web portal can be said to aggregate information from multiple sources and make this information available to various users (Tatnall, 2005c). It consists of a Web site that can be used to find and gain access to other sites, but also to provide the services of a guide that can help to protect the user from the chaos of the Internet and direct him or her toward a specific goal. More generally, however, a portal should be seen as providing a gateway not just to sites on the Web, but to all network-accessible resources, whether involving intranets, extranets, or the Internet. In other words, a portal offers centralised access to all relevant content and applications.

BACKGROUND

The Web-portal concept developed from search-engine sites such as Yahoo, Excite, and Lycos, which offered access to a large amount of general information and acted as general jumping-off points to the contents of large parts of the Web. These general portals then began offering extra services in addition to search capabilities (Rao, 2001) as the first step in their evolution. In an attempt to describe the early stages of this evolution of the general portal, Eckerson (1999) outlines four generations of portals whose focus, in each case, was on the generic, personalised, application, and role (Tatnall & Davey, 2007).

An early classification of portals had them being either horizontal or vertical (Lynch, 1998). The original portal sites mentioned above would have been considered horizontal portals because they were used by a broad base of users, whereas vertical portals were focused toward a particular audience. Davison, Burgess, and Tatnall (2004) offer the following list of portal types.

- General portals provide links to all sorts of different sites of the user's choosing. Many of these general portals have developed from being simple search tools (such as Yahoo), Internet service providers (such as AOL), and e-mail services (like Hotmail).
- Vertical industry portals are usually based around specific industries. They aggregate information relevant to particular groups or online trade communities of closely related industries to facilitate the exchange of goods and services in a particular market as part of a value chain. They often specialise in business commodities and materials.
- Horizontal industry portals are portals utilised by a broad base of users across a horizontal market. Horizontal industry portals are typically based around a group of industries or a local area.
- Community portals are often set up by community groups, or based around special group interests. They attempt to foster the concept of a virtual community where all users share a common location or interest, and provide many different services depending on their orientation.
- Enterprise information (or corporate) portal is the term being applied to the gateways to corporate intranets that are used to manage the knowledge within an organisation. These are designed primarily for business-to-employee processes and offer employees the means to access and share data and information within the enterprise.
- E-marketplace portals often offer access to a company's extranet services and are useful for business-to-business processes such as ordering, tendering, and supplying goods.
- Personal or mobile portals are increasingly being embedded into mobile phones, wireless PDAs (personal digital assistants), and the like. Some appliances are also being equipped with personal portals aimed at allowing them to communicate with other appliances, or to be used more easily from a distance.
- Information portals can be classified into one of the other categories; however, they can also be viewed as a category in their own right as portals whose prime aim is to provide a specific type of information.
- Specialised or niche portals are designed to satisfy specific niche markets. In many cases, these can also be classified as information portals.

A major problem with any classification, however, is that new types and categories of portals are appearing all the time, portal types are reclassified, and most classification schemes include overlapping categories. Even given the difficulty in classifying portals or attempting to count the numbers of each type, it has become clear that specific rather than general portals are very much the topic of research interest around the world (Tatnall, 2005a, 2005b).

RESEARCH IN A WIDE RANGE OF WEB PORTAL APPLICATIONS

Web portals are now quite ubiquitous, and researching their use in organisations and by individuals is an important aspect of information systems research (Tatnall, 2007a). To illustrate the range of quite specific applications now being filled by portals, the following list of topic categories (Tatnall, 2005b) comes from articles by many academics from around the world who contributed to the *Encyclopaedia of Portal Technology and Applications* (Tatnall, 2007b). Anyone with an interest in conducting a research project needs to see what else has been done in this area, and this list of topics is provided to give such an indication. It does not show the level of usage of the different types of portal, but should be seen as much more than just a list. Rather, it provides an indication of the current research interest in portals and portal technology, and gives an idea of possible future research directions in this area.

Education Portals

To begin, there is considerable interest in education portals, and the topics covered include academic management portals; large-scale, integrated academic portals; mobile education portals; artificial intelligence and education portals; high school portals; primary school portals; corporate e-learning portals; Weblogs; knowledge portals in education; and subject-teaching portals.

Health and Medical Portals

This is another popular area with topics such as empowerment and health portals, bioinformatics portals, biotechnology portals, nursing knowledge portals, network-centric health care and the entry point into the network, and genomic and epidemiologic medical data portals.

Community, Personal, and Mobile Portals

Topics researched in this area included how to promote community portals, a community geographic domain names portal, designing a portal and community-to-community generator, local community Web portals and small businesses, the paradox of social portals, accessible personalised portals, mobile portal technologies and business models, mobile portals as innovations, mobile portals for knowledge management, the MP3 player as a mobile digital music-collection portal, widgets as personalised mini portals, wireless local communities in mobile commerce, and portals supporting a mobile learning environment.

Government and National Portals

In a related area, there was much research interest in government portals around the world: portals in the public sector, e-government portals, e-value creation in a government Web portal in South Africa, government portals as a gateway for enhancing electronic governance in Singapore, interoperability in integrating e-government portals, modeling public administration portals, service quality in the case of e-government portals, and state portals as a framework to standardise e-government services.

There is also research into portals relating to national issues: African Web portals, business module differentiation and a study of the top three Chinese portals, cross-cultural dimensions of national Web portals, the growth of e-portals in Dubai, how portals help Chinese enterprises operate successfully in global markets, impacts and revenues models from Brazilian portals, Web museums, and a case study of the French population.

Knowledge Management, Libraries, and Professional Societies

Knowledge management, especially relating to libraries and professional societies, is another area that attracts a number of researchers. They are interested in topics such as designing portals for knowledge work, mobile portals for knowledge management, knowledge servers, the portal as information broker, portal strategy for managing organisational knowledge, a prototype portal for use as a knowledge management tool to identify knowledge assets in an organisation, library portals and an evolving information legacy, open access to scholarly publications and Web portals, the IFIP portal, and portal features of major digital libraries.

Portal Concepts, Design, and Technology

As one might expect, portal concepts are also an area of particular interest with topics such as defining the portal, benefits and limitations of portals, comparing portals and Web pages, the evolution of portals, factors affecting the adoption of portals using activity theory, information visualisation, the ubiquitous portal, and portals of the mind.

Research on portal design and technology also features prominently with topics such as collaborative real-time information services via portals, digital interactive channel systems and portals, designing spatiotemporal portals to continuously changing network nodes, dynamic taxonomies and intelligent user-centric access to complex portal information, factors affecting portal design, developing semantic portals, an evolutionary approach to developing online learning portals in low-bandwidth communities, the role of ontologies in portal design, the evaluation of Web portals, portal quality issues, Java portals and the Java portlet specification API, the large-scale ASP replication of database-driven portals, WSRP specification and alignment with the JSR 168 portlet specification, and user-centric knowledge representation for the personalisation of Web portals.

Portal Uses and Applications

The largest area of research interest is in how portals are applied and used, and most of this research refers to quite specific applications, such as the Bizewest portal, the Bluegem portal, the European quality observatory portal, the future of portals in e-science, hosting portals on an e-marketplace, how corporate portals support innovation, how the Internet is modifying the news industry, industry portals for small businesses, portals for business intelligence, strategic planning portals, study of a wine industry portal, supplier portals in the automotive industry, supply chain management and portal technology, portal economics and business models, portals for integrated competence management, cultivating memories through the Beijing Olympics (2008) "advertainment" portal, portals for workflow and business process management, economical aspects when deploying enterprise portals, project management Web portals, the provision of product support through enterprise portals, e-management portals and organisational behaviour, employee self-service portals, a generic model of an enterprise portal, portal technologies and executive information systems implementation, user acceptance affecting the adoption of enterprise portals, the role of portals in consumer search behaviour and product customisation, guided product selection and comparison of e-commerce portals, enabling technology and functionalities of shopping portals, business challenges of online banking portals, Web museums as the last endeavour, Web portals as an exemplar for tourist destinations, and a Web portal for the remote monitoring of nuclear power plants.

APPROACHES TO RESEARCHING THE ADOPTION OF PORTALS

Before any technology can be used, however, it must first be adopted. Unfortunately, the adoption of any technology is not a straightforward process as it involves many factors, both human and technological.

The adoption of a portal, by an organisation or an individual, is particularly complex as by its very nature such an investigation must involve both humans and technology and so be treated as a sociotechnical study. I would argue that innovation translation, informed by actor-network theory (ANT), has many advantages as an explanatory framework over both the more commonly applied approaches of innovation diffusion and the technology acceptance model (TAM) in sociotechnical studies like this.

Both innovation diffusion (Rogers, 1995) and TAM (Davis, 1986) suggest that adoption decisions are made primarily on the basis of perceptions of the characteristics of the technology concerned (Tatnall & Davey, 2007). Using an innovation-diffusion approach, a researcher would probably begin by looking for characteristics of the specific portal technology to be adopted, and the advantages and problems associated with its use. He or she would think in terms of the advantages offered by portals in offering a user the possibility of finding information, but would do so in a fairly mechanistic way that does not allow for an individual to adopt the portal in a way other than that intended by its proponent: It does not really allow for any form of translation. If using TAM, this researcher would similarly have looked at characteristics of the technology to see whether the potential user might perceive it to be useful or easy to use.

One of the problems of using approaches based on innovation diffusion or TAM is that of essentialism: the idea that the technology has some characteristics that determine whether and how it will be adopted and used. This means that fixed and unproblematic properties or essences can then be assigned to the technology and used in any explanation of change. Whilst initially appealing, the problem with an approach like this is that it can lead to a simplistic explanation that fails to reveal the true complexities of the situation under investigation (Tatnall, 2003).

A researcher using an innovation-translation approach (informed by ANT) to study innovation, on the other hand, would concentrate on issues of network formation, investigating the human and nonhuman actors, and the alliances and networks they build up. The researcher would attempt to identify the actors and then follow them (Latour, 1996) in identifying their involvement with the innovation and how they affect the involvement of others. The researcher would then investigate how the strength of these alliances may have enticed the individual or organisation to adopt the portal or, on the other hand, to have deterred them from doing so (Tatnall, 2002; Tatnall & Burgess, 2006; Tatnall & Gilding, 1999). This approach allows the innovation to be translated into a different form by each potential adopter rather than just simply being accepted or rejected. Especially in investigations involving the interaction of humans and nonhumans (technical artefacts), such an approach has much value.

FUTURE TRENDS

The demise of the portal has been predicted for a long time (Tatnall, 2006). White (2003) noted some years ago that portals were undergoing a metamorphosis in which they were merging with technologies such as content management, collaboration, and business intelligence. Predictions that the portal would disappear into application servers have also proved untrue (Plumtree Software, 2003).

The first Web portals were designed by companies like Yahoo, Excite, and Lycos to act as general jumping-off points to the contents of large parts of the Web. The goal of these general portals was to become the user's home page, from which the user could select from a wide variety of categories of Web sites and return to the portal when they had finished looking at each site. Useful research has been done on portals of this type (Burgess & Tatnall, 2007; Sieber & Valor-Sabatier, 2002, 2005). Current research, however, is much more into specialised portals designed to provide a gateway to Web content in a specific area, and in enterprise portals that act as gateways to a corporate intranet (Tatnall, 2005b).

The marketing value of portals is considerable, and Schneider and Perry (2001) note that Web managers have discovered that increased sales and advertising income can result from the portal's ability to attract more people and retain them longer. They point out that Web portal companies have added "sticky" features like chat rooms, e-mail, and calendar functions in order to retain visitors longer at their sites. The success of the portal industry is closely linked to marketing, but Michael (2005) points out that advertisers and marketers have yet to understand the full potential of the Internet. Michael argues that a key function of marketing is to match buyers and sellers and to facilitate transactions, but to do this a proper institutional infrastructure is required. He points out that marketers need to be aware of new demographic segments that are being attracted to the Internet for searching and shopping purposes, and that portals should be regarded as strategic tools in the marketing process (Tatnall, 2006).

To give a rough idea of the growing need for researching the Web portal, a Google search of the Web in December 2003 showed 36 million entries. In late 2007, this had increased to 1,500 million entries relating to portals. Now, of course, not all these entries are concerned with research, and some will be duplicates of other entries, but these figures do provide a crude measure of the increasing importance of this topic. Future research of all types is required, both into portal applications and technology.

CONCLUSION

Research interest in the applications and technology of Web portals is high. The portal has now become quite ubiquitous, and researching its applications and design has become an important aspect of information systems and computer science research. While research into portal technology and design follows scientific principals, research into the applications and uses of portals requires a sociotechnical perspective. There is a considerable amount of research into the impact and use of Web portals, but not much into explaining the uptake of this technology. I have argued that for research of this type, it is useful to consider the portal in terms of technological innovation and to make use of an approach based on innovation theory. Actor-network theory provides a perspective that can resolve the dilemma of how to handle both the human and nonhuman contributions to technological innovation, and provides a useful explanatory system for doing so.

KEY TERMS

Community Portals: Often set up by community groups or based around special group interests, they attempt to foster the concept of a virtual community where all users share a common location or interest, and provide many different services.

E-Marketplace Portals: They are extended enterprise portals that offer access to a company's extranet services.

Enterprise Information Portals: These are the gateways to corporate intranets that are used to manage knowledge within an organisation. They are designed primarily for business-to-employee processes and offer employees the means to access and share data and information within the enterprise.

General (or Mega) Portals: General portals provide links to all sorts of different sites of the user's choosing, often from a menu of options.

Horizontal Industry Portals: They are portals utilised by a broad base of users across a horizontal market.

Information Portals: Information portals can also be viewed as a category in their own right as portals whose prime aim is to provide a specific type of information.

Personal/Mobile Portals: These portals are embedded into mobile phones, wireless PDAs, appliances, and the like.

Specialised/Niche Portals: They are portals designed to satisfy specific niche markets. Sometimes they provide detailed industry information, often available only for a fee.

Vertical Industry Portals: Usually based around specific industries, they aim to aggregate information relevant

to these groups of closely related industries to facilitate the exchange of goods and services in a particular market as part of a value chain.

Web Portal: It is a special Internet (or intranet) site designed primarily as a gateway to provide access to other sites.

Web Services Coordination for Business Transactions

Honglei Zhang
Cleveland State University, USA

Wenbing Zhao
Cleveland State University, USA

INTRODUCTION

Many e-commerce companies such as Amazon.com, Yahoo.com, and eBay.com started to offer Web services to their partners and customers. Through such Web services, new value-added services could be provided and hence higher revenues would be generated. Essentially, the Web services technology is transforming the World Wide Web from a predominantly publishing platform to a programmable platform, which undoubtedly will make it easier to conduct business online, and enable automated business-to-business communications (Papazoglou, 2003). The Web services technology is particularly useful for Application Service Providers that offer various on-demand services and software-as-a-service (SAAS) to their customers (Chakrabarty, 2007). Such service-oriented computing is attractive to many businesses because they can save valuable resources and money by avoiding installing and maintaining sophisticated enterprise software on-site. Furthermore, most of business interactions are transactional, which require well-defined coordination support. To meet this requirement, a number of specifications have been proposed, and OASIS has recently rectified the Web Services Transactions specifications (Feingold & Jeyaraman, 2007; Freund & Little, 2007; Little & Wilkinson, 2007).

In this chapter, we provide an overview of the Web services technology, together with the set of standard specifications for Web services transactions. The core components of the Web services technology include eXtensible Markup Language (XML), HyperText Transfer Protocol (HTTP), Simple Object Access Protocol (SOAP), and Web Services Description Language (WSDL). Both SOAP and WSDL are based on XML. All these protocols and languages have the characteristic of strong extensibility, which lays a solid foundation for the success of the Web services technology. Due to the extensibility design, the protocols specified in the Web services transactions standards can be plugged into the Web services core seamlessly to provide the additional coordination needed for business transactions. Furthermore, we point out the need to protect the business transactions from the hardware failures and malicious faults, and for more robust coordination for Web services transactions.

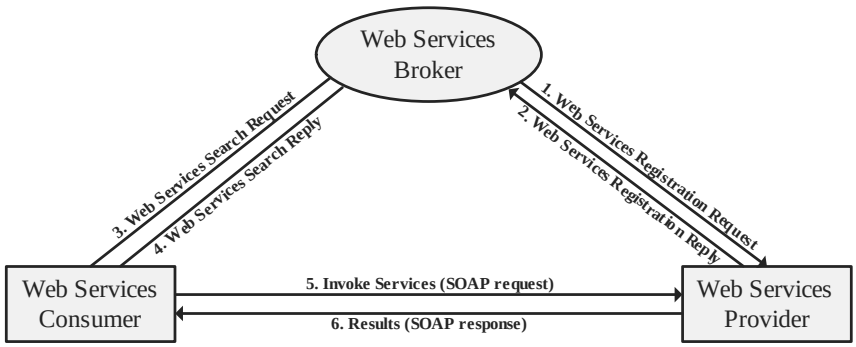
BACKGROUND

In this section, we introduce the Web services concept and the basic building blocks of the Web services platform. There is no universal definition of the term Web services and its interpretation varies drastically. Web services can be loosely defined as any services offered over the World Wide Web. On the other hand, only the services enabled by the Web services technology are referred to as Web services by many researchers and practitioners. In this chapter, we use the latter interpretation. The Web services technology refers to the set of standards that enable automated machine-to-machine interactions over the Web. The corner stone of the Web services technology consists of eXtensible Markup Language (XML) (Bray, Paoli, Sperberg-McQueen, Maler, Yergeau & Cowan, 2006), HyperText Transfer Protocol (HTTP), Simple Object Access Protocol (SOAP) (Gudgin, Hadley, Mendelsohn, Moreau, Nielsen, Karmarkar et al., 2007), Web Services Description Language (WSDL) (Christensen, Curbera, Meredith & Weerawarana, 2001), and the Universal Description, Discovery and Integration (UDDI) service (Clement, Hately, Riegen & Rogers, 2004). From an architecture point of view, the Web services platform consists of Web services providers, Web services consumers, and UDDI registries that broker the providers and the consumers, as shown in Figure 1. If a Web services consumer wants to request a service, it can search for available service providers via UDDI. Based on the returned information, the consumer can invoke the service by sending the request directly to the service provider.

EXTENSIBLE MARKUP LANGUAGE

XML is designed to facilitate self-contained, structured data representation and transfer over the Internet. It allows users to define their own tags, which is why it is easily extensible. XML messages enable different applications to communicate with each other over the network using a variety of transport-level protocols such as HTTP and SMTP. To invoke a Web service, a user only needs to send an XML request message to the Web services provider. The provider will then send

Figure 1. The architecture of Web service



back an XML reply message containing the results the user wanted. Typically, the XML messages must conform to the SOAP standard.

Simple Object Access Protocol

SOAP, a communication protocol for message exchanges over the Internet, provides a standard modular packaging model, a data encoding method and a way to perform remote procedure calls (RPCs). SOAP is easy to use and it can be easily extended due to its use of XML as the messaging format. Like many public-domain application-level protocols, such as SMTP, a SOAP message contains a SOAP Envelop and a SOAP Body. A SOAP message often contains an optional SOAP Header element and a Fault element if an error is encountered by the sender of the SOAP message.

Web Service Description Language

WSDL provides a structured way to describe a Web service based on an abstract model. For each Web service, the corresponding WSDL document specifies the available operations, the messages involved with the operations, and a set of endpoints to reach the Web service. Due to the use of XML, WSDL is also extensible. In particular, it allows the binding of multiple different communication protocols and message formats.

Universal Discovery Description and Integration

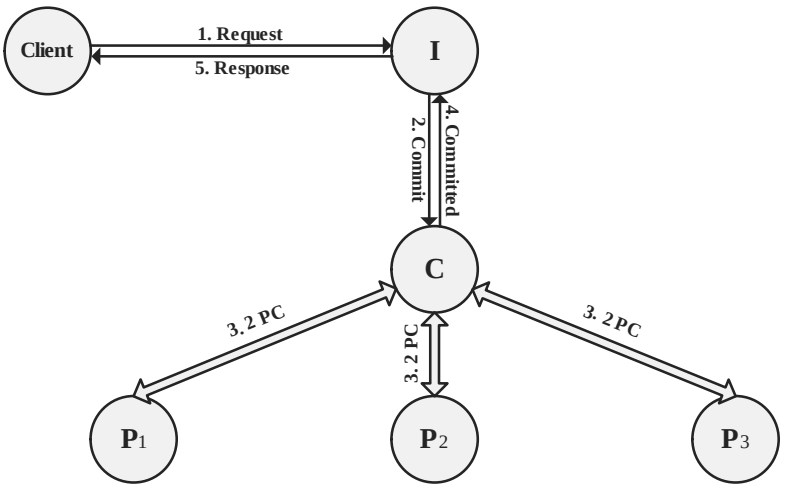
A UDDI registry service acts like yellow pages for business providers and consumers. Business owners publish their Web services to the UDDI registry, and their partners and consumers can locate the Web services they needed and obtain detailed information regarding the services by searching the registry. There are three main components in UDDI, often referred to as White Pages, Yellow Pages, and Green Pages. The White Pages provide the Web service provider's information, such as name, address, contact information and identifiers. The Yellow Pages describe industrial categories based on standard taxonomies. The Green Pages present technical information in detail regarding the Web services. The UDDI also support several ways to carry out the search, for example, one can search by service provider's location, or by specified service types.

Web Services Coordination of Business Transactions

Web services interactions are becoming more and more complex in structure and relationships. More complex means we need longer time to execute them, because of business latencies and user interactions. The Web Services Coordination specification (WS-Coordination) (Feingold & Jeyaraman, 2005) describes an extensible framework for plugging in protocols that coordinate the actions of distributed applications. Such coordination protocols can be used to support a variety of business applications, including those that require strict consistency and those that require agreement of a proper subset of the participants. The framework enables a Web service to create a context needed to propagate an activity to other Web services and to register for a particular coordination protocol.

There are two types of business transactions. One follows the traditional atomic transaction semantics, and the other is referred to as business activities, which implies that the atomicity property may be relaxed. The former is suitable for short transactions that require strong atomicity, such as a fund transfer transaction. The latter is more suitable long running transactions, such as those used in supply chain management. Based on WS-Coordination, two specifications, namely Web Service Atomic Transaction (WS-AtomicTransaction) (Little & Wilkinson, 2007) and Web Service Business Activity (WS-BusinessActivity) (Freund & Little, 2007), have been

Figure 2. The architecture of WS-AT



recently standardized by OASIS to address the coordination needs for common types of business transactions.

Web Services Atomic Transactions

The Web Services Atomic Transactions specification defines a coordination framework for Web services atomic transactions. In a distributed atomic transaction, all participants must reach the same final agreement as to whether the transaction has succeeded or not. This is ensured by the coordination mechanisms specified in WS-AtomicTransaction. In WS-AtomicTransaction, there are three actors for each transaction: Completion Initiator, Coordinator and Participants. Each provides a different set of services for the atomic transaction, and they interact with each other via two protocols, the Completion Protocol and the Two-Phase Commit Protocol (Gray & Reuter, 1993) (Tanenbaum & Steen, 2002). The architecture of WS-AtomicTransaction is shown in Figure 2.

The completion initiator is responsible to start and terminate a transaction. It also provides the Completion Initiator Service so that the coordinator can inform it the final outcome of the transaction, as part of the completion protocol. The coordinator provides the following services:

- Activation Service: At the beginning of a transaction, the initiator invokes the Activation Service for creating a coordinator object, which will generate a new coordination context for the transaction and return it to the initiator. The coordination context contains a unique transaction identifier and an endpoint reference for the Registration Service. This coordination context will be included in every request messages within the transaction boundary.
- Registration Service: The participants and the completion initiator use this service to register their endpoint references for other associated participant-side services. Later these endpoint references will be used by the coordinator to contact the participants during the two-phase commit.
- Coordinator Service: When a participant gets a Prepare request from the coordinator, it places its vote by invoking the coordinator service. The participants also use this service to notify the coordinator their acknowledgments to the commit/abort request. The participants obtain the endpoint reference of the Coordinator Service during the registration step.
- Completion Service: The initiator invokes this service to notify the coordinator to start a distributed commit. The Completion service, together with the Completion Initiator service on the participant side, implements the WS-AtomicTransaction completion protocol. The endpoint reference of the Completion Service is returned to the initiator during the registration step.

The participant provides the Participant Service, which allows the coordinator to solicit votes from, and to send the transaction outcome to the participants according to the two-phase commit protocol.

The Completion Protocol is used by the completion initiator to initiate the atomic termination of a transaction. When the initiator decides that it is time to commit the transaction, it sends a Commit request to the coordinator. The coordinator will then launch an instance of the Two-Phase Commit (2PC) protocol to carry out the coordination for atomic commitment of the transaction. When the 2PC completes, the coordinator notifies the initiator the outcome of the transaction (i.e., committed or aborted). If the request

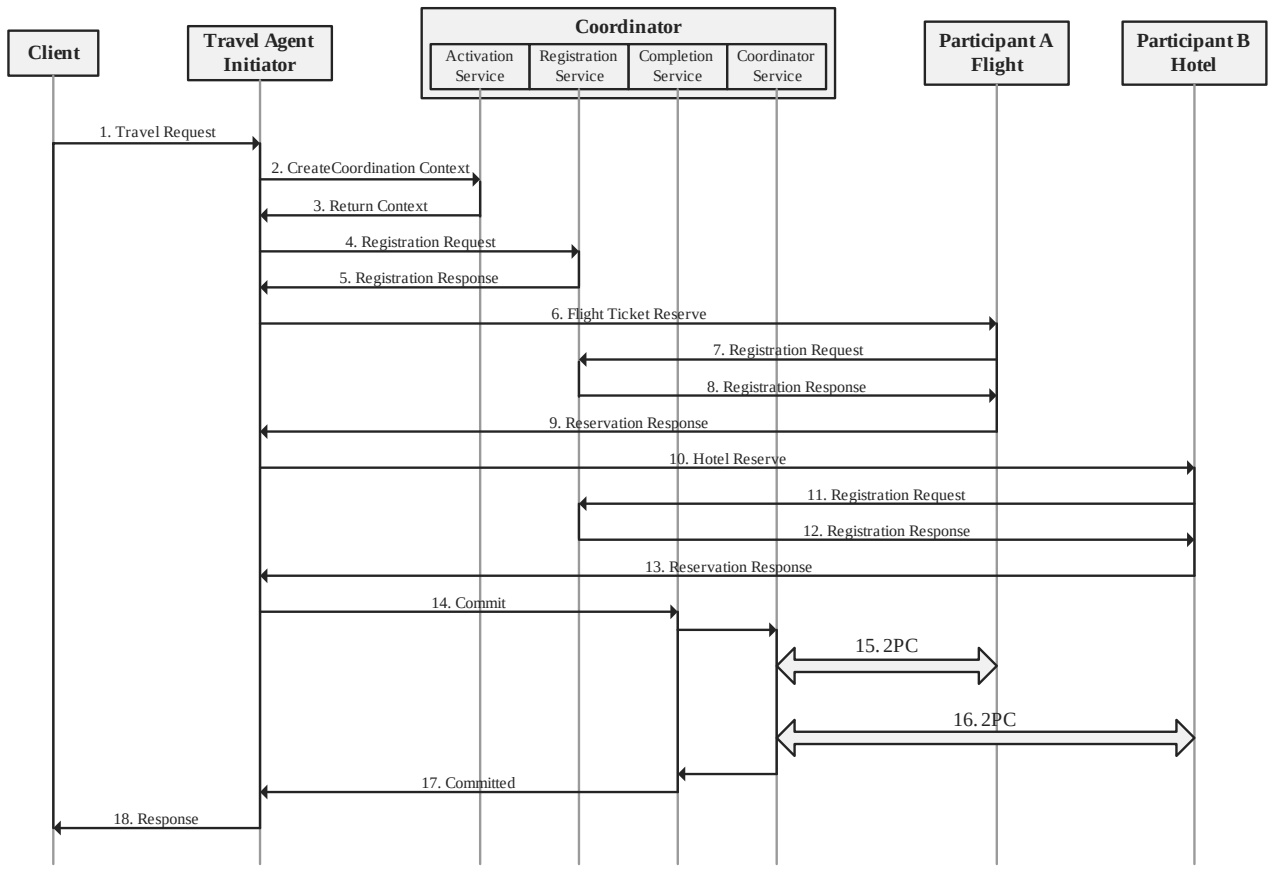
from the initiator is Rollback instead, the coordinator will abort the transaction directly.

The 2PC Protocol is used by the coordinator and participants to guarantee atomic commitment of a transaction, and it executes in two phases. During the first phase, that is, the prepare phase, the coordinator sends a Commit request to all registered participants soliciting their votes. When the coordinator receives votes from all participants, or a timeout has occurred, it starts the second phase, that is, the commit phase, to notify the participants the outcome of the transaction.

2PC has two variants used for different resources, Volatile 2PC and Durable 2PC. Volatile 2PC is used for volatile resources such as caches and Durable 2PC focuses on durable resources like a database. Participants must register in an appropriate protocol before the termination of the transaction. A participant can register in more than one protocol. Upon receiving a Commit request from the initiator in the completion protocol, the coordinator begins the prepare phase first for every participant who has registered in the Volatile 2PC protocol by sending a Prepare request to them before it begins the prepare phase for Durable 2PC. The participant that gets the request must respond with a Prepared, Aborted or ReadOnly message based on its own decision. During this period, other participants can continuously register with the coordinator for Durable 2PC, but the registration progress has to be done by the coordinator before the start of the first phase for durable resources. After the prepare phase for Volatile 2PC, the coordinator begins to take care of the prepare phase for Durable 2PC participants. Same as the prepare phase of Volatile 2PC, all participants in the Durable 2PC protocol have to respond appropriately before the protocol advances to the second phase, in which the coordinator will issue the Commit requests to all participants for both Volatile and Durable 2PC protocols if all participants have provided positive feedbacks. If there are any negative votes, even if only one, the coordinator has to abort the transaction. After the participants get a Commit notification, they will commit the transaction and send the Committed acknowledgement back to the coordinator.

Figure 2 shows an example of a Web services atomic transaction for a travel reservation coordinated by WS-AtomicTransaction. In this example, a client contacts a Travel Agent to make travel arrangement. The Agent, which

Figure 3. A travel reservation example using WS-AtomicTransaction



acts as the completion initiator, is responsible to make flight and hotel reservations in the context of an atomic distributed transaction, on behalf of the client. We assume that the Agent relies on a Flight reservation Web service and a Hotel reservation Web service, for booking a plane ticket and a hotel room for the traveler.

To begin this transaction, the client sends a request to the initiator (step 1). The initiator invokes the Activation Service on the Coordinator which will create a unique coordination context for the transaction (step 2). This context contains the Endpoint Reference for the Registration Service. After the Activation step, the initiator gets the reply back with the transaction context (step 3). In next step, the initiator registers the Completion Initiator Service with the coordinator so that the coordinator could inform the initiator after it obtains the outcome of the transaction (steps 4 and 5). Now the booking service offered by the initiator carries out the reservations for the plane ticket and a hotel room (steps 6 and 10). The flight and hotel booking Web services must register their participant endpoint references with the coordinator (steps 7 and 8; 11 and 12). After the registration step, these services will send their responses for the reservation requests (steps 9 and 13). Subsequently, the initiator asks the Completion Service to commit the transaction (steps 15 – 17). Finally, the Travel Agent sends the result back to the client (step 18).

Web Services Business Activity

WS-BusinessActivity is different from WS-AtomicTransaction because it focuses on the coordination of long running business activities where the atomic transaction model is not appropriate. WS-BusinessActivity is also built on top of the WS-Coordination framework. The WS-BusinessActivity specification describes two coordination types, Atomic-Outcome and Mixed-Outcome, and two coordination protocols, Business-Agreement-with-Participant-Completion and Business-Agreement-with-Coordinator-Completion. Either protocol can be used with either coordination type. If the Atomic-Outcome Coordination type is used, all participants must reach an agreement about the activity outcome (i.e., either to close or to compensate). If the Mixed-Outcome coordination type is used, some participants may be directed to close while others to compensate. All WS-BusinessActivity frameworks must implement the Atomic-Outcome coordination type.

In a WS-BusinessActivity framework, a participant registers either one of the two protocols, which are managed by the coordinator of the business activity. The only difference between the two protocols is that the Business-Agreement-with-Participant-Completion protocol assumes that the participants know when the coordinator has completed all the processing related to a business activity and the Business-Agreement-with-Coordinator-Completion protocol notifies the participants when the coordinator has received all requests.

A participant who has registered the Business-Agreement-with-Participant-Completion protocol informs its coordinator by sending a Completed notice when it has done its entire works for a business activity. The coordinator should reply with either Close or Compensate message depends on the circumstance. The participant receives a Close instruction if the activity has completed successfully. If it gets a Compensate instruction instead, the coordinator will undo the completed work and will have to restore the data recorded from the initial condition. The participant may encounter a problem or fail during the processing of the activity, in which case, it must signal the coordinator with an error message. If it gets the Fail message, the coordinator will acknowledge the participant by a Failed notification.

Upon receiving a CannotComplete notification, the coordinator learns that the participant cannot successfully finish its work. On sending out this message, the participant discards all its pending work and cancels all related executions, and exits the current business activity. On receiving such a message, the coordinator is required to notify the participant with a NotCompleted message. In the active state, the coordinator could cancel any transaction by using the Cancel notification, and the participant will respond with a Canceled message if it receives the message.

In the Business-Agreement-with-Coordinator-Completion protocol, the completion decision comes from the coordinator. The coordinator sends a Complete message to the participants informing them that they won't receive any new requests within the current business activity and it is time to complete the processing. The participant then replies with a Completed message if it could successfully finish its work.

FUTURE TRENDS

We identify two future research directions regarding Web services coordination for business transactions. First, the coordinator plays a critical role in both the WS-AtomicTransaction and WS-BusinessActivity frameworks. The integrity of the coordinator services directly impact the expected outcome among the participants involved in an atomic transaction or a business activity. For example, if the coordinator is compromised by an adversary, it could easily cause non-atomic commitment of transactions, which would cause serious trouble for transaction participants. For business activities, a compromised coordinator could also render an inconsistent outcome among the activity participants. Due to the untrusted Internet operating environment, such threat cannot be ignored, which calls for enhancement of the WS-AtomicTransaction and the WS-BusinessActiv-

ity frameworks by intrusion tolerance design (Zhao, 2007). The Byzantine fault tolerance technology (Castro & Liskov, 2002; Lamport, Shostak & Pease, 1982) might be a good fit to achieve the goal. Byzantine fault tolerance ensures that as long as the number of compromised coordinator replicas is below some threshold, the replicated coordinator cannot disseminate conflicting information (i.e., the transaction outcome) to different transaction participants, which is how it protects the coordinator's integrity. Byzantine fault tolerance also protects the system against hardware failures, which has the benefit of high availability.

Second, even though WS-BusinessActivity recognized the need for flexible transaction outcomes for business activities, its reliance on compensation transactions might limits its use for some applications. The reservation-based extended transaction protocol (Zhao, Moser & Melliar-Smith, 2005) seems to be an excellent candidate to augment the compensation-based approach. The basic idea of the reservation-based transaction protocol is that any business activity is carried in two steps. In the first step, a reservation is placed on a set of resources. Depending on the outcome of the reservation step, the coordinator could choose to confirm some reservations while cancel the remaining ones. The use of the extra reservation step eliminates the need for compensation transactions, which could be very expensive and error prone in practice.

CONCLUSION

In this chapter, we introduced the Web Service technology and the related technical standards such as XML, SOAP, WSDL and UDDI. We focused on the issues about the Web services business transaction coordination and presented three related Web services specifications, WS-Coordination, WS-AtomicTransaction and WS-BusinessActivity. We note that the Web services technology is still rapidly evolving. We have seen more standards being rectified and some old specifications are rendered obsolete. The Web services technology is also of great interest to the research community. In particular, there has been a tremendous effort to enhance the security and dependability of Web services.

KEY TERMS

Atomic Transaction: An atomic transaction in the context of Web services refers to a distributed transaction to be executed atomically. It should exhibit the atomicity,

consistency, isolation and durability properties, just like a local transaction.

Distributed System: A distributed system is a computer network system, shown to end users as a single machine but actually work with a set of independent computers connected.

Endpoints Reference (EPR): A collection of information used in web service to describe a resource's address, such as a URI (uniform resource identifier). This information is contained in the header of a SOAP message.

Remote Procedure Calls (RPC): A technical way that allows a call to a subroutine or a procedure which may run on another machine. To the caller, the call appears to be no different from a local call.

SOAP: Stands for Simple Object Access Protocol. It was originally designed to conduct remote procedure calls over the Web. It has evolved to become the main communication protocol to exchange XML documents. A SOAP message contains a SOAP Envelop and a SOAP Body. A SOAP message often contains an optional SOAP Header element, and a Fault element if an error is encountered by the sender of the SOAP message.

UDDI: Stands for Universal Description, Discovery and Integration. UDDI provides the standard way for Web services providers to describe their services, and the consumers to search and discover the available services.

Web Services: Electronic services enabled by the Web services technology. The Web services technology refers to the set of standards that enable automated machine-to-machine interactions over the Web. The core standards include XML, HTTP, SOAP, WSDL and UDDI.

WSDL: WSDL stands for Web Services Description Language. It is an XML-based language used to describe Web services. For each Web service, the corresponding WSDL document specifies the available operations, the messages involved with the operations, and a set of endpoints to reach the Web service. Due to the use of XML, WSDL is also extensible. In particular, it allows the binding of multiple different communication protocols and message formats.

XML: XML stands for eXtensible Markup Language. It is designed to facilitate self-contained, structured data representation and transfer over the Internet. It is extensible because it allows users to define their own tags.

Web Usability

Florida Institute of Technology, USA

INTRODUCTION

The study of computing technology and user interfaces was initiated during the 1970s when industrial research laboratories began to focus on human-computer interaction (HCI) (Badre, 2002). In the 1980s, the personal computer was introduced, thus expanding the need for designing effective user interfaces. HCI became a discipline during this time, and the Association for Computing Machinery (ACM) established the Special Interest Group in Computer Human Interaction. One of the first textbooks on HCI, *Designing the User Interface: Strategies for Effective Human-Computer Interaction* (Schneiderman, 19891), was published. Shortly thereafter, HCI became part of the ACM curriculum promoting the development of effective user interfaces. Software tools were developed in order to assist in designing usable interfaces while employing usability engineering methods. Many of these methods focused on usability from the perspective of ease of use, ease of learning, user satisfaction, and zero defects (Nielsen, 1993).

The World Wide Web (Web) became an integral part of HCI research in the 1990s, as organizations rushed to deploy a corporate Web site. Many of these Web sites took advantage of cutting-edge technology, including graphics and animation, with little regard for the impact on the user. As a result, users became disgruntled by lengthy download times, complex navigation schemes, nonintuitive search mechanisms, and disorganized content.

While others were predicting a "Y2K meltdown," Jakob Nielsen (1999a) correctly predicted a "Web meltdown" due to the number of poorly designed Web sites that cluttered the Internet. Numerous studies showed that users were frustrated with glitzy Web sites that had too many usability barriers. A Forrester report estimated a 50% loss of potential online sales due to users not finding a product or service on the Web site (Manning, McCarthy & Souza, 1998). As importantly, 40% of users did not return to a site when their initial visit was a negative one.

Shortly after 2000, electronic commerce sites (dot coms) began to fail at an increasing rate. A Deloitte and Touche report found that many retailers had developed online sites to "test the waters" for consumer demand with no clearly articulated strategy for success (Speigel, 2000). The demise of many dot coms has been attributed to unfriendly user interfaces that negatively impacted the online experience.

BACKGROUND

Many researchers and practitioners alike have studied usability in order to develop Web sites that are navigable, consistent, appealing, clear, simple, and forgiving of user mistakes (Murray & Costanza, 1999). Existing user interface design recommendations were extended to include user interfaces for the Web (Lynch & Horton, 1999; Schneiderman, 1998). Those experienced in designing user interfaces provided heuristics and guidelines for designing Web pages, often by identifying design layout, navigation, and performance issues associated with particular Web sites (Flanders & Willis, 1998; Hurst, 1999; Spool, Scanlon, Schroeder, Snyder & DeAngelo, 1999). Jakob Nielsen, a well-known usability expert, provided much needed guidance on Web usability through featured online articles (www.useit.com/alertbox) and published guidelines (Nielsen, 1999b; Nielsen & Tahir, 2002).

Web usability has been defined as the measure of the quality of the user's online experience. There are several factors that are commonly used as a means of measuring this experience. These factors include (www.usability.gov):

- Learnability – A measure of the user's learning time for accomplishing basic tasks given that the user interface has not previously been used (or used infrequently).
- Efficiency – A measure of the user's time and error rate for task completion.
- Effectiveness – A measure of user productivity in performing a task.
- Satisfaction – A measure of the attitude, perceptions, and feelings about the site.
- Memorability – A measure of user recall such that a previously visited site can be used effectively with no new learning curve.

It is commonly accepted that the usability of a Web site is impacted by the user's online goal, the user's profile, and his or her computing environment. A user, for example, would have some tolerance for lengthy download times when searching for medical information with graphic illustrations. This tolerance level is greatly reduced when searching for information on the cost of an airline ticket. The user profile, including age, gender, income, education, computer skills, and other factors, influences the online experience. Web

content written at a high reading grade level, for example, may be difficult to comprehend for users with low English proficiency. The use of color to convey meaning on a Web site may impede its use by those who have color-deficient sight. Small font size, patterned background images, and pastel colors may become Web barriers to older adults experiencing vision degradation due to aging (Morrell, 2002). The user's computing environment also has an impact on Web usability. Environmental factors, such as hardware, software, browsers, connectivity, and bandwidth, impede the use of a Web site when it is cluttered with graphics, animation, and other objects adding little value to the online experience.

Since 1998, much has been accomplished in promoting Web usability for persons with disabilities. Section 508 of the 1973 Rehabilitation Act was enacted to eliminate information technology barriers in order to provide those with disabilities equal access. The law applies to all federal agencies when they develop, procure, maintain, or use electronic and information technology (http://www.Section508.gov). As a result of this initiative, significant strides have been made to electronic government access by enforcing the Web content guidelines put forth by the World Wide Web Consortium. Though not mandated by law, many commercial and nonprofit Web sites have implemented Section 508 in order to provide access to a broad user base.

WEB USABILITY ASSESSMENT METHODS

There are several popular methods that have been employed to effectively study Web usability. The inquiry approach makes use of field observation, interviews, self-reporting logs and online sessions. The inspection approach utilizes heuristic evaluations, walkthroughs, and checklists. Usability testing may also be used in conjunction with the other approaches to gather feedback during and after Web site design (Hom, 1998).

- Field Observation – The user is observed while surfing a Web site in order to gather usability data in a real-world setting.
- Interviews, Surveys, and Questionnaires – The objective of these methods is typically to gather feedback about the user's perspective of usability. In terms of data gathering, the interview is a formal, structured process, whereas the survey is an informal, interactive process. Interviews and surveys may involve one or more users in a focus group setting. The questionnaire provides the means to obtain written responses regarding a user's online experience.
- Session and Self-Reporting Logs – The user records his or her actions and makes observations during an online session. Software is often used during a session to automatically record data about the user's online experience. The self-reporting log requires the user to manually record data while surfing the Web.
- Heuristic Evaluation – A usability expert (or group of experts) assesses a user interface to determine whether the Web design follows established usability practices (heuristics).
- Walkthrough – A usability expert (or group of experts) evaluates online experiences by constructing scenarios of Web use and then role-playing the targeted user.
- Usability Inspection – A usability expert (or group of experts) conducts usability inspections of a user interface in order to uncover usability problems in the design.
- Checklists – A usability expert (or group of experts) uses a checklist often in conjunction with an inspec-

tion to ensure that established usability practices are evaluated.
- Usability Testing – Experiments are conducted regarding usability aspects of a Web design. The objective is to gather data about an online experience in order to draw conclusions about the usability of the site. Though usability testing can involve sophisticated technology including usability labs, videotaping, and eye-tracking, this does not have to be the case (Murray & Costanzo, 1999). Often, usability test cases can be generated from an existing Web design without the use of sophisticated technology.

WEB RESOURCES

There are valuable online resources promoting usable Web designs. Many of these sites offer links for usability design and testing, good practices and lessons learned in the field. Some of the more popular sources for Web usability guidance are listed in Table 1. Though too numerous to list, there are many educational sites that offer resources on research activities and course materials. The Trace Research and Development Center at the University of Wisconsin-Madision, in particular, offers usability resources and links promoting universal usability (*http://trace.wisc.edu/world/web/*).

FUTURE TRENDS

Murray and Costanzo (1999) point out that from a HCI perspective, Web development is significantly different from software development. As such, there are challenges facing developers who are pursuing usable Web designs. These challenges include the following:

- The demographic diversity of online customers makes it difficult to develop user-friendly interfaces to meet all needs. For example, older adult users (60 years and older) may have trouble seeing Web content based on the use of color, font size, font type, and patterned background images (Becker, 2004; Morrell, Dailey, Feldman, Mayhorn & Echt, 2002). These design elements may have no usability impact on a younger adult for whom aging vision changes have not yet occurred. Web site images or textual references to religious holidays (e.g., Valentine's Day), as another example, may be offensive in certain global regions due to local religious or cultural beliefs (Becker, 2002).
- There is significant diversity among hardware, software, and network components being used to surf the Web. The usability of mobile technology, for example, must take into account the tiny screen in which Web content is displayed (Russell & Chaparro, 2002).
- Slower network access speeds impact usability due to performance degradation for a Web page with graphics and animation. Usability is also impacted by the browser version being used to surf the Web. Web content may display differently in older browser versions of Netscape© and Internet Explorer© than newer versions.
- The internationalization of many Web sites must account for culture, religion, and language in designing localized, user-friendly interfaces. Too often, organizations develop localized versions that do not meet the needs of regional customers (Marcus & Gould, 2000). The localized site may still have design aspects of the country of origin such as: English content, clichés, acronyms, and abbreviations (Becker & Mottay, 2001). Graphics may become a usability issue when cultural and religious beliefs are not taken into account during Web design (e.g., scantily clad figure on a homepage).
- Unlike software, users do not have a vested interest in a particular site. Often times, a user has purchased software and therefore is willing to accept usability barriers associated with it. Since there is no personal investment in a Web site, a user is more likely to leave and not return to a Web site that is perceived as unusable.

CONCLUSION

Web usability remains an important consideration in the design of effective user interfaces. There has been significant research on Web usability in terms of design layout, performance, navigation, and searches, among other areas. This initial work has been broadened to include usable Web designs for all users regardless of age, skills, education, culture, language, or religion. The Web accessibility initiative has promoted Web designs that take into account users with vision, physical, and cognitive disabilities. The internationalization of Web sites has promoted Web designs that meet the needs of a particular locale taking into account the customs, culture, religion, education, and other factors. Though much has been accomplished in developing usable Web sites, there is still work to be done. New technologies and expanded marketplaces pose unique challenges for universally usable Web designs.

KEY TERMS

Dot Com: A Web site that is intended for business use, though the term is commonly used to represent any kind of Web site. The term evolved from the "com" part of a Web site's address, which represents commercial sites. It came to be associated with Internet companies that failed during the mid 2000s (*www.searchWebservices.com*).

Internationalization: It is the process of making a Web site interoperable in a specific market or locale. In general, interoperability means that the functionality of the site is not dependent on a specific language or culture and is readily adaptable to others.

Localization: It is the process of adapting an internationalized Web site to meet language, culture, religion, and other requirements of a specific market or locale.

Universal Usability: Universal usability can be defined as having more than 90% of all households as successful users of information and communications services at least once a week (Schneiderman, 2000, p. 85).

Usability: The ISO 9241-11 standard states that usability is the "effectiveness, efficiency and satisfaction with which a specified set of users can achieve a specified set of tasks in a particular environment".

Usability Engineering: It is a systematic approach to making software (Web designs) easy to use, thus meet the needs of the targeted users.

Web Accessibility: Web accessibility means that any person, regardless of disabilities, is able to use Web technology without encountering any barriers.

ENDNOTES

Web Usage Mining

Stu Westin
University of Rhode Island, USA

INTRODUCTION

Research studies concerning the use of the World Wide Web (WWW) have become quite common in the MIS, education, marketing, and e-commerce literature. Increasingly, the research methodology employed in these studies involves some form of Web usage mining. This research technique seeks to uncover the Web user's access and navigation behaviors through analysis of real-time data artifacts of Web usage. These data artifacts are sometimes referred to as *mouse droppings* since each datum results from a specific user action involving the mouse. The so-called *click streams*, the sequence of URLs visited by a Web user, are often the focus of Web usage mining. These data can be supplemented with timestamp information to reveal page viewing time. Mouse click coordinates (i.e., X, Y location) can also be of interest, depending on the research question.

Studies that rely on Web usage mining can be experimental or observational in nature. The focus of such studies is quite varied and may involve such topics as predicting online purchase intentions (Hooker & Finkelman, 2004; Moe, 2003; Montgomery, Li, Srinivsan, & Liechty, 2004), designing recommender systems for e-commerce products and sites (Cho & Kim, 2004; Kim & Cho, 2003), understanding navigation and search behavior (Chiang, Dholakia, & Westin, 2004; Gery & Haddad, 2003; Johnson, Moe, Fader, Bellman, & Lohse, 2004; Li & Zaiane, 2004), or a myriad of other subjects. Regardless of the issue being studied, data collection for Web usage mining studies often proves to be a vexing problem, and ideal research designs are frequently sacrificed in the interest of finding a reasonable data capture or collection mechanism. Despite the difficulties involved, the research community has recognized the value of Web-based experimental research (Saeed, Hwang, & Yi, 2003; Zinkhan, 2005), and has, in fact, called on investigators to exploit "non-intrusive means of collecting usage and exploration data" (Gao, 2003, p. 31) in future Web studies.

In this article we discuss some of the methodological complexities that arise when conducting studies that involve Web usage mining. We then describe an innovative, software-based methodology that addresses many of these problems. The methods described here are most applicable to experimental studies, but they can be applied in ex-post observational research settings, as well.

BACKGROUND

Approaches to Web usage mining can be server-centric or client-centric. In the former case the data are harvested from a server machine. In some instances this approach requires no special software mechanisms since server logs are maintained routinely by server software. Client-centric approaches always require special data collection mechanisms because standard browsers do not document user actions. An example of this is the *PCMeter* usage mining software application. This software runs in the background on the client machine recording click-stream data as the research subject interacts with a Web browser (see Johnson et al., 2004, and Montgomery et al., 2004, for usage examples).

Server logs provide the most frequent data source for usage mining studies. This is because the data are readily available in a standard, machine-readable format, and preexisting Web sites can be used as long as the server log data can be procured for analysis. However, the literature is rife with criticism and complaints about the shortcomings of this data source (e.g., Bracke, 2004; Fenstermacher & Ginsburg, 2003; Huysmans, Baesens, & Vanthienen, 2004; Montgomery et al., 2004; Spiliopoulou, Mobasher, Berendt, & Nakagawa, 2003). The problems arise from such confounding elements as multiple server types (e.g., proxy servers, image servers, and application servers), server farms and load balancing procedures, caching activities, stateless nature of sessions, and so forth. In the words of Shahabi, Banaei-Kashani, and Faruque (2001, p. 1) "... usage data acquisition via server logs is neither reliable, nor efficient. It is unreliable due to the side effects of the network ... [it is] inefficient because of usage data requiring extensive preprocessing before it can be utilized."

Other server-centric data collection approaches based on server-side scripting (e.g., ASP, ASP.NET, etc.) can prove useful in some circumstances. Consider, for example, the situation where one wants to investigate the impact of download time as a factor affecting user satisfaction or Web site success. Using server-side scripting, a delay mechanism can be easily built into a Web page so that the server will delay serving the requested page to the client until some precise, predetermined time has passed. Different experimental treatment levels are accomplished by merely manipulating the delay time that is scripted into the Web page. Here, the

experimental subject, using an ordinary browser, will have the perception that the page is slow to download because of the delay between when the page is requested (e.g., by clicking a hyperlink) and when the page is available in the browser.

As another scenario, consider the situation where the researcher wants to study the end user's Web search strategy by analyzing the click-streams (e.g., Chiang et al., 2004). Here again, server-side scripts in the Web pages could provide a simple data collection mechanism by logging each page request (page ID, server timestamp) in a server database. The advantages of this approach over relying on server logs are that the server-side scripts can be designed to capture the precise data objects in the particular format that is desired, and many of the aforementioned confounding items can be circumvented.

In considering these scripting approaches, it is obvious that client-side data collection mechanisms can be constructed just as easily. In most cases, Java applets, Java scripts, or VB scripts can be embedded into Web pages to handle the required tasks. The only difference in this client-side approach is that the data collection is being handled by the client rather than by the server machine. Neither approach provides any obvious benefits over the other, although in the client-side approach the Web pages for an experiment could be stored locally and thus WWW, or even network access, is not required. In all of the previous research settings, including those that harvest data from server logs, standard Web browser software such as Internet Explorer (IE) can be used in the research study.

One flaw in all of these research approaches (except, perhaps, the *PCMeter* tactic) lies in the fact that experimental access must be restricted to either (1) a limited set of Web pages that have been appropriately scripted for data collection, or (2) a specific set of servers from which log data can be procured ex-post. If the experimental subject is allowed to "wander" beyond this limited set of pages or sites (an activity that is quite fundamental to the nature of using the Web), then these actions will be unrecorded or inaccessible, and the validity of the research will be nullified. In the script-based approaches, a related complexity stems from the fact that all Web pages used in the experiment must be developed and maintained by the investigator—a task that can be quite labor intensive if a large number of pages are to be made available. Obviously, the experimental pages should usually be large in number and professional in appearance if external validity is to be preserved.

In some situations the research data can be collected without the use of client- or server-side scripting, or server logs. Click-stream data, for example, can often be gleaned through the use of standard network management software, or through *network sniffers* that can be configured to monitor Internet requests and/or page downloads. In this case the experimental subject can be allowed to roam beyond a predefined set of pages, and, again, standard browser software can be used on the client side. The problem here can be in the precision or in the format of the data, as the software was not designed for this purpose. Pages containing multiple frames, for example, may be logged as individual (frame) downloads in some circumstances and as a single page download in others. Client requests that are satisfied through the local cache may not be logged at all. Indeed, this approach suffers from many of the problems that plague server logs.

A problem with all of the data collection methodologies discussed thus far is that they suffer from a lack of experimental control. This lack of control comes from the fact that the instrument with which the experimental subject is interacting (a standard Web browser such as IE) was not designed to be used as a research tool.

Consider the situation in which we wish to study WWW use behavior through analyzing click-stream data. There are numerous ways of gathering data on page requests or page downloads, as noted previously. However, there are no means, short of direct visual observation, of recording *how* a particular page was requested. The page request could have come in the form of a click on a hyperlink, but the request could just as likely have been generated automatically through a dynamic action on the page (e.g., *meta refresh*), or through the *Back* or *Forward* buttons in the browser interface. Normal click-stream data will not distinguish between these circumstances, so the precise behavior or intentions of the experimental subject cannot be determined. This specific problem is noted by Montgomery et al. (2004, p. 580) as a shortcoming of the aforementioned *PCMeter* usage mining software: "However, the meter does not distinguish how the user navigates between pages (e.g., whether the user selects a hyperlink, a bookmark, or directly types in the URL to navigate to a page)."

Another problem has to do with the occurrence of multiple windows. Many hyperlinks open in new browser windows, and the user often has the option of requesting a new window at his or her discretion. The problem here is that the data collected cannot reflect which of the open windows is active when actions occur, or even that there are multiple windows in use (the opening and closing of windows are not logged). Again, the data cannot capture, or misrepresent the behavior in question; true *streams* cannot be traced.

A CLIENT-CENTRIC ALTERNATIVE

As noted earlier, the methodological problems, for the most part, stem from a lack of experimental control. Logic and research experience suggest that, for maximum experimental control, any experimental manipulations (treatments) and the data collection mechanisms should be as close to the experimental subject as possible. That is, they should be

Table 1. Sample WebBrowser members

Event/Method	Behavior/Details	Possible Use
BeforeNavigate2 event	Triggered after page request, but before navigation begins. Provides target URL and frame information. Allows cancellation of navigation.	Can analyze URL request and covertly cancel or redirect inappropriate requests. Software can contain list of irrelevant URLs or heuristic rules (e.g., requests containing forbidden protocols or Web domains can be halted) (e.g., no returns to prior pages).
Navigate2 method	Forces browser to navigate to a new location (URL).	Can be used to covertly modify target for (cancelled) navigation request. Can be used to covertly effect programmatic delay between user's request and download activity.
DocumentComplete event	Triggered when a page has been successfully downloaded and is available for browsing. Provides full URL details.	Can be used to capture click-stream data (record URL). Can be used to timestamp click-stream data and to determine and record page-viewing time.
NewWindow3 event	Precedes creation of a new browser window. Window creation can be canceled and target redirected to main browser window.	Can force all URL targets to a single window. Can be used to block popup windows that might enter noise into experimental setting.
GoForward/*GoBack* methods	Forces navigation to subsequent (or previous) page in system-maintained URL history list.	Can emulate full behavior of IE Forward (and Back) buttons, but this behavior can be modified if needed. Note that button action can be included in click-stream data record to indicate source of request (see example later).
TitleChange/ *StatusTextChange* events	Fires whenever title (status information) of an IE session would change. Provides new text.	Can emulate behavior of an IE Title Bar (Status Bar) as needed.
GoHome, *GoSearch*, *Refresh*, *Stop* methods	Forces appropriate action of browser control.	Can easily emulate remaining features of IE interface, but all actions can be filtered through programmed decisions.

embedded in the browser itself. This leads to the development of a custom IE-look-a-like browser for use in Web-based research. The creation of such a software application is quite feasible with currently available programming tools and software techniques. The numerous benefits of this approach certainly outweigh the software development costs. The benefits are greatest when research designs are complex and when precision is of prime importance. This particular methodology has been employed in several research studies including Chiang et al. (2004) and Norberg (2003).

With custom browser software there is no need to depend on scripts or applets in experiment-specific Web pages to administer experimental treatments or to record user actions, nor is there the need to gain access to server logs. Consequently, there is no need to restrict the experimental domain to a limited set of custom Web pages, or even to a specific set of servers. With this approach, the experimental domain can include the entire Web. The custom browser software can be built with the ability to precisely record user activity and to preempt or modify actions that could be harmful or inappropriate in the experimental context. Experimental control and experimental manipulation can be integrated into the browser itself.

The software that we know as Internet Explorer (iexplore.exe) is essentially a software interface to a dynamic link library (DLL) that provides the requisite Internet processing functionality. This software component is named shdocvw.dll, but it is commonly referred to as the *WebBrowser Control* (see Microsoft Corporation, 2006a). Object-oriented programs developed for a Windows platform (e.g., C++, C#, or VB applications created in the *Visual Studio.NET* software development suite) can host this *WebBrowser* object to add Web browsing functionality to software applications. The *WebBrowser* object works with the standard event-based model of Windows computing.

With the *WebBrowser* object, event handlers are provided for all of the major occurrences in an Internet session such as *request to navigate to a page*, *page download complete*, or *request for a new window*. Key data such as URL, Target Frame, and Page Title are available with the events. In some cases, actions can be preempted through a *Cancel* argument in the event handler. One important example of this is the *BeforeNavigate* event handler. This routine is triggered *after* a navigation has been requested by the client, but *before* the request is fulfilled. This allows the hosting software application to inspect and evaluate the situation, and to possibly modify or cancel the request before it is allowed to proceed.

Properties and methods of the *WebBrowser* object can be used to dynamically emulate all of the features of the IE interface such as the status bar, the browser window caption, and the standard buttons (Back, Forward, Stop, Refresh, Home, etc.). In short, an emulation of IE can be built with the inclusion of as few or as many features of the IE interface as are needed in the research context.

Table 2. Data record structure

	Field	Details
1	Subject_ID	Auto generated by application.
2	URL_Sequence#	Auto generated by application.
3	Target_Frame	If any.
4	URL_Start_Time	Since session began (sec./1000).
5	URL_Duration	Sec./1000.
6	User_Action	Click, Back-Button, Forward-Button, Home-Button, Automatic.
7	Full_URL	Can be parsed if needed.

Table 1 describes selected events and methods of the *WebBrowser* object that are pertinent to this discussion. See Microsoft Corporation (2006b) for a full list and description of the members of this object.

Table 2 provides a sample structure of click-stream data that has been generated with this methodology. This represents one of several system-generated data tables analyzed by Chiang et al. (2004). This data table holds one record per subject per URL visited (i.e., one item in a stream). Fields 1 and 2 were generated automatically by the custom software, and provide primary and secondary sort fields for click-stream analysis. Field 3 provides data for frame-based pages and is derived from the *BeforeNavigate2* event. Field 4 (captured in *BeforeNavigate2* event), records the time at which the page was initially requested (e.g., user click). Field 5 records the duration for which the page was available to the user (*DocumentComplete* event for *current* page → *BeforeNavigate2* event for *next* page). Field 6 indicates how this page was requested ("Automatic" indicates a redirect, as by a script action or a meta refresh). Field 7 was captured by the *DocumentComplete* event handler. By writing the data record within the *DocumentComplete* event routine, unsuccessful or aborted downloads were culled from the stream. Sequence gaps in Field 2 indicate such.

In this particular experimental study, randomized assignment of subjects to treatment cells, as well as experimental session duration, was managed completely by the browser software application (after a fixed duration, the browser was programmatically disabled and the user was shown a "thank you" page). A second data table holding Subject_ID and experimental treatment information was later merged with Table 2 for analysis.

FUTURE TRENDS

As WWW becomes more and more woven into the fabric of our personal and professional lives, software developers, marketers, e-tailers, and social scientists will become increasingly interested in understanding Web access and search patterns. Most likely, this will result in an even greater proliferation of research studies involving Web usage mining. There is no reason to presume that harvesting from server logs will become significantly more efficient or reliable. Consequently, we should expect that the use of real-time, software-based approaches such as scripted data collection, the *PCMeter*, and the custom browser approach described previously will become more commonplace, especially in experimental research settings. Improvements in object-oriented software development environments such as .NET should facilitate this trend.

CONCLUSION

By developing software to host a custom browser research instrument, many of the problems that afflict other Web usage mining approaches can be circumvented. With this tactic, the investigator is free to include (covertly) all of the requisite mechanisms of experimental control and data capture into the software itself; no external scripting, log access, or network monitoring is needed. Timers to control the duration of the experiment or the occurrence of experimental treatments can be embedded into the application.

Experimental treatment randomization can also be built in. User activity down to the keystroke or mouse-click level can be monitored and recorded with millisecond accuracy if needed. Certain events can also be blocked or modified if necessary. For example, an attempt to open a page in a new window can be intercepted and the page redirected to the initial window. No special (e.g., scripted) Web pages are needed, but attempts to "wander" to irrelevant sites or inapposite protocols (e.g., *mailto*, *ftp*) can easily be halted if desired. The local cache can be controlled programmatically, thus avoiding systematic bias. Once the basic system is developed, modifications and new features are a fairly simple to put into effect.

The previous discussion and summary tables touch on the basic advantages and capabilities of this custom software approach. Many of the complexities, such as the need to override the standard context menus and some key sequences, are ignored here. Also beyond the scope of this discussion are many of the advanced capabilities such as how to gain access to an additional rich source of experimental data through use of the document object model (DOM). A more thorough presentation is presented by Westin (2003).

KEY TERMS

ASP (Active Server Page) Scripting: A simple server-side scripting approach where script code (usually VBScript or Jscript) is mixed with HTML code on a Web page. The script code is processed by a script engine before the page is rendered by the server. This can be used to create dynamic Web pages and to share data within or between Web sessions. This is a predecessor of ASP.NET technology and is sometimes called *Classic ASP*. ASP pages are identified by an ".asp" file extension. (See **ASP.NET**.)

ASP.NET: The new generation of ASP provided by the Microsoft .NET environment. ASP.NET supports a number of advanced features including server-side controls, dynamic data binding, Web services, and Web forms. All .NET programming languages (e.g., C++, C#, VB) are fully supported, so the developer is no longer restricted to using simple scripting languages. ASP.NET components are compiled thereby providing major security and performance enhancements. ASP.NET pages are identified by an ".aspx" file extension. (See **ASP Scripting**.)

Click-Stream: In Web research, the click-stream is the sequence of Web pages that is visited by the experimental subject. A click-stream data record can be as simple as URL and sequence number, or a timestamp can also be added. This latter approach allows for analysis of page viewing time.

Client-Side/Server-Side Scripting: In a Web environment, this term relates to the fact that scripted tasks can be handled by the browser software (client side) or by the Web server software (server side). A single Web page may contain both client side and server side scripts. The script host is determined by the *RUNAT* attribute of the *SCRIPT* tag.

Event Handler: A procedure (subroutine) that executes in response to an event. The event may represent a specific user action (e.g., a mouse click), or may be a manifestation of a system process (e.g., page has finished loading). Details surrounding the event are provided as arguments of the procedure.

Meta Refresh: A special HTML tag that automatically redirects the visitor to a new page. The result is that the final destination of the navigation is different from the initial target.

Method: In Object Oriented Programming, methods are the actions or behaviors that an object can perform. At the coding level, a method is created by including a procedure (function or sub) within the class.

Network Sniffer: A hardware and/or software mechanism that monitors, and possibly records, data traffic on a network.

Web Usage Mining: Harvesting and processing data for the purpose of uncovering usage and navigation patterns of Web users. This is usually recognized as a sub-category of *Web Mining*. The additional elements of this broader term are *Web Content Mining* and *Web Structure Mining*. These focus, respectively, on the information content of Web documents, and on the hyperlink structure among Web documents.

INTRODUCTION

Spurred by development in computer science and network technology, the use of the Internet has been expanding exponentially. It is now extensively used as a connectivity and reference tool for numerous commercial, personal, and educational purposes. In education, the Internet opens a variety of new avenues and methodologies for enhancing the experience of learning as well as expanding educational opportunities for a larger pool of students. Specifically, distance education and non-traditional classrooms have the capability to reach more students using specialized instruction and self-paced learning.

In the area of distance education, many **Web-based real time experimentation** systems have been reported in the literature (Ando, Graziani, & Pitrone, 2003; Daponte, Grimaldi, & Marinov, 2002; Ko, Chen, Chen et al., 2000; Ko et al., 2001; Kumar, Sridharan, & Srinivasan, 2002; Yeung & Huang, 2003). These Internet-based remote laboratories allow users or students to carry out physical experimental work at their own pace anytime anywhere. They generally require very little physical space and minimal manpower to maintain, and are ideal for the sharing of expensive equipment. However, all these experimental systems can only provide 2D operation panels. Due to this limitation, the actual shapes of 3D instruments and equipment, some of which may have controls or display components on different sides, may not be possible to be reflected on the remote user's client display window.

BACKGROUND

Although many 3D visualization schemes on the client side have been presented (Geroimenko & Geroimenko, 2000; Hobona, James, & Fairbairn, 2006; Nakano, Sato, Matsuo, & Ishimasa, 2000; Oellien, Ihlenfeldt, & Gasteiger, 2005; Osawa, Asai, Takase, & Saito, 2001; Ueda, 2006; Vormoor, 2001) and some additional collaborative functions have been proposed for communication amongst multiple remote users or between client and server (Bender, Klein, Disch, & Ebert, 2000; Engel, Hastreiter, Tomandl, et al., 2000; Nielsen, 2006; Zhuang, Chen, & Venter, 2000), applications and issues such as Web-based real time control and 3D-based monitoring have not been addressed. We present in this article the development of **Web-based 3D real time experimentation** using Java 3D visualization tools.

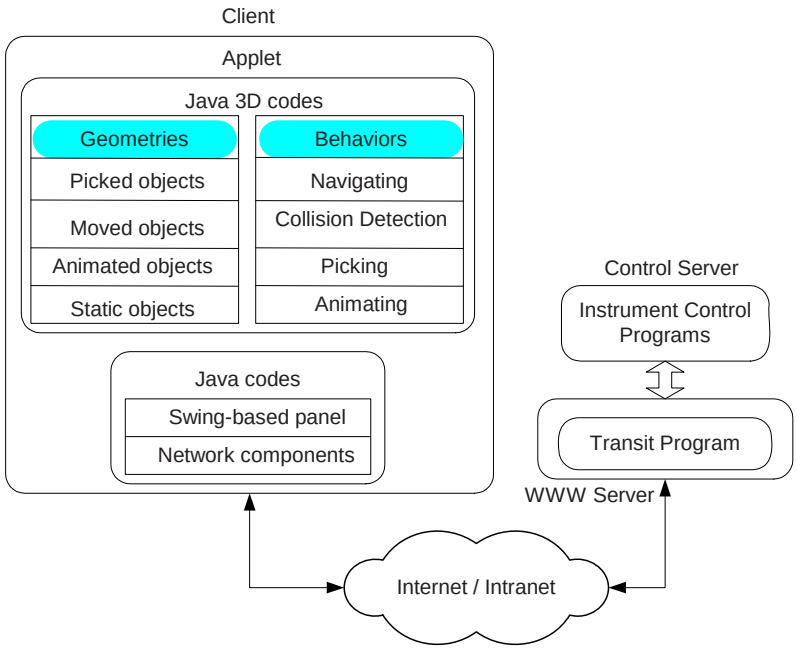
Among the various tools available, **Java 3D** is ideal from certain perspectives. Specifically, **Java 3D** is an efficient tool that provides a very flexible platform for building a wide range of Web-based three-dimensional graphics applications, and is becoming one of the most attractive tools for creating 3D user interfaces, **3D visualizations** and virtual environments. It provides not only strong **3D programming** but also excellent integration with previous version of Java components.

In comparison with other 3D virtual experimental systems, this chapter attempts to address all the important issues with an emphasis to provide a complete solution. Specifically, issues on connecting actual experimental instruments, real time data transmission, three-dimensional virtual scene and three-dimensional behaviors are addressed. These ensure that the user will get a more realistic feeling when operating and controlling three-dimensioanl experimental instruments as well as monitoring actual experimental results without any significant delay.

PROPOSED SYSTEM REFERENCE MODEL

Figure 1 shows our reference model for the creation of **Web-based, 3D, real-time experimentation** using Java 3D visualization tool. Note that on the client side, the combination of Java 3D API and Java realizes 3D visualization and network connection. Usually, 3D visualization consists of geometry and **behavior objects**. The former includes the picked, moved, animated and static objects, and the lat-

Figure 1. System reference model for creating Web-based, real-time experimentation



ter consists of navigating, collision detection, picking and animating behaviors.

The picked objects cover all controls such as buttons, knobs, sliders and connectors of the virtual equipment and experiment, while the moved objects include curve, text and screen displays on the **virtual instruments**. The animated objects cover all active and periodically moved objects. The other visual objects, such as walls, windows, tables and certain components of some **virtual instruments**, are taken to be static ones. These **geometry objects** designed using Java 3D helps to promote the rendering efficiency of the 3D virtual scene. In the relevant behavior objects, only the animating behaviors provided by Java 3D API are used without modifications.

PROPOSED HARDWARE ARCHITECTURE

The system reference model of Figure 1 can be supported by the double-server-client distributed hardware architecture of Figure 2. The whole system includes a user's computer on the client side, the Internet and/or an intranet to transmit command and data, a Web server to host the Web site of the remote experimentation, and a control server with control cards attached to programmable instruments together with some circuit boards.

In particular, programmable instruments have to be connected to the control server through control cards and cables in a 3D remote experimentation system. For example, two separate TCP/IP interface modules are used for real time control and retrieval. The commands coming in through the TCP/IP control interface are converted into the format required before being sent to the programmable instrument to be controlled. Experimental data for the generation of real time curve or text for the user is transmitted to the client through the TCP/IP retrieval module.

3D INSTRUMENTS AND SCENE

To be as realistic as possible, and to overcome certain limitation posed by 2-D operation panels, using which the actual shapes of **3D instruments** and equipment cannot be shown, the use of 3D visualization tools in real time Web-based experimentation may be considered. Figure 3 shows a typical example GUI realization on the client computer developed based on Java 3D.

Ideally, anyone conducting an experiment through the Internet should be able to do it in the same manner as in a real laboratory. This can be accomplished in a 3D environment through three behavior modules on navigating, collision detection and picking in the GUI interface.

Figure 2. Hardware architecture for creating web-based real time experimentation

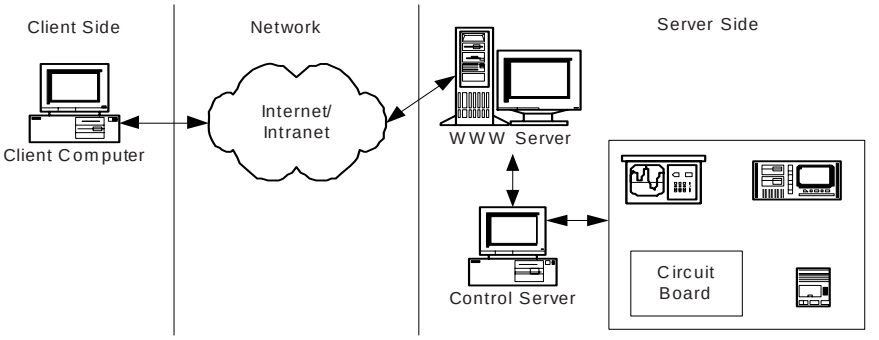


Figure 3. 3D view on an experiment with a battery

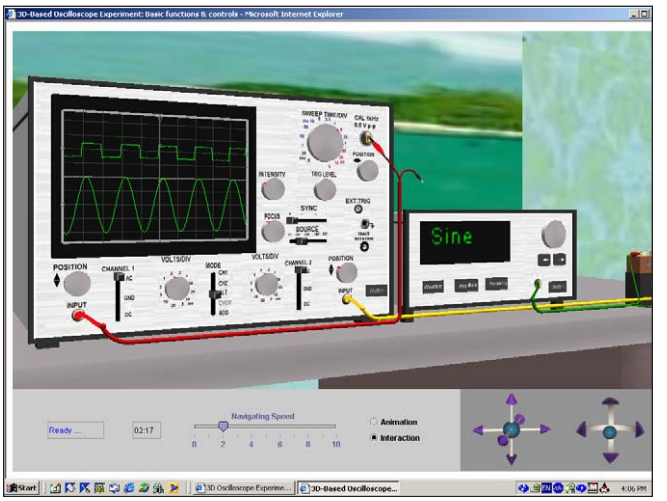


The module on **navigating behavior** controls how the user walks around in the **virtual laboratory**. Also, as the user attempts to get a better view, it controls indirectly the positions and angles of the view platform. The **collision detection** module ensures that the user does not traverse any solid objects such as walls, tables and instruments. Through the picking behavior module, the user will be able to adjust the controls of available experimental apparatus precisely.

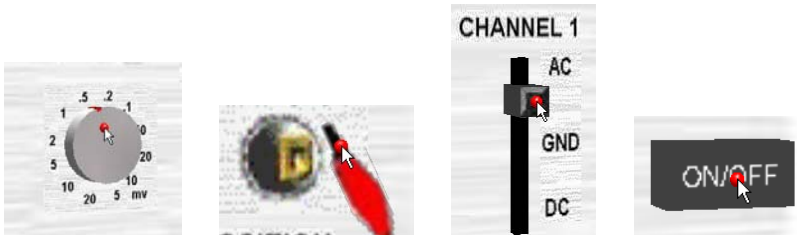
The experiment is performed when the user enters a virtual laboratory as shown in Figure 4. Apart from the **virtual instruments** and circuit board placed on a table, the virtual laboratory also includes the floor, the ceiling, a few walls, two windows and one door. To enter the virtual laboratory, a user will need to "walk" to the door and press the door open button. Upon opening, the user can walk through the door, move around and carry out the experiment by adjusting the instruments and circuit board on the table.

MAIN FUNCTIONS

The main functions and features in such a **Web-based 3D remote laboratory** system are summarized below:

1. A 3D remote laboratory controlling actual instruments and displaying real signals is implemented through a dynamic **virtual scene** via the Internet. In the example in Figure 3, the laboratory has an oscilloscope, a signal generator, a battery, a few cables and some other visual objects.
2. A navigation tool for walking around the virtual laboratory is provided. For example, the tool on the bottom right hand corner in Figure 3 allows the user to move around the virtual laboratory and view instruments from different positions and directions through the mouse.

Figure 5. Picking controls for instruments



(5a) **(5b)** **(5c)** **(5d)**

3. A collision detection mechanism is implemented. This guarantees that the viewing platform will not traverse any solid objects such as walls, doors, windows, tables and virtual instruments.
4. Through the appropriate picking function, the user can adjust individual controls on the instruments in the 3D environment and connect circuits in the same way as he or she operates an actual instrument in the real laboratory. As shown in Figure 5, the operations of turning a knob, adjusting a slider, pressing a button, and making a connection to a terminal can be performed by simply dragging the mouse to move the relevant control when the control is in "focus." To make it as user friendly as possible, a red point is displayed when the mouse is over a control that has received focus.
5. The adjusted controls are converted into the relevant commands and sent to a control server to control real instruments in the actual physical laboratory. The result of the experiment is sent back by the server to the client to be displayed in the 3D virtual laboratory in real time.

FUTURE TRENDS

Despite a number of efforts, there are still some limitations on the widespread application of **Web-based, 3D experimentation system**. Specifically, such systems generally require more complicated software and hardware configurations and support such as high-end display card and DirectX/OpenGL plug-in to run DirectX or OpenGL graphic libraries. Also, the Internet has certain inherent constraints for the transmission of large experimental data streams. Lastly, due partly to the variety of non-standard development systems that need to be used and the complexity of integration hardware apparatus and software applications, the number of sites that supports such systems is still rather small.

Nevertheless, as powerful computer hardware becomes more readily available and new development and software tools are introduced, these problems may be overcome to a certain extent in the next five to ten years. Web-based 3D experimentation will perhaps provide an evolutionary influence on 3D network applications, and as the Internet becomes faster and more universities and research institutes become interested in this area, more experimental sites may become available.

CONCLUSION

A 3D Internet oscilloscope experiment has been developed, and has been used to support the teaching of undergraduate courses in the Department of Electrical and Computer Engineering, National University of Singapore. It has also received good rating from experts in the Java 3D interest group on aspects such as user interface, ease of use and usefulness.

KEY TERMS

Internet Remote Experimentation: The use of the Internet to carry out physical experimental work at a remote location.

Online Experiment: An experiment that is running and controlled by a computer terminal.

Virtual Laboratory: A computer accessible laboratory which may be simulated by running a software package or which may involve real remote experimentation.

Web-Based Control: The control of instruments or apparatus through the Internet.

Web-Based Laboratory: A laboratory that typically involves physical experiments and that can be accessed remotely through the use of the Internet.

Web-Based 3D Navigation: The use of the mouse or keyboard to navigate in a Web-based three-dimensional virtual scene.

Web-Based 3D Picking: The use of the mouse to manipulate the controls of Web-based three-dimensional virtual or real instruments.

Web-Based 3D Visualization: A 3-dimensional scene display that can be accessed through normal Internet explorer such as IE or Netscape.

Web-Based Algorithm and Program Visualization for Education

INTRODUCTION

Programming is a central activity in the computing profession. It is facilitated by different tools (editors, compilers, debuggers, etc.), which are often integrated into programming environments. Programming also plays a central role in computer science education. For this purpose, a number of complementary tools were developed during the last decade: algorithm animators, program visualizers, problem generators, assignment graders, and so forth.

After the Web explosion, teachers of programming rapidly turned their attention to the Web. Although the Web has speed and power limitations, it also has several advantages that make it invaluable for educational purposes. Mainly, it provides universal accessibility and platform independence, and solves the distribution problem by always making available the last version of any tool.

Probably, the most common use of the Web for programming courses is as a communication medium, facilitating submission and administration of assignments and grades (Burd, 2000). Another common use of the Web for programming education is as a public repository of high quality problems, such as the *Lab Repository* (Knox, 2006) and the *ACM International Collegiate Programming Contest* (Skiena & Revilla, 2003). Web sites may also host other resources, such as slides and audio lectures (Skiena & Revilla, 2003), algorithm animations (Brummond, 2001), or programming tools (English, 2001). These collections have no structure or, at best, are lineally or hierarchically structured, but more advanced repositories are possible. In this case, a management system must be delivered that, using (semi)structured mark-up languages, allows retrieving, maintaining, and publishing. A good representative is the eXercita system (Gregorio-Rodríguez et al., 2000, 2002). Finally, programming tools have been ported to be executed on the Web (Pareja-Flores & Velázquez-Iturbide, 2002).

This article describes a different class of Web-based tools for programming education, namely tools for algorithm and program visualization. After the Background section, we describe the evolution of these systems, educational uses, and lessons learned. Finally, we outline future trends in the use of the Web for programming education and our personal conclusions.

BACKGROUND

Algorithm animation is a research field that is now 20 years old and still evolving. There is a consensus with respect to the videotape *Sorting out Sorting* presented in 1981 by Baecker (1998), which is considered a landmark on animation. It included animations of nine sorting algorithms. Afterward, some works established the main techniques for specifying and implementing algorithm animation: BALSA (Brown, 1988), Tango (Stasko, 1990), and Pavane (Roman, Cox, Wilcox, & Plun, 1992). Systematic categorizations of software visualizations have been proposed since then (Price, Baecker, & Small, 1998).

In a general setting, software visualization studies the visual representation of software entities (Stasko, Domingue, Brown, & Price, 1998). Visualization requires an effort to abstract the target entity to visualize and to make a good graphical design that may yield many different representations: text versus graphics, level of abstraction, displaying control versus data structures, static versus dynamic visualizations, one or multiple views, behavior versus performance, and so forth. This general aim can be achieved in different ways. Program visualization is aimed at the visualization of a piece of software so that the representation has a close relationship to the source code. Algorithm animation is aimed at the dynamic visualization of a piece of software illustrating the main ideas or steps (i.e., its algorithmic behavior), but without a close relationship to the source code. The graphical nature of software visualization in general and algorithm animation in particular makes them very conductive to the hypermedia features of the Web.

WEB-BASED ALGORITHM AND PROGRAM VISUALIZATION SYSTEMS

In the mid 1990s, many of the algorithm animation systems were ported to the Web, and many additional systems were specifically designed for the Web. A representative work from these years is that of Naps (1996), in which he carried out a study of the technical alternatives that could be used to make animations produced by previous systems available on the Web. Other pioneer systems are Mocha (Baker, Cruz, Liotta, & Tamassia, 1996), JCAT (Brown & Raisamo, 1997), and Jeliot (Haajanen et al., 1997).

Some animation systems are general purpose, so they can be used to generate visualizations of any entity, including non-programming entities. They typically provide a scripting language that makes animation creation a relatively easy task. Good representatives are the ANIMAL (Roessling & Freisleben, 2002), JAWAA (Pierson & Rodger, 1998), and Samba (Stasko, 1997) systems. The JHAVÉ system (Naps, Eagan, & Norton, 2000) is not an algorithm visualization system itself, but rather a support environment to render visualizations from a variety of visualization systems. Currently, it supports algorithm visualizations in three scripting languages: ANIMAL, GAIGS (Naps, 1990), and Samba. With JHAVÉ, students can explore algorithms, controlling movement and responding to pop-up questions. Leonardo Web (Bonifaci, Demetrescu, Finocchi, & Laura, 2003) is a collection of tools for creating animated representations via the use of a visual editor and a Java library. The presentations can be viewed by a simple Java player, so being possible to integrate the animations in Web pages, or to browse them off-line.

Another category of systems automatically produce program animations, enhanced with graphical representations. Some of these systems are computer-supported learning systems that only provide visualization support for a given domain and with a specific didactic purpose. For instance, the KIEL system (Berghammer & Milanese, 2001) gives support to learning the ML functional language. The system allows students to input a program and an expression to evaluate and then graphically displays the evaluation of the expression. The student may navigate both forward and backward through the evaluation process. A successful experience comes from the "problets" by Kumar (2003). They are tutors aimed at specific programming topics, which randomly generate problems and ask questions to the student. Visualizations are used as a visual aid for problem solving. Problets have been developed for a number of topics: expression evaluation, identifier scope, and so forth. A similar approach has been addressed elsewhere for data structures (Baker, Boilen, Goodrich, Tamassia, & Stibel, 1999).

A different category of systems providing automatic visualizations are based on the availability of complete language processors. The WinHIPE system (Velázquez-Iturbide, Pareja-Flores, & Urquiza-Fuentes, 2006) is an integrated development environment (IDE) for functional programming that allows (semi)automatically generating animations of the evaluation of a functional expression. Then, the animation can be played within the IDE or exported to the Web (Urquiza-Fuentes & Velázquez-Iturbide, 2005), also giving support to manage collections of animations.

Other automatic visualization systems use the Web as a user interface for programming, and allow loading and executing programs. For instance, the ISVL is designed to learn Prolog programming online (Domingue & Mulholland, 1998). ISVL allows students to generate animations based on AND-OR trees that can be communicated to the course tutor and even stored as films. The tutoring may insert annotations on the student animations to respond to their questions or to explain where a programming error was made.

The Jeliot family (Ben-Ari, Myller, Sutinen, & Tarhio, 2002) is a collection of program and algorithm visualization tools designed for novices learning programming, algorithms, and data structures with Java. The last member of the family is Jeliot 3 (Moreno, Myller, Sutinen, & Ben-Ari, 2004), specially focused to animate object oriented features, such as inheritance.

The last class of animation systems is based on simulation. MatrixPro (Karavirta, Korhonen, Malmi, & Stalnacke, 2004) enables instructors to create algorithm animations by direct manipulation of a data structures library. Teachers can demonstrate the visual simulation of an algorithm by providing on the fly different input sets. "What-if" questions can also be invoked in lectures. A related tool, TRAKLA2 (Korhonen, Malmi, & Silvasti, 2003), is designed for building and solving interactive algorithm simulation exercises, made available as applets, for learning data structures and algorithms. In these exercises, students directly manipulate conceptual visualizations of data structures in order to simulate the working of algorithms.

EDUCATIONAL USES OF WEB-BASED ALGORITHM AND PROGRAM VISUALIZATION

From the outset, the main use of algorithm animation was educational, rather that industrial (for instance, as a debugging tool). Algorithm animation systems have been used in several ways: as a complement to lectures on algorithms, for self-study, or within laboratories. A more demanding use of animation systems consists in requiring students to build their own animations.

The best documented experience ran for about 20 years at the Computer Science Department of Brown University (Bazik, Tamassia, Reiss, & van Dam, 1998). All the experiences reported in the available literature agree that students

are highly motivated by algorithm animations. Hundhausen (Hundhausen, Douglas, & Stasko, 2002) provides a comprehensive review of experiences in using animations for education.

Design of Effective Visualizations

It is difficult to provide canned recipes for the design of visualizations. Several authors (Gloor, 1998; Khuri, 2001; Saraiya, Shaffer, McCrickard, & North, 2004) summarize some general recommendations for their design. Some commonly accepted suggestions for educational use follow:

- Make the meaning of the different graphical representations explicit, explained either by embedding them in the system or reinforced by allocating time to the subject during the course.
- Adapt to the knowledge level of the user, either novice or expert. In the first case, the system must be easy of use, whereas in the second case, it may be more comprehensive.
- Complement visualizations with explanations.
- Be interactive, allowing flexible control of animations (including movement in a backward direction), customization, input data, or unfolding unexpected short questions.
- Provide multiple views, which must be consistently coordinated.
- Include performance information, for example, data collected during the execution of an algorithm, or animating several algorithms simultaneously.
- Include execution history.
- Include canned examples.

Issues for Educational Use

Unfortunately, visualization systems have failed to find widespread use in computer science education. Two main problems can be identified (Naps, Roessling, Almstrum et al., 2003). The first problem is the lack of evidence on the educational effectiveness of visualization systems, that is, whether students learn more using them. In last years many evaluations have been performed on the educational effectiveness of visualization systems. The results vary and even contradict. Researchers in the field have finally come to the conclusion that these systems are effective only if students are actively engaged (Hundhausen et al., 2002).

Based on this conclusion, a taxonomy consisting in several levels of engagement has been proposed (Naps, Roessling, Almstrum et al., 2003). The lowest level of engagement corresponds to no-visualization, the next one to passive viewing, and the following levels successively force the student to engage in answering questions, changing the visualization, constructing a new visualization, and finally presenting a new visualization to an audience.

A second problem is on the instructor's side. Using a visualization system often poses a heavy workload on the instructor (Naps, Roessling, Almstrum et al., 2003; Naps, Roessling, Anderson et al., 2003). The many issues the instructor must face have been identified, and suggestions to constructors of these systems have been given (Naps, Roessling, Anderson et al., 2003). Many of these suggestions are solved or alleviated by means of the Web. For instance, the availability of an official and comprehensive Web site is a good way to announce a system and give support to potential users.

The main bottleneck is the huge amount of time necessary to build new visualizations. The term "effortlessness" has been coined (Ihantola, Karavirta, Korhonen, & Nikander, 2005) to refer to the feature of an algorithm or program visualization system that supports the creation or use of visualizations in a course without much effort from the instructor's perspective. There is no definitive definition of a system being effortless, but is seems to be related to how wide its scope is, how easy its adaptation to a given course is, and how easy different educational uses are supported.

FUTURE TRENDS

Algorithm and program animation achieved technical maturity in the early 1990s. In the years thereafter, most efforts have focused on porting to the Web and on enhancing their educational adequacy. We believe that we will see more efforts aimed at designing and evaluating the elements of effective and effortless animations.

Currently, there are several research efforts aimed at designing and developing dynamic electronic books, with dynamic contents and virtual laboratories. We believe that these virtual laboratories for programming will incorporate interfacing with programming tools such as program compiling and execution, and will include automatic visualization and animation. Some inspiration can be obtained from the hypertext books by Rockford Ross (Ross & Grinder, 2002) on automata theory.

CONCLUSION

We have provided a panoramic view of the educational use of algorithm and program visualization on the Web. We have offered an overview of the main technical achievements and the educational uses of them. We have also explained issues to consider in an educational setting and some of the lessons that have been learned from experience. In the near future, we expect that there will be increased interest in Web-based tools to support these activities.

KEY TERMS

Algorithm Animation: Visualization of a piece of software illustrating the main ideas or steps (i.e., its algorithmic behavior), but without a close relationship to the source code.

Effortlessness: Feature of an algorithm or program visualization system that refers to its support to create or use visualizations in a course without much effort from the instructor's perspective.

Engagement Levels: Taxonomy that communicates the degree of involvement of the learners in an educational situation that includes visualization.

Information Visualization: Visualization of phenomena by means of appropriate representations. It is a field different from scientific visualization since information visualization emphasizes delivering visualizations that improve comprehension, whereas scientific visualization emphasizes delivering realistic visualizations.

Multiple Views: Visualization technique consisting in showing several aspects or views of a program, where any view typically shows few aspects and must be comprehen-

sible by itself. Typical views are code vs. data, several levels of abstraction, logic vs. performance, history, and several simultaneous algorithms.

Program Visualization: Visualization of a piece of software so that the representation has a close relationship to the source code.

Visualization: To make something visible by means of some representation. Visualization consists of two elements: a mental process and a graphical language. Note that "to visualize" is different from "to see."

Web-Based Customer Loyalty Efforts and Effects on E-Business Strategy

INTRODUCTION

Despite continued market growth, a number of Web sites have been unprofitable. Some notable failures were eToys.com, boo.com, bluefly.com, buy.com, and valueamerica.com. An examination of the companies' IPO filings suggests that the collapses were caused by cut-price strategies, over-investment, incorrect expectations, and non-profitability. Surviving in the digital market has become a critical challenge for Web managers.

To face the business challenge, Web managers and marketers demand information about Web site design and investment effectiveness (Ghosh, 1998). As the rate and diversity of product/service innovation declines and competition intensifies, Web managers need better research on Internet-related investment decisions (Donath, 1999; Hoffman, 2000). The original article examined the role of customer retention actions in these decisions (Forgionne & Ingsriswang, 2005). This article updates the original analysis by incorporating new research on comprehensive e-business strategy models.

BACKGROUND

Since online consumers can switch to other Web sites or competitive URLs in seconds with minimal financial costs, most Web sites invest heavily in programs to attract and retain customers. The Web site's ability to capture consumers' attention is known widely as "stickiness."

From one perspective (Rubric, 1999, p. 5), stickiness is the ability of a Web site to capture and keep a visitor's attention for a period of time. Alternatively, stickiness can be described as the ability of the site in attracting longer and more frequent repeat visits or the ability of the site to retain customers (Anders, 1999; Davenport, 2000; Hanson, 2000; Murphy, 1999; O'Brien, 1999; Pappas, 1999). On the other hand, Demers and Lev (2000) represent stickiness by the average time spent at the site per visit.

These views suggest that stickiness is similar to, if not the same as, the marketing concept of customer loyalty (Morgan & Hunt, 1994). The idea is to develop and maintain long-term relationships with customers by creating superior customer value and satisfaction (Reichheld, 1996). Enhanced customer satisfaction results in customer loyalty and increased profit (Anderson, Fornell, & Lehmann, 1994; Reichheld & Sasser, 1990). Loyal customers, who return again and again over a period of time, also are valuable assets of the Web site. The ability to create customer loyalty has been a major driver of success in e-commerce (Reichheld, Markey, & Hopton, 2000; Reichheld & Schefter, 2000) since enhanced customer loyalty results in increased long-term profitability.

On the basis of marketing theory, then, stickiness can be viewed as the ability of a Web site to create both customer attraction and customer retention for the purpose of maximizing revenue and profit. Customer attraction is the ability to attract customers at the Web site both frequently and for long durations, while customer retention is the ability to maintain customer loyalty.

MODELING E-COMMERCE LOYALTY

E-commerce customer loyalty, or stickiness, results from goodwill created by the organization's marketing efforts (Reichheld, 1996; Reichheld & Sasser, 1990), or

$$\text{Stickiness} = f(\text{Goodwill}) \quad (1)$$

and

$$\text{Goodwill} = f(\text{Marketing Mix}). \quad (2)$$

By encouraging current and return visits, stickiness will influence the organization's sales volume. Marketing theory also suggests that the mix of price (including switching costs to consumers), product/service (including site characteristics), and promotion (including banner and other

Web site ads), as well as other factors (including consumer characteristics), will influence this volume (Page, Pitt, & Berthon, 1996; Storbacka, Strandvik, & Gronroos, 1994). Conceptually, then,

Sales Volume = f (Stickiness, Promotion, Product, Price, Other Factors). (3)

Such volume will determine revenue, cost, and thereby profit for the Web site.

According to standard accounting practice and economic theory, profit is defined as the excess of revenue over cost, or

Profit = Revenue - Cost, (4)

while revenue will equal sales volume multiplied by price, or

Revenue = Sales Volume × Price. (5)

The same standard accounting and economic theory indicates that an organization's costs will have fixed and variable components, or

Total Cost = Fixed Cost + Variable Cost, (6)

and variable cost will equal sales volume multiplied by unit cost, or

Variable Cost = Sales Volume × Unit Cost (7)

with sales volume as defined in equation (3).

These marketing-economic-accounting-based relationships are illustrated in Figure 1. This figure and equations (1) through (7) provide a conceptual model that specifies the manner in which the stickiness investment contributes to an e-business's success by generating sales volume, revenue, and profit. As such, the model identifies the information that must be collected to effectively evaluate investments in an e-commerce customer loyalty plan. These equations also provide a framework to objectively evaluate these plans and their impact on organizational operations and activities.

In practice, the model can be applied in a variety of ways. The general relationships can be used for strategy formulation at the macro-organizational level. In addition, the equations can be decomposed into detailed micro level blocks with many variables and interrelationships. At this micro level, tactical policies to implement the macro strategies can be specified and evaluated.

Empirical Testing

Much of the required model information is financial in nature. Such data are largely proprietary and therefore not readily available.

Summarized financial information is available from some Internet companies' quarterly (10-Q) and annual reports and other public sources. In particular, data were obtained from the 10-Q and annual (10-K) reports for 20 Internet companies over the period of 1999-2000. These pooled cross-section, time series data provided values for the revenue and marketing mix variables found in equations (1) through (7). Customer characteristics were proxied through demographic variables, and data for these variables were obtained from the U.S. Census Bureau, Statistical Abstract of the United States for the period of 1999-2000. The quarterly and annual report and Census data provided 120 observations to operationalize the model embodied in equations (1) through (7).

Goodwill, as defined in the economic and marketing literature (repeat business based on happy customers) is not available from the annual and quarterly reports. However, an accounting measure of goodwill, amortization of goodwill and other intangible assets, is available from the reports. Although not strictly the same concept as marketing goodwill, the accounting measure is likely to be correlated with economic goodwill and is thereby used as a proxy for

Figure 1 Stickiness conceptual model

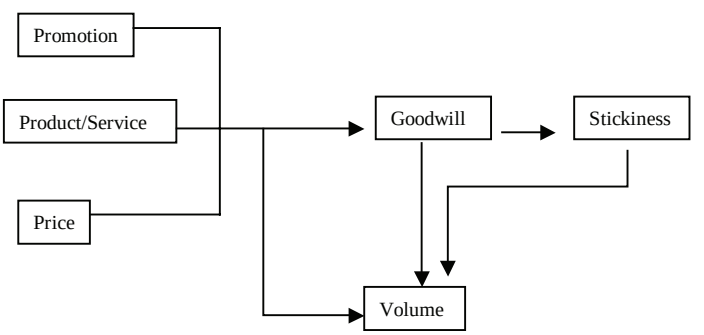

Table 1. Variables with data

VARIABLE	DEFINITION
Volume **V**	total sales volume of the Internet company
Goodwill **GW**	amortization of goodwill and other intangible assets
Promotion **A**	sales and marketing expenditures
Product Quality **Q**	product development costs, which includes research and development and other product development costs
Average Income **AI**	average consumer income
Stickiness **S**	number of unique visitors at the firm's Web site

economic goodwill (Chauvin & Hirschey, 1994; Jennings, Robinson, Thompson, & Duvall, 1996; McCarthy and Schneider, 1995).

No other data were provided by the available sources on a consistent and reliable basis. These data limitations reduced the variable list that could be used to operationalize the stickiness model specified in equations (1) through (7) to the list summarized in Table 1. To test the theory, then, it was necessary to use a truncated form of Figure 1's stickiness model.

Since, equations (4) through (7) in Figure 1's stickiness model are identities, only equations (1) through (3) must be estimated statistically from the available data. Prior research has shown that marketing investments in one period can continue to affect volume in subsequent periods (Hanson, 2000). Marketers call this phenomenon the carryover, lagged, or holdover effect. Stickiness investments and the marketing mix can be expected to create such an effect from new customers who remain with the Web site for many subsequent periods. Because of the data limitations, this important lagged effect had to be measured quarterly, and the carryover had to be restricted to one period. From the relationships in Figure 1, it seems reasonable to assume that the holdover will be expressed through the goodwill variable. Namely, goodwill in the previous quarter is assumed to affect revenue in the current quarter.

At time period *t*, the inputs may have joint, rather than independent, effects on sales volume. Moreover, elasticities (the percentage change in an output generated by a 1% change in an input) can provide useful information for resource allocation analysis. To account for the non-linearities, to facilitate the computation of elasticities, and to account for the carryover effect, equations (1) through (3) can be specified with the popular Cobb-Douglas production function or in log-linear form as follows:

$$\log (V_t) = \log (a_0) + a_1 \log(S_t) + a_2 \log(A_t) + a_3 \log (AI_t) + a_4 \log(GW_{t-1}) + z_1 \quad (8)$$

$$\log (S_t) = \log (b_0) + b_1 \log (GW_t) + z_2 \quad (9)$$

$$\log (GW_t) = \log (c_0) + c_1 \log (Q_t) + z_3 \quad (10)$$

with *t* being the considered time period (quarter), the a, b, c, and z labels denoting parameters to be estimated, and the other variables as defined previously. Price is excluded from the volume equation because data for the price variable are not available from the annual and quarterly reports or from any other published sources.

Equations (8) through (10) form a simultaneous system of equations. Hence, simultaneous equation estimation techniques should be used to separate the effects of the marketing instruments and stickiness on sales volume. Otherwise, there will be a statistical identification problem.

There are several simultaneous estimation techniques that can be used to estimate the operational stickiness model (equations [8] through [10]). Using coefficients of determination, theoretical correctness of the estimated parameters, and forecasting errors as guidelines, the best results were generated by seemingly unrelated regressors (SURs). These results are summarized in Table 2 and Table 3.

Table 2 shows that the volume equation (8) has an $R^2 = 0.74$ and thereby accounts for about 74% of the variation in this variable. More importantly, Table 3 shows that the estimated coefficient of the stickiness variable in equation (9) is significant at the $\alpha = .05$ level, suggesting that sales volume is significantly influenced by the stickiness of the Web site.

Table 2 shows that the model accounts for a relatively small percentage of the variation in stickiness and goodwill. Nevertheless, Table 3 indicates that goodwill has positive and significant effects on the stickiness of the Web site, while

Table 2. Results of the SUR estimation

Equation	MSE	R-Square	Adj. R-Square
Volume (equation [8])	0.3894	0.7408	0.7299
Stickiness (equation [9])	0.2190	0.1944	0.1862
Goodwill (equation [10])	3.5312	0.1296	0.1208

Table 3. SUR-estimated log-linear result

Variable	Volume (V_t)		Stickiness (S_t)		Goodwill (GW_t)	
	Est.	Prob>|T|	Est.	Prob>|T|	Est.	Prob>|T|
Constant	-5.09	.8282	8.74	<.0001	1.19	.0037
Stickiness	0.58	.0002				
Promotion	0.95	<.0001				
Income	0.09	.9885				
Lagged Goodwill	0.05	.1739				
Goodwill			0.17	<.0001		
Product Quality					0.77	<.0001

marketing instruments, such as product quality, also create positive effects on goodwill.

In short, the operational stickiness model provides reasonable statistical results. These results validate the theory that stickiness is an investment that, along with the marketing mix, will influence organizational performance. The results also indicate that sales volume will have inelastic responses to stickiness and promotion investments, that is, a 1% increase in such investments will lead to a less than 1% increase in sales volume. There are similar inelastic responses of stickiness to goodwill and goodwill to product quality.

E-Business Strategy Models

Recently, comprehensive e-business strategy models have been developed and tested that build on and incorporate the original stickiness model. In one model (Ha & Forgionne, 2006), current, rather than lagged, goodwill is treated as a determinant of quantity demanded (sales volume). In addition, there is a competition equation that includes supply chain, rivalry, and other customer loyalty measures that replaces the stickiness (9) and goodwill (10) equations in the operational stickiness model. The first e-business strategy model also offers equations for quantity supplied and employee efficiency. Empirical results, not yet reported in the literature, offer support for the e-business strategy model.

In another model (Wang & Forgionne, 2006), a balanced scorecard approach is used to provide a comprehensive view of quantity demanded and supplied and their roles in determining revenue, cost, and profit. This model explicitly links goodwill, customer retention, customer loyalty, and customer satisfaction. In this view, goodwill and customer satisfaction are determinants of quantity demanded, and customer satisfaction is determined by the product and supply characteristics. The second e-business strategy model also involves more relationships between the various factors than presented in the first e-business strategy or operational stickiness model. Empirical results, not yet reported in the literature, offer support for the second e-business strategy model.

While the two recent strategy models offer different perspectives, each indicates that e-business management is a complex problem involving many interrelated factors. Stickiness, or customer retention and loyalty as expressed in the recent models, is only a component in a comprehensive view of e-business management. Developing a strategy that focuses on stickiness while downplaying the other factors and relationships, then, is likely to result in less than optimal e-business performance. Moreover, the incomplete focus may create problems in managing the other aspects of the e-business.

FUTURE TRENDS

The stickiness analysis suggests future research directions. Neither of the recent e-business strategy models considers dynamic effects. It is useful to determine whether there are significant carryover effects from goodwill. If significant carryover effects are discovered, research should examine how long the investment in stickiness (or customer retention and loyalty) would contribute to the firm's short-term or long-term financial success. The recent e-business strategy models considered competition, and such research should continue. In particular, research should evaluate what role competition plays in stickiness (or customer retention and loyalty). For example, additional research may examine how competitors' stickiness (or customer retention) investments impact the firm.

The recent e-business strategy models demonstrated that empirical e-commerce evaluations will require the collection, capture, and retrieval of pertinent and consistent operational financial and other data for evaluation purposes. Appropriate statistical methodologies will be needed to estimate the proffered model's parameters from the collected data. The recent e-business strategy research also indicated that information systems will be required to focus the data, assist managers in the estimation process, and help such users to evaluate experimental customer loyalty plans. These tasks and activities offer new, and potentially very productive, areas for future research.

CONCLUSION

Figure 1's stickiness model shows how to measure the impact of online stickiness on revenue and profit, and the model also shows how stickiness and goodwill are related. While this operational model can forecast the long term revenue, profit, and return on investment from a Web site's products/services, the new e-business strategy models provide a more comprehensive view of the underlying relationships. In addition, the operational stickiness model, and its e-business strategy successors: (a) provide a mechanism to evaluate Web redesign strategies, (b) help Web managers evaluate market changes on custom loyalty plans, and (c) provide a framework to determine the "best" stickiness and other marketing policies.

In sum, in the e-commerce and e-business world, marketing still provides leadership in identifying consumer needs, the market to be served, and the strategy to be launched. Web managers must realize that desirable financial outcomes depend on their marketing effectiveness. With Figure 1's conceptual stickiness model and the recent e-business strategy models, Web managers and marketers have tools to evaluate their investment decisions.

KEY TERMS

Customer Attraction: The ability to attract customers at the Web site.

Customer Loyalty: The ability to develop and maintain long-term relationships with customers by creating superior customer value and satisfaction.

Customer Loyalty Plan: A strategy for improving financial performance through activities that increase stickiness.

Customer Retention: The ability to retain customers and their allegiance to the Web site.

Goodwill: The amount of repeat business resulting from happy and loyal customers.

Stickiness: The ability of a Web site to create both customer attraction and customer retention for the purpose of maximizing revenue or profit.

Stickiness Model: A series of interdependent equations linking stickiness to an organization's financial performance.

Web-Based Expert Systems

Yanqing Duan
University of Luton, UK

INTRODUCTION

Convergence of technologies in the Internet and the field of expert systems (ES) offer new ways of sharing and distributing knowledge (Sedbrook, 1998). Power (2000) argues that rapid advances in Internet technologies have opened new opportunities for enhancing traditional decision support systems and expert systems. Internet technology can change the way that an expert system is developed and distributed. For the first time, knowledge on any subject can directly be delivered to users anywhere and anytime through a Web-based ES. Because the main function of an ES is to mimic expertise and distribute expert knowledge to nonexperts, these benefits can be greatly enhanced with the emergence of the Internet.

The current focus on networked and Internet-based applications demands new architectures for "intelligent" systems as well as creating new possibilities for research and development in this field (Caldwell, Breton, & Holburn, 2003). This article provides an overview of Web-based expert systems with examples. Benefits and challenges are discussed by comparing Web-based ES with traditional standalone ES from both the development and the application perspectives using Turban and Aronson's knowledge engineering framework.

BACKGROUND

An expert system is "*a system that uses human knowledge captured in a computer to solve problems that ordinarily require human expertise*" (Turban & Aronson, 1998, p. 440). Durkin (1996) reports that many organisations have leveraged ES to increase productivity and profits through better business decisions. Although there have been reports of ES failures (Wong, 1996), research (Yoon, Guimaraes, & O'Neal, 1995) shows that many companies have remained enthusiastic proponents of the technology and continue to develop important ES applications.

The early applications of ES were standalone applications based on mainframe, Artificial Intelligence (AI) workstation or PC platforms. Later came local area network (LAN)-based distributed applications. Grove (2000) identified several problems associated with traditional ES applications, including knowledge bottleneck, performance brittleness, availability of the system, problems with individual software installation and upgrading, and a lack of common protocols for knowledge transfer.

Web-Based ES Application

The Internet offers an ever-expanding set of capabilities and Web-based ES is capable of offering much more than traditional ES. However, the literature appears to offer contradictory pictures on the current status of Web-based ES in practice. Grove (2000) provides some examples of Web-based ES in industry, medicine, science and government and claims that "there are now a large number of ES available on the Internet" (p. 130). Grove (2000) argues that there are several factors that make the Internet, by contrast to stand-alone platforms, an ideal base for Knowledge Based System (KBS) delivery.

Grove (2000) also identifies several problems that are associated with the development of Web-based KBS, such as to keep up with rapid technological change, including servers, interface components, inference engines, and various protocols; and the potential delivery bottleneck caused by communication loads and limited infrastructure. Adams (2001) points out in line with Grove that there are numerous examples of expert systems on the Web, but many of these systems are small, noncritical systems.

Perhaps the most successful example is Web-based legal ES, reported by Bodine (2001), which enable law firms to collect hundreds of thousands of dollars in subscription fees from clients who use their advisory services based on the Web. PT Consulting Partners in the USA (2005) reported that they have helped its clients build a number of successful Web-based ES, which have brought significant benefits to the client company. Grupe (2002) reported a Web-based ES called Student Advisement, which is an online ES helping students select an academic major.

The question remains: are there really not many ES on the Web or is it the case that most Web-based ES are not being reported in academic literature? It is evident that the situation on Web-based ES in practice is not very clear and further formal investigation needs to be carried out to offer better insight into the current situation.

As well as the limited number of reports on applications of Web-based ES, there also appears to be a lack of a general methodology for the development of Web-based ES. While there is a significant promise in the idea of developing Web-

based ES, there are also some challenges that have not yet been fully explored.

Knowledge Engineering for Expert System Development

To better understand the challenges and benefits of Web-based ES, the traditional knowledge engineering process for ES development is revisited. According to Turban and Aronson (2001), Knowledge Engineering (KE) is a process unique to ES development. It deals with knowledge acquisition, validation, representation, inferencing, explanation, and maintenance.

In order to cover all issues related to Web-based system development and application, the KE process in this article is extended to include evaluation, implementation and maintenance, which is depicted in Figure 1. This extended KE process is used as a framework that informs the analysis and discussion of ES benefits and challenges.

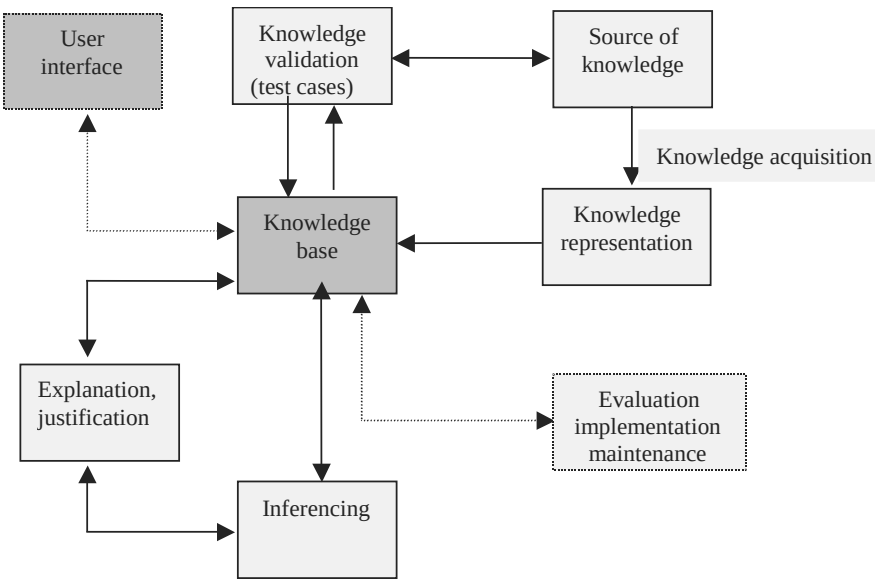
EXAMPLES OF WEB-BASED EXPERT SYSTEMS

Example 1: WITS

WITS is a Web-based Intelligent Training and Support system. It is developed for providing training and intelligent support for Small and Medium sized Enterprises (SMEs) on the use of Information and Communication Technologies (ICT). The research was inspired by the evidence from the literature that lack of adequate skills and knowledge is one of major barriers for SMEs in successfully adopting and running e-commerce and e-business. As a result of this deficiency, there is an emerging need for better education and decision support to SME managers who are eager to embrace the technology and afraid of being left behind.

WITS advisor has three subsystems, which are designed to facilitate SME managers' decision making process in e-commerce and e-business adoption. Compared with traditional ES, Web-based ES makes the evaluation and implementation of WITS much easier. There is no need to install the system in advance. It is easy to collect feedback from online forms. By using Web site analysis software, visitors can be easily traced and analyzed. By collecting visitors' information, it is possible to profile the users, and determine the usefulness of the system. The use of Web design software makes the user interface design easier. HTML-based user interfaces allow the incorporation of rich media elements. Hyperlinks in HTML provide an extra facility in enhancing ES explanation and help functions as users can access the relevant Web site easily. This is normally not possible with stand alone ES. Also, WWW has been proven to be a useful knowledge source for knowledge acquisition in constructing the WITS knowledge base. With a Web-based knowledge base, any knowledge updating and maintenance can be handled centrally, and no reinstallation needs to be carried out. Useful links are incorporated in the system which can help the user to understand and interpret the expert system's recommendations. E-mails, feedback forms and other Internet communication functions allow users to question and comment on the system, thus making an expert system more interactive and personal.

Figure 1. Extended process of knowledge engineering (Adapted from Turban and Aronson, 1998)



As with all ES, WITS also has certain limitations. It does not have an easy to use knowledge updating facility. Any attempt to update and modify domain knowledge has to be done by the system developers using the original programs. As e-commerce and e-business is a fast moving area, keeping the system's knowledge base updated is a serious challenge.

Example 2: Fish-Expert

Fish disease diagnosis is a rather complicated process in aquaculture production activities. Fish-Expert is a Web-based expert system for fish disease diagnosis in China. This Web-based expert system can mimic human fish disease expertise and diagnose a number of fish diseases with a user-friendly interface. A fish disease diagnosis expert system contains a large amount of fish disease data and images, which are used to conduct online disease diagnosis. More information about Fish-Expert can be found in Li, Duan and Fu (2002). The system has been tested and is in pilot use in certain regions of North China.

A number of points related to the benefits and challenges of Web-based ES emerged with the development and use of Fish-Expert, and these include:

- Online knowledge acquisition is welcomed by domain experts, but a knowledge engineer is still needed to check and transfer the knowledge into the knowledge base.
- The online user feedback form and online evaluation of ES seem to be effective and popular.
- Internet access speed is seen as a bottleneck for Web-based ES applications, especially in developing countries.
- The multimedia interface in Fish-Expert is effective in helping the user to query the system, but it slows down the access speed to it.
- ES are known for their inability to deal with exceptions or complex problems due to the inflexibility and limits of the knowledge base. The interactive nature of Internet communication provides an opportunity to reduce these limitations of ES with a Web-based telediagnostic system. In this case, users can talk to a human expert via telediagnostic equipment in either a synchronous or asynchronous manner.

Example 3: Online Legal Expert Systems

People may argue that the variety of skills and breadth of knowledge required of a lawyer mean that a computer could not feasibly be built to replace a lawyer (Booth, 2003), but one of the most successful online ES applications is online legal expert systems. Bodine (2001) reports that law firms find new paths to profit on the Web. "They are collecting hundreds of thousands of dollars in subscription fees from clients who use their question-and-answer advisory services based on the Web" (Bodine, 2001, p. 1). These online "expert systems" are working from local legal aid societies all the way up to international mega law firms. It is argued that rather than acting as a static Intranet repository of policies, the expert system responds to the user's input and generates tailored output, highlighting key issues for further consideration (Booth, 2003).

According to Bodine's (2001) report, Web-based legal expert systems are working like a question-and-answer session. Users go to a Web site, where the expert system prompts them to explain their question. The questions vary according to the answers and facts that the users give in response. The session concludes when the user reaches the Web page with the answer; a copy is typically e-mailed as a report to a lawyer in the firm.

Although it may be expensive to set up an online ES, the long term benefits and potential profit are also prominent. The advantages of using online legal expert systems include:

- **Internal:** The system operates on an Intranet to provide expertise and answer routine legal questions among a firm's employees (Bodine, 2001).
- **Private for clients:** The system operates on an extranet. Clients pay a fee and get a username and password to log on to the system (Bodine, 2001).
- **Public on a Web site:** The public can visit a Web site to get answers about their legal rights or complete an intake form (Bodine, 2001).
- **24/7 and worldwide access** to some legal advice and **documentary evidence** of compliance (Booth, 2003).

The profits are found in the private client expert systems. For example, a large international law firm in Australia operates its Advertising Copy Compliance Advisor to give legal guidance to brand managers at a client corporation. The lawyers were not always available immediately, so the law firm created the system on the Web that is running all day, every day. A London law firm runs an online service, which gives practical legal advice in many jurisdictions on setting up an e-commerce venture. The firm charges $3,000 per topic per jurisdiction per year for unlimited users. One big accounting firm operates an online business advisor. Subscribers pay $5,000 per year to log onto the system for answers to questions about tax, technology and business matters.

"The question is not whether computers can replace lawyers," said Kevin Mulcahy, Director of Jnana Technologies in New York. "The question is how will lawyers use the Web to optimize the way they sell their knowledge and expertise" (Bodine, 2001, p. 3). Challenges to the implementation of

Web-based legal expert systems identified by Booth (2003) include setting up cost, identifying suitable processes or areas of law, cultural and behavioral factors, relationships and business improvements.

BENEFITS AND CHALLENGES OF WEB-BASED EXPERT SYSTEMS

Challenges related to Web-based ES can be examined from different perspectives: technological, methodological, economic, and social. The aforementioned three examples have demonstrated some of the benefits and also the technological and methodological challenges of developing and using Web-based ES. The following paragraphs provide some discussion on the benefits and challenges using Turban and Aronson's knowledge engineering process presented in Figure 1.

Knowledge acquisition–The impact of the Internet on knowledge acquisition can be profound. Firstly, it provides another valuable knowledge source for knowledge acquisition. Secondly, it makes knowledge elicitation from the domain expert possible at a distance, thus eliminating the time and space barriers for experts to contribute to the knowledge base. Thirdly, as Basden (2000) argued, not only can knowledge be made available, but also the users can be closely involved in its selection and generation. For example, online communities can be a potential knowledge source, as one of the aims people have in joining such a community is to share knowledge in their domain of common interest. However, these benefits bring with them associated problems and challenges. These include dealing with information overload with effective knowledge mining techniques, locating and verifying online "experts," filtering knowledge collected via the Web, managing conflict when multiple online experts are involved, and security and reliability considerations.

Knowledge representation and inferencing-Traditional development methodology, tools and techniques which work effectively in a standalone environment may not work well in a Web environment. It appears that there is a need to investigate if the development methodology for a traditional expert system needs to be revised to suit the nature of the Web-based environment. Some Web-based ES have been developed following an ad hoc approach. There is a lack of systematic methodology or process suitable for Web-based ES development and implementation (Dokas, 2005). There is a lack of skilled knowledge engineers and an absence of standard procedures and development practices for online ES (Booth, 2003).

Knowledge validation–The knowledge validation, verification and testing process is likely to be one of the most affected processes in ES development and applications. Users can directly submit their test cases or provide feedback to system developers via the Internet. Alternatively, the knowledge base can be uploaded for validation and be accessed directly by users with their test cases. However, this user-centred approach needs a centrally managed validation process. Generic online debugging tools, such as rule base debugging in the cases discussed here, would be very welcome to developers.

Explanation and justification–One of the distinguishing features of an ES is its capability for explanation and justification. Compared with stand-alone ES, this function can be greatly enhanced with Internet technology. Explanation and justification can be improved with online hyperlinks to external resources, such as other relevant sites, and also with extensive use of graphics which do not have to be stored locally. It is also possible to receive explanation and justification from a human expert via Internet facilities such as video conferencing, chat room, message board or e-mail.

System evaluation, implementation and maintenance. As with the validation process, great benefits can be obtained by making an expert system available on the Web. From the users' point of view, systems can be easily accessed globally. Users will not be disadvantaged by their location. From the technical point of view, no installation is needed at the users' location. Any updating and maintenance can be carried out centrally at the server side. ES can provide users the means to submit their thoughts experiences and knowledge. Users' feedback on the overall system performance can be collected via online feedback forms and automatically saved in the database for easy analysis afterwards. Web-site analysis tools can be installed to trace the number of visitors and their visiting behaviour, which is not normally possible with traditional ES. The challenge is how to turn this valuable information directly into knowledge for system improvement and enhancement.

Web-based ES development tools-Traditional ES were developed for stand-alone computers and a number of development tools have long been available for their development. However, many traditional ES shells do not support the openness and interoperability required for deploying ES over a wide area network (Sedbrook, 1998). With the rapid development of the Internet, more Web-based ES are beginning to emerge. Unfortunately, the Web was originally conceived simply as a document distribution infrastructure (Riva, Bellazzi, & Montani, 1998) and any attempt to use it for distributing ES must cope with certain difficulties (Huntington, 2000; Riva et al., 1998).

Culture and behavioural challenges associated with the wide spread of online ES should also not be underestimated. The take up of Web-based ES requires a culture shift for staff to move from traditional face-to-face communication to an online inquires. This lack of human interaction will stir up the ongoing debate around the dehumanisation of society through increased use of machines, the role of ICT and its impact on interpersonal communication and relationships.

Moreover, ICT support staff needs to be well trained on how to deal with a large number of ES users if an online ES is to be widely deployed.

FUTURE TRENDS

It is envisaged that Web-based ES will become more sophisticated, complex, and capable (Grove, 2000) and fulfil their great promise in enhancing traditional ES. However, this relies on further research to address the challenges posed by developing and implementing Web-based ES, as discussed in this article. Web-based ES could bring new life to the somewhat "out of fashion" field of ES and generate a new era for expert system applications. A number of Web-based ES have been reported in the literature, but this number is expected to grow (Dokas, 2005). It is a technology that has yet to realise its full potential (Booth, 2003). Eventually, online ES will be an essential integral component of any online system by working along with online database and information processing systems and performing critical intelligent functions.

CONCLUSION

This article aims to provide an overview of Web-based ES and its associated benefits and challenges. The integration of Internet technology with the field of ES offers new ways of sharing and distributing knowledge and has changed the way that ES can be developed and distributed. The development and application of Web-based ES have benefits in many ways. The essence of an expert system is to mimic expertise and distribute expert knowledge into nonexperts' hands. This ultimate benefit can be enhanced greatly with the Internet technologies. However, the development of Web-based ES also brings a number of challenges to its development and applications.

KEY TERMS

Artificial Intelligence (AI): The study on human intelligence and on how to simulate human intelligence via machines, such as computers.

Decision Support Systems (DSS): An interactive computer-based information system to support decision-making activities by utilising databases and model bases.

Expert Systems (ES): A computer-based system that uses human knowledge captured in a computer to solve problems that ordinarily require human expertise.

Inference Engine: A computer program that tries to derive answers from a knowledge base.

Knowledge-Based Systems (KBS): A computer system that is programmed to imitate human problem-solving by means of artificial intelligence. Its core components are the knowledge base and the inference mechanisms. An expert system can be considered as one type of KBS.

Knowledge Engineering: An entire process of developing and maintaining artificial intelligent systems. The major activities in the process include knowledge acquisition, validation, representation, inferencing, explanation, and maintenance.

Web-Based Expert Systems: An expert system developed and distributed using Internet technologies.

Web-Based Personal Digital Library

Sheng-Uei Guan
National University of Singapore, Singapore

INTRODUCTION

Memex became an influential ideal and was hailed as the inspiration for hypertext and other new ways for information retrieval and organization. To deal with the explosion of scientific information, Bush's proposal for Memex focused on the problems of "locating relevant information in the published record and recording how that information was intellectually connected" (Bush, 1945). The expansion of information will be more and more serious as the Internet grows and most future computers are network-based. Thus, researchers have to consider the problems of "locating relevant published records in the published machines and recording how those records are intellectually connected".

This article proposes a mechanism that provides a new service paradigm for a network-based personal computer to browse, search, retrieve, organise, share, and publish information on the Web. Information in a machine should be made shareable with other machines, and other machines could be part of a machine's "memory extender".

As collections of relevant information either for public use or for personal use in a Web-based personal computer look like a digital library to its owner, this mechanism is called a Personal Digital Library (PDL). PDL will realise the selections of books, PDLs, and related persons through intellectual associations. As a server, PDL can store information simply and efficiently for easy retrieval and search, and provide intelligent supports for users (clients) to browse and find information. On the other hand, as a client, PDL can concurrently browse and automatically retrieve information from different PDLs (servers), and find a related person to communicate with during browsing. In addition, other PDLs can serve as memory extensions to overcome storage limitation in the local computer and avoid information duplication on the Web. PDL has potential uses in many areas such as personal use, education, commerce, finance, and entertainment. Personal users can employ any PDL with an Internet connection to manipulate their distributed information from anywhere around the world.

This article introduces PDL design and prototyping. The prototype implemented shows that the PDL concept is feasible under existing technologies. Although PDL is designed to manage personal information collections in a network-based personal computer, it will be fruitful if the design or ideas presented in this article can stimulate further development in the Digital Library research.

BACKGROUND

Memex

Bush described Memex as "a sort of mechanised private file and library" and as "a device in which an individual stores his books, records, and communications, and which is mechanised so that it may be consulted with exceeding speed and flexibility". Memex would store information on microfilms, which would be kept on a user's desk. Memex would have a scanner to enable the user to input new material, and it would also allow him to create hand-written marginal notes and comments.

In addition to the establishment of individual links, Bush also wanted Memex to support the building of trails through the material in the form of a set of links that would combine information of relevance for a specific topic. Bush emphasised (1967), that the mechanisation of "selection by association" would bring about a successful personal machine that would allow a human being to "think creatively and wisely, unencumbered by unworthy tasks," and that would allow people to "face an increasingly complex existence with hope".

The proposed PDL is a network-based Memex, which will be embedded in a personal computer. Information including bookmarks in a PDL can be made shareable with other PDLs. A Web-based "memory extender" is formed by linking PDLs together. Another essential feature of PDL is to allow people to locate and browse a certain or similar resource quickly and easily through intelligent associations.

Digital Library

Although PDL is not a particular digital library (DL) project, it has very similar goals as most DLs. In terms of service and resource provision in a DL, a number of service levels should be considered (Ormes & McClure, 1997): no services or resources provided, resource provision, self-assisted services, interactive services, video-on-demand services (Lin & Guan, 1996), and knowledge-based services.

PDL still needs to focus on the Internet, resource sharing and providing access to more information. However, there are some reasons that PDL can reach the top level. First, it is fully self-assisted because any PDL uses the same way to organise its collections, and has the same user interface,

therefore, users do not need to be assisted. Second, as to interactive service, a PDL user might discuss the use of a particular book or PDL with other users, authors, or PDL owners. Third, PDL has knowledge-based services. Examples include regularly checking changes of the favourite books or PDLs and then automatically informing the owner; providing access details and statistics of each book; and automatically forwarding a query to other PDLs. Due to such similarities with digital libraries, this proposed mechanism is called the Personal Digital Library.

In the following, we introduce two DL research projects (Cousins, 1996; Fox, 2003; Frew, Freeston, Freiras, Hill, Janee, Lovette, Nideffer, Smith, & Zheng, 2000; Guan, Yu, & Yang, 1998; Hassan & Paepcke, 1997; Kamiya, Röscheisen, & Winograd, 1996; Liu, Maly, Zubair, & Nelson, 2001; Paepcke, Cousins, Hector, Hassan, Ketchpel, Röscheisen, & Winograd, 1996; Wilensky, 1995, 1996) and some recent work on personalized bookmark services (Chen, Chen, & Sun, 2002; Kanawati & Malek, 2000, 2002; Li, Vu, Agrawal, Hara, & Takano, 1999; Yamada & Nagino, 1999).

The U.C. Berkeley Digital Library Project (Wilensky, 1995)

The goal of this project is to develop technologies that support "work-centred" digital library services, oriented to address the mission of work groups. Research areas include automated indexing, intelligent retrieval and search processes; database technology to support digital library applications; new approaches to document analysis; and data compression and communication tools for remote browsing.

PDL is a work-centred digital information system because the services provided by PDL also concentrate on the user needs. PDL improves the way to organise information for easy retrieval and search. PDL users can browse and even use different types of collections (books) not only from the local PDL but also from external PDLs. In addition, PDL provides users with a universal, customisable interface to perform information organising, browsing, retrieving, searching, and publishing.

The Stanford Digital Library Project (Stanford Group, 1995)

This project focuses on integration and interoperation (Hassan & Paepck, 1997; Paepcke et al., 1996). Its research areas include information sharing and communication models (Kamiya et al., 1996), client information interfaces (Cousins, 1996), and information finding services (Guan, Yu, & Yang, 1998).

The Integrated Digital Library will create a shared environment that links everything from personal information collections, to collections found today in conventional libraries, to large data collections shared by scientists. PDL is an integrated information system designed for network-based personal computers. Information including bookmarks in a PDL can be made shareable with other PDLs. Since bookmarks become shared resources, the information collections from other PDLs can be linked together with the local collections.

PowerBookmarks (Li et al., 1999)

PowerBookmarks (Li et al., 1999) provides personalized organization and management of bookmarks by combining the database with Web technologies. It can achieve advanced query, classification, and navigation functions and classifies the bookmarks of all users.

Personal Web Map (PWM) (Yamada & Nagino, 1999)

SeiJi Yamada and Norikatsu Nagino (1999) proposed a database named Personal Web Map (PWM) and developed the Anytime-Control algorithm to let users control their own Web map construction. PWM can help users to gather relevant information in the WWW to a small database for convenient retrieval. It will be interesting to see how their work can be extended for group work.

Semantic Web Personal Agents

Subhash, Kunjithapatham, Sheshagiri, Finin, Joshi, Peng, and Cost (2002) described the semantic Web as a vision to simplify and improve knowledge reuse on the Web. It uses software agents to collect, process, and exchange information. The PDL differs from the semantic Web personal agent in the sense that the PDL is a Memex-based approach as opposed to an agent based approach.

DESCRIPTION OF PERSONAL DIGITAL LIBRARY

Architecture

Figure 1 shows a typical PDL architecture and information flow. A PDL consists of the following components:

- **Library Explorer:** An integrated tool for information organising, browsing, retrieving, publishing, and representing. It is also a control panel to manipulate other mechanisms and application tools, and can give assistance to visitors during navigation through a series of views and facilities. Thus, the Library Explorer is a service centre in a PDL.

- **Reading Area:** Books (information collections) collected for reading (using) are placed in the Reading Area together with the corresponding reading tools (application packages). The Book Browser is the tool for reading hypermedia books and has traditional browser features.
- **Communication Area:** This area contains communication and collaboration tools such as e-mail, online chat and net conferencing. PDL provides a new type of one way collaboration with a Remote Bookshelf pane.
- **Interoperability and Protocol:** PDL can be embedded in either a personal computer or a mainframe account, which can be network-based and can run a Web server. PDL is therefore platform independent.
- **Local Storage:** A repository in which information collections are made shareable and organised in a topic-based hierarchy.

Features

PDL offers a number of important features in seven key areas: information organising, information browsing, information publishing, information searching, communication and collaboration, intelligent support, and security protection. Once these features are implemented, PDL will give Internet users a completely new browsing experience on the Web. We will detail some of them in the following sections.

Information Organising

In PDL, a book is a collection of relevant information for a specific purpose and are classified by subjects, and placed into related folders. As a folder can have sub-folders, PDL is structured as a hierarchical tree. Figure 2 shows how books and folders are hierarchically organised.

In Figure 2, it can be seen that bookmarks are located in a hierarchical tree. This is an important innovation, compared to traditional bookmark management. The hierarchical tree is used to organize shared bookmarks and facilitate searching.

- **Book:** A collection of relevant information (hypermedia, application software) and is a leaf node in the PDL hierarchical tree.
- **Folder:** A container of related books and sub-folders in a PDL. Since a folder might have children, those properties, except for *Title*, *Description*, *Type*, *Address* and *Access Times*, depend on the corresponding values of its children.
- **Bookmark:** PDLs, books, folders and bookmarks can be bookmarked. In this way, the information that summarises the item can be kept. Bookmarks can also work as a reference for an item to be used in the local PDL.

Figure 1. PDL architecture

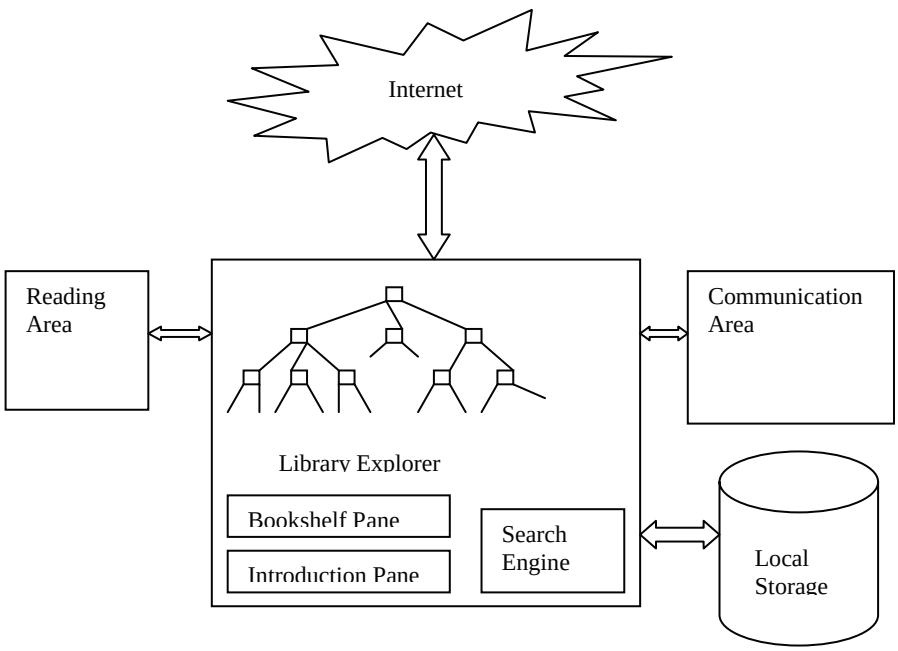

Figure 2. PDL hierarchical tree

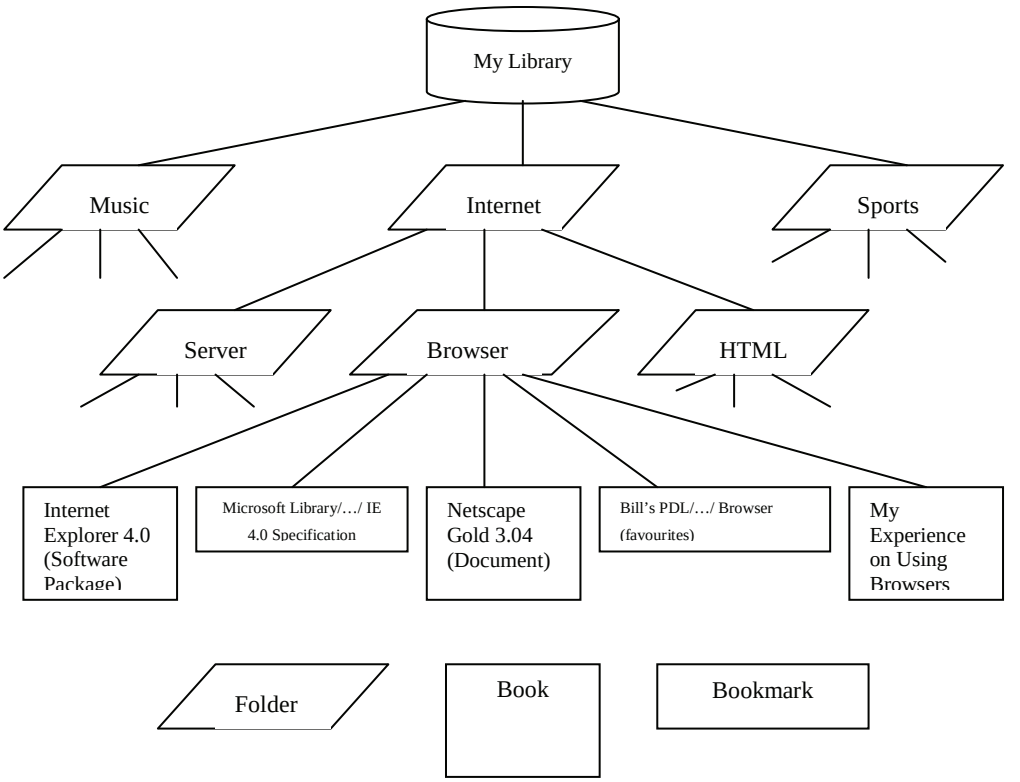

In fact, together with the shareable, hierarchical information structure, this data structure will also bring benefits to other areas, such as information searching and intelligent support.

Information Browsing

Figure 3 shows the GUI design of the Library Explorer and the view of Figure 2. The Library Explorer provides four display panes to show information in a PDL. The Library Pane shows the currently connected PDLs and the local PDL with a tree-view structure. The Main Pane shows folders, books, and bookmarks in the currently opened folder with a list-view structure. The books that are more frequently accessed are displayed in the Introduction Pane together with the description of a selected item. The Bookshelf Pane contains the books selected from different PDLs (including the local PDL) by the PDL owner. In the Main Pane, a flag or colour is used to identify those top accessed items in the opened folder. This pane is also designed for showing a list of search results, a guest list of a selected item, and the content files of a selected book.

PDL realises true offline browsing. The PDL owner can decide whether to build a mirrored PDL for the connected PDL in the local storage during navigation or to create a cache folder for information retrieved as is done in current browsers. PDL does not assign a fixed place for cache contents. When a folder in the PDL is first opened, its corresponding cache folder is created using the same name under the "parent" cache folder in the local storage. The mirrored PDL is removed from the local storage after disconnection. This is implemented by deleting the "root" folder.

Information Searching

PDL offers title and keyword searches as in a traditional Web search engine, but both the *Title* and the *Description* fields of each related item will be searched in a keyword search process with more matched results. Figure 4 shows this unique interface linking the PDL search mechanism. The first three boxes decide what type of item is to be found. The others tell the search engine how to search.

Figure 5 illustrates how PDL handles a query either from the external PDL or the local PDL.

Intelligent Support

PDL offers a series of intelligent support during navigation. PDL provides an area (i.e., Introduction Pane) to inform

Figure 3. GUI design of the Library Explorer

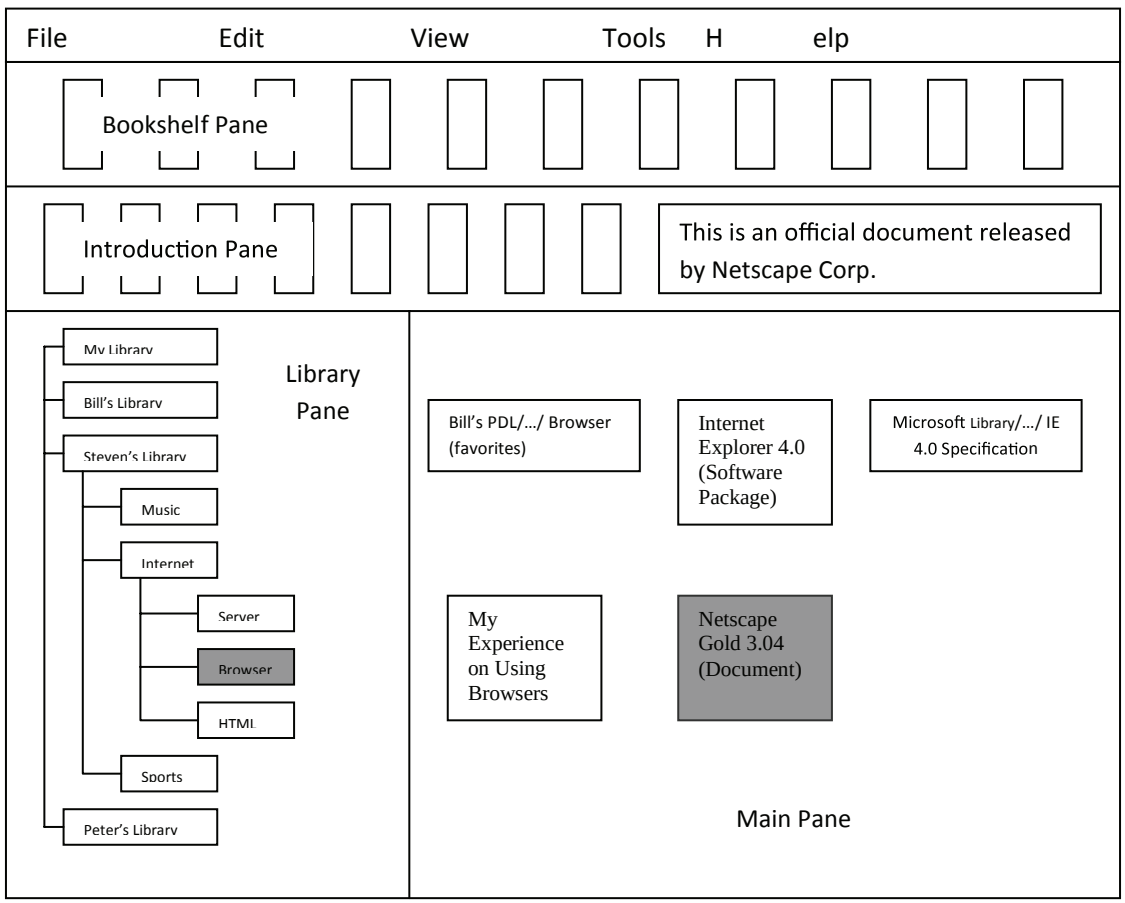

Figure 4. PDL search engine GUI

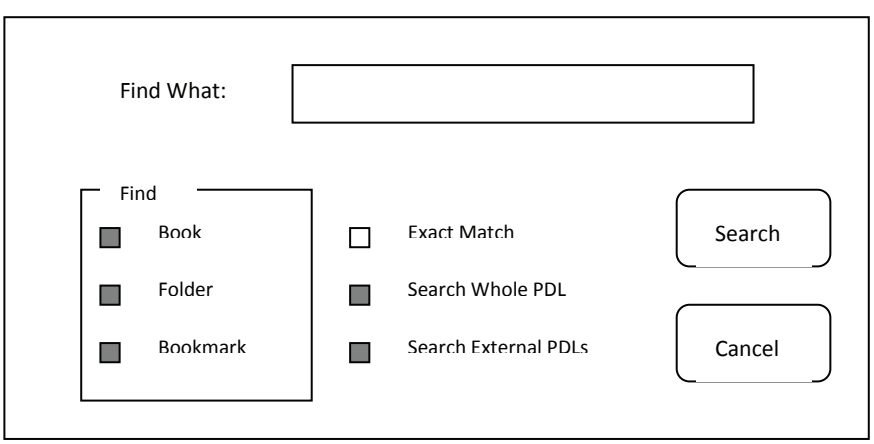

Figure 5. PDL processing query

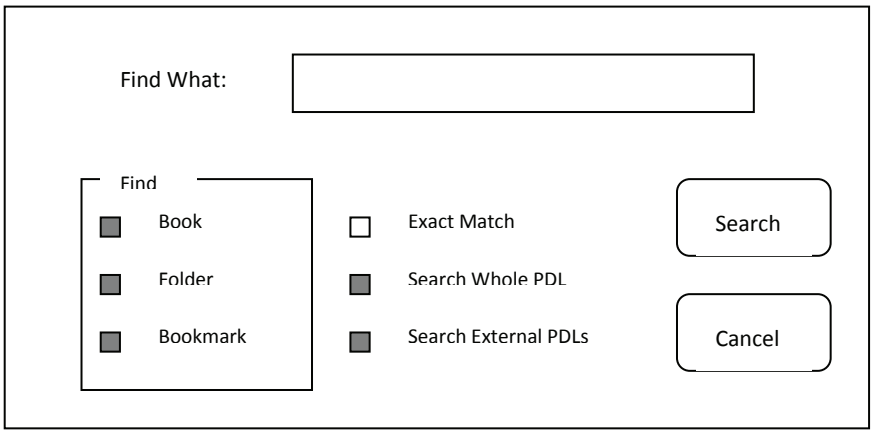

visitors which books are more frequently visited by other people.

PDL is able to inform the owner automatically and accurately when those bookmarked items have been changed. In addition, PDL provides two options for keeping bookmarks updated and consistent: it background checks regularly and checks when there is little or no workload.

PDL also provides efficient subscription for bookmarked hypermedia books. Figure 6 illustrates the process to subscribe to a book regularly. PDL starts this subscription process regularly in the background for each bookmark marked by the PDL owner and places the subscribed books in a special folder. The PDL owner can go to this folder and read those books when desired.

Implementation

A runtime PDL prototype has been developed under Windows 95 using Microsoft Visual Basic 5.0 (Microsoft Corporation, 1998). To demonstrate that PDL can be available across platforms, a PDL is set up manually in Sun OS (Release 4.1.1) Unix machine running a Web server. By using this PDL as a server role, the communication between two PDLs can be tested. Any Web server can be used at this stage. The current selection is Apache 1.3.

FUTURE TRENDS

Research on PDL is still in a primary stage. Several further research and implementation issues include remote application use, remote management, the development of a search protocol, security, error recovery, and a 3D user interface.

Figure 6. Book subscription process

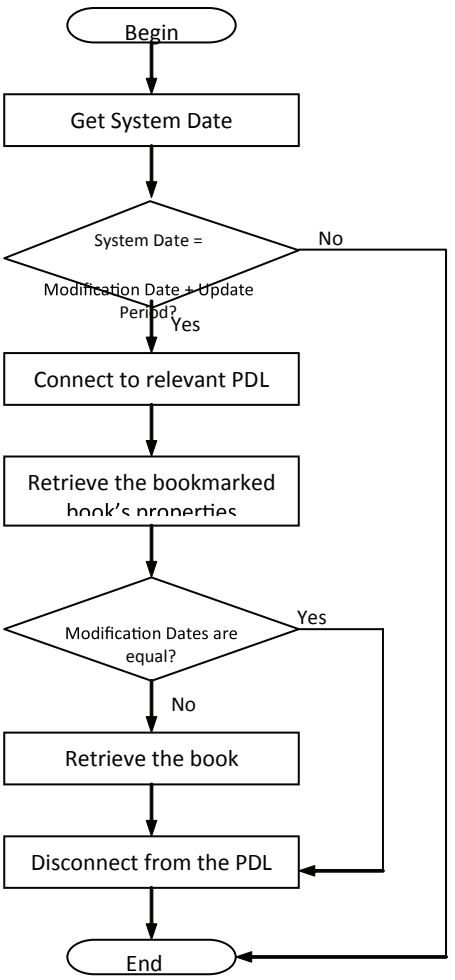

Figure 7. A Library Explorer for navigation

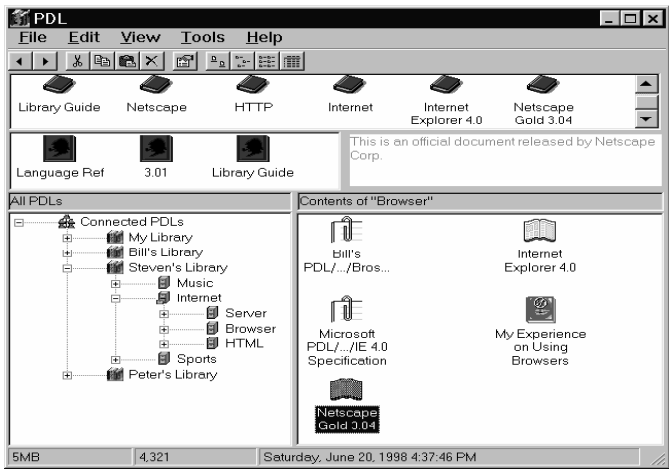

CONCLUSION

As a mechanism for providing a new service paradigm on the Web, the Personal Digital Library goes further to address the "trails" problems by hierarchically organising information and also making it shareable. By linking PDLs together, a Web-based "memory extender" is formed.

Although the PDL architecture still inherits hierarchical information organisation from a traditional file system, innovations are made to facilitate information sharing. One important feature is to organise and classify bookmarks along with other shareable information rather than place them into a separate folder or a file. In addition, two facilities are designed for recording "trails". These are the Library Pane, which shows the currently connected PDLs and the current navigating "trails" in each PDL, and the Bookshelf Pane, which shows a book list for the reading "trail".

On the other hand, PDL owners can quickly do a search not only in the local PDL but also in external PDLs. As the same search engine is embedded in every PDL, the search interface, the query, and the result format will be uniform. In addition, a query can be forwarded to other PDLs by the searched PDL if no results are available.

In conclusion, PDL is a Memex-like entity enhanced with the ability to connect to other PDLs and interact with their users. A fully implemented PDL can fulfil Bush's vision in more aspects than Memex. Therefore, this Memex-like entity will become a successful personal machine that allows a human being to "think creatively and wisely, unencumbered by unworthy tasks," and that allows people to "face an increasingly complex existence with hope" on the Internet.

KEY TERMS

Database Technology: Organization of a collection of data in digital format.

Digital Library: Like a traditional library, a collection of books and reference materials.

Distributed Information: Information distributed across and cross accessible from several machines.

Hypertext: User interface paradigm allowing display of documents which branch or perform on request.

Information Retrieval (IR): The art and science of searching for information in documents for text, sound, images, or data.

Integrated Digital Library: Enterprise resource planning for a digital library system.

Internet: The Internet, or simply the Net, is the publicly available worldwide system of interconnected computer networks that transmit data by packet switching using a standardized Internet Protocol (IP) and many other protocols.

Knowledge-Based Systems: Systems based on the methods and techniques of *artificial intelligence*. Their core components are the knowledge base and the inference mechanisms.

Memex: The "Memex" was a theoretical analog computer described by the scientist and engineer Vannevar Bush. It is proposed as a device linked to a library, allowing automatic cross referencing.

Personal Digital Library: A personal database of documents where a significant portion of resources are in machine readable format.

Personalized Bookmark: Extended bookmarks for the PDL with scope for sharing and distribution.

Search Engine: A program designed to help find information stored on a computer system such as the World Wide Web or a personal computer.

World Wide Web: The World Wide Web ("WWW", or simply "Web") is an information space in which the items of interest, referred to as resources, are identified by global identifiers called Uniform Resource Identifiers (URI).

A Web-Enabled Course Partnership

Ned Kock
Texas A&M International University, USA

Gangshu Cai
Texas A&M International University, USA

INTRODUCTION

Notwithstanding fluctuations in enrollment, virtually every university in the U.S. and overseas has seen a significant increase in demand for information technology (IT) courses and programs in the last 15 years (Greenspan, 1999; Monaghan, 1998; Ross, 1998). At the source of this demand is an ever-growing need for qualified IT professionals in most companies, whether the companies are in technology industries or not (Alexander, 1999; Andel, 1999; Kock, 2005; Lee, 2006; Trunk, 2000; Wilde, 1999).

Given the previous practical motivation, one would expect university IT courses to be closely aligned with the industry's basic needs. Nevertheless, the gap between industry and academia in the field of IT (King, 1998; Kock, 2006; Kock, Auspitz, & King, 2002; Richter, 1999) seems to be widening rather than contracting, which is evidenced by some symptoms: (a) students complaining about their lack of "real world" IT experience when they graduate; (b) industry representatives pointing out that universities do not prepare students for the challenges and complexity of corporate IT management; and (c) faculty teaching topics that are related to their research yet far removed from the daily reality faced by IT professionals.

One way of addressing the problematic situation just mentioned is to establish industry-university partnerships. Such partnerships, particularly those involving research universities, have been commonplace for quite some time, and are arguably on the rise (Burnham, 1997; Wheaton, 1998). Irrespective of economic sector or industry, the vast majority of industry-university partnerships are of the *research partnership* type, which predominantly involves applied firm-specific research. In this type of partnership, funding from the industry partner is received in exchange for "intellectual horsepower" in the form of research services and technology transfer (Hollingsworth, 1998; Meyer-Krahmer, 1998).

A much less common type of industry-university partnership is what we refer here to as a *course partnership*, which gravitates around a regular university course (or set of courses) rather than a research project or program. In these types of partnerships, the industry partner agrees to sponsor one or more courses in which the students are expected to apply concepts and theory learned in class to the solution of some of the industry partner's key problems. Students benefit from the direct contact with the industry they are likely to join after they graduate as well as professional relationships they are able to establish during the course.

This article discusses a *course partnership* involving a large engineering and professional services company, and a public university, both headquartered in Philadelphia,. An action research study of the course partnership is used as a basis.

Like typical action research studies (Checkland, 1991; Lau, 1997; Peters & Robinson, 1984; Winter, 1989; Wood-Harper, 1985), ours aimed at providing a service to the research clients (Jonsonn, 1991; Rapoport, 1970; Sommer, 1994), while at the same time performing an exploratory investigation of the effect of Web-based collaboration technologies on course partnerships. The research clients in question were the students and the industry partner. Also, in line with a subclass of action research, namely participatory action research (Greenwood, Whyte, & Harkavy, 1993; Elden & Chisholm, 1993; McTaggart, 1991; Whyte, 1991), one of the research clients, the industry partner, participated actively in the compilation and analysis of the exploratory research data, as well as in the interpretation of the findings.

BACKGROUND

Our study was centered on a different and arguably promising approach to implementing course partnerships that was recently proposed to address the problems outlined previously (Kock, Auspitz, & King, 2000, 2002, 2003). The approach involves conducting certain courses, particularly senior undergraduate and graduate courses, in close partnership with companies. Such courses are designed so that the concepts and theory discussed in class are applied in team course projects geared at solving immediate problems at the company partner. Other fundamental characteristics of these course partnerships are:

- **All Team Projects are Conducted in One Single Organization:** Letting student teams identify organizations they would want to work with, based on criteria defined by the instructor, usually leads to dif-

ferent student teams conducting projects in different organizations, and thus to significant discrepancies in project complexity, project scope, and organizational support across different student teams. These problems can have a negative impact on learning and are considerably reduced when all team projects are conducted in one single organization.

- **Potential Projects are Identified in Advance:** The identification of a potential project by student teams can take up to five weeks of a 14-week course. One may argue that this is acceptable, as long as concepts and theory are covered in the classroom during those initial five weeks. However, in addition to identifying a project, a student team also needs to learn about the organizational culture, key people, and specific business processes they will be dealing with. This can easily take up another five weeks, leaving little time for other key project activities (e.g., business process redesign and IT implementation). The solution to this problem is to identify potential projects in advance, prior to the formal start of the course, and distribute them among student teams in the first week of the course.
- **Top Management Personally Sponsors the Course Partnership:** Often, when students are asked to come up with their own company-sponsored course projects, the individuals who sponsor the projects are not senior managers. As a result, a project sponsor may be reluctant or lack the authority to approve organizational changes or purchases of hardware and software necessary for a project to be effectively completed. These difficulties are mitigated when top management directly sponsors team projects.

It is important to note that course partnerships with these characteristics require a considerable amount of extra time and effort from the students and instructor, well beyond what is usually expected in traditional courses. In addition to applying the concepts and theory learned in class, students would also have to learn "on-the-fly" how to effectively deal with issues that are found in real-world projects (e.g., organizational culture and politics). The instructor, on the other hand, has to also take on project management, industry-university liaison, and inter-organizational team facilitation responsibilities, in addition to traditional course delivery and student mentoring duties.

IMPLEMENTING A COURSE PARTNERSHIP: TEMPLE UNIVERSITY AND DAY & ZIMMERMANN, INC.

The course partnership idea discussed previously has been implemented through a collaboration between Temple University, a large public university located approximately two miles from downtown Philadelphia, and Day & Zimmermann, Inc., a U.S. $1.5 billion engineering and professional services company headquartered in downtown Philadelphia. The course was a pilot version of CIS650—Process Design and Information Technology, a newly developed course in Temple's Computer and Information Science Department dealing with process analysis and redesign issues.

The course instructor (the author of this article) initiated the course partnership by sending a letter to one of the senior executives at Day & Zimmermann. In the letter, the course instructor inquired if the company would be interested in partnering with Temple University, providing details about the partnership. The partnership was approved after an initial meeting involving the course instructor and senior managers at the company.

The course project required students to analyze and redesign five of Day & Zimmermann's business processes using the concepts, theory, and techniques taught in class. The course partnership and related project had direct support from Day & Zimmermann's chief information officer (CIO) from the outset. A senior manager at Day & Zimmermann, who reported directly to the CIO, was assigned the responsibility of managing the project together with the course instructor. The project involved, directly and indirectly, over 30 Day & Zimmermann employees and 26 Temple students.

The students were split into five process redesign teams, which periodically met with key Day & Zimmermann employees at the company's headquarters in downtown Philadelphia. Each team analyzed and redesigned one process, generated three reports, and delivered an oral presentation to Day & Zimmermann management at the end of the course. The first report generated by each team contained a detailed description of the process targeted; the second a detailed description of the redesigned process and the rationale behind the redesign decisions; and the third a detailed analysis of IT solutions to enable the new (redesigned) process.

WEB SITE REMOVES OBSTACLES TO PARTICIPATION

Before the course partnership was started, two main obstacles had to be dealt with. First, Day & Zimmermann employees were expected to actively participate in the process redesign efforts. In order to do so, they had to understand the concepts and theory used by the students. Yet, most of the Day & Zimmermann employees likely to be involved in this project could not come to Temple to audit the course together with the students. Also, given that Temple students and Day & Zimmermann employees were not co-located, a great deal of their interaction would have to occur by means other than face-to-face meetings. The solution to overcome these two obstacles was the development of a password-protected

Table 1. Course evaluation scores

Question/statement	Score
The objectives and requirements of the course were made clear.	3.82
The instructor clearly communicated the subject.	3.88
The instructor was open to questions and comments.	3.82
The instructor was accessible outside the classroom.	3.70
The instructor was impartial in evaluating my performance.	3.47
The instructor expected academic excellence from students.	3.47
Overall, the instructor did an excellent job teaching.	3.82
Overall, I have learned a great deal from this course.	3.41
Overall, this is one of the best courses I have had at Temple.	3.53

Note: Score = average score for the class regarding the question; Range: 0-4)

Web site, which allowed Day & Zimmermann employees to access all the course material online. The Web site also supported interaction between them and Temple students through shared document areas, multimedia components, and discussion boards.

WAS THE COURSE PARTNERSHIP SUCCESSFUL?

The partnership was considered a success by Day & Zimmermann management and employees, as well as by Temple students. Managers emphasized the anytime/anyplace collaboration between Day & Zimmermann employees and Temple students enabled by the Web site as one of the key elements that made the course partnership a very successful collaborative effort.

Temple students emphasized the real-world experience as one of the most positive aspects of the course. Following is a representative comment by a student extracted from one of the anonymous course evaluation forms completed at the end of the course: "The learning experience was very rich. The group project gave us hands on experience in applying the redesign techniques we learned in the course. It was a great experience to work with upper level IT management!"

Table 1 shows the average scores for several question/statements asked from the students in connection with the course. The question/statements were part of a standard course and faculty evaluation, and were answered anonymously.

Several students pointed out that the course required considerably more time and effort from them than most traditional university courses they had taken before. In spite of that, their anonymous evaluations of the course were very positive, as it can be seen in Table 1. The average answer to the question/statement "Overall, this is one of the best courses I have had at Temple" was 3.53, on a 0-to-4 scale. The average answer to the question/statement "Overall, I have learned a great deal from this course" was 3.41, also on a 0-to-4 scale.

An added benefit for Day & Zimmermann was the ability to identify young talent based on observation of business-relevant action (as opposed to the traditional analysis of résumés). Day & Zimmermann was able to observe a group of 26 students in action over a two-month period and identify several students whom they would like to consider hiring. This is not as easy to accomplish with other approaches for identifying new graduates for hiring, of which internships are perhaps most popular. There are two key reasons for this. First, the number of interns that could be hired for a two-month period by an organization would typically be considerably smaller, thus significantly reducing the number of students that Day & Zimmermann managers would be able to observe in action during that period of time. Second, the tasks that the interns would be assigned to would not usually be nearly as complex and strategically relevant as those carried out in this course would.

CONCLUSION AND LESSONS FOR FUTURE PARTNERSHIPS

The general perception at the end of the course partnership was that it had been an exciting and rewarding experience for all those involved. Students saw the course as a valuable experience that provided them with a unique view of IT management and which complemented the concepts, theory, and techniques learned in the course and throughout their university program. Day & Zimmermann managers perceived the input provided by the students as very valuable and likely to lead to concrete business process improvements.

Also, a few lessons have been learned along the way that can be useful for universities and companies planning to implement similar course partnerships in the future. These lessons are summarized next.

- **The Course Partnership Should have Two Main Co-pProject Managers, One From Academia and One fromIndustry:** As with most inter-organizational initiatives, the scope of management authority does not usually extend beyond organizational boundaries. Students will respond more quickly to requests by the instructor than to requests by a manager of the partner organization. Similarly, employees of the partner organization will respond more quickly to a request by someone who has formal authority within the organization than to a request by the instructor. Therefore, the instructor should share the responsibility of managing the project with a member of the partner organization who has enough formal authority to oversee all the team projects.
- **The Course Partnership Should Include at Least One Purely Social Activity:** Social activities allow for important information exchanges that would not normally occur in formal meetings. For example, prior to the final oral presentation by student teams at Day & Zimmermann, a pizza party (paid for by the company) was held in downtown Philadelphia. After the party, several people remarked that the personal knowledge they learned from informal conversations during the party was invaluable to them. The party was also seen as a "thank you" gesture by the partner organization to the students. Not only did this boost morale, but it also helped the students relax for the presentation the next day, as they got to know the people they would be presenting to at a more personal level.
- **The Business Problems Addressed through the Course Partnership Should be "Real" and of High Relevance to the Partner Organization:** Because students are involved, not professional consultants, the partner organization may be tempted to create "toy" problems to be solved through the course partnership, rather than address real and relevant business problems. The motivation for this may be the perceived risks linked to not accomplishing the goals of the project (e.g., wasted time, internal conflicts, and reluctance to engage in future organizational change efforts). The problem with this approach is that it is likely to relieve the students from any real responsibility and, at the same time, decrease the motivation for employees to get involved. A better alternative to reduce risk is to involve experienced consultants at critical points in the course partnership (the costs are relatively low since few consultant-hours are likely to be used).
- **Partner Organization Employees Should be Asked to Report on and Make an Oral Presentation of their Projects, too:** Course partnerships such as the one described here are, as the name implies, collaborative endeavors in which members of the two organizations involved should contribute evenly. Therefore, key members of the partner organization should also be asked to make presentations about their projects. This is particularly important because, in some cases, despite full dedication from the students, a project may fail to accomplish its initial goals. And, a closer examination may indicate that the failure was not the students' fault, but that it was caused by lack of interest or commitment from the part of one or more employees. Employee reporting and presentations are useful in assessing whether this is the case, which in turn is important for appropriately grading the students' coursework. Moreover, the requirement to report and present their projects communicates to the partner organization employees that they are equally responsible for the outcomes of the project, which is likely to increase their level of commitment and dedication to the project.

The course partnership discussed in this article went well beyond the idea of having students conduct their course projects in real organizations, which is an approach adopted by many project-based courses around the world. It seems that the close cooperation between Temple University and Day & Zimmermann that characterized the course partnership presented here was the key reason for its success. This type of cooperation requires extra time and effort from everyone involved—students, instructor, company management, and employees. Yet, the positive (tangible and intangible) outcomes of the partnership seem to easily outweigh its costs.

KEY TERMS

Action Research: Type of research approach in which the researcher attempts to improve the research client, which can be an organization, while at the same time generating relevant academic knowledge.

Co-Partnership Managers: The course instructor, on the university side, and a senior manager of the client organization, who jointly manage a course partnership project.

Course Partnership: Course-based industry-university partnerships, where a course is designed so that the concepts and theory discussed in class are applied in team course projects geared at solving immediate problems at the company partner.

Industry-University Gap: Disconnect between the knowledge and skill needs of industry practitioners and the knowledge and skills imparted on students by universities.

Process: Set of interrelated activities through which an organization transforms inputs into value-added outputs. Inputs and outputs can be tangible (e.g., materials, parts) or intangible (e.g., services, information) items.

Process Redesign: Approach to organizational improvement through transformation of business processes. The term refers to business process change approaches emphasizing gradual change (e.g., total quality management) or radical change (e.g., business process reengineering).

Research Partnership: Industry-university partnership involving collaboration in applied firm-specific research. In this type of partnership, funding from the industry partner is received in exchange for "intellectual horsepower" in the form of research services and technology transfer.

Web-Based Course Partnership: A course partnership in which a Web site is developed to serve as a central communication hub and document repository for the partnership.

INTRODUCTION

The design of a Web-geographical information system, Web-GIS (Worboys & Duckham, 2004; Zhong Ren & Ming Hsiang, 2003), strongly requires methodological and operational tools for dealing with information distributed in multiple, autonomous and heterogeneous data sources, and a uniform data publishing methodology and policy over Internet Web sites. In this article we describe the experience of the Politecnico di Milano group in the activities of requirement analysis and conceptual design of the DEAFIN Web-GIS (Schreiber et al., 2003), whose objective is to provide a common environment for comparison of information about available vacant industrial sites coming from different regional data sources. Heterogeneity and Web availability requirements have been taken into account in the system architecture design; the system is thus conceived as a federated Web-based information system, apt to manage and provide access to all the regional relevant information in an integrated and complete fashion. Furthermore, since the data available by a given region partner can be both spatial and alphanumeric, a Web-GIS is defined for each regional component system.

BACKGROUND

The DEAFIN (development agencies and their impact on foreign direct investments) project has been launched with the purpose of allowing companies and investors to get a comprehensive information framework about areas located in European regions suited for potential investments. The aim is to make the regional data about possible investment areas homogenous and comparable, and internationally accessible. Potential investors need both a survey and a detailed view of vacant sites in different locations in order to compare different opportunities and decide their convenience. Quite naturally, such requirements call for a federated information system (FIS), which grants local sites a great deal of autonomy while enabling interoperation by means of a global integrated conceptual schema, that is, the federated data schema. Furthermore, owing to the capillarity of the end-user locations and to the need of a simple and widely known interface, Web-based access is mandatory. To define the functional specification of the system, the following activities have been carried out:

- *analysis of the requirements* of a distributed Web-based information system relying on a common conceptual database schema of the regional information that was initially (almost completely) available on paper support;
- *conceptual design* of the DEAFIN FIS, centered on the conceptual design of the federated conceptual database schema. The regional databases must be built according to the federated schema and then made accessible via the Web. The availability of data on the Web allows potential investors to navigate in the DEAFIN site according to various and customizable

criteria, based on a benchmarking model developed within the project.

INFORMATION REQUIREMENTS

Three regional administrations from Germany, Italy, and Sweden were involved. The project started with a data-gathering phase, aimed at collecting requirements about data and processes managed at the partner Public Administrations. A questionnaire-based tool was circulated to collect common information to be stored in the FIS.

The basis of the questionnaire is a set of the data categories managed in Public Administration information systems. The relevant data categories concern land use plans (master and regional or specific), territorial services, industrial vacant sites, mobility data, statistical and social-economic data, base cartography data, and information on cadastral units data. Information on vacant industrial sites is the main focus of the investigation. For each category, the questionnaire collected the data characteristics reported in Table 1.

In general, the data collected at the sites show uniformity with respect to the attention paid to cartographic availability, regulations and laws about reuse of vacant areas, and centralization of resources. In particular, the need exists at each regional site to introduce tools able to treat heterogeneous data, since these data more and more intensively are to come from various data sources, to be mapped into the federated schema. Also, the degree of automation is similar, since cartographic systems and basic data management tools are available at the three partners' sites.

Several ongoing local projects concern the digital acquisition of land use plans, the automation of document management, and the development of various thematic databases and Web sites. What is required is a unified common schema for the regional databases. Moreover, the need of a uniform data publishing methodology and policy over Internet Web sites emerges clearly from the participants and involves almost all data categories.

Table 1. Summary of data characteristics collected in the data-gathering phase

DATA CHARACTERISTICS
Availability of the data category
Location of the data source
Support technology and name of products/tools
Data format
Data owner
User roles involved in data access
Restrictions applying to data access
Performances
Maintenance policies
Availability on the Web

USAGE MODES

The data-gathering phase has also detailed a set of user profiles, which specify how different access demands can be supported by the system towards a variety of user groups. The design and implementation of profiles have obviously a deep impact on the usability of the system. Hence, a careful analysis of user typologies and profiles has been performed during the specification phase, while an enrichment of profiles and access modes has been planned in a post-implementation follow-up. The purpose is to have the system start with a set of pre-configured access typologies, and then tune the access modes and user profiles against the most typical uses observed for a fixed period on the DEAFIN pilot implementation. The first broad difference is between the profile of public administrations and that of private users, due to different data needs. Moreover, two basic interaction modes must be provided: browsing (using thematic areas and other refined search parameters) and querying (using simple and user-friendly interfaces). The system can be regarded as: a passive tool, when responding to user questions; an active tool, when used as a decision support system or when used as a standard application, allowing new European partners to join the DEAFIN consortium.

As a passive tool, the contents of the federated database can show the advantages and disadvantages of an area: the information provided can be related to the specific search needs of a specific user. These searches are different according to user types, but apart from the function of locating (or re-locating) business activities, the motivation probably exists to retrieve general information about a region.

SYSTEM ARCHITECTURE

In the literature, several approaches and tools for handling heterogeneous data sources have been developed, and standards for distributed information systems have been defined (Mylopoulos & Papazoglou, 1997; Wiederhold, 1992). For these systems, the use of multiple layer, mediator-based architectures, and of a common data model have been

employed (Garcia Molina et al., 1997). Wrapper/extractor and mediator tools (see Key Terms section) are proposed to obtain a uniform data representation (abstracting from the formats of the original data sources) and to facilitate federated access. Following this direction, in order to handle heterogeneity at each regional site, an architecture has been defined where extractors translate data coming from local heterogeneous data sources to a common reference format defined at the mediator level (Schreiber et al., 2003).

The aspect of data publishing over Internet Web sites has emerged clearly as a need from the partner regions. The system is thus conceived as a Web-based federated information system, apt to manage and provide access to all the regional relevant information in an integrated and complete fashion, thus satisfying the Web availability need.

Generally, data made available by a given partner region can be both spatial and alphanumeric, requiring each regional component system to be a GIS. Each regional site is in charge of data publishing and certification over the system according to the common federated schema. Each regional Web site contains a specific interface and stores regional data in a database by means of a Web-GIS technology, and operates as a central server that contains the common interface and some aggregate data. The global system is composed of Web-interconnected sites: the central Web site is the reference site for aggregate data and for requirements about new regional sites to be added in the federation or new applications to be developed in the component systems.

FEDERATED DATABASE CONCEPTUAL DESIGN

The federated database conceptual schema provides an integrated high-level representation of all data to be handled by the FIS. In order to achieve the highest readability and the widest possible diffusion, a common set of terms is needed. We adopted the dictionary of terms as defined by the EuroDicAutom (EuroDicAutom, 2001) of the EU; the international system of measurements, and commonly agreed upon data categories were adopted.

The database conceptual design produced a set of conceptual views, represented in terms of ER diagrams (see Key Terms section), that provide schematic requirement representations, each related to a specific information set. The following views were defined: vacant site description view, land use plan view, administration view, eco/reclamation view, transportation view, service view, document view, procedure and task view; the global conceptual data schema is a merge of these different views.

The design identified 36 entities (including entities with spatial representation that describes their shape, extension and location on the earth surface, marked as georeferenced), with a total number of about 200 attributes. The XML (eXtensible Markup Language) language was chosen for logical specification, providing a common reference format to facilitate data customization, translation and mediation.

The FIS should enable the user to dynamically query the databases and in particular the geographical data they contain; these requirements, as we discussed previously, are fulfilled by a Web-GIS system able to perform advanced operations guided by the client side.

THE WEB-GIS

The interface of the central Web site allows the users to access data in two search modes: direct search, which leads directly to the vacant area of interest, including also information about the surroundings; and navigation, which presents a list of vacant sites to be filtered progressively, according to various criteria. Indeed, a static benchmarking table presents a list of site features, along with the corresponding values for each partner: from this table the user can choose a partner and obtain pages that describe the partner's area, highlighting its most attractive features. Some aggregate data about the vacant sites of each region are also displayed for subsequent browsing operations, where the user can execute queries in order to filter the vacant sites on the basis of preferences or specific criteria, such as: the type of usage, area size, costs, surrounding services, and accessibility. Finally, links to the regional Web sites are provided.

The Web interfaces of regional sites support more specific functions: the exploration of the partner area by choosing a specific theme such as land planning, business and market activities, mobility system, services, demographic and macroeconomic data and development strategies; the access to business information such as contact offices and particular business opportunities that are currently available for some vacant sites of the area; the access to aggregated data about vacant sites of the area and to a benchmarking table where the user can apply some selection conditions based on the available comparison parameters; the search

of vacant sites based on forms that guide the user in the specification of the query, including geography related conditions (SQL with geographic extensions) like "search the vacant sites with a railway station within a radius of <parameter value> km"; the selection of specific features of the chosen vacant site, for example, buildings, eco quality, themes presenting the characteristics technological networks, land planning, mobility system, territorial services, procedures and tasks and documents.

FUTURE TRENDS

Web-GIS applications are becoming more and more important to a growing number of activities. Geography, geology, environmental studies, business marketing, and other disciplines have gained benefits from GIS tools and methods. Continual improvements in GIS hardware and software will lead to a much wider application of this technology throughout government, business, and industry. In particular, integrated geodata services based on data format standardization will increasingly facilitate the exchange of information among users of different systems by allowing data sharing and improving cooperation and communication among the organizations involved in environmental protection, planning, and resource management.

CONCLUSION

The development of the DEAFIN Federated Information System started from an analysis of the requirements and of the locally available information, performed through a data-gathering phase. The federated database was modeled in the form of a set of conceptual views, both as ER diagrams and XML specifications. The architecture of the overall system is in the form of a federated Web-GIS: at the main Web site a high-level view over the entire federated system is allowed, while local specializations are allowed at the level of every regional Web site adhering to the recommendations for the entire database.

The proposed system offers a marketing and information platform in a European context based on advanced Web functions, integrating geographic information systems (GIS), decision support tools, and database federation features. Analogous projects in the European area have been developed, mainly in the field of tourism (Pühretmair & Wöß, 2001), where integration of data sources and access to GIS in a graphical context are needed.

Further details about the project can be found in Schreiber et al. (2003).

KEY TERMS

Conceptual Schema of a Database: A semi-formal high-level description of the database, independent of its implementation.

ER (Entity-Relationship) Diagrams: The most widely used model to express the database conceptual schema.

eXtensible Markup Language (XML): Markup language proposed by the World Wide Web Consortium [W3C] for data and documents interchange.

Federated Information System (FIS): An information system is named federated when it supports interoperation among several autonomous and possibly heterogeneous information systems, by means of a shared global data schema.

Geographical Information System (GIS): Information system storing geographical data along with alphanumeric and spatial components. GIS systems also provide the data structures and algorithms to represent and efficiently query a collection of geographical data.

Mediator: A software component providing a uniform integrated interface to process and execute queries over data stored in multiple, heterogeneous data sources.

Web-GIS: A GIS system empowered with a Web-based interface.

Wrapper: A software tool to extract content from data sources and perform data format translation.

Wireless Ad Hoc Networking

Fazli Erbas
University of Hanover, Germany

INTRODUCTION

Mobile ad hoc networks represent a new form of communication consisting of mobile wireless terminals (e.g., handset, PDAs, notebooks). These type of networks are wireless multi-hop packet networks without any fixed infrastructure and centralized administration, in contrast to today's wireless communications, which is based on a fixed, pre-established infrastructure. The design of wireless ad hoc networks faces many unique challenges. In this article, mobile ad hoc networks and their characteristics are described, and the design issues, applications and future trends of such networks will be discussed.

BACKGROUND

In recent years, widespread availability of wireless communication and handheld devices stimulated the research and development on self-organizing networks that do not require a pre-established infrastructure and any centralized architecture. Those spontaneous networks provide mobile users with ubiquitous communication capability and information access regardless of their location. This type of networking is called mobile ad hoc networks.

The idea of mobile ad hoc networks has been under development from the 1970s and 1980s in the framework of Mobile Packet Radio Technology (PRNET-1973) (Jubin & Tornow, 1987) and Survivable Adaptive Networks (SURAN-1983) (Schacham & Westcott, 1987). These projects supported research on the development of automatic call set up and maintenance in packet radio networks with moderate mobility. However, interest in this area grew rapidly due to the popularity of a large number of portable digital devices, such as laptop and palmtop computers, and the common availability of wireless communication devices.

In the middle of the 1990s, with the definition of standards, commercial radio technologies have begun to appear and the wireless research community identified in ad hoc networks a challenging evolution of wireless networks. The success of a network technology is associated with the development of networking products that can provide wireless network access at a competitive price. A major factor in achieving this goal is the availability of appropriate networking standards. Today's emerging standards and technologies for constructing a mobile ad hoc network are IEEE 802.11, Bluetooth and ETSI Hiperlan/2. The deployment of mobile ad hoc networks opens a wide-range of potential utilisation from military to miscellaneous commercial, private and industrial scenarios (Perkins, 2001).

MOBILE AD HOC NETWORKS AND THEIR CHARACTERISTICS

A mobile ad hoc network (MANET) consists of a collection of mobile wireless and autonomous hosts –in this sense simply referred to as "*nodes*"– which spontaneously form a temporary network. The devices may be of various types (e.g., notebook computers, PDAs, cell phones, etc.) and various capacities (e.g., computing power, memory, disk, etc.).

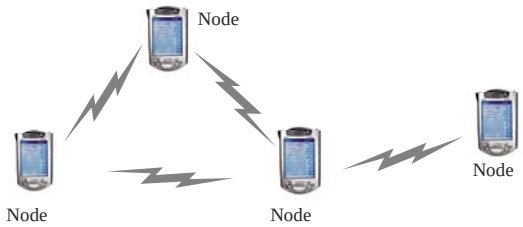
The most important characteristic of such a network is its independence of any fixed infrastructure (e.g., base station or access point) or centralized administration. All networking functions, such as determining the network topology, multiple access, and routing of data over the most appropriate paths, must be performed in a distributed way. These tasks are particularly challenging due to the limited communication bandwidth available in the wireless channel.

Actually, the idea of ad hoc networking is sometimes also called infrastructureless networking (Frodigh, Johansson & Larsson, 2000). An ad hoc network is able to operate autonomously and is completely self-organized and self-configured. Therefore, it can be easily and rapidly installed. In an ad hoc environment people and vehicles can be interworked in areas without a pre-existing communication infrastructure, or when the use of such infrastructure requires wireless extension.

Autonomous nodes may move arbitrarily so that the topology changes frequently without any prior notice. The wireless transmission range of the nodes is also limited; therefore the connection (e.g., wireless link) between the neighboring nodes may break as soon as they move out of range. Consequently, topology of the network and the interconnection patterns among nodes may change dynamically so that links between nodes become unusable. Because of the dynamic nature of ad hoc networks, new routes must be considered and maintained using routing protocols.

Another important property of ad hoc networks is the multi-hop capability. It is given that cellular networks — also called single-hop networks — rely on a fixed wired infrastructure to achieve the task of routing and maintain the

Figure 1. A mobile ad hoc network



connection end-to-end. On the contrary, a mobile node in an ad hoc network that cannot reach the destination directly, because it does not lie within its radio transmission range, will need to relay its information flow through other nodes. This implies the mobile hosts to incorporate routing functionality so that they can act both as routers and hosts.

Other important characteristics of MANET include (Perkins, 2001):

- **Dynamic topologies:** Nodes are free to move arbitrarily; thus, the network topology may change randomly and rapidly at unpredictable times.
- **Bandwith-constrained links:** Caused by the limits of the air interface. Furthermore, multiple access, multipath fading, noise and signal interference decrease the limited capacity available at the allocated frequency rate.
- **Energy-constrained operation:** MANETs inherently imply an underlying reliance on portable, finite power sources.
- **Limited security:** Mobile networks are in general more vulnerable to eavesdropping, spoofing and denial-of-service attacks than fixed-cable networks.

DESIGNING ISSUES

Physical Layer and MAC Layer

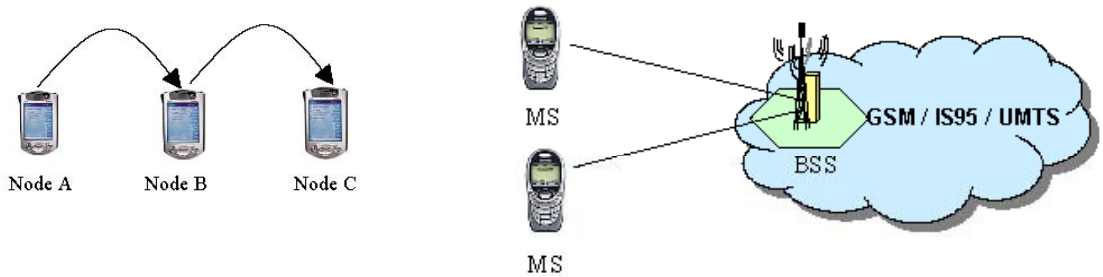
A well-designed architecture for mobile ad hoc networks involves all networking layers, ranging from the physical layer to the application layer. Information as node distribution, network density, link failures, and etcetera, must be shared among layers, and the MAC (medium access control) layer and the network layer need to collaborate in order to have a better view of the network topology and to optimise the number of messages in the network (Bruno, Conti, & Gregori, 2001; Kurose, Schwartz, & Yemini, 2000).

The main aspects of designing the physical transmission system are dependent on several characteristics of the radio propagation channel such as path loss, interference and fading. In addition, since mobile terminals usually have limited power resources, the transceiver must be power efficient. These aspects are taken into account while designing the modulation, coding, and power control features in the radio equipment. In principle, the radio equipment in the nodes forming a mobile ad hoc network can use any technology as long as it provides reliable links between neighboring mobile terminals on a common channel. Candidate physical layers that have gained prominence are infrared and spread spectrum radio techniques.

The MAC (medium access control) layer plays the key role in determining the channel usage efficiency by resolving contention amongst a number of unsupervised terminals sharing the common channel. An efficient MAC protocol allows coordinated access to the limited resources. The main goal of a MAC protocol is therefore maximizing the probability of successful transmissions and maintaining fairness amongst all users.

Though research on medium access schemes for wired local area networks (LANs) have been done for many years, the same concepts cannot be directly applied to wireless

Figure 2. Mobile ad hoc networks (multi-hop networks) in comparison to today's cellular (single-hop) networks



(Node C is reached from node A via node B in multihop way)

LANs. In a wired medium, the transmitted signals are almost received with the same signal strength at all terminals connected to the same shared medium. Hence a terminal in a LAN can avoid contention by sensing the presence of a carrier to determine if any other terminal is using the channel before it starts a transmission.

However, designing MAC protocols for wireless networks faces a different set of challenges. Propagation path losses in the wireless channel cause the signal power to decline with distance.

Since the strength of the received signal depends on the distance from the transmitter, the same signal is not heard equally well by all terminals. Hence carrier sensing is not very effective in wireless. Typical problems of using carrier sensing to determine the availability of the wireless channel are *hidden node problem* and *exposed node problem* (Nasipuri, 2002). Both the hidden node and the exposed node problems arise due to the fact that carrier sensing is only performed at the transmitter, whereas its effect is determined by the interference power at the receiver, which are usually different due to propagation path loss characteristics.

In order to address the hidden terminal problem, IEEE 802.11 has the option of adding the mechanism of an exchange of *REQUEST TO SEND (RTS)* and *CLEAR TO SEND (CTS)* control packets between a transmitting and receiving nodes before initiating the transmission of a data packet.

Several concerns with the IEEE 802.11 MAC has motivated researchers to explore newer techniques to improve the channel utilization and throughput in mobile ad hoc networks. The basic access method of the IEEE 802.11 MAC protocol is susceptible to inefficiencies due to the hidden and exposed terminal problems. The RTS/CTS option reduces the hidden terminal problem but not the inefficiency caused by the exposed terminal problem.

A wireless transceiver cannot transmit and receive at the same time as the transmitted signal will always be far stronger than any received signal. Hence, a wireless terminal cannot detect if its transmission has been successful. To inform the transmitting node about the successful packet transmission, the receiver sends an ACK (acknowledgement) packet back to the transmitter after it receives a data packet. If the transmitter does not receive an ACK within a fixed period of time, it assumes that the transmitted packet has been lost. Many different schemes have been designed for reducing these problems in wireless channel access.

ROUTING

Movements of nodes in a mobile ad hoc network cause the nodes to move in and out of range from one another. Consequently, topology of the network and the link and connection patterns between nodes may change dynamically so that links between nodes become unusable. As depicted, in contrast to conventional wireless networks, mobile ad hoc networks have no fixed network infrastructure or centralized administrative support for their operations. Because of the dynamic nature of ad hoc networks, new routes must be considered and maintained using routing protocols. Since the network relies on multi-hop transmissions for communication, this imposes major challenges for the network layer to determine the multi-hop route over which data packets can be transmitted between a given pair of source and destination nodes.

Because of this time-varying nature of the topology of mobile ad hoc networks, traditional routing techniques, such as the shortest-path and link-state protocols that are used in fixed networks, cannot be directly applied to ad hoc networks. A fundamental quality of routing protocols for ad hoc networks is that they must dynamically adapt to variations of the network topology. This is implemented by devising techniques for efficiently tracking changes in the network topology and rediscovering new routes when older ones are broken. Since an ad hoc network is infrastructureless, these operations are to be performed in a distributed fashion with the collective cooperation of all nodes in the network (Royer & Toh, 1999; Perkins, 2001). Some of the desirable qualities of dynamic routing protocols for ad hoc networks are:

- **Routing overhead:** Tracking changes of the network topology requires exchange of control packets amongst the mobile nodes. These control packets must carry various types of information, such as node identities, neighbor lists, distance metrics, and etcetera, which consume additional bandwidth for transmission. Since wireless channel bandwidth is at a premium, it is desirable that the routing protocol minimizes the number and size of control packets for tracking the variations of the network.
- **Path optimality:** With constraints on the routing overhead, routing protocols for mobile ad hoc networks are more concerned with avoiding interruptions of communication between source and destination nodes rather than the optimality of the routes. Hence, in order to avoid excess transmission of control packets, the network may be allowed to operate with suboptimal (which are not necessarily the shortest) routes until they break. However, a good routing protocol should minimize overhead as well as the path lengths. Otherwise, it will lead to excessive transmission delays and wastage of power.
- **Loop freedom:** Since the routes are maintained in a distributed fashion, the possibility of loops within a route is a serious concern. The routing protocol must incorporate special features so that the routes remain free of loops.

- **Complexity:** Another problem of distributed routing architectures is the amount of storage space utilized for routing. Ad hoc networks may be applied to small portable devices, such as PDA and handhelds, which are memory and hardware scarce. Hence, it is desirable that the routing protocol be designed to require low storage complexity.
- **Scalability:** Routing protocols should be able to function efficiently even if the size of the network becomes large. This is not very easy to achieve, as determining an unknown route between a pair of mobile nodes becomes more costly in terms of the required time, number of operations, and expended bandwidth when the number of nodes increases.

Because of its many challenges, routing has been a primary focus of researchers in mobile ad hoc networks. The MANET working group within the IETF (IETF, 2004) studies solutions for routing framework and develops IP-based routing protocols for mobile ad hoc networks. (Macker & Corson, 1998; Corson & Macker, 1999). Consequently, a large number of dynamic routing protocols applicable to mobile ad hoc networks have been developed.

APPLICATIONS

The term ad hoc means "as needed for a specific case," "done or set up solely in response to a particular situation or problem without considering wider issues." Both definitions stress out the urgent, specific and short-term need character. Indeed, an ad hoc network will be deployed in an area where a support for mobile communication is not available due to low expected usage and high costs. The network can disappear after its function has been served.

One of the original motivations for the development of this technology lay in satisfying military needs like battlefield survivability. Soldiers must be able to move about freely without any restrictions imposed by wired communication devices. Moreover, the military cannot rely on access to a fixed preplaced communication infrastructure especially during manoeuvres in enemy territories (Perkins, 2001).

Other potential practical utilities of mobile ad hoc networks could include:

- Commercial and industrial scenarios: Associates sharing information during a meeting, participants in a conference exchanging documents or presentations
- Educational scenarios: Students using laptop computers to participate in an interactive lecture
- Emergency coordination in disaster areas, where a hurricane or earthquake have destroyed the communication infrastructure
- Extension of the coverage area of cellular networks
- Communication between smart household appliances in the home environment
- Communication between "wearable" computing devices
- Inter-vehicle communication like within a convoy or in highway
- Sensor Networks: represent a special kind of ad hoc networks. They typically consist of nodes equipped with sensing, processing and communication abilities. Sensor networks are used to monitor remote or inhospitable physical environments

FUTURE TRENDS

Need for wireless ad hoc networking will arises in the context of shared desktop meetings (e.g., cooperate learning, workshops, conferences), disaster recovery, wireless inter-vehicle communication, proprietary local networks for private, commercial, business and governmental, use (universities, hospitals, home environments, office environments) or in various military applications.

New technological standards, regulations (e.g., IEEE 802.11, IEEE 802.15), emerging products (e.g., PDAs, notebooks) and new business models will enable fast deployment of such networking concepts.

CONCLUSION

Wireless ad hoc networking is a new form of communication offering new emerging technologies and applications. Several issues have to be considered which are arising due to characteristics of this type of networks. The critical issues discussed in this article offer many implications and challenges to technology, business and the user community as well.

The successful deployment and a broad acceptance of such networks will depend on the availability of appropriate standards and regulations. Further, the development of new products and business models at a competitive price will play key role.

KEY TERMS

Carrier Sensing: Determination that the medium is not being used by a neighboring transmitter before accessing the channel.

Cellular Networks: A network consisting of several cells served by fixed, pre-established infrastructure to cover a geographic area, for example, GSM, IS-95, UMTS.

Dynamic Topology: Due to the node mobility the network topology of mobile multi-hop ad hoc networks are changing continuously in time.

Exposed Node: This is the reverse problem, where a transmitting or "exposed" node is within range of a sender, but is out of range of the intended destination.

Hidden Node: A node may be hidden or out of range from a sender but within range of its intended receiver.

MANET (Mobile Ad Hoc Networks): A network of wireless mobile nodes formed dynamically, self-organizing and without any central administration.

Multi-Hop: The mobile nodes are cooperating to forward data on behalf of one another node to reach distant stations that would otherwise have been out of range of sending node.

Node: Mobile terminal.

RTS/CTS (Request To Send/Clear To Send): Control packets between the transmitting and receiving nodes before initiating the transmission of a data packet.

Single-Hop: Direct communication between two nodes or entities without any intermediate station or network entity.

INTRODUCTION

Vehicular Ad hoc NETworks (VANETs) is an area under intensive research that promises to improve security on the road by developing an intelligent transport system (ITS). The main purpose is to create an inter-communication network among vehicles, as well as between vehicles and the supporting infrastructure. The system pretends to offer drivers data concerning other nearby vehicles, especially those within sight.

The problem of information sharing among vehicles and between the vehicle and the infrastructure is another critical aspect. A general communication infrastructure is required for the notification, storage, management, and provision of context-aware information about user travel. Ideally an integrated vehicle-to-vehicle (V2V) and vehicle-to-infrastructure (V2I) communication paradigm enriched with an information management system would solve the problem. The infrastructure should manage all the collected safety events garnered from vehicles and the interesting information to be provided to the user, which is adapted to the car context and driver preferences.

Finally, security issues should be considered. Since the information conveyed over a vehicular network may affect critical decisions, fail-safe security is a necessity. The first directive for any V2V communication scheme is, therefore, that every safety message must be authenticated. Because of the high speed and therefore short duration within which communication between two cars is possible, communication must be non-interactive, and message overhead must be very low. The urgency of safety messages implies that authentication must be instantaneous without additional communication.

Moreover, providing strong security in vehicular networks raises important privacy concerns that must also be considered. Safety messages include data that is dangerous to the personal privacy of vehicle owners. Most relevant is the danger of tracking a vehicle through positional information. A set of security basics to address these challenges should be proposed that can be used as the building blocks of secure applications.

In this article we will focus on the aforementioned technologies and engineering issues related to vehicular ad-hoc networks, emphasizing the challenges that must be overcome to accomplish the desired vehicular safety infrastructure.

BACKGROUND

Ubiquitous computing is nowadays an emerging research field in mobile communications, due to more and more integration of heterogeneous services over different operation environments. The capacity of customizing services to the client, and the adaptation of its behavior according to the context, will offer the user value-added features in the new age of computer communications. Taking into account this premise, in this article our aim is to create a feasible environment for providing integrated services in the vehicle field.

Wireless communications in the vehicle field through ad hoc networks (or Vehicular Ad hoc NETworks–VANETs) are currently being used as a novel and promising technology to improve driving safety. Mainstream research usually considers these communication patterns to offer intelligent transportation systems (ITSs), where one of the most important aims is the creation of communication networks among vehicles, in vehicle-to-vehicle transmissions (V2V),

but without forgetting communications between vehicle and infrastructure (V2I). The usefulness of these developments is focused on providing every vehicle with information about the surrounding vehicles, and especially the ones not located in the field of vision.

Due to the continuous improvements of communication technologies, a great number of considerations must be taken into account when a network system is elected. Although VANET developments have predominated in V2V communications, it is necessary to study whether the facilities offered by the network design cover the requirements collected from the future deployable services. Collision avoidance applications have been the main safety service implemented for the vehicle field. However, a great number of non-safety services are appearing. When the amount of services for the vehicle side grows, more consideration is needed. It is mandatory to research in technological solutions which deal with the requirements of a generic and flexible architecture for service provisioning and usage.

For a correct design of such systems, it is necessary to take into account the vehicular environment. Here, high-speed mobility and special movement patterns can be found, where the creation and breakage of links between nodes appear continuously. The presence of an excessive or null rate of equipped vehicles is another important factor which must be considered. This fact and the need for reliable end-to-end communication make the design of a vehicular communication system a complex task.

The main objective of any project in this area is to offer an integrated solution for the deployment of an ITS using the VANET communication technology overall. The schema considered can be seen in Figure 1. The system should apply techniques inside the field of ubiquitous computing in the vehicle field, where numerous programmatic devices can interact with the user in a transparent way. This way, the system should have enough intelligence to analyze the context and efficiently detect hazardous and emergency situations, generate driver warnings in critical cases, and interact with the infrastructure when a global knowledge can be useful.

A CROSS-LAYER APPROACH TO VANET DESIGN

The design of a complete VANET solution must cover different technological areas, and several disciplines are involved in the development of such a system. In the following we will outline all the interrelated layers that must work together to provide a comprehensive architecture.

Modeling, Evaluation, and Simulation

In classical MANETs, researchers often use a typical set of simulation parameters. These parameters are inadequate for

Figure 1. Overall scheme of the proposed architecture

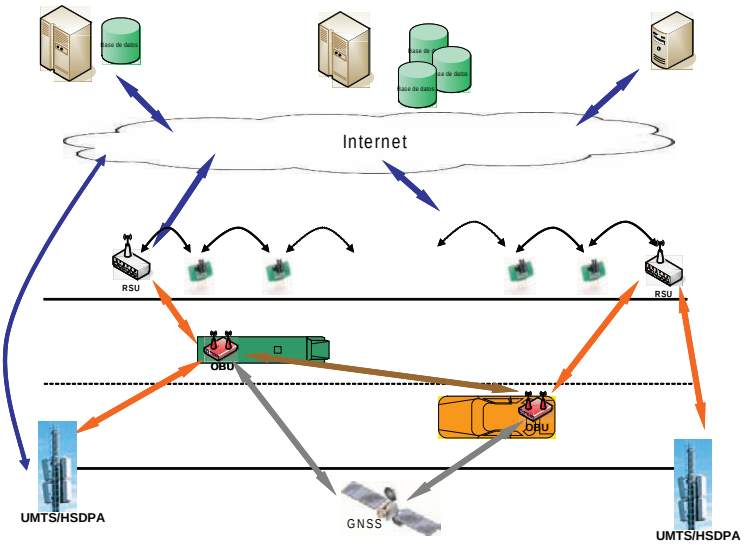

Figure 2. A VANET system vertical architecture

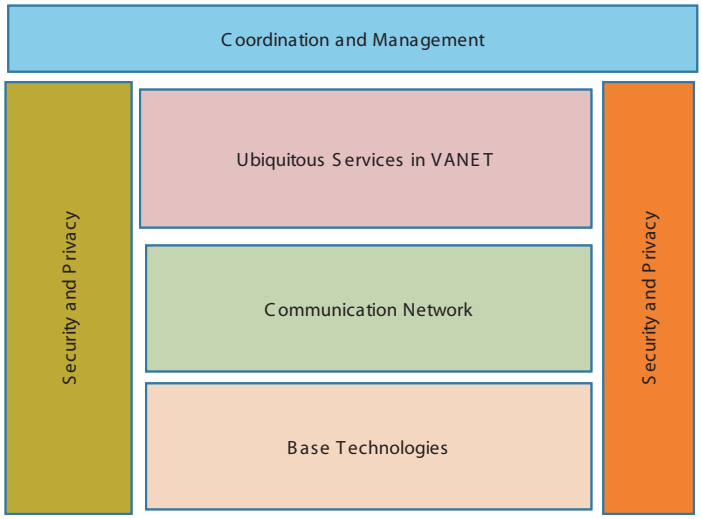

many MANETs, and particularly for VANETs. The MANET research community is aware of resulting limitation because of the simplification of some hypotheses (Kotz et al., 2004). In the VANET context, different researching groups are working to improve models in order to perform experiments close to reality. For example, Wu, Fujimoto, Guensler, and Hunter (2004) use their own simulator, called CORSIM, for creating mobility traces for other simulators. In the same way, Choffnes and Bustamante (2005) use a new mobility model called STRAW for modeling real traffic patterns. This model has an easy car persecution model and the chance of controlling the traffic to create congestion situations.

On-Board and Roadside Equipment

Current studies about technologies for on-board equipment are directed to the hardware that is needed to incorporate into the vehicle in order to offer one or several services with certain functionality (Skarmeta et al., 2002; Massaki, Xuchu, Hideki, Mami, & Masaki, 2004). An important issue will be the implementation of a positioning system with a high degree of reliability. Also we will pay special attention to the computer considered in the on-board unit. At the start there was a tendency to employ specific-purpose computers. Nevertheless, the development of several services advises the employment of general purpose computers (Simonds, 2003; Santa, 2007). This computer must be fitted with the communication interfaces needed to connect to the communication system that will be proposed in the project. In the car environment, although having used many communication technologies (Nolte, Hansson, & Lo Bello, 2005), the most interesting ones are the 802.11 and cellular networks. 802.11 networks have usually been considered in VANET networks and allow the deployment of cooperative services among vehicles. Nevertheless, new solutions were developed for communicating with the infrastructure (Okabe, Shizuno, & Kitamura 2005). On the other hand, UMTS is the most appropriate cellular technology for the vehicular environment. Usually, connections through the cellular network are being directed to infrastructure communications. However, in the project development, a V2V and V2I communication architecture based on cellular networks will be proposed.

A V2I communication infrastructure will need roadside support. Although in cellular networks operators offer hardware deployment, the research in new V2I communication technologies must take into account several technological considerations of the road infrastructure.

Horizontal and Vertical Handoffs Between Communication Systems

The interest in offering Internet access in heterogeneous scenarios and on mobile platforms like trains, buses, or airplanes has caused the creation of the NEtwork MObility

Working Group (NEMO) of the IETF (Internet Engineering Task Force). This group is in charge of defining mechanisms for managing network mobility as a whole, allowing network handoffs between different physical systems, but maintaining the same logical connection over IP (Internet Protocol). NEMO objectives are becoming real due to the improvement of cellular networks and the integration of WLAN technologies like WAVE (IEEE 802.11p, or Wireless Access in the Vehicular Environment) or CALM (Continuous Air interface for Long and Medium distance).

An important objective resides in offering mobile nodes an efficient and scalable mechanism for changing their network attachments, keeping their IP address, and keeping alive all the high-level connections (Yabusaki, Okagawa, & Imai 2005). In this way there are some interesting works, like MIPv6 and Hierarchical Mobile IPv6 (HMIPv6) (Yan & Atwood, 2006), with the aim of improving mobile communications in certain circumstances, making the handoff a secure and efficient process.

Security in Data Networks

Being able to protect members of possible security attacks is essential in this kind of network, without eliminating the possibility of giving context services. Attacks can be classified into passive attacks and active attacks. Passive attacks consist of "listening" to the information that is transmitted in the network, without directly affecting to the network operation (Yanchao, Wei, & Wenjing, 2005). Generally, hackers enter with the aim of examining the general state and the network traffic. This analysis can be made with the objective of damaging the network availability or traffic. The privacy about position is a special type of information confidentiality, which is defined as the possibility of stopping third parties from knowing the current or a previous vehicle position.

Active attacks (Liu, Fu, Xiao, & Lu, 2007) imply a bigger attacker interaction with the network, by means of devices manipulation, "man-in-the-middle" techniques, or denial-of-service strategies. To solve these problems it is necessary to use cryptography-based techniques, which allow authenticating both the transmitted information and the sender, for example by means of digital signatures and hash functions. The aim is providing VANET vehicles with classic services of authentication, non-repudiation of origin, and information integrity, as well as specific for VANET networks. Due to the high speed of movement, techniques for detection of so-called "false alarms," which are produced by information delays or alarms repetition, must been researched. In monitoring systems where an information management station for vehicles is situated at the infrastructure, security issues for information transmissions are also an important fact to be considered (Hoh, Gruteser, Xiong, & Alrabady, 2006).

Vehicle to Infrastructure Communications and Alternatives to VANET

Though VANET networks are the main research point in vehicular networks, there are situations where current developments can limit the use of some services. When the distance between two transmitting vehicles increases considerably, a communication based on VANET can present poor performance. On the other hand an interconnection with a fixed network requires efforts that can not be scalable in cost. With this meaning, the project will direct an effort in finding other alternatives that complement the VANET communication system.

Some authors have noticed VANET cadences and the usefulness of P2P (peer-to-peer) networks to create an architecture that allows cooperative work between vehicles (Rybicki et al., 2007) or a connection with the infrastructure (Baresi et al., 2005), this way avoiding VANET network restrictions. By means of a P2P network, nodes can use in a transparent mode an underlying network infrastructure and work cooperatively using a logical interconnection mesh. Vehicles can take advance of this system and communicate with its environment through several services in a V2V or V2I pattern. However, an underlying technology is necessary to "physically" connect the vehicle to the network.

Cellular networks were especially important in connecting with the infrastructure. Previous connection rates, of approximately 300kps, have been overcome by HSPA technology, which already offers significant improvements in delay and bandwidth to start considering UMTS as an appropriated technology for vehicular networks. For this reason, the project will cover issues regarding the use of cellular networks in vehicles and will consider an alternative network system for V2V and V2I communications based on P2P over UMTS.

FUTURE TRENDS

Vehicular networks introduce a new complex environment for communication engineers. The communication channel varies from a simple point-to-point microwave link for cars in open areas, to rich Rayleigh fading within the cities. Also the channel varies considerably every few seconds and the blockage of line of sight can occur frequently. Adaptive and efficient channel estimation algorithms must be found, diversity techniques to overcome fading effects should be examined, and Doppler effects should be carefully considered. The link layer is expected to provide a varying delay and different QoS classes to satisfy the different requirements of the applications.

Techniques of service provision which make use of vehicle position are the so-called location-based services (LBSs). The traffic environment and the information that vehicles receive require a more complete modeling about the destination of the user and his or her preferences in order to reach the so-called context-based services. The subscription strategy is of special interest, talking about a generic service provision system. Typical Internet services, like Web navigation, transactions management, bookings, and so forth, use a client/server strategy where the server replies to a previous client request, and operation requisites of vehicular services respond to other, more suitable communications strategies, known as publish/subscribe. Using this methodology, the user does not have to send an explicit request to the system to receive certain information, but neither would receive continually non-desired information, as happens with the vehicular RDS (radio data system). In a publish/subscribe scheme, the user manifests his or her interest about receiving certain information, and the system is in charge of sending pertinent notifications (Cugola & Jacobsen 2002). This way, a publish/subscribe system perfectly operates not only with a context-aware service provision, but also with users' requirements modeling.

The Ontology Web Language (OWL) and the adaptation of Web content by means of captive portals will be combined in this project with the service subscription strategy in order to present a ubiquitous environment of services for the driver. The usefulness of OWL has been proven in different environments, including aiding systems for museum visits (Chou, Hsieh, Gandon, & Sadeh 2005). These applications model the museum environment and adapt the information to the user according to his or her movement throughout the facilities. The adaptation of this idea to a vehicular environment is considered of special interest (Santa, 2007).

CONCLUSION

In this article, we presented the VANET research area, a very active area that is expected to truly enhance car drivers' lives. The main focus is security, but also infotainment (the combination of information and entertainment) is of interest, especially from the economic point of view.

We described the areas where most of the research activity is focusing and evidenced that a transversal solution is crucial for this type of network.

Fast and reliable dissemination of alerts on accidents or other road hazards is a critical application of vehicular networks. A protocol that supports the dissemination of emergency messages should ensure the timely delivery of such messages to all the vehicles passing through the potentially affected region during the lifetime of an emergency. This protocol might exploit a hybrid, cluster-based vehicular network architecture, where the bulk of communication between vehicles takes place over ad hoc networks for improved scalability and efficiency. Cellular communication can also be used to improve reliability when network partitions hinder the message delivery.

KEY TERMS

Global Navigation Satellite System (GNSS): A satellite system that is used to pinpoint the geographic location of a user's receiver anywhere in the world.

Mobile Ad-hoc NETwork (MANET): A type of wireless network, made of a self-configuring network of mobile devices. These devices are connected by wireless links. The union of all these devices forms an arbitrary topology.

On-Board Unit (OBU): Computing device located in a vehicle that establishes the connection with the RSU and the other OBUs on nearby vehicles.

Roadside Unit (RSU): Computing device located on the roadside that provides connectivity support to passing vehicles.

Universal Mobile Telecommunications Service (UMYS): A third-generation (3G) broadband, packet-based transmission of text, digitized voice, video, and multimedia at data rates up to 2 Mbps.

Vehicle to Infrastructure (V2I): Involves all the communication aspects between vehicles and the supporting infrastructure.

Vehicle to Vehicle (V2V): Relates all the data communication that takes place between various vehicles on the road.

Vehicular Ad hoc NETwork (VANET): A mobile network whose node are vehicles (i.e., car, trucks, etc.); considered an extension of a MANET (Mobile Ad hoc Networks) because of the possibility of working without a fixed infrastructure.

Wireless Technologies to Enable Electronic Business

Richi Nayak
Queensland University of Technology, Australia

INTRODUCTION

Research and practices in electronic business (e-business) have witnessed an exponential growth in the last few years (Liautand & Hammond, 2001). Wireless technology has also evolved from simple analog products designed for business use to emerging radioactive, signal-based wireless communications (Shafi, 2001). The tremendous potential of mobile computing and e-business has created a new concept of mobile e-business or e-business over wireless devices (m-business).

BACKGROUND

M-business can be defined as the use of mobile technology in exchange of goods, services, information, and knowledge. M-commerce is the execution of transactions done on mobile equipment via mobile networks, which may be wireless or switched public networks. M-business includes the range of online business activities, business-to-business and business-to-consumer, for products and services through wireless devices such as mobile phones with display screens, personal digital assistance (PDA), two-way pagers, and low-end or reduced-size laptops.

Example applications are mobile ticketing and receipting, banking, gaming, e-mail communication, weather forecast, sport scores access, movie database access, stock exchange information, ordering of books, and other daily needs such as food and groceries. With new emerging mobile applications, users only receive selective and real-time information personalized to their interests (Ratsimor, Korolev, Joshi & Finin, 2001). For example by using a positioning system, the advertising information of local services and entertainment can be sent whenever a user is passing by a shopping mall. Another application is "inventory management" that tracks the location of goods, services, and people to determine delivery times. Multiple trucks carry large amounts of inventory that companies could access for just-in-time delivery (Varshney & Vetter, 2002).

Significant benefits of m-business to consumers are convenience, portability, safety, integrating existing mobile phones with mobile computing technology, verifiable receipts, and transaction records that can be made available instantly and permanently on a smartcard. Significant advantages of m-business to service providers and content providers include driving additional revenue and decreasing consumer attrition by offering new m-business services to specific groups of customers.

WIRELESS TECHNOLOGIES TO ENABLE M-BUSINESS

Many wireless technologies exist to enables m-business services (Tsalgatidou, Veijalainen, Markkula, Katasonov & Hadjiefthymiades, 2003). All technologies try to achieve benefits such as being powerful, simple, economical, and secure. Some examples of these techniques follow.

Wireless Application Protocol technology links wireless devices to the Internet by optimizing Internet information so it can be displayed on the small screen of a portable device.[1] Web pages accessed by WAP-enabled mobile portals during m-business transactions must be written in WML.[2] It is not sure how well WAP will be able to proliferate (Tsalgatidou et al., 2000). Developments such as third-generation (3G) mobile communications and XYPOINT WebWirelessNow applications (Wen, 2001) already allow mobile phone consumers to experience the Web services without WAP.

Wireless Internet connecting technologies that offer textual interface such as WAP significantly suffer from the constraints of wireless communication such as having a small display screen. An alternative solution is providing voice access to users. Advances in speech recognition and text-to-speech technologies have made voice-based communication possible between computers and users over the phone.

VoxML[3] technology, based on the W3C XML standard, enables the application interface to be in the form of dialogues. However, there is an extra overhead for content providers to offer the same Web service through different channels, for example, providing a voice-enabled browser for their wireless customers along with the HTML/XML/WML browser. Another overhead is the processing power that speech recognition requires. Also this type of data transfer mode is not appropriate for applications with confidential data where one could be overheard. Overall, the success of this technology depends on public acceptance of mobile

phones as data-delivering tools and the type of applications best suited to their use.

The *Bluetooth* technology further enhances the sphere of mobility by conducting m-business without a heavy network infrastructure unlike WAP and VoxML technologies.[4] The Bluetooth technology is designed to allow low-cost, short-range data (asynchronous) and voice (synchronous) radio link (2.4 GHz, 1 Mb/sec) to facilitate protected connections for stationary (homes, buildings, shopping centers, restaurants, cars, etc.) and mobile (phones, PDAs) computing environments. A simple example of a Bluetooth application is to automatically update mobile phone contents such as phone list, e-mails, and memos without any user involvement when the phone comes within the range of the home/office PC. Currently, the Bluetooth networks providing m-business services are limited to 10 meters only. Also, it has too many flaws in terms of security for the services to be trusted. A promising future of Bluetooth technology is its integration with WAP or VoxML.

Based on infrared technology, the *IrDA (Infrared Data Association)* easy-to-use technology provides low-cost, short-range, point-to-point connectivity between devices, interoperable/cross-platform at a wide range of speeds (115.2kb/s to 4Mb/s) with a physical range of 1 meter. IrDA technology is embedded into 40 million new devices each year such as personal computers, laptops, mobile phones, PDAs, digital cameras, pagers, and so forth.[5] The keyword of IrDA advantages is simplicity for ad-hoc, point-to-point exchange. However, the requirement of direct line of sight for devices to communicate is surely a disadvantage for conducting m-business.

IEEE802.11 (Wi-Fi) technology provides a high data rate over different ranges (54Mbps using the 2.4 and 5 GHz ISM band, 11Mbps using the 2.4 GHz ISM band).[6] The single Media Access Control protocol helps to keep the cost down, but interoperability is a problem. The data transmission rate has to be defined before the transmission between devices can start. In terms of the transmission itself, it is based on the well-known TCP/IP protocol. The availability of unlicensed spectrum is a significant enabler for broad acceptance of this technology. However, the technology has some security flaws. Because of the large physical range (100+ meters) and "always-on" connection model, this technology consumes a lot of power, limiting its use in PDAs, phones, and other lightweight mobile devices. The greatest advantage of this technology for conducting m-commerce is its speed.

HiperLAN, a specification substandard of IEEE802.11, is a short-range technology (from 10 to 100 meters) adapted to 3G networks with low power requirements.[7] HiperLAN provides flexible services such as mobility management and quality of service at low cost. The technology has a potential for conducting m-commerce in terms of supporting both ad hoc and client/server networks.

Ultra Wideband technology is a recent RF technology with advantages like large bandwidth, high data transfer rates, and immunity to interference.[8] Still, the technology is in its early stage of development, and there are not many products using this technology yet. However, in the future this network technology may be a very good alternative for conducting m-commerce.

Mobile Agent technology offers a new computing paradigm in which a program, in the form of software agents, is initiated at the host, can suspend its execution on a host computer, launch itself to another agent-enabled host on the network, resume execution on the new host, and return back to its host with the result (Hayzelden & Bigham, 1999). This type of paradigm advocates the client/server model where the client is a mobile portal and the server is a fixed network. The mobile agent performs various optimizations on the server in lieu of its mobile portal to reduce the problems such as C-autonomy, limited bandwidth, and limited computational power. The fixed network offers its services to the agent such as access to local resources and applications, the local exchange of information between agents via message passing, basic security services, creation of new agents, and so froth. Many research papers emphasize that one of the most promising approaches for developing e-business applications is mobile agent technology (Dikaiakos & Samaras, 2001; Tsalgatidou et al., 2000).

Figure 1. A typical platform enabling m-business services

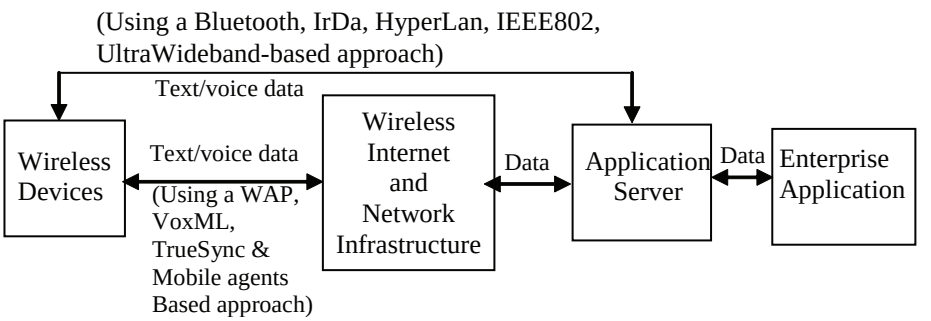

Figure 2. A mobile commerce cycle (Varshey & Vetter, 2002)

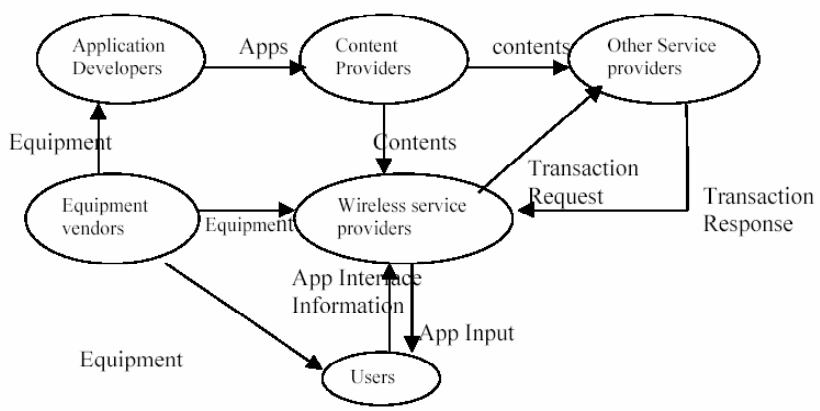

Figure 1 illustrates a typical platform to enable an m-commerce application. According to the wireless technology, a request from the wireless device is passed on to the application server, where the request is processed and output is returned.

Varshey and Vetter (2002) proposed a mobile commerce cycle that shows the possible interaction between various entities (see Figure 2).

CHALLENGES IN M-BUSINESS

As m-business bears its roots in e-business, many technical, legal, and business perspectives are extrapolated from e-business. But m-business embraces a number of technologies to enable its activities, such as wireless devices, software, and protocols, as well as eliciting a number of issues of its own.

Limited Environment of Mobile Devices

These devices usually have limited display size, input capabilities, data transfer rate, computation power, storage, power usage, and so forth; some may be overcome with the technological developments. For example, low bandwidth problem can be handled by the use of software compression techniques or by only sending the relevant information with the use of positioning systems to reduce the traffic. Such mobile applications should be developed so that a large footprint is not required (one innovation is NTT DoCoMo).[9] However, a low-power, inexpensive, and high-resolution color and larger size display will positively affect the m-business.

Security

Consumers should feel the same sense of security when they shop using a mobile phone as when they shop in the physical world. Connection to a wireless link does not require physical access to the network or devices in an "always-on" mode when connected, as in 3G devices. This makes wireless devices more susceptible to attack. In addition, mobile devices are prone to be lost or stolen. Various encryption and integrity mechanism are required to protect digitally encoded speech and control information in m-business services (Chari, Kermani, Smith & Tassiulas, 2001).

Transactional Issues

Usually transactional models with ACID (Atomicity, Consistency, Isolation, Durability) properties assist an application developer in providing powerful abstraction and semantics to concurrent executions and recovery in transaction management. M-business transactions require these properties to be redefined due to additional requirements such as: (1) the need to transfer money and goods along with data transfer, and (2) increased risk of incomplete transactions as mobile terminals can easily lose network connections.[10] Approaches such as the asymmetric cryptographic algorithms (also called Public Key algorithms) with certification authorities are utilized to fulfill ACID properties of m-business transactions (Veijalainen, 1999; Tsalgatidou et al., 2000).

Interoperability

The m-business market is still in its infancy with many standards, and many standards are competing with each other. This creates doubt for the success of global roaming and for the infrastructure. There is interference to one technology with the use of another technology in terms of broadband

spectrum. There have been some improvements in convergence of functions between phones and PDAs. But still, each PDA device comes with its own operating system.

Slow Growth

M-business has not lived up to the promises of the past. Users are not keen to upgrade their mobile phones to take full benefit of m-business applications. Users feel that existing m-business applications do not drive the force to adopt new communications such as 3G. Accordingly, there is delay in implementing system infrastructure such as 3G mobile networks.

FUTURE TRENDS AND CONCLUSION

M-business applications improve the value of the service for the providers, and give an easy and natural interfacing and interacting to the users with mobile portals. Considering it is difficult to provide full convenience due to the limited nature of the wireless devices, the application seems to be able to offer ease of navigation and provide real-time information to users using mobile devices, anytime anywhere.

Many optimists see m-business as a technology that is just one step from everyday use. Many pessimists see many unsolved problems and predict that m-business will not break through in the next few years. As usual, the truth lies somewhere in the middle. Basic techniques are already available. Millions of people are already using mobile portals. Businesses are making profit by moving on to e-business solutions. The potential of m-business is enormous.

So why not integrate them all? Major mobile service providers are taking initiatives (such as MeT,[11] GMCF,[12] WDF,[13] NTT DoCoMo) to envision this technology to flourish. The remaining tasks are rigorous testing and refining of protocols especially suited for m-business applications, resolving related technical and business issues, thus winning the trust of consumers to use m-business services.

KEY TERMS

Electronic Business (E-Business): Any type of business transaction or interaction in which the participants operate or transact business or conduct their trade electronically.

Mobile Electronic Business (M-Business): A range of online business activities, business-to-business and business-to-consumer, for products and services through wireless devices such as mobile phones with display screens, personal digital assistance (PDA), two-way pagers, and low-end or reduced-size laptops.

Voice Markup Language (VoxML): Based on the W3C XML standard; designed to support interactive dialogues.

VoxML masks the technology behind the voice-to-voice communications by using XML data-tagging structures to link the text-to-speech that generates audio with the speech-recognition software that interprets a user's command.

Wireless Application Protocol (WAP): An approach to link wireless devices to the Internet by optimizing Internet information so it can be displayed on the small screen of a portable device.

The World Wide Web and Cross-Cultural Teaching in Online Education

Tatjana Takševa Chorney
Saint Mary's University, Canada

INTRODUCTION

The increasing number of virtual universities and online training with a global reach indicates that the opportunities and demands for successful cross-cultural communication expand exponentially, and that instructional paradigms are shifting. Online and distance education is increasingly becoming part of traditional universities as well (Irele, 2005). In 1997, over 60% of all public institutions of higher learning in the U.S. offered distance education courses; by 2001, that number rose to 90% (IES, 1997; 2001). In Canada that number is currently estimated to be 85%[a]. An online teaching environment "goes beyond the replication of learning events that have traditionally occurred in the classroom and are now made available through the Internet"; it provides for different and new approaches to learning, and calls for "flexible teaching….that incorporates a variety of access opportunities as well as a variety of learning modes" (CATL, p. 1). Online teaching here refers to teaching that takes place in programs and courses that incorporate an online component such as WebCT, those that rely completely on WebCt and other similar applications to deliver course or program content, as well as courses offered internationally as part of institutions' distance education degree programs. As online teaching is gaining prominence, educators are compelled to interact meaningfully with individuals from different cultures daily. These interactions demonstrate that teaching and learning are culturally-based processes and that instructional content and how it is experienced reflects the values and practices of a particular cultural group.

The new realities place new demands on educators' knowledge and skills. The cross-cultural context of instruction poses a number of challenges associated with cross-cultural communication in general, such as different communication and decision-making styles, different approaches to task-completion, knowledge, disclosure, and different attitudes toward the learning situation in general. These challenges can lead to misinterpreting the intentions behind certain actions and behavior. In addition, teaching in an environment where many students possess knowledge that they do not, educators have to become collaborative designers, instructional planners, mentors and facilitators of learning, rather than transmitters of authoritative knowledge in a traditional sense. They need to acquire greater familiarity with different learning styles, as well as understand that many of the components determining the nature of learning styles and attitudes toward learning are culture-based (Chorney, 2007; Hao, 2004; Kim, 2001).

Computer-mediated communication (CMC) and the properties of the online environment in general are inherently suited to help educators reconceptualize their role and engage in constructive cross-cultural communication. This is due to the new technologies' potential to enable collaborative teaching in an environment of diverse users and to support multiple learning styles. At the same time, the presence of collaborative technology itself does not guarantee that successful cross-cultural communication and learning will take place. The disembodied nature of online communication can sometimes add to the inherent challenges that accompany face-to-face cross-cultural communication.

Instructors who teach in cross-cultural contexts online will need to engage with the new technologies in a more purposeful way and apply that engagement to program design and teaching practice. They will need to devote some time to designing for interaction and collaboration in order to overcome common challenges in cross-cultural communication.

A more systematic study of the open-ended and interaction-enabling properties of the World Wide Web would help those who design for diversity in online educational environment. The open-ended and interactive nature of the World Wide Web, as the main platform for online cross-cultural teaching, can serve as a conceptual model to help teachers overcome common challenges in cross-cultural communication.

BACKGROUND

As e-learning is gaining prominence, and as distance education turns our world into a "global village", compelling educators to interact meaningfully with individuals from different cultures daily, it is becoming clear that both learning and teaching and culturally-based processes, and that instructional design is not culturally neutral (Campbell, 2004; Chorney, 2007). Instructional content, and the way that content is experienced, reflects the values and practices of a particular cultural group—most commonly, English speaking western cultures. Unless greater care is taken, this situation can alienate a number of students.

Since all education is based on interaction and communication, and cultural differences are often at the root of communication challenges, educators' ability to deal with those differences will determine largely how successful they are in practice. In cross-cultural contexts, teachers acknowledge that learners bring prior knowledge and experience to the learning environment. In these contexts, teachers can no longer see themselves as exclusive sources of knowledge. Rather, they need to see themselves as guides who facilitate the learners' navigating through networks of existing meanings to create new ones. They need to encourage learners to make connections between previous and new knowledge, to integrate previous knowledge with new knowledge, and transfer it from one context to another. In the new paradigm, teachers teach "for transfer", and embrace collaborative teaching.

Collaborative teaching rests on the assumption that learning is "more of a process than a product, in which internal meaning is made through the building and reshaping of personal knowledge through interaction with the world" (Campbell, 2004, p. 152). Collaborative teaching means engaging learners in the learning process and encouraging them through various activities to construct knowledge in a way that is meaningful to them. Teaching collaboratively means being willing to recognize and practice explicitly the reality that there is always more than one way to solve a problem, and more than one point of view in interpretation. Collaborative teaching is reflective, as it implies that instructors will be willing to reflect on their teaching, words, claims, and so on, on an ongoing basis, and be prepared to change their perspective at any given point if change is needed. The instructor who is committed to teaching collaboratively will be teaching students the nature and value of successful communication and collaboration by example.

Like the organization of materials on the WWW, this teaching model is inherently nonlinear, as it encourages the making of connections and identifying of differences among a multiplicity of perspectives on the same issue in no particular linear order. The collaborative model is based on flexible thinking, and is best achieved through the practice of so-called "transformative communication". There are a number of indicators that transformative communication is happening. Among them are the following:

1. The student teaches the instructor something that he or she did not know before, either about the technology or about content.
2. More emphasis is placed upon finding support or backing for a position than on conforming to an authority.
3. Students participate in setting the agenda for the class by helping choose content, learning methods, or both.
4. Students are calling the instructor's attention to valuable learning resources.
5. While the instructor helps establish expectations and articulates a clear assessment standard, the students collaboratively guide much of their own learning.
6. The instructor finds him or herself saving student work—not merely as examples of student work, but as content resources for future reference (cf. Sherry & Wilson, 1997).

This flexibility of approach relying on collaboration and learning as a process becomes crucial in the context of cross-cultural instruction. Individuals process information and approach learning in different ways, which results in different learning or "mind" styles. There are a number of different classifications concerning learning styles (cf. Gardner, 1983, 1993, 1999; Keefe, 1979). One such classification accounts for cognitive differences among learners according to two criteria: the way learners acquire information—though concrete experience or abstract conceptualizations; and according to how they internalize or process information—through active experimentation based on the method of scientific, deductive reasoning, or reflective observation (Kolb, 1984, 1985). Some learners prefer and appropriate knowledge and information offered through text, others through images and graphic representation. While most students have become proficient in interpreting text or print, only a portion of those students is actually composed of so-called "verbal learners," those who prefer to learn from texts and lectures (Campbell, 2004, p. 178).

Individual responses to the learning situation will be influenced by the learners' prior knowledge and the way they think of the individual's past experience, and this, in turn, will depend in some definite measure upon each person's background, including the individual's culture. While models of cognition are not entirely predetermined, they are also shaped through social interaction (Helwig, 2005; Nations Johnson, 1993; Oishi, Hahn, Schimmack, Radhakrishan, Dzokoto & Ahadi, 2005; Smetana, 2002). Since individual development is mediated by social interaction in a culture-specific, historical setting, and since culture influences one's cognitive processes, including the attitudes governing the assimilation of information, there is common ground on which culture and its impact on cognition can be studied (Abi-Nader, 1999; Neff & Helwig, 2002). The relationships between learning styles and cultural backgrounds are therefore strong and complex (Hao, 2004; Kim, 2001).

The nature of this relationship and its implication for cross-cultural education can be understood in the context of the often cited differences among cultures and the attitude those differences shape. There are a number of ways according to which cultural differences have been conceptualized (cf. McCutcheon, 1993). One recent model interprets the differences in terms of a "global learning style," associated with Japanese learners, vs. an "analytical learning style," associated with learners from Europe, North

America, Australia, and New Zealand (Ito, 2002). Japanese students, who are seen as exemplifying the "global learning style" are generally image-oriented, cooperative, learn by experience, depend on insight and intuition, prefer indirect expressions, value the subjective, and avoid standing out. On the other hand, learners associated with the "analytical learning style" generally learn by reasoning; they compete, assert themselves, value the objective, are text oriented, and prefer direct expressions (Ibid.).

What is clear is that attitudes toward learning are built into the education system, and that as difficult as they are to systematize, they will influence the learners' own approaches to learning and knowing. In turn, this is likely to result in different communication styles, different attitudes toward task completion, disclosure, assertiveness, and so forth. However, it is very important that these classifications, like any other attempt at systematizing human thought and behavior, are understood in a broad, nonrestrictive sense. Individual characteristics will always vary and overlap and no single model can completely define any one person.

Although we can and should continuously strive to learn as much as we can about the values and assumptions of different cultures, we can never hope to learn everything there is to learn about all cultures. The issue, here, therefore, is not so much about learning cultural content, as much as it is about learning a method of approaching and dealing with cultural differences in general. Since we tend to design "from our own experience and based on our own needs and values" (Ito, 2005), educators who teach online and in a cross-cultural context need to reflect on the diversity among the students they teach, and the implications of diversity for the course and program design. The activity in which knowledge is developed and used is neither separable not ancillary to what is learned, but an integral part of it, as both learning and cognition are fundamentally situated and embedded in the context in which they take part (Seely Brown, Collins, & Duguid, 1998). Teaching and learning, in both content and methodology, are interdependent processes, just as activity, concept, culture, and affect and cognition are interdependent and inextricably linked (cf. Seely Brown et al., 1989).

Due to these realities, educators need to reflect on their own cultural and pedagogical assumptions. Seeing that our own culture provides the lens though which we see ourselves and others in the world, it is of paramount importance to reflect purposefully and specifically on the values and experiences that have shaped our own pedagogical approach. This kind of reflection with the purpose of attaining greater understanding of ourselves as members of a particular culture will aid in instructional planning and design in a cross-cultural context, and lead to the practice of collaborative teaching. This approach is of crucial relevance in cross-cultural communication where the existence of multiple perspectives will be the beginning point of interaction.

Although it may seem that the instructor who teaches collaboratively teaches only method and not content, this is not the case. This practice, on the one hand, demonstrates the teacher's engagement with his or her discipline or subject, which is an active process and the basis of good scholarship. On the other hand, it enables students to develop a composite understanding of the subject matter and understand the connections that exist between different approaches. It shows students the "the legitimacy of their implicit knowledge"; it stresses that "heuristics are not absolute but assessed with respect to particular tasks" and thus always situated. It also helps students to "generate their own solution paths…making them conscious, creative members" in the process of knowledge creation (Seely Brown et al., 1989, p. 40).

As a conceptual model and a platform where most online education takes place, the World Wide Web offers unprecedented opportunities for instructors to accommodate preferences relating to different learning or "mind" styles, different models of acquiring and processing information, and different ways of creating knowledge.

THE WORLD WIDE WEB AND CROSS-CULTURAL COLLABORATIVE TEACHING

The nature of the online environment can support the features of active and collaborative teaching and the reconceptualization of the teacher's role. The World Wide Web is a "universe of network-accessible information" (W3C, 2001). Through the use of hypertext, multimedia techniques and Web 2.0 applications, "the web is easy for anyone to roam, browse and contribute." Examples of Web 2.0 applications, such as Wiki projects, refer to collaborative computer software used to create collaborative websites that now provide an infrastructure for an even more dynamic user participation, social interaction and collaboration, and demonstrate the direction of future knowledge creation and dissemination. As a concept, the WWW thus represents a "seamless world in which all information, from any source can be accessed" and connected though links (Ibid.).

As a conceptual model, the WWW demonstrates the coexistence of and interrelationships between multiple and apparently contradictory perspectives on a single issue. It is a good example of a "space" allowing for various "narratives", and "knowledges" to circulate, and to be added to existing collections and systems of meaning (cf. Seely Brown et al.,1989, p. 39). The WWW exemplifies that there is not only one kind of valid knowledge that can be viewed as absolute and universally applicable. It shows instead that there are various kinds of knowledges, situated within various communities of knowing, each operating according to

particular cultural dynamics, yet sharing in universal issues that affect us all. When applied to the educational context, these properties also point toward a collaborative model of instruction, suitable for a culturally diverse student body.

Collaborative teaching practices are in many ways exemplified by the open-ended structure and nonlinearity of the Web, which has great potential to support communication across and among diverse communities of knowers (Campbell, 2004). The diversity of materials found on the Web and their coalescence is similar to the diversity of perspectives and knowledges that coalesce within a cross-cultural community of learners. Like collaborative teaching and learning, the loose organization of the World Wide Web demonstrates the coexistence of multiple and apparently contradictory perspectives on a single issue. One Google keyword search will retrieve hundreds of documents linked by one single term, but applied in a variety of contexts. This characteristic of the Web environment, just like collaborative and cooperative teaching, emphasizes the importance of individual contexts to which a single concept can be applied productively. In the fluid online environment, supported by teaching that is social and interactive, learners no longer rely on a situation where the instructor provides a single learning context and suggests the desired connections among the offered concepts. They are encouraged to generate connections between problems and solutions, and apply the findings in a transformative way to a variety of contexts meaningful to them.

The Web, as a platform in which collaborative teaching can happen, is open, flexible, multimodal, and networked, and as such it provides "the richest opportunity to date to bring the elements of active learning together" (Campbell, 2004, p. 154). It resists systematization in a traditional sense, it allows for multimodal teaching and learning, and it accommodates multiple 'literacies' and learning styles. The non-linear and interactive multimedia capacity inherent in the Web and forms of CMC can present knowledge and information in ways that combine orality, literacy and "videocy" (Ulmer, 1989, p. vii). In this way, CMC and the properties of the World Wide Web can support the complex range of learning needs, characteristics and preferences. Web-based communication tools such as email, relay-chat, forums, and synchronous (i.e., realtime) conferencing are seen as potentially enabling dialogue. In turn, dialogue encourages critical thinking and cooperative learning, and enhances opportunities for "generative learning, wider diversity of ideas, most reflective thinking, and increased creative responses" (Oliver, Omari & Herrington, 1998). The hypermedia most effectively support tasks and forms of interaction requiring high-level reasoning, problem-solving skills, and critical thinking (Nunes & Fowell, 1996; Ryser, Beeler & McKenzie, 1995).

Forms of online teaching and learning relying on CMC, in general, have been termed "collaborative technologies" since they have an inherent affinity with definitions of learning emphasizing social, interpersonal, and collaborative interaction. Even simple, text-based CMC "equalizes the participants to the extent that everyone, regardless of gender, race, authority, age, etc., is limited to exchanging texts" (Markham, 1998, p. 155). There are factors that need to be taken into consideration, such as economic status or individual facility with manipulating texts in CMC, as they may affect the potential equality of participants (Mason, 2002). It is clear, however, that new models of communication enabled by the WWW lead to breaking down, or at least diminishing the distinction between "private and public writing" (Bolter, 1991, p. 102), and thus potentially create a space for constructive communicative intimacy. This trait is valuable in cross-cultural CMC where the onus is on the instructor to create a sense of trust and open-mindedness in an inclusive and culturally diverse learning community. The potential of the Web to support collaborative teaching, multiple learning styles, and to foster critical thinking is especially important for cross-cultural teaching where the diversity of learning styles is matched and often conditioned by diversity in cultural perspectives.

The nonlinearity of the presentation of materials and ides on the World Wide Web is a useful conceptual and philosophical model for collaborative, cooperative teaching and learning. The nature of the presentation of material and ideas on the WWW encourages active, intentional involvement on the part of learners, as there is no longer one "solution" or a single "interpretation," but a variety, all situated within their own context and knowledge. Due to its multimedia capacity, online communication and the WWW facilitate the use of tools promoting connectivity, transfer, the seeking of interrelationships among texts and/or audio-visual materials. They enable the creation of various interpretive contexts in instruction, relevant given the cultural differences in learning and communication styles. The nonlinearity of the Web models scaffolding as a way of grouping materials; it promotes the idea that conceptual knowledge cannot be separated from the contexts in which it is represented, as well as that learning works best when it is situated in the individual learner's implicit knowledge.

There are a number of practical issues that instructors who teach collaboratively in cross-cultural contexts in online education could consider in order to utilize the conceptual potential of the WWW. What follows are some issues arising from the ideas presented:

1. **Success in communication depends on the context of reception:** The outcome and success of communication in general is largely dependent on the context of reception. In face-to-face interaction, body language allows interlocutors to interpret meaning that may not be present in verbal content. This context is mostly absent in online communication. With cross-cultural communication in particular, educators should be aware

that "cultures vary in what they consider humor and taboo, which may give rise to misinterpretation and resentment, and that speed of delivery…as well as turn-taking should be respected, as much as the rules for entering conversations in progress" (Zeinstejer, 2002). In addition to using emoticons to reveal the intention in which a statement is made and the hoped-for response, a good way of dealing with potential ambiguity would be to acknowledge openly at the beginning of the learning unit that language, as a communicative tool, is embedded in a number of culture-specific uses, and as such, it can be ambiguous[b].

2. **Design for interaction and collaboration by gaining a clear sense of "audience":** In order to avoid some of the common challenges that accompany cross-cultural communication, instructors could ask participants to fill out a "pre-course" questionnaire. In designing the questionnaire, the instructor may consider how to obtain answers to questions such as: Who are the learners? What is their attitude toward interaction? What do they need or want to learn? In what contexts will the learning be applied? What do they already know?
3. **Organize material in a nonlinear, open-ended format and provide opportunities for learning in context:** Part of the interaction and the structuring of materials should be done in the form of scaffolding, which is a nonlinear, open-ended way of organizing data and enabling learners to adopt the suggested material in a way that allows them to apply it to their own needs, values and contexts. Scaffolding also enables learning in context in that it encourages "continuous sorting and sifting as part of a 'puzzling' process—the combining of new information with previous understanding to construct new ones" (McKenzie, 1999). Open-endedness of approach can be also encouraged by involving students at all level of instruction in "the choice of content, method, medium, reward, assistance, feedback, quantity, pacing, sequencing, or difficulty of instruction" (Sutton, 2004, p. 34), and by creating opportunities for group-learning.
4. **Set clear and explicit expectations for online behavior and communication:** Because of different cultural attitudes toward communication and participation in a group, it will be the instructor's role at the beginning of the learning unit to express general expectations for online behavior and communication. These expectations should be explicit about removing language that appears to stereotype learners and reducing the violations of cultural rules during discussions (Zeinstejer, 2002). The instructor may model continuously the idea that many of the beliefs we take for granted are in fact culturally determined, and that successful communication is based on an honest, benevolent and non-judgmental approach to cross-cultural differences.
5. **Provide opportunities for different kinds of online interaction:** Collaborative interaction occurs when learners have the opportunity to engage in activities enabling individual learning, learning done in pairs or through email (one-to-one), through the use of a bulletin board (one-to-many), and the use of computer conferencing techniques (many-to-many) (Hao, 2004, p. 25). The variety of interactions will successfully address the variety of different learning styles, as well as the students' culturally-determined approaches to communication and to knowing.
6. **Asynchronous communication is preferable for online learning:** Asynchronous communication—enabled by tools such as discussion and bulletin boards, blogs, messaging, surveys and polls—provides opportunities for active input from all members of the learning community with flexibility in time and place, so learners have greater control over the learning environment (Carr, 1998; Graham, Scarborough & Goodwin, 1999; Hao, 2005), as well as an opportunity for "vicarious interaction". Vicarious interaction takes place when a student actively observes and processes both sides of interaction between another student and instructor. This type of interaction is of special value in cross-cultural education as it promotes indirectly, but through conversational situations, awareness and understanding of the issues involved in cross-cultural communication (Chorney, 2007). Synchronous or "realtime" interaction enabled by tools such as Web, audio or video conferencing, chatting, instant messaging and white boarding, is a good supplement to the asynchronous delivery medium (Hao, 2004).
7. **The evaluation scheme should be varied and flexible:** When knowledge is understood as an active, flexible process of "meaning negotiation" in which multiple ways of arriving at different "knowledges" exist, are validated and lead to the same learning goals, the nature and design of student evaluation shifts. In a cross-cultural educational context, content itself may be redefined from emphasizing the gathering and arrangement of factual information in traditional academic formats, to emphasizing various aspects of the research process resulting in a variety of nontraditional formats that can be evaluated with equal academic rigor. Content can be information, as well interpretation of information by experts, novices or students. It can be in the form of research reports generated individually or with a partner/group, arguments, journalistic accounts, and essays represented through text, graphics or any other multimedia format. Similarly, in addition to the instructor, peers can provide feedback.

These practical approaches can help instructors create online learning environments that are inclusive, and that demonstrate the dynamic of successful cross-cultural communication in an educational context using the potential offered by the WWW and CMC.

FUTURE TRENDS

The long-term value of the collaborative approach in cross-cultural teaching contexts can be seen in the correlation between dominant media and cultural practices, including education. Whereas traditional "mass education tended to see life in a linear fashion based on print models and developed pedagogies which broke experience into discrete moments and behavioral bits," new critical pedagogies enabled through the online medium could produce "skills that enable individuals to better navigate the multiple realms and challenges of contemporary life" (Kellner, n.d., p. 9).

A more systematic study of the ways diverse information can be linked and presented on the WWW can take us one step further toward revisioning the goals of education in the 21st century. Most important for the future, further study of collaborative online education in relation to cross-cultural contexts has the potential to provide concrete answers to the call for meaningful reform of higher education (cf. Association of American Colleges and Universities, 2002). Technology and international distance education are already an undeniable presence and a growing trend in higher education. The student body increasingly reflects an extraordinarily diverse array of cultural backgrounds. These facts place an increasing need on institutions and instructors to develop new approaches to educational quality in a way that would serve meaningfully the needs of contemporary students who live in complex, technologized and interconnected world.

Modeling collaborative teaching practices on the WWW may promote the forms of learning needed for the 21st century, as they have been identified by the "Greater Expectations National Panel Report" (Association of American Colleges and Universities, 2002). Taking into consideration that the intellectual and practical skills today's students need are extensive, sophisticated and expanding with the explosion of new technologies, and the changes they have brought to education, cross-cultural collaborative teaching in the online environment will help students become "intentional learners". Intentional learners are those who can "adapt to new environments," who can integrate different kinds of knowledge from a variety of sources, who can "demonstrate intellectual agility and the ability to manage change," and who have the skills to engage in a meaningful dialogue and deal with the interrelations within and among global and cross-cultural communities (adapted from the recommendations of the National Panel Report, pp. xi-xii). Future research may investigate whether systematization of training in cross-cultural communication and collaboration in a variety of contexts, including online education, would help alleviate many of the crises in cross-cultural communication we face today.

CONCLUSION

As a concept, the WWW can illustrate many of the philosophical aspects that should accompany successful cross-cultural communication. Many of the practices associated with collaborative teaching and not new and are being used by many instructors in any classroom. However, the increase in online educational programs compels us to thoroughly examine pedagogical practices and the goals of teaching in an increasingly interconnected global world. These new educational trends encourage us to explore and apply systematically certain teaching practices that can improve the quality of cross-cultural education, especially when delivered by monocultural teachers.

Intentional assessment of the nature the World Wide Web in its potential to enable successful cross-cultural communication in online education can result in the development of pedagogical strategies suited to contemporary realities and the needs of contemporary students (cf. Association of American Colleges and Universities, 2002). The changes will ensure a decrease of instances where many cultural groups feel excluded from e-learning opportunities because the instructional content and the nature of the interaction is not culturally inclusive (cf. Campbell, 2004).

The online environment, usually synonymous with the World Wide Web, can be used as a tool and a model to encourage cross-cultural interactivity and to support forms of open-ended, collaborative teaching techniques. The structural flexibility that is the hallmark of this kind of instruction is similar to the structural flexibility and conceptual "open-endedness" of the Web. The multiplicity of perspectives represented on the Web and their coexistence could remind us that being exposed to and learning to see the world from another's point of view is a process of

cognitive and social growth that can deepen our understanding of ourselves and others.

KEY TERMS

Analytical Learning Style: (In contrast to global learning style); According to one classification, a style of learning associated with students from Europe, North America, Australia and New Zealand, and with being text -oriented and competitive, asserting oneself, learning by reasoning, preferring direct expressions, and valuing the rational and objective.

Collaborative Teaching: "Open-ended" teaching practice according to which learning is a process achieved through social and interpersonal interaction. It demonstrates the coexistence of multiple and often contradictory perspectives on the same issue; it encourages the discovery of connections among those perspectives, and emphasizes the importance of individual contexts to which new concepts can be applied productively.

Collaborative Technologies: Technologies enabling computer-mediated communication (CMC) have been termed "collaborative" because of their inherent affinity with definitions of learning emphasizing social, interpersonal, and collaborative interaction.

Cross-Cultural Communication: Communication between members of different cultures through which each member's values and patterns of thinking, communication and behavior are often revealed as contrasting the values,

patterns of thinking, communication, and behavior of the other.

Culture: Sets of social relationships, values, patterns of thinking, communicating and behaving that reflect ideas and actions established and accepted by one group of people as habitual, appropriate, or traditional.

Global Learning Style: (In contrast to analytical learning style); According to one classification, a style of learning associated with Japanese students, and with being image-oriented and cooperative, avoiding standing out, depending on insight and intuition, learning by experience, preferring indirect expressions, and valuing the subjective.

Intentional Learners: Model learners of the 21st century, as identified in the Association of American Colleges and Universities Report (2002). They are those who can adapt to new environments, engage in meaningful dialogue, integrate different kinds of knowledge from different sources, demonstrate intellectual agility, and the ability to deal successfully with interrelations within and among global and cross-cultural communities.

Learning Styles: a broad, nonrestrictive combination of cognitive, affective and physiological factors influencing how a learner perceives, interacts and responds to the learning environment.

Transformative Communication: The model of communication between students and instructor through which collaborative teaching happens. It emphasizes the instructor's willingness to learn from students while helping to establish expectations and clear assessment standards.

Vicarious Interaction: Indirect kind of interaction that takes place when a student actively observes and processes both sides of interaction between two other students or between another student and instructor.
