- **LDQ caching:** Validity region is the essential information for LDQ caching schemes. Much research has been done in algorithms to generate LDQ result VR; and there are several algorithms for the DB server to determine the VR for an NN query result. Zheng and Lee (2001) built a static *Voronoi diagram* (VD) to index the objects in SDBS by partitioning the plane into Voronoi cells (VC), one for each object. The VC is a convex polygon that consists of the points closer to the object in this VC than to any other objects. As a result, VD is the most suitable mechanism to find the NN and the corresponding VR: the object in the same VC with the querying locations is the NN result, and the VC is the corresponding nearest neighbor validity region (NNVR). It is, however, expensive to maintain VD due to DB updates, and it is also inapplicable for the *k* nearest neighbor (*k*-NN) query when *k* is unknown. Even when *k* is known, an order-*k* VD is very expensive in terms of computational and storage overhead (Zhang, Zhu, Papadias, Tao, & Lee, 2003). Consequently, Zhang et al. (2003) introduced algorithms to calculate NNVRs during run time that avoids the large storage overhead at the expense of extra computing overhead.

A window VR is therefore the region within which the result set remains unchanged. The Minkowski region (MR) is introduced to examine the VR of a window query result set, which may contain zero, one, or multiple results. The MR of an object is an axis-parallel rectangle identical to the query window whose geometric center is the corresponding object. If the querying position is within the MR of an object *a*, then object *a* will be a result. Otherwise, object *a* is not in the window query result set. Thus, the VR of a window query result set is the area that is within the MRs of all result objects, and outside the MRs of all other objects.

LDQ caching has attracted much research attention. Ren and Dunham (2000) proposed a semantic caching scheme for location dependent results. An incoming query is decomposed into two disjointed parts: a probe query that can be answered by the cached data and a remainder query that has to be answered by the DB server. This scheme reduces the network traffic, allows query resolution during the disconnection, and in some cases allows partial query resolution. Zheng, Xu, and Lee (2002) presented algorithms for cache invalidation and cache replacement strategies that takes the validity of information into account. Zheng, Lee, and Lee (2004) presented a semantic NN caching scheme and addressed mobile user's intercell roam issues. The aforementioned caching schemes rely on DB servers to provide VRs for the LDQ results. Considering that DB servers may not always provide VRs for LDQ results due to the computation and storage overhead, Gao and Hurson (2005) and Gao, Sustersic, and Hurson (2006) suggested an LDQ proxy caching scheme where the proxy can calculate the estimated validity regions (EVR) for the LDQ result based on the querying history and the cache contents.

FUTURE TRENDS

In the next few years, LBS growth will continue with the following trends (Desiniotis, Markoulidakis, & Gaillet, 2006):

- **Market value:** Several reports published around 2000 claimed that LBS would become the most promising "killer applications," with billions of revenue in a few years. Unfortunately, those predictions were not met. A recent Juniper Research report estimates the total available market for mobile LBS will reach $8.5 billion by end of 2010 (Juniper, 2005) considering the fast growth of markets in Asia Pacific region.
- **Mobile devices:** The mobile devices will have more functions, better connection, and improved usability.
- **Vehicle navigation devices:** One major pushing power for the growth of LBS market is the increasing popularity of portable navigation devices such Garmin and Tom-Tom. These devices will be less expensive and equipped with more functions such as music player, hands-free phone kit, a Web browser, and so forth.
- **Improved accuracy:** Accuracy and compatibility of LBS are going to be critical competitive factors for carriers to compete for customers in the future. Most LBS carries currently using GPS system will move toward A-GPS that offers greater accuracy levels.

The research topics in LBS system will continue in LDQ query processing and caching. At the same time, more attention might be given to emerging topics or concerns. Vehicular users desire to exchange information between neighboring vehicles; thus, short range communication protocols need to be proposed for various applications. Security is always a concern and deserves continuous study in the future LBS system. LBS system tends to collect users' information and statistics to improve system performance, which raises the research topics on user privacy.

CONCLUSION

LBS have attracted much attention from both researcher and service providers in the past a few years. This article reviewed different types LBS services and described its system components. It also discusses several important research issues and the future trend of LBS.

KEY TERMS

Geographic Information Systems: A computer system designed for storing, manipulating, analyzing, and displaying data in a geographic context.

Location Aware Query: is the query with certain location constraints.

Location-Based Services: Personalized services based on certain location constraints, normally the user's current location.

Location Dependent Query: The query whose result depends on the users' current location.

Nearest Neighbor: A query that returns the nearest objects to the user.

Spatial Database: A database system that offers spatial data types in its data model and query language and supports spatial data types in its implementation.

Validity Region: A regions where a location dependent query result remains valid.

Window Query: A query that returns all satisfying database objects within an axis-parallel rectangle centered at the querying position.

Machine Learning

INTRODUCTION

Machine learning techniques have been successfully applied to several real world problems in areas as diverse as image analysis, Semantic Web, bioinformatics, text processing, natural language processing,telecommunications, finance, medical diagnosis, and so forth.

A particular application where machine learning plays a key role is data mining, where machine learning techniques have been extensively used for the extraction of association, clustering, prediction, diagnosis, and regression models.

This text presents our personal view of the main aspects, major tasks, frequently used algorithms, current research, and future directions of machine learning research. For such, it is organized as follows: Background information concerning machine learning is presented in the second section. The third section discusses different definitions for Machine Learning. Common tasks faced by Machine Learning Systems are described in the fourth section. Popular Machine Learning algorithms and the importance of the loss function are commented on in the fifth section. The sixth and seventh sections present the current trends and future research directions, respectively.

BACKGROUND

Machine learning can be seen as a subfield of artificial intelligence (Bratko, 1984) and is influenced by works on statistics (inference and pattern recognition [Duda & Hart, 1973; Fukunaga, 1990]), databases (analytical and multivariate databases [Berson & Smith, 1997]).

Machine learning is strongly linked to search, optimization, and statistics. Several models present optimization mechanisms, like support vector machines. Others are based on statistics inference, for instance, Bayesian classifiers.

Machine learning models have been extensively used in data mining. Data mining is concerned with the discovery of useful information in large databases. Very often, the observations need to be collected, selected, and preprocessed before machine learning techniques can be employed. It is important to mention that data mining relies not only on machine learning, but also on statistics, artificial intelligence, databases, and pattern recognition.

WHAT IS MACHINE LEARNING?

Informally speaking, the main goal of machine learning is to build a computational model from past experience of what has been observed. For such, machine learning studies the automated acquisition of domain knowledge looking for the improvement of systems performance as result of experience.

In the beginning of the 1980s, Michaslky, Carbonell, and Mitchell (1983) presented one of the first definitions of machine learning "Self-constructing or self-modifying representations of what is being experienced for possible future use" (p. 10).

The focus of this definition is on programs that modify themselves in response to feedback from their environment. This definition reflects the main research lines at that time: expert systems (Weiss & Kulikowski, 1991), automatic programming, and reinforcement learning (Sutton, 1998).

A more recent definition appears in (Hand, Mannila, & Smyth, 2001) "Analysis of observational data to find unsuspected relationships and to summarize the data in novel ways that is both understandable and useful for the data owner" (p. 1).

An even more recent definition is due to (Alpaydin, 2004), where machine learning is defined as "Programming computers to optimize a performance criterion using example data or past experience" (p. 3).

Clearly, the task here is much closer to a data analysis task, enlarging the range of practical applications, mainly industrial and commercial, where machine learning is frequently employed. In any case we can define machine learning as the acquisition of a useful (understandable) representation of a data set from its extensional representation.

MACHINE LEARNING TASKS

In a basic learning task, observations take the form of pairs. $\{\vec{x}, y\}$ The elements of the vector $\vec{x}$ are named *independent*

variables or *attributes* and the dependent variable $y=f(\vec{x})$ is an unknown function. The learning task is to obtain a predictive model or an approximation function $\hat{f}$ able to predict ŷ for future observations of the independent variables $\vec{x}$ (Mitchell, 1997). In this framework, we can consider two different problems: *classification problems,* whenever *y* takes values in a finite set of unordered values (e.g., $y \in \{C_1,...,C_n\}$), and *regression problems,* when *y* takes values in a subset of *R*. In machine learning theory, these observations are assumed to be independent and generated at random, according to a stationary probability distribution. This task is referred as *predictive or supervised learning*, because the value of the target variable *y* in the observations or training set is known.[1] When there is no clear target variable in the training set, we have an unsupervised learning task.

Several areas of human activity can involve *supervised machine learning*: predicting the use of land based on satellite images; assigning credit to individuals on the basis of financial information; sorting letters on the basis of machine readable post codes; preliminary diagnosis of a patient's disease; and so forth. Several problems in industry, commerce, and science are *decision problems* and require the analysis of complex and extensive data. Most of these problems can be analyzed from a supervized machine learning perspective (Witten & Frank, 2005).

In contrast to predictive learning, *descriptive or unsupervised learning models* provide compact representations for the whole data or for the process generating the data. Examples of such descriptions include models for density estimation, clusters analysis and segmentation, and models describing relations between variables. This task includes data synopsis or signatures (Arasu & Manku, 2004), data visualization, and cluster analysis (Berthold & Hand, 1999; Duda, Hart, & Stork, 2001).

MACHINE LEARNING ALGORITHMS

We can formalize a machine learning problem as either a parameter optimization problem or a hypothesis search problem. In the former, examples are points in a multi-dimensional space associated with a metric. The goal is to minimize a loss function. Illustrative examples following this approach are *k-nearest neighbor* (Aha, 1997), discriminant functions (Duda et al., 2001), and neural networks (Ripley, 1996). In the later, a language used to represent generalizations of examples defines a search space of possible hypothesis. The learning algorithm performs a search in this space. The goal is to find the best hypothesis, a state in the search space that maximizes some objective function. Illustrative examples of this approach are decision trees (Breiman, Friedman, Olshen, & Stone, 1984; Quinlan, 1993), decision rules (Quinlan, 1993), and Bayesian networks (Neapolitan, 2003).

Each approach employs a different representation schema and explores different search strategies. A representation is the decision structure of a certain type (i.e., a decision tree, a set of discriminant equations, a table of conditional probabilities, etc.) used to generalize the examples. The representation used by a learning algorithm restricts the set of hypotheses considered by the algorithm. Some authors call it the *restricted hypotheses space bias* (Mitchell, 1990).

A *search strategy* is the set of methods and heuristics used to explore the search space defined by the set of possible representations. Associated with each search strategy is the *evaluation component.* This component is used to guide the search, by either preferring one hypothesis over others or by ranking the set of possible hypotheses. Both the search strategy and the evaluation component have preferences on the possible set of hypotheses. Such preference is also known in the machine learning literature as *preference bias*, because it imposes a certain preference order on the elements of the hypotheses space. A commonly used heuristic is *to prefer general hypotheses over specialized ones*. For example, if we consider decision trees, this corresponds to the preference of small trees to larger ones.[2] This kind of preference that minimizes the syntactic complexity of the hypotheses representation reduces the chance of the model overfitting the training observations. Overfitting occurs when the model is over-adjusted to the training data. Overfitting decreases the model generalization, that is, its capacity to correctly classify new observations.

There is a strong relation between overfitting and the *Occam's razor* (Blumer, Ehrenfeucht, Haussler, & Warmuth, 1990), which states, "The simpler of two competing hypotheses should always be preferred."

One argument in favor of simplicity is that there are fewer simple hypotheses than complex ones (based on combinatorial arguments). As such, if both fit the data, we should prefer the simpler hypothesis because it is less likely to be a statistical coincidence (Mitchell, 1997). Domingos' (1998a) work presents a thorough discussion about the interpretation of Occam's razor in the context of machine learning. Domingos concludes "if a model with low training-set error is found within a sufficiently small set of models, it is likely to also have low generalization error" (p. 37). Therefore a fully adequate model evaluation is only possible if the search process by which the models are obtained is also taken into account (Domingos, 1998b).

Another general heuristic claim is, "Examples that are near in the instance space correspond to similar concepts." This heuristic is fully exploited in the so-called *instance-based learning*, also known as *lazy learning,* where learning consists in memorizing previous observations, as in k-nearest neighbor and *case-based reasoning* (Aamodt & Plaza, 1994). The term *lazy learning* is used because instead of estimating the target function once for the entire instance space, these algorithms delay learning until they need to output a pre-

diction. The approximate function is estimated locally and differently for each query example. Further developments of lazy learning lead to *local weighted regression* (Moore, Schneider, & Deng, 1997), *radial basis functions* (Powell, 1992), and so forth.

Other machine learning models extract general hypotheses from a set of previous observations, process named employ Inductive Learning. These models can obtain an arbitrarily good fit to the data by considering very complex hypotheses.

Some of these models, like decision trees, are symbolic, knowledge-based models. Decision trees approximate discrete functions by building a tree where each node tests the value of a particular attribute. Branches are associated to the possible results of this test (Mitchell, 1997). The hypothesis space of decision trees is within the disjunctive normal form (DNF) formalism. The conditions along a branch represent conjuncts, and the individual branches can be seen as disjuncts. Each branch forms a rule with a conditional part and a conclusion. The conditional part is a conjunction of conditions. There are clear relations between decision tree learning and rule-based learning algorithms (Wnek & Michalski, 1994). Both use the same representation language, and use a hill-climbing algorithm. While most of decision tree learning algorithms use a top-down, general-to-specific strategy, in rule learning both general-to-specific and specific-to-general (bottom up) are possible.

In order to avoid overfitting, they require a technique to balance the complexity of the hypothesis against the number of training examples misclassified by the hypothesis. One such technique is the *minimum description length* (Rissanen, 1983) which states, "The best hypothesis is the one that minimizes the total length of the hypothesis plus the description of the exceptions to the hypothesis" (p. 420).

The intuition is that the ad hoc hypothesis consists of a list of examples that make them no shorter than the examples. In contrast, good hypotheses reduce many examples to a single, general rule.

Other models have strong roots in statistics, particularly neural networks, support vector machines, hidden Markov models (HMM), and Bayesian networks. It must be observed that both machine learning and statistics infer hypothesis from observations. But unlike statistics, machine learning is also concerned with the analysis of the computational complexity of the algorithms employed.

Neural networks learning methods are based on the structure and functionalities of the nervous system (Haykin, 1998). Several different models have been proposed. The most popular being *multi-layer perception* is based on layers of processing units computing simple mathematical functions. These units are linked by weighted connections whose values are adjusted by the back propagation learning algorithm (Rumelhart, Hinton, & Williams, 1986). This algorithm overcomes problems pointed out by Minsky and Papert (1969).

Support vector machines are based on the *statistical learning theory* (Vapnik, 1995). Binary classifiers show high generalization capability by looking for a hyperplane that maximizes the separation margin between observations from different classes. The use of kernels allows their use for nonlinear problems.

HMM are probabilistic models, stochastic finite state automata, used for making a sequence of decisions [Rabiner, 1989]. They are and have been frequently applied to time series and linear sequences. They model a temporal problem by a set of discrete states and transition probabilities between the states. Thus, an HMM is a model that generates sequences. They are frequently used in speech recognition and prediction of protein structure.

Bayesian networks (Neapolitan, 2003) are probabilistic models for knowledge representation under uncertainty. They represent the joint probability distribution of a set of variables. Bayesian networks consist of a graphical model representing the set of independent assumptions and a set of probabilistic conditional tables representing $P(x \mid Parents(x))$. Graphical models can be used in a set of learning tasks, like prediction, diagnosis, and clustering.

Each machine learning algorithm can be characterized by the representation used for the acquired knowledge and the approach employed for hypothesis search. Both *representation* and *search* define a unique *learning bias* for each algorithm (Merz, 1998). A key issue in machine learning is the interdependence between representation and learning. In the next section we present some machine learning techniques used to extend the representational ability of systems.

Loss Functions

A requirement in any learning problem is to identify what we would like to minimize or approximate. We need to define a criterion to measure the quality of any estimator $\hat{f}$. In the machine learning literature, the criteria frequently considered include error rate, comprehensibility, compactness, learning speed, classification speed, and so forth.

In predictive learning, the most relevant dimension is the *error rate*. It is an estimator of the difference between $\hat{f}$ and the unknown *f*. We need to distinguish between two notions of error rate. One, denoted as *resubstitution error rate*, estimates the error rate from the training set. The other, the *generalization error rate*, estimates the error from an independent test set. What we usually wish to know is the generalization error rate, because this is the error that can be expected when applying the model to future examples. The error rate is computed as the ratio between the number of misclassifications and the total number of examples. In a most general scenario we are interested in measuring the loss incurred by a model, $\hat{f}$ given an example $\vec{x}$. The loss

measures the difference between $\hat{f}(\vec{x})$ and the true label $f(\vec{x})$. In the classification setting, the 0-1 loss function is the most commonly used. The loss is 0 if $\hat{f}(\vec{x}) = f(\vec{x})$ and 1 otherwise. In the regression setting, the *squared loss* defined as $(f(\vec{x}) - \hat{f}(\vec{x})^2$ is commonly used. The 0-1 loss function assumes equal loss for all misclassifications. To minimize this problem, a promising research line is the *receiver operational characteristic* (Provost, Fawcett, & Kohavi, 1998). The squared loss has interesting properties: It is derivable and decomposable into bias plus variance. Similar decompositions appear recently for 0-1 loss (Kohavi & Wolpert, 1996). The desirable characteristics of loss functions include: fast computation, derivable, decomposable, and must be convex in order to ensure uniqueness of the solution.

In 1995, Vapnik proposed another minimization criterion: the *risk minimization principle*. Algorithms like support vector machines, instead of minimizing a function of the error, minimize the margin, which is defined as the distance between the nearest examples (the support vectors) and the decision surface. This criterion has been shown to be very powerful in minimizing the generalization error (Duda et al., 2001; Hastie, Tibshirani, & Friedman, 2000).

CURRENT TRENDS IN MACHINE LEARNING

A main issue in current machine learning research is the model selection problem. This issue can be summarized as: For a given dataset what is the most suitable model? When the learning problem is defined by a fixed set of examples the most common strategy consists of estimating the error rate employing a pool of learning algorithms using some sampling method. The most common used sampling strategies are *cross validation*, *leave-one-out,* and *holdout*. In any case, we must guarantee that the error estimate is unbiased, meaning that it should be obtained as the error in a set of examples independent from those used to train the algorithm.

Any learning algorithm has its own area of applicability: There are problems where an algorithm exhibits good generalization performance and other problems without generalization capacity.

A promising research area is metalearning (Brazdil, Gama, & Henery, 1994), which try to characterize the applicability of learning algorithms using data characteristics, like statistical measures (e.g., class distribution, correlation between attributes, etc.) and data information based measures (mean entropy of attributes, noise-signal ratio, etc.). Characterizing the area of applicability of learning algorithms is useful for model selection in similar problems. Most of the works in metalearning use cross validation and statistical hypothesis testing to evaluate the significance of differences. Nevertheless, several authors refer that there is a trade-off between the systematic errors due to the representational language used by an algorithm (the *bias*) and the *variance* due to the dependence of the model to the training set (Breiman, 1998). When using more flexible representations the bias is reduced. Model selection using cross validation does not provide the complete picture. Whenever comparing algorithms with different degrees of complexity the bias-variance decomposition of the error rate could provide useful information.

Another approach to the model selection problem are the *ensemble models* (Kittler, 1998; Kuncheva, 2004). Instead of using a single learning algorithm, we should train a large set of classifiers, whose predictions are averaged to obtain a final prediction for a test example. Averaging over a large set of models has clear impact in the variance of individual models. This is the case of *bagging*, a successful technique when used in conjunction with decision trees (Breiman, 1998). Another popular ensemble technique able to reduce the bias and the variance components of the error is *boosting* (Schapire, Freund, Bartlett, & Lee, 1997).

Until now, we have assumed an attribute-value representation for data. Each example is described by a set of variables (a record in database terminology) and a set of examples is stored in a matrix (a relation or table in database terminology). Some of the most challenging applications of machine learning are: data are better described by sequences (i.e., DNA data), trees (XTML documents), and graphs (chemical components, network analysis). Inductive logic programming (Muggleton, 1992, 1998) goes behind the propositional representation of data by learning from relations and generating decision models in the form of logic programs. A very good review of the state of the art of graph-based mining appears in (Washio & Motoda, 2003). Related areas involve learning from scientific data (Bock & Diday, 2000), semi-structured text, or relational databases (Berson & Smith, 1997).

Most of the machine learning research in the past focuses on improving learning algorithms either by using more powerful representation languages or by improving search. Most of the algorithms were memory based and required all training data to fit in the memory. However, the exponential increase of data stored in large databases, usually collected over time during months or years, poses new algorithmic problems. Moreover, in some situations like sensor networks, TCPIP traffic, e-commerce, and Web sites, data flow at high speed. It is now more possible to store all data in memory and perform multiple scan over training data. To increase the difficulty of the learning problem the target concept can change over time. These observations lead to the development of research on scaling-up learning algorithms (Provost & Hennessy, 1996), sequential learning from data streams and dynamic environments (Guha, Meyerson, Mishra, Motwani, & O'Callaghan, 2003), and very fast machine

learning (Domingos & Hulten, 2000; Hulten, Spencer, & Domingos, 2001).

This and other related issues related to the design and analysis of machine learning models are the main focus of a research area known as *computational learning theory* (Valiant, 1984). This area investigates aspects as model complexity, accuracy estimation, and sample complexity.

FUTURE TRENDS

The key issue in the first machine learning definition, "Self-constructing or self-modifying representations of what is being experienced for possible future use" (p. 10) is the word *self*: systems that modify themselves to better fit or accommodate to the environment. The future of machine learning points to autonomous systems that can incorporate domain knowledge; learn from distributed sources in nonstationary and dynamic environments; and can transfer knowledge between learning systems.

CONCLUSIONS

In this text, we presented our view of the main aspects of machine learning, a research area that is facing a fast and steady growth. As the results of this growth, new research lines and application opportunities are continually emerging.

Machine learning research is fastly growing in both academic and industry. In academia, machine learning research groups can be found in different areas, like computer science and engineering, electrical engineering, statistics, economics, and business. In industry, several companies have started using machine learning either in the development of their products or as part of them.

Research in machine learning has benefited several social and economic sectors, providing new approaches for medical diagnosis, fault detection, time series analysis, and environmental monitoring, among several others.

ACKNOWLEDGMENT

The authors would like to thank the project ALESII sponsored by Fundação Ciência e Tecnologia, POSI/EIA/55340/2004, and CNPq for the financial support.

KEY TERMS

Artificial Intelligence: The area of information technology concerned with the automation of reasoning, learning, and perception.

Bayesian Networks: Probabilistic models for knowledge representation under uncertainty.

Data Mining: The process of extraction of useful information in large databases.

Decision Tree: A symbolic learning classifier that represents a discrete function by a decision tree.

Hidden Markov Models: Stochastic models capable of performing a sequence of decisions.

Inductive learning: A learning approach based on the induction of a general concept from a limited set of observations.

LazyLearning: A learning approach where the instances are memorized.

Machine Learning: The programming of computers to optimize a performance criterion using example data or past experience.

Neural Networks: Learning models based on the structure and processing of the nervous system.

Support Vector Machines: Large margin models based on statistical learning theory.

ENDNOTES

1 We should note that *classification* is known in statistics as *discriminant analysis* (Hastie et al., 2000).

2 In nested trees smaller trees correspond to more general ones.

Machine Learning Through Data Mining

Diego Liberati
Italian National Research Council, Italy

INTRODUCTION

In dealing with information it often turns out that one has to face a huge amount of data, often not completely homogeneous and often without an immediate grasp of an underlying simple structure. Many records, each one instantiating many variables, are usually collected with the help of various technologies.

Given the opportunity to have so many data not easy to correlate by the human reader, but probably hiding interesting properties, one of the typical goals one has in mind is to classify subjects on the basis of a hopefully reduced meaningful subset of the measured variables. The complexity of the problem makes it worthwhile to resort to automatic classification procedures.

Then, the question arises of reconstructing a synthetic mathematical model, capturing the most important relations between variables, in order to both discriminate classes of subjects and possibly also infer rules of behaviours that could help identify their habits.

Such interrelated aspects will be the focus of the present contribution. The data mining procedures that will be introduced in order to infer properties hidden in the data are in fact so powerful that care should be put in their capability to unveil regularities that the owner of the data would not want to let the processing tool discover, like for instance, in some cases the customer habits investigated via the usual smart card used in commerce with the apparent reward of discounting.

Four main general purpose approaches will be briefly discussed in the present article, underlying the cost effectiveness of each one.

In order to reduce the dimensionality of the problem, simplifying both the computation and the subsequent understanding of the solution, the critical issues of selecting the most salient variables must be addressed. This step may already be sensitive, pointing to the very core of the information to look at.

A very simple approach is to resort to cascading a divisive partitioning of data orthogonal to the principal directions (PDDP) (Boley, 1998) already proven to be successful in the context of analyzing micro-arrays data (Garatti, Bittanti, Liberati, & Maffezzoli, 2007).

A more sophisticated possible approach is to resort to a rule induction method, like the one described in Muselli and Liberati (2000). Such a strategy also offers the advantage to extract underlying rules, implying conjunctions or disjunctions between the identified salient variables. Thus, a first idea of their even nonlinear relations is provided as a first step to design a representative model, whose variables will be the selected ones. Such an approach has been shown (Muselli & Liberati, 2002) to be not less powerful over several benchmarks than the popular decision tree developed by Quinlan (1994). An alternative in this sense can be represented by Adaptive Bayesian networks (Yarmus, 2003) whose advantage is also to be available on a commercial wide spread data base tool like Oracle.

Dynamics may matter. A possible approach to blindly build a simple linear approximating model is thus to resort to piece-wise affine (PWA) identification (Ferrari-Trecate, Muselli, Liberati, & Morari, 2003).

The joint use of (some of) such four approaches briefly described in this article, starting from data without known priors about their relationships, will allow to reduce dimensionality without significant loss in information, then to infer logical relationships, and, finally, to identify a simple input-output model of the involved process that also could be used for controlling purposes, even those potentially sensitive to ethical and security issues.

BACKGROUND

The introduced tasks of selecting salient variables, identifying their relationships from data, and classifying possible intruders may be sequentially accomplished with various degrees of success in a variety of ways:

- Principal components order the variables from the most salient to the least one, but only under a linear framework.
- Partial least squares do allow to extend to nonlinear models, provided that one has prior information on the structure of the involved nonlinearity; in fact, the regression equation needs to be written before identifying its parameters.
- Clustering may operate even in an unsupervised way without the a priori correct classification of a training set (Boley, 1998).
- Neural networks are known to learn the embedded rules with the indirect possibility (Taha & Ghosh,

1999) to make rules explicit or to underline the salient variables.
- Decision trees (Quinlan, 1994) are a popular framework providing a satisfactory answer to the recalled needs.

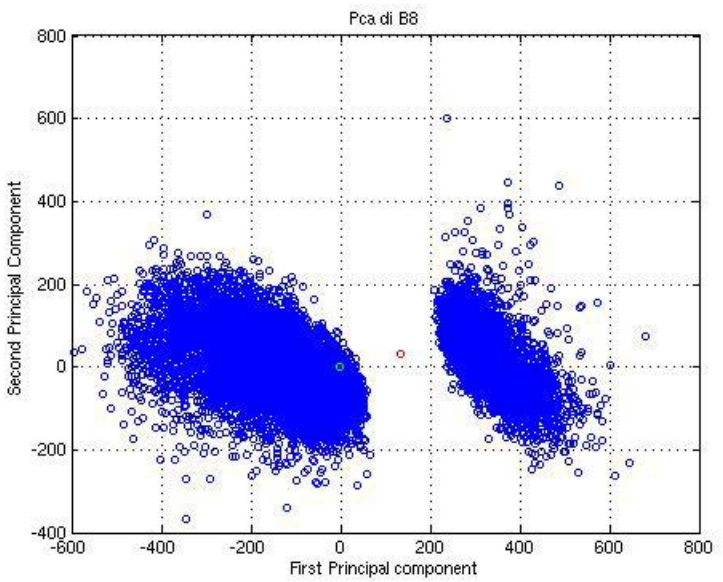
RECENT DEVELOPMENTS

Unsupervised Clustering

In this contribution, we will firstly resort to a quite recently developed unsupervised clustering approach, the Principal Direction Divisive Partitioning (PDDP) algorithm, proposed in Boley (1998). According to the analysis provided in Savaresi and Boley (2004), PDDP is able to provide a significant improvement of the performances of a classical k-means approach (Hand, Mannila, & Smyth, 2001; MacQueen, 1967), when PDDP is used to initialize the k-means clustering procedure. The approach taken herein may be summarized in the following three steps, the second of which is the core of the method, while the first one constitutes a preprocessing phase useful to ease the following tasks, and the third one is a postprocessing step designed to focus back on the original variables.

1. A principal component analysis defines a hierarchy in the transformed orthogonal variables according the principal directions of the data set. Principal Component Analysis (O'Connel, 1974; Hand et al., 2001) is a multivariate analysis designed to select the linear combinations of variables with higher intersubject covariances. Such combinations are the most useful for classification. More precisely, it returns a new set of orthogonal coordinates of the data space, where such coordinates are ordered in decreasing order of intersubject covariance.
2. The unsupervised clustering is performed by cascading a noniterative technique, the PDDP, (Booley, 1998) based upon singular value decomposition (Golub & van Loan, 1996), and the iterative centroid-based divisive algorithm k-means (MacQueen, 1967). Such a cascade, with the clusters obtained via PDDP used to initialize k-means centroids, is shown to achieve best performances in terms of both quality of the partition and computational effort (Savaresi & Boley, 2004). The whole dataset is thus bisected into two clusters, with the objective of maximizing the distance between the two clusters and, at the same time, minimizing the distance among the data points lying in the same clusters. The classification is achieved without using a priori information on the user (unsupervised learning), thus automatically highlighting the user belonging to a (possibly unknown) user class.
3. By analyzing the obtained results, the number of variables needed for the clustering may be reduced by pruning all the original variables that are not needed in order to define the final partitioning hyperplane, so that the classification eventually is based on a few variables only.

Figure 1. Clustering according to principal components



Binary Rule Inference and Variable Selection While Mining Data Via Logical Networks

Recently, an approach has been suggested—Hamming clustering—that is related to the classical theory exploited in minimizing the size of electronic circuits, with the additional care taken to obtaining a final function able to generalize from the training dataset to the most likely framework describing the actual properties of the data. In fact, the Hamming metric tends to cluster samples whose code is less distant. This is likely to be natural, if variables are redundantly coded via thermometer (for numeric variables) or only-one (for logical variables) code (Muselli & Liberati, 2000). The approach followed by Hamming clustering in mining the available data to select the salient variables and to build the desired set of rules consists of the three following steps:

Step 1: A critical issue is the partition of a possibly continuous range in intervals. In this way, the training process does not require floating point computation, but only basic logic operations. This is one reason for the algorithm speed and for its insensitivity to precision.

Step 2: In literature, classical techniques of logical synthesis are specifically designed to obtain the simplest AND-OR expression able to satisfy all the available input-output pairs without an explicit attitude to generalize. To generalize and infer the underlying rules, at every iteration, Hamming clustering groups together, in a competitive way, binary strings having the same output and close to each other. A final pruning phase does simplify the resulting expression, further improving its generalization ability. Moreover, the minimization of the involved variables intrinsically excludes the redundant ones, thus enhancing the very salient variables for the investigated problem. The low (quadratic) computational cost allows managing quite large datasets.

Step 3: Each logical product directly provides an intelligible rule, synthesizing a relevant aspect of the searched underlying system that is believed to generate the available samples.

The Hamming clustering approach has the following remarkable properties:

- It is fast, exploiting (after the mentioned binary coding) just logical operations instead of floating point multiplications.
- It directly provides a logical understandable expression (Muselli & Liberati, 2002), which is the final synthesized function directly expressed as the OR of ANDs of the salient variables, possibly negated.

Adaptive Bayesian Networks Under Minimum Description Length

An alternative learning strategy that looks for a trade-off between a high predictive accuracy of the classifier and a low cardinality of the selected feature subset may be derived according to the central hypothesis that a good feature subset contains features that are highly correlated with the class to be predicted, yet uncorrelated with each other. Based on information theory, the Minimum Description Length (MDL) principle (Barron, Rissanen, & Yu, 1998) states that the best theory to infer from training data is the one that minimizes the length (i.e., the complexity) of the theory itself and the length of the data encoded with respect to it. In particular, MDL can be employed as a criterion to judge the quality of a classification model.

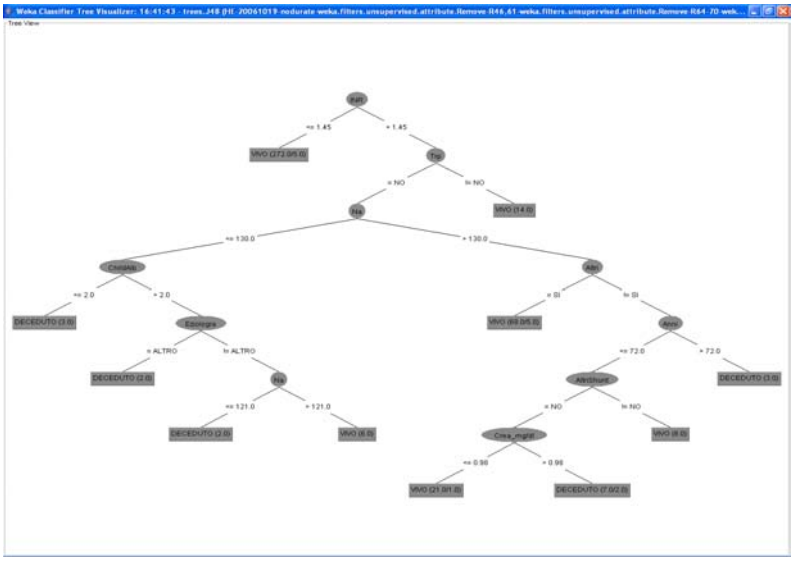
The motivation underlying the MDL method is to find a compact encoding of the training data. To this end, the MDL measure introduced in Friedman, Geiger, and Goldszmidt (1997) can be adopted, weighting how many bits one needs to encode the specific model (i.e., its length), and how many bits are needed to describe the data based on the probability distribution associated to the model.

This approach can be applied to address the problem of feature selection, by considering each feature as a simple predictive model of the target class. As described in Kononenko (1995), each feature can be ranked according to its description length, which reflects the strength of its correlation with the target. In this context, the MDL measure is given by Yarmus (2003), again weighting the encoding length, where one has one submodel for each value of the feature, with the number of bits needed to describe the data based on the probability distribution of the target value associated to each submodel.

However, once all features have been ordered by rank, now a priori criterion is available to choose the cut-off point beyond which features can be discarded. To circumvent this drawback, one can adopt a wrapper approach that starts with building a classifier on the set of the n-top ranked features. Then, a new feature is sequentially added to this set, and a new classifier is built, until no improvement in accuracy is achieved.

In the framework of Bayesian Networks, it is useful to step from Naïve Bayes (NB) to the Adaptive Bayesian Network (ABN), as recalled in the following. NB is a very simple Bayesian Network consisting of a special node (i.e., the target class) that is the parent of all other nodes (i.e., the features or attributes) that are assumed to be conditionally independent, given the value of the class. The NB network can be "quantified" against a training dataset of preclassified instances, that is, one can compute the probability associated to a specific value of each attribute, given the value of the class label. Then, any new instance can be easily classified

Figure 2. Decision tree obtained from Bayesian Networks. The rounded nodes of bifurcation are the salient variables, and the branches are labeled with their sets implying either outcome, represented by the squared leaves counting the corresponding events over the number of wrong attributions.



making use of the Bayes rule. Despite its strong independence assumption among variables is clearly unrealistic in most application domains, NB has been shown to be competitive with more complex state-of-the-art classifiers. (Cheng & Greiner, 1999; Friedman et al., 1997; Keogh & Pazzani, 2002).

In the last years, a lot of research has focused on improving NB classifiers by relaxing their full independence assumption. One of the most interesting approaches is based on the idea of adding correlation arcs between the attributes of a NB classifier. On these "augmenting arcs" are imposed specific structural constraints (Friedman et al., 1997; Keogh & Pazzani, 2002), in order to maintain computational simplicity on learning. The algorithm here proposed, the Adaptive Bayesian Network (Yarmus, 2003), is a greedy variant, based on MDL, of the approach proposed in Keogh and Pazzani (2002).

In brief, the steps needed to build an ABN classifier are the following. First, the attributes (predictors) are ranked according to their MDL importance. Then, the network is initialized to NB on the top k-ranked predictors, which are treated as conditionally independent. Next, the algorithm attempts to extend NB by constructing a set of tree-like multidimensional features.

Feature construction proceeds as follows. The top ranked predictor is stated as a seed feature, and the predictor that most improves feature predictive accuracy, if any, is added to the seed. Further predictors are added in such a way to form a tree structure, until the accuracy does not improve.

Using the next available top ranked predictor as a seed, the algorithm attempts to construct additional features in the same manner. The process is interrupted when the overall predictive accuracy cannot be further improved or after some preselected number of steps.

The resulting network structure consists of a set of conditionally independent multi-attribute features, and the target class probabilities are estimated by the product of feature probabilities. Interestingly, each multidimensional feature can be expressed in terms of a set of if-then rules enabling users to easily understand the basis of model predictions.

Piece-Wise Affine Identification Through a Clustering Technique

Once the salient variables have been selected, it may be of interest to capture a model of their dynamical interaction. A first hypothesis of linearity may be investigated, usually being only a very rough approximation, when the values of the variables are not close to the functioning point around which the linear approximations computed.

On the other hand, to build a nonlinear model is far from easy. The structure of the nonlinearity needs to be a priori known, which is not usually the case. A typical approach consists of exploiting a priori knowledge, when available, to define a tentative structure, then refining and modifying it on the training subset of data, and finally retaining the structure that best fits a cross-validation on the testing subset of data. The problem is even more complex when the collected data

exhibit hybrid dynamics (i.e., their evolution in time is a sequence of smooth behaviours and abrupt changes).

An alternative approach is to infer the model directly from the data without a priori knowledge via an identification algorithm capable of reconstructing a very general class of piece-wise affine model (Ferrari-Trecate et al., 2003). This method also can be exploited for the data driven modeling of hybrid dynamical systems, where logic phenomena interact with the evolution of continuous-valued variables. Such an approach will be described concisely in the following.

Piece-wise affine identification exploits k-means clustering that associates data points in multivariable space in such a way to jointly determine a sequence of linear submodels and their respective regions of operation without even imposing continuity at each change in the derivative. In order to obtain such a result, the following five steps are executed:

Step 1: The model is locally linear; small sets of data points close to each other likely belong to the same submodel. For each data point, a local set is built, collecting the selected points together with a given number of its neighbours (whose cardinality is one of the parameters of the algorithm). Each local set will be pure if made of points really belonging to the same single linear subsystem; otherwise, it is mixed.

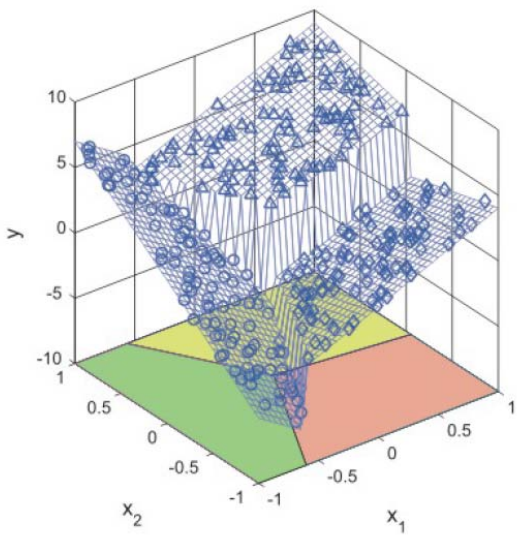
Step 2: For each local dataset, a linear model is identified through usual least squares procedure. Pure sets belonging to the same submodel give similar parameter sets, while mixed sets yield isolated vectors of coefficients, looking as outliers in the parameter space. If the signal to noise ratio is good enough, and if there are not too many mixed sets (i.e., the number of data points is enough more than the number of submodels to be identified, and the sampling is fair in every region), then the vectors will cluster in the parameter space around the values pertaining to each submodel, apart from a few outliers.

Step 3: A modified version of the classical k-means, whose convergence is guaranteed in a finite number of steps (Ferrari-Trecate et al., 2003), takes into account the confidence on pure and mixed local sets in order to cluster the parameter vectors.

Step 4: Data points are then classified, each being a local dataset one-to-one related to its generating data point, which thus is classified according to the cluster to which its parameter vector belongs.

Step 5: Both the linear submodels and their regions are estimated from the data in each subset. The coefficients are estimated via weighted least squares, taking into account the confidence measures. The shape of the polyhedral region characterizing the domain of each model may be obtained via linear support vector machines (Vapnik, 1998), easily solved via linear/quadratic programming.

Figure 3. Piece Wise Affine identification of dependence of measurements Y on conditioning variables X_1 and X_2



FUTURE TRENDS

The proposed approaches are now being applied in several contexts, such as bioinformatics, geo-informatics, neuro-informatics, systems biology and in general complex systems modeling. Nonetheless, on the methodological side, even further improvements are under consideration, like for instance Dynamics Bayesian Networks, aiming to join the inference capabilities of the Bayesian Networks with the identification of a dynamical model proper of approaches like the piece-wise affine one.

CONCLUSION

The proposed approaches are very powerful tools for quite a wide spectrum of applications in and beyond data mining, providing an up-to-date answer to the quest of formally extracting knowledge from data and sketching a model of the underlying process. The fact that a combination of different approaches, taken from partially complementary disciplines, proves to be effective may indicate a fruitful direction in combining in different ways classical and new approaches

to improving classification, making machine learning more and more sensitive to a variety of scientific issues.

KEY TERMS

Hamming Clustering: A fast binary rule generator and variable selector able to build understandable logical expressions by analyzing the Hamming distance between samples.

Hybrid Systems: Their evolution in time is composed by both smooth dynamics and sudden jumps.

***k-means*:** Iterative clustering technique subdividing the data in such a way to maximize the distance among centroids of different clusters, while minimizing the distance among data within each cluster. It is sensitive to initialization.

Model Identification: Definition of the structure and computation of its parameters best suited to mathematically describe the process underlying the data.

PDDP (Principal Direction Divisive Partitioning): One-shot clustering technique based on principal component analysis and singular value decomposition of the data, thus partitioning the dataset according to the direction of maximum variance of the data. It is used here in order to initialize k-means.

Principal Component Analysis: Rearrangement of the data matrix in new orthogonal transformed variables ordered in decreasing order of variance.

Rule Inference: The extraction from the data of the embedded synthetic logical description of their relationships.

Salient Variables: The real players among the many apparently involved in the true core of a complex business.

Singular Value Decomposition: Algorithm able to compute the eigenvalues and eigenvectors of a matrix; also used to make principal components analysis.

Unsupervised Clustering: Automatic classification of a dataset in two of more subsets on the basis of the intrinsic properties of the data without taking into account further contextual information.

Making Sense of IS Failures

Darren Dalcher
Middlesex University, UK

INTRODUCTION

Researchers with a keen interest in information systems failures are faced with a double challenge. Not only is it difficult to obtain intimate information about the circumstances surrounding such failures, but there is also a dearth of information about the type of methods and approaches that can be utilized in this context to support such information collection and dissemination. The purpose of this chapter is to highlight some of the available approaches and to clarify and enhance the methodological underpinning that is available to researchers interested in investigating and documenting phenomena in context-rich and dynamic environments. The chapter concludes by introducing a new range of antenarrative approaches that represent future developments in the study of IS failures.

BACKGROUND

Contemporary software development practice is regularly characterized by runaway projects, late delivery, exceeded budgets, reduced functionality, and questionable quality that often translate into cancellations, reduced scope, and significant re-work cycles (Dalcher, 1994). Failures, in particular, tell a potentially grim tale. In 1995, 31.1% of US software projects were cancelled, while 52.7% were completed late, over budget (cost 189% of their original budget), and lacked essential functionality. Only 16.2% of projects were completed on time and within budget; only 9% in larger companies, where completed projects had an average of 42% of desired functionality (Standish, 2000). The 1996 cancellation figure rose to 40% (ibid.).

The cost of failed US projects in 1995 was $81 billion. In addition, cost overruns added an additional $59 billion ($250 billion was spent on 175,000 US software projects, however $140 billion out of this was spent on cancelled or over budget activities) (Standish, 2000). In fact, Jones (1994) contended that the average US cancelled project was a year late having consumed 200 percent of its expected budget at the point of cancellation. In 1996, failed projects alone totalled an estimated $100 billion (Luqi and Goguen, 1997). In 1998, 28% of projects were still failing at a cost of $75 billion, while in 2000, 65,000 of US projects were reported to be failing (Standish, 2000). As of 2004 partial failures still accounted for over 50% of all projects (Standish, 2004), whilst the figure for total failures continues to hover around the 20-25% mark.

The Standish Group makes a distinction between failed projects and challenged projects. Failed projects are cancelled before completion, never implemented, or scrapped following installation. Challenged projects are completed and approved projects which are over-budget, late, and with fewer features and functions than initially specified. Lyytinen and Hirschheim (1987) identify correspondence failures (where the system fails to correspond to what was required), process failures (failure to produce a system or failure to produce it within reasonable budgetary and time-scale constraints), interaction failures (where the system cannot be used, or is not satisfactory in terms of the interaction) and expectation failures (where the system is unable to meet a specific stakeholder group's expectations). Many situations contain behavioral, social, organizational, or even societal factors that are ignored and, therefore, the definition of failure needs to encompass a wider perspective. The general label "system failures" is often utilized in order to embrace a wider grouping of failures, including ones with undesirable side effects which may impact other domains and the organizational context (e.g., Fortune & Peters, 1995). As information becomes more embedded in other domains, the scope and impact of failure becomes more wide-reaching. This was clearly evident from the extensive effort to minimize the impact of the "year 2000 bug" from any system containing computers and underscores our interest in utilizing the term IS failure to describe a wider class of systems failures that impact on individuals, organizations and societal infrastructure.

IS failure investigations start with extensive attempts to collate relevant evidence. However, in most cases the researcher is exposed to specific information post-hoc, that is, once the failure is well established and well publicized and the participants have had a chance to rationalize their version of the story. Most of the available sources are, therefore, already in place and will have been set up by agencies other than the researcher.

The purpose of a forensic investigation is to explain a given failure by using available information and evidence. The term *forensic* is derived from the Latin 'Forensis', which is to do with making public. *Forensic science* is the applied use of a body of knowledge or practice in determining the cause of death. Nowadays extended to include any skilled investigation into how a crime was perpetrated, forensic systems engineering is the post-mortem analysis and study

of project disasters (Dalcher, 1994). The work involves a detailed investigation of a project, its environment, decisions taken, politics, human errors, and the relationship between subsystems. The work draws upon a multidisciplinary body of knowledge and assesses the project from several directions and viewpoints. The aim of forensic analysis is to improve the understanding of failures, their background, and how they come about (Dalcher, 1997). The concept of systems is a central tool for understanding the delicate relationships and their implications in the overall project environment.

Forensic systems engineering is primarily concerned with documentary analysis and (post-event) interviews in an effort to ascertain responsibility lines, causal links, and background information. The primary mode of dissemination of findings, conclusions, and lessons is through the publication of case study reports focusing on specific failures. However, there are limited research methods to explore the dynamic and fragmented nature of complex failure situations. Lyytinen and Hirschheim (1987) noted that more qualitative research methods were needed for IS failure research as well as more extensive case studies that explored problems in more detail and viewed solution arrangements in light of what transpired. The same methods also need to account for group issues and cultural implications. Sadly, twenty years on, the same constraints in terms of methods are still in evidence.

DESCRIBING FAILURE

Making sense of IS failures retrospectively is difficult. In general, there is very little objective quantitative failure information that can be relied upon. This makes the utilisation of quantitative methods less likely, until all relevant information is understood. Interpretation requires understanding of and engagement with the wider context. Indeed, a specific feature of failure is the unique interaction between the system, the participants, their perspectives, complexity and technology (Perrow, 1984). Lyytinen and Hirschheim (1987) pointed out that failure is a multifaceted phenomenon of immense complexity with multiple causes and perspectives. Research into failures often ignores the complex and important role of social arrangement embedded in the actual context. This is often due to the quantitative nature of such research. More recently, Checkland and Holwell (1998) argued that the IS field requires sensemaking to enable a richer concept of information systems.

Understanding the interactions that lead to failures likewise requires a humanistic stance that is outside the conventional positivist norm to capture the real diversity, contention, and complexity embedded in real life. Forensic analysis thus relies on utilizing qualitative approaches to obtain a richer understanding of failure phenomena in terms of action and interaction.

The fact that a failure phenomenon is being investigated, suggests that attention has already been drawn to the complexities, breakdowns, and messy interactions that such a situation entails (i.e., the investigation is problem-driven). Many such inquiries deal with subjective accounts including impressions, perceptions, and memories. The aim of the researcher is to increase, in a systemic way, the understanding of a situation, yet do so from a position that takes in the complexity of the entire situation and incorporates the different perspectives and perceptions of the stakeholders involved.

Overall, the purpose of a failure research method is to enable the researcher to make sense of the complexity of detail and the complexity of interaction, and chart the contributory role of different causes and issues in the build up to failure. However, the armoury of research methods in this domain is often limited to case studies.

The term "case study" is an umbrella term used in different contexts to mean different things that include a wide range of evidence capture and analysis procedures. Yin (1994, p.13) defines the scope of a case study as follows:

"A case study is an empirical inquiry that:

- investigates a contemporary phenomenon within its real-life context, especially when
- the boundaries between phenomenon and context are not clearly identified".

A case study can be viewed as a way of establishing valid and reliable evidence for the research process as well as presenting findings which result from research (Remenyi, 1998). According to Schramm (1971) the case study tries to illuminate a decision or a set of decisions and, in particular, emphasize why they were taken, how they were implemented, and with what results. A case study is likely to contain a detailed and in-depth analysis of a phenomenon of interest in context; in our case, the failure scenario. Table 1 summarizes some of the main advantages of using case studies.

The general aim of the case study approach is to understand phenomena in terms of issues in the original problem context by providing the mechanism for conducting an in-depth exploration. They often result from the decision to focus an enquiry around an instance or an incident (Adelman, Jenkins, and Kemmis., 1977), as they are principally concerned with the interaction of factors and events (Bell, 1999). The combination of a variety of sources offers a richer perspective which also benefits from the availability of a variety and multiplicity of methods that can be used to obtain new insights about this single instance. A case study allows the researcher to concentrate on specific instances in their natural setting and thereby attempt to identify the interacting perceptions, issues, and processes at work, ultimately resulting in in-depth understanding. Crucially, the focus on

Table 1. Main advantages of using case studies

✓	ability to identify and focus on issues
✓	richness of detail
✓	multiple perspectives
✓	multiple sources and types of data
✓	multiple explanations (no absolute truth)
✓	cross disciplinary remit
✓	ability to recognise and minimise inherent complexity
✓	ability to handle conflict, disparity and disagreement
✓	ability to show interactions
✓	ability to observe emerging patterns
✓	opportunity to focus on the particular
✓	gain real insight and understanding of a situation
✓	conducted in real-life (natural) setting
✓	encompasses original problem context
✓	ability to deal with interpretations
✓	features intensive analysis
✓	can extend the boundaries to include aspects of wider system environment
✓	can be accumulated to form an archive of cases
✓	can be strengthened and expanded with longitudinal features
✓	often retold in story format, which is more accessible to practitioners

a single incident thus enables the study of the particularity and complexity of a case, thereby coming to understand the activity within important circumstances (Stake, 1995).

There are a number of general objections that are associated with the use of case studies (see Table 2). However, one must recognize that case studies are more likely to be used retrospectively rather than as an on-going perspective (especially from a failure point-of-view), as researchers are unlikely to know the potential for useful results and interest from the outset and may have difficulty in negotiating access to the location.

Comprehensiveness of coverage is not necessarily a requirement. The richness of detail can be controlled through the careful placement of systems boundaries and consideration of the wider system environment that is relevant to the specific phenomenon under study. Case studies can

Table 2. Main objections to the use of case studies

❖	sometimes viewed as soft data (but some argue it is hard research)
❖	biases inherent in accepting views and perceptions
❖	questions about generalizability of findings (especially from a single case), but it is possible to build a library of such cases
❖	issues regarding objectivity of approach and perceived lack of rigour
❖	negotiating access to settings
❖	boundaries are difficult to define; but this could also be a strength!
❖	mainly retrospective
❖	sometimes viewed as likely to take too long and result in massive documentation
❖	the observer effect
❖	reliability of conclusions
❖	there is little control over events, but this may also be a strength

be utilized as a source of understanding, which is tolerant of ambiguity, paradox, and contradiction. A case study is viewed as interpretative when events in the real world are observed and then an effort takes place to make sense of what was observed, that is, when one tries to make sense of a failure from the perspectives of participants. They also offer the potential for generating alternative explanations from the different stakeholder perspectives thereby allowing the researcher to highlight contradictions, conflicts, and misunderstandings.

FROM CASE STUDIES TO CASE HISTORIES

The generally liberal use of the term *case study* requires a tighter definition of its meaning in failure research. While there may be a tradition of using case studies within the IS community, this is perhaps more often borrowed from the MBA culture than as a result of self-conscious effort to adopt them as a research approach (Cornford and Smithson, 1996; Walsham, 1993). Indeed, the case study is typically used more in its capacity as a teaching tool than as a *research tool*. The shift to studying the impact of issues within the organisational context renders case studies particularly useful for investigating failure scenarios. However, the use of the term often leads to some confusion.

Moreover, one of the major complications in failure investigations is in relating causes to effects (and possibly events) through extended time horizons (Dalcher, 2000). The implications of actions may not be witnessed for years, or even generations. Delays between making a decision and observing the result distort the causal link between the two. As a result, people tend to associate a different level of severity to events occurring following a delay. The perceived severity is, thus, diminished with the length of the delay further complicating the task of identifying patterns and interactions that contributed to a given failure. Failure researchers are, thus, required to provide adequate historical accounts of the interaction between actions, perceptions, and the passage of time.

Case studies have typically been used to explore issues in the present and the past and comprise of ethnographic studies, single case studies, and comparative case studies (Jankowicz, 2000), as well as action research, evaluative, exploratory, explanatory, and descriptive case studies (Bassey, 1999). In our experience there is a need to add the failure case study as a special example of a case study focusing primarily on the background, context, perception, interactions and patterns, especially as the failure investigation is likely to take place after the (failure) event. We, thus, propose the use of the label *case histories* to refer to the specialized historical research studies focusing on failure incidents.

The time dimension (sequencing) is critical to understanding interactions and identifying their impacts. Case histories are concerned with providing the background and context that are required to endow words and events with additional meaning. Background refers to previous history of the system itself, while context refers to interactions with the environment. As failures are time-and-place-dependent, the case history framework enables readers to obtain an understanding of the intimate context surrounding the main event. The primary tool available to the community is the case histories of failures (derived from the use of the case study method). These represent a detailed historical description and analysis of actual processes from a relevant perspective. Their value is in tracing decisions (and recorded rationale) to their eventual outcomes by utilizing techniques borrowed from decision analysis and systems engineering. Indeed, the historical description and presentation of a chronology of events infused with meaning, intention, and understanding are based on the recognition that real life is ambiguous, conflicting, and complex.

Case histories thus contain observations, feelings and descriptions. They can be used to construct, share, dispute and confirm meanings, interpretations and scenarios in the context of real events (e.g., Dalcher, 1995, 2004, 2007). Rather than simply highlight a chronicled sequence of happenings, they convey a story encompassing a specific perspective, focus, and possibly some inevitable biases. The interpretation plays a key part in transmutating the chronicle into a meaningful story with plot, coherence, and purpose. However, constructing a convincing narrative of a complex story with competing meanings, alternative perspectives, and inherent prejudices is a challenge in itself.

FUTURE TRENDS

Failures, in common with other activities that take place in organizations, are based on stories. The verbal medium is crucial to understanding behavior within organizations and systems, and researchers are, thus, required to collect *stories*, grounded in practice, about what takes place (Brown, Denning, Groh and Prusak, 2005; Denning, 2007; Easterby-Smith, Thorpe and Lowe, 2002; Gabriel, 2000; Gargiulo 2005; Matthews and Wacker, 2008; Simmons, 2007; White, 1973). Gargiulo (2005) further asserts that effective organizational communication and learning is dependent upon stories. Listening to them is critical to the success of the organization. Understanding failures often entails the retrospective untangling of complicated webs of actions and events, and emergent interaction patterns. Failure storytelling can, thus, be understood as a combination of narrative recounting of empirical events with the purposeful unlocking of meaningful patterns, or a plot.

Historically, storytelling has been an acceptable form of conveying and sharing ideas, norms, values, experience, and knowledge of context. It plays a key role in communicating the cultural, moral, or historical context to the listener. Indeed, Arendt, (1958) argued that the chief characteristic of human life is that it is always full of events which ultimately can be told as a story. There are even strong claims that the narrative is the main mode of human knowledge (Bruner, 1990; Schank, 1990), as well as the main mode of communication, learning, and thinking (Denning, 2001; Fisher, 1987; Gargiulo, 2005; Schank, 1990). Moreover, children are often initiated into culture (and its boundaries) through the medium of storytelling, offering models for emulation or avoidance.

In practice, the essence of any good case study revolves around the ability to generate an effective storyline, normally with a unique style, plot, or perspective. In a large case, a general theme can be obtained from selected excerpts weaved together to illustrate a particular story. Personal stories that form part of a case study can, thus, be viewed as a valid source of data organized to make sense of a theme or problem. This is particularly useful when the researcher is trying to portray a personal account of a participant, a stakeholder, or an observer in an incident, accident, or failure. The implication is that the need to address personal aspects of interaction and story is fulfilled by the development of a research-valid narrative. Indeed, Remenyi, et al. (1998) contend that a story, or a narrative description, is valid if the resulting narrative adds some knowledge. Furthermore, White (1973) describes a story as "the process of selection and arrangement of data from the unprocessed historical record in the interest of rendering the record more comprehensible to an audience of a particular kind" by inserting a sense of perspective and purpose.

Storytelling can endow listeners with different meanings as stories can be understood in multiple ways. Narratives are neither discovered, nor found; they are constructed. Understanding IS failures is, therefore, more complicated than the discovery of a simplistic chronology of events as stories are crystallized through infusion with meaning and context. Narrative inquiry is evolving into an acceptable research approach in its own right in the social sciences and in management research circles (Bell, 1999; Boje, 2001; Czarniawska, 1998, 2004; Gabriel, 2000; Easterby-Smith, et al., 2002) as the story format provides a powerful way of knowing and linking disparate accounts and perspectives. When different accounts are combined, the emerging story line benefits from the richness of multifaceted insights.

Developing a narrative requires plot as well as coherence as a story is made out of events and the plot mediates between the events and the story (Boje, 2001; Carr, 2001; Kearney, 2002). The narrative can, thus, become a powerful mechanism for eliciting and sharing experience through intimate reflection. In failure stories, the plot often emanates from the actions and perceptions of participants emerging out of the flux of events, in (direct) contradiction with expectations. The storyteller is concerned with the perspective and purpose of participants as well as with the plausibility of the emerging plot. The combination of plot, purpose, and perspective dictates the selection of elements, the filling in of links, and the removal of "irrelevant" noise.

Post-modern interpretation contends that most real life stories are fragmented, non-linear, discontinuous, multivariate, and incoherent. This has already been highlighted as a feature of failure stories. Such stories also tend to be dynamic, polyphonic (multi-voiced), and collectively produced as they occur in asymmetrical, random, and turbulent environments full of tensions and ambiguities. The stories are not plotted as such and they appear to flow, emerge, and network offering complex clustering of events, emergent phenomena, causes, and effects. Moreover, the accounts are often subjective, counter-intuitive, and contradictory. This leads to interacting and conflicting webs of narratives, characterized by coincidences, predicaments, and crises.

Generally, stories appear to be improperly told, as a story is an "ante" state of affairs existing previously to a carefully constructed narrative (Boje, 2001). The *antenarrative*, or the "real" story, is the fragmented, messy, and dynamic, multivocal, multi-plotted, multi-version, and complex tale. Indeed, modern storytellers look for new ways and mediums for weaving and depicting a multi-vocal reality, as exemplified by Mike Finggis's digitally shot film *Time's Arrow,* where the screen is split in four to allow for four separate perspectives and sub-stories that occasionally intersect or overlap. In the tradition of post-modern inquiry, a real life researcher is often faced with fragments rather than a whole story to tell; and many of the fragments may reflect contrary versions of reality. This is potentially more acute when the accounts attempt to justify roles of participants in the lead-up to disaster. It would also appear from past analysis that there are hierarchies of stories and stories that exist within, or interact with, other stories. Using the terminology provided by Boje, (2001), the purpose of narrative methods is to take a complex situation characterized by collective (yet often conflicting) memory and an antenarrative, and construct the plot and coherence that can be used to narrate the story of interest.

The reality in failure stories is of multi-stranded stories of experiences and reactions that lack collective consensus. Indeed, the discipline of decision making has also recognized that making choices is about forming and selecting interpretations from a mosaic of possibilities (March, 1994, 1997; Weick, 1995). Not surprisingly, disasters or traumatic stories are hard to narrate, understand, and justify. Stories have three basic properties: time, place, and mind (Boje, 2001), which interact and build up as the story evolves. In forensic case histories, these are further clarified through the

identification of the background and context which clarify and justify the interpretation in the context of the emerging phenomena.

Boje (2001) and Kearney (2002) contend that the current view is of sequential single voice stories and implies excessive reliance on the hypothetical-deductive approach (akin to simplistic causal pairings). Imposing a meaning is insufficient and inadequate as actors need to find their own voice and make collective sense of a situation. The answer is not to develop Harvard type case studies, but to rewrite stories as polyvocal tapestries enabling different perceptions and interpretations to exist, thereby explaining webs of actions and interactions. What is new in this approach is the antenarrative reading which enables narrative analysis methods to be supplemented by antenarrative methods, allowing previously fragmented and personal storytelling to be interpreted as a unified whole. This focus offers alternative discourse analysis strategies that can be applied where qualitative story analyses can help to assess subjective, yet "insightful" knowledge in order to obtain "true" understanding of complex interactions.

As for the long term future, good stories can also benefit from pictures. Once we have mastered the techniques of telling complex, modern stories, we need to focus on composing that information. Even the most gripping story needs to be made attractive and believable. Textual information needs additional support not only in "emplotting" and in maintaining coherence and perspective, but also in ascertaining the plausibility of constructed stories and in differentiating between noise and narrative. Developing improved techniques for organizing or visualizing knowledge (such as Net maps) can, therefore, help in untangling some of the fragmented strands as well as in making the stories more readable and understandable, and, ultimately, more appealing.

CONCLUSION

Stories provide a powerful research tool that can be used to reflect, share, and make sense. With the benefit of hindsight, it is possible to reconstruct a systematic re-telling of events that have led to a failure. The narrated structure provides an explanation as to how and why failures occur. The purpose of the structure is to make sense of a rich tapestry of interactions and connections by following an identified storyline that chronicles and links the relevant issues within the environment. Engaging with the world of others through the medium of a story enables a deeper and richer reflection. Indeed, recounted life may prize open perspectives that would have been inaccessible using ordinary methods and thinking arrangements. Moreover, failure tends to highlight missing and incorrect assumptions, and faulty defensive mechanisms, and can, therefore, serve as a pretext to updating the frame of reference or the context for understanding as the listeners learn to construct a meaning and make sense of a highly multifaceted, multilayered, and complex situation.

KEY TERMS

Antenarrative: The fragmented and messy and dynamic stories of real life in their original context before a clear narrative is developed to explain away a certain aspect.

Case History: Specialized historical research focusing on failure incidents. Case histories emphasize the background and context that can help in untangling relationships and causes thus making sense of the events leading to the failure.

Case Study: Investigation of phenomena in naturalistic setting, conducted in order to enable in depth analysis of that phenomena.

Challenged Projects: Completed and approved projects which are late, over budget, and have fewer features and functions than originally specified. The degree of challenge depends on the way constrains are applied and interpreted within the organisation.

Failed Projects: Projects that are: cancelled before completion, are never implemented or are scrapped following installation. May also apply to projects that involve significant litigation.

Forensic Systems Engineering: Post-mortem analysis and study of a project failure or disaster aimed at uncovering causes and relationships.

Storytelling: A method of communicating and sharing ideas, experiences and knowledge in a specific context.

Management Considerations for B2B Online Exchanges

Norm Archer
McMaster University, Canada

INTRODUCTION

Information systems that link businesses for the purpose of inter-organizational transfer of business transaction information (inter-organizational information systems, or IOIS) have been in use since the 1970s (Lankford & Riggs, 1996). Early systems relied on private networks, using electronic data interchange (EDI) or United Nations EDIFACT standards for format and content of transaction messages. Due to their cost and complexity, the use of these systems was confined primarily to large companies, but low-cost Internet commercialization has led to much more widespread adoption of IOIS. Systems using the Internet and the World Wide Web are commonly referred to as B2B (business-to-business) systems, supporting B2B electronic commerce.

Technological innovations have led to several forms of B2B Internet implementations, often in the form of online exchanges. These are virtual marketplaces where buyers and sellers exchange information about prices, products, and service offerings, and negotiate business transactions. In addition to substituting proprietary lines of communication, emerging technologies and public networks have also facilitated new business models and new forms of interaction and collaboration, in areas such as collaborative product engineering or joint offerings of complex, modularized products. During the years 1999-2001 a number of online exchanges were introduced, but many of these failed (Gallaugher & Ramanathan, 2002), due mainly to an inability to attract participating business partners. Those that have survived are often owned by companies or consortia that are also exchange customers or suppliers.

The objective of this overview is to describe the evolution and the characteristics of B2B Internet implementations, and to discuss management considerations, the evaluation and adoption of B2B applications, and the technical infrastructure supporting these systems. We also indicate some of the open issues that remain as the technology and its adoption continues to evolve.

BACKGROUND

Although there are many classification schemes available for online exchanges (Choudhury, 1997; Kaplan & Sawhney, 2000), we will use a more generic and functional focus, with three categories: sell-side, buy-side, and neutral/market-type applications (Archer & Gebauer, 2001). Early B2B sell-side applications featured online catalogs, made available to the Internet community by distributors and manufacturers, often complemented by features such as shopping baskets and payment functionality. Many now provide customized and secure views of the data, based on business rules from contract agreements with individual customers. In some cases, buying processes of the customers are supported, including features such as approval routing and reporting. While some sophisticated applications exist to support collaborative forecasting or the configuration of complex products, many sell-side systems handle only the simpler transactions, such as maintenance, repair, and operation (MRO) supplies. Recently, more advanced features have become more widely available, such as CPFR (collaborative planning, forecasting, and replenishment) to support joint initiatives between customer and supplier (Holmstrom, Framling, Kaipia & Saranen, 2002).

Buy-side applications support procurement, moving order processes closer to the end user, and alleviating structured workloads in functional departments such as purchasing and accounts payable. For smaller companies, an affordable alternative is to work through hosted solutions, using Internet browsers to access procurement functionality provided by a third-party vendor or application service provider (ASP). Some applications provide functionality beyond the automation of highly structured procurement processes, including production tendering, and multi-step generation requests for proposals, as they are relevant for the procurement of freelance and management services. Interfacing purchasing systems to internal systems such as enterprise resource planning systems (ERP) makes it possible to automate many transactions, thus greatly increasing processing speed and reducing costs. Buy-side solutions that involve long-term inter-organizational relationships are typically set up by the purchasing organization, which then controls catalog content, data format, and back-end system functionality. Benefits

include a reduction in maverick buying, and freeing purchasing and accounts payable personnel from clerical work to handle more strategic tasks. Suppliers typically benefit from long-term relationships, and in many cases the relationships between the buyer and its suppliers were in place before the buy-side operation was established.

The third group of applications, often referred to as B2B electronic markets or hubs, can either bring together multiple buyers and sellers on an ad hoc basis involving various types of auctions, or support more permanent relationships (a many-to-many relationship, equivalent to IOIS). Those that have been more successful are likely to have been sponsored by a consortium (e.g., GlobalNetXchange, in the retail industry, sponsored by buying organizations, and Global Healthcare Exchange in the health care industry, sponsored by selling organizations). They may feature auctions, electronic catalogs, and auxiliary value-added functions, such as industry news and online forums. The initiator typically controls the catalog content, aggregates supplier input, and provides additional functionality and standardized data access to buyers. These marketplaces may eliminate the need for market participants to link directly to their business partners, circumventing costly value-added EDI network services. Their business models typically include service charges based on transaction volume and setup costs. They provide a standard for suppliers to deliver catalog content, increase flexibility if they support access to suppliers and customers outside pre-established relationships, and create customer value through competitive pressure. Participation in such marketplace solutions may also provide a low-cost alternative for SMEs (small and medium enterprises).

MANAGEMENT CONSIDERATIONS

A market assumes an intermediary role that supports trade between buyers and suppliers, including (Bailey & Bakos, 1997): a) matching buyers and sellers, b) ensuring trust among participants by maintaining a neutral position, c) facilitating market operations by supporting certain transaction phases, and d) aggregating buyer demand and seller information. Supporting the marketplace through an electronic exchange has characteristics of (Bakos, 1991): 1) cost reductions, 2) increased benefits with the number of participants, 3) potential switching costs, 4) capital investments but economies of scale and scope, and 5) significant uncertainties in benefits. Many of the management issues of B2B electronic commerce systems relate to the need to coordinate decisions and processes among multiple firms, often through differences in business processes, information systems, business models, and organizational cultures.

Early transaction cost theory recognized markets and hierarchies as the two main methods of governance for coordinating flows of goods and services. Markets such as stock exchanges coordinate the flow through supply and demand forces, with price as the main coordination vehicle. Hierarchies such as production networks consist of predetermined relationships among customers and suppliers, and rely on managerial decisions to coordinate flows. There are many intermediate forms of governance, such as network organizations and strategic alliances (Gulati, 1998). A common theme among all these governance structures is collaboration among the participants, but the level of collaboration varies. These levels can be described as cooperation, coordination, and collaboration (Winer & Ray, 1994). In cooperation, there is little sharing of goods, services, or expertise; coordination requires mutual planning and open communication among participants, who share resources; collaboration involves deeply synergistic efforts that benefit all parties. Collaboration at different levels between buyers and sellers is emphasized by online exchanges, but this can also take place among buyers and among sellers (Wang & Archer, 2004).

In recent years there has been a "move to the middle," with a growth of outsourcing arrangements and more cooperative, integrated long-term inter-organizational relationships with a relatively small number of preferred suppliers (Clemons, Reddi & Row, 1993). Distribution of market power is often an overriding factor. For example, auto manufacturers, as a concentrated industry, will be likely to adopt an approach that involves long-term collaborative relationships among business partners rather than the short-term market-driven relationships that traditionally characterized this industry. On the other hand, companies in fragmented industries such as construction are characterized by short-term relationships and low levels of trust, where transactions such as online procurement are more likely to be through B2B tendering and auctions (Stein, Hawking & Wyld, 2003).

EVALUATION AND ADOPTION

The task of evaluating an electronic exchange becomes difficult when network effects are taken into account (benefits from participating are usually positively related to the number of participants). As a result of complications such as these (strategic necessity, dependence on the commitment of business partners, additional risk, external effects, etc.), the evaluation of an electronic exchange is much more complex than for systems deployed within organizations (Gebauer & Buxmann, 2000). B2B market mechanisms focus on four factors that favor one market mechanism over another: degree of fragmentation, asset specificity, complexity of product description, and complexity of value assessment (Mahadevan, 2003). These have a significant impact on the choice of an appropriate market mechanism for B2B interactions.

From the organizational perspective of setting up a successful B2B application, there are initiators and (potential)

participants. Initiators bear the majority of the cost and risk, but on the other hand also enjoy the majority of the benefits, and they typically decide on technology infrastructure, type of systems used, corporate identity, representation of partners, and selection of participants. Success of the system depends on the participation of a critical mass of business partners. Supplier participation considerations in a buy-side solution, for example, include investments necessary to prepare and upload catalog data, integration with back-end systems, training of staff, and adjustments of business processes. Depending on individual arrangements, benefits include reduced time and costs for order processing, improved customer service, increased customer reach in a globalized marketplace, and an increase in revenues from long-term and trusted customer relationships. Neutral intermediaries in such markets face a difficult balancing task, as they have to be careful to satisfy suppliers as well as buyers, and a business model must be chosen that will attract the desired participants.

Although B2B exchanges have received a great deal of attention in the press and among researchers, their rate of adoption by business has not been high. While their aggregate transaction growth rate is higher, they are still (in 2004) outranked by at least a factor of 10 in transaction volume by EDI installations, which are still firmly in place in many large corporations (Jakovljevic, 2004). In addition, by utilizing EDI over the Internet, companies and organizations also benefit from the ability to facilitate a seamless bridging between XML and EDI that can now co-exist on the same infrastructure and use common protocols to handle electronic procurement, invoicing, and logistics information. With the need to electronically exchange volume-intensive catalogue and product specification information, organizations can significantly reduce the high cost of this exchange by using Internet EDI. Although EDI is able to support only text content, the combination with XML provides support for images and graphics (Hamdar, 2002).

SMEs can and often do handle B2B transactions through e-commerce solutions without fully automated transaction management systems, including hosted procurement applications. Supply-side solutions with Web access can also be used as parallel and partially automated channels for larger businesses that wish to deal with small suppliers or customers. In practice, SMEs execute small numbers of transactions and may not wish to make the investment in resources, training, and internal integration required to link to their business partners (Archer, Wang & Kang, 2003). Motivations for joining online exchanges include (Gebauer & Raupp, 2000): a) coercion (through market power), b) long-term commitment to business relationships and reduction of associated uncertainty, c) subsidies to support system installations for potential partners, and d) general system improvements that result in improved efficiencies and effectiveness. SMEs that link to online exchanges are most likely to be motivated through pressure from their larger partners and by long-term commitments. Many use alternative interactions utilizing a combination of manual and online functions. For example, a medium-sized value-added retailer might use ad hoc purchasing procedures such as searching the Web for catalogue information on major suppliers, and then use the telephone to negotiate prices and delivery schedules (Archer et al., 2003).

TECHNICAL INFRASTRUCTURE

Software products to support B2B interactions are continuing to mature as more complex functions are added, such as collaborative planning, forecasting, replenishment, negotiation and decision support, and procurement and asset management of complex and highly customizable items and systems (Paul et al., 2003). Linking data from many different sources, including legacy systems, through Web services (Iyer, Freedman, Gaynor & Wyner, 2003) is still in its infancy, but supported by diffusion of industry standard Extensible Markup Language (XML). Technical issues are complicated by the critical role of security and confidentiality in inter-organizational settings, particularly when using public networks such as the Internet as compared to the private networks that were traditionally used for EDI implementations. Meeting these needs may require significant investments in software, training, business process reengineering, technical support, and time, all of which favor larger organizations.

Complexity of transactions is an important adoption factor, and is determined by factors such as the number of sub-processes and organizational units that are involved, as well as their possible interactions, interdependencies and relationships with the process environment (Gebauer & Buxmann, 2000). This in turn depends on the type of goods or services. Acquiring indirect or non-production supplies and services is the least complex type of transaction, followed by direct goods, and capital goods and other types of ad hoc purchases tend to be the most complex. A high degree of automation is economically viable only for high volume, less complex transactions. As complexity increases and volume decreases, human intervention is more likely to be needed to handle exceptions and ad hoc transactions.

B2B applications can have major impacts on inter-organizational business processes, depending on the level of IOIS integration required (Stelzer, 2001). After planning and designing the system business model and infrastructure, a careful plan of how to implement it, how to train employees, and how to adapt business processes is the next step towards a successful project (Archer & Gebauer, 2001). Partner adoption, catalog management, and integration with a heterogeneous system of back-end applications are frequently listed as major stumbling blocks. For example, an organization could start out by reengineering and then automating an inefficient process that causes long lead times

and possibly frequent complaints, such as management approval of end-user requests. As a next step, putting together an online catalog that contains the offerings of preferred suppliers can be useful as a first step to reduce "maverick" buying outside pre-established contracts. While the exact steps will depend on the situation within the individual firm, the stepwise approach will also allow frequent adjustments during the project planning and implementation process, including the addition of new requirements. The adoption of a B2B e-commerce solution is a strategic company decision and it is important to evaluate the potential overall impact of this innovation on the firm before proceeding (Pant & Hsu, 1996), as it may require substantial reengineering before it will be effective (Maull, Childe, Smart & Bennett, 1995).

FUTURE TRENDS

There is little doubt that rapid growth will continue in the relative value of B2B transactions handled through electronic commerce solutions, especially as they become less costly and easier to implement in SMEs. However, most of the growth in such offerings is likely to be in sell-side or buy-side online exchanges, as there has been significant supplier resistance to participating in neutral market-type exchanges. Although these exchanges offer the greatest theoretical benefit because of the potential for standardized linkages among participating companies, and the collaborative functionalities offered by such systems, this does not outweigh resistance from suppliers who see declining profit margins due to transaction cost payments and competitive price bidding. Meanwhile, EDI systems continue to link many large companies, due to their reluctance to give up related investments or to change business processes to accommodate the newer solutions.

CONCLUSION

A clear understanding of the possibilities of emerging technologies is crucial to take advantage of new opportunities in the B2B marketplace. There have been failures in this environment due to a lack of consideration of the wide range of technical, managerial, and economic issues involved. No widely adopted frameworks have been developed to assist in the choice of level of integration or in reengineering boundary spanning business processes. Although technology continues to develop, it is still immature in many areas. In particular, the integration with current IT infrastructures is often extremely complex and difficult to justify for medium to low transaction rates. Meanwhile, B2B applications continue to evolve, changing the rules of the game in subtle ways, but providing fruitful areas for research and new developments.

KEY TERMS

Application Service Provider (ASP): An ASP is a service company that can support and relieve a firm from the daunting challenges of finding, hiring, inspiring and training technical personnel to manage an application in-house. An ASP provides software applications on a pay-per-use or service basis via the Internet and leased lines.

Collaborative Planning, Forecasting, and Replenishment (CPFR): CPFR is a global, open, and neutral business process standard for value chain partners to coordinate the various activities of purchasing, production planning, demand forecasting, and inventory replenishment, in order to reduce the variance between supply and demand and share the benefits of a more efficient and effective supply chain.

Electronic Data Interchange (EDI): A standard used to govern the formatting and transfer of transaction data between different companies, using networks such as the Internet. As more companies are linking to the Internet, EDI is becoming increasingly important as an easy mechanism for companies to share transaction information on buying, selling, and trading. ANSI (American National Standards Institute) has approved a set of EDI standards known as the X12 standards. Although not yet a global standard, because of EDIFACT, a standard developed by the United Nations and used primarily in non-North American countries, negotiations are underway to combine the two into a worldwide standard.

Enterprise Resource Planning (ERP): A business management system that can integrate all facets of the business, including planning, manufacturing, sales, and marketing, through a common database. As the ERP methodology has become more popular, software applications have been developed to help business managers implement ERP in business activities such as inventory control, order tracking, customer service, finance and human resources.

Extensible Markup Language (XML): Document type definitions that can be used to specify or describe various types of objects. When a set of these is used on the Web to describe product information, it is referred to as cXML or commerce XML. It works as a meta-language that defines necessary information about a product, and standards are being developed for cXML in a number of industries, performing a function similar to that of EDI for non-Web-based systems. It will help to standardize the exchange of Web catalog content and to define request/response processes for secure electronic transactions over the Internet. The processes include purchase orders, change orders, acknowledgments, status updates, ship notifications and payment transactions.

Inter-Organizational Information System (IOIS): (Sometimes referred to as an IOS). An automated information system, built around computer and communication technology, which is shared by two or more companies. It facilitates the creation, storage, transformation, and transmission of information across a company's organizational boundaries to its business partners.

Maintenance, Repair, and Operations (MRO): Supplies and services purchased for use internally in the company, often referred to as indirect or non-production supplies and services (such as office supplies, computer equipment and repairs, cleaning supplies, etc.). These tend to be low unit cost, low volume, and off-the-shelf purchases.

Small and Medium Enterprise (SME): The definition of small and medium enterprises varies from country to country. If the definition is based on number of employees, SMEs in the U.S. have from 1 to 499 employees. The dividing line between a small and medium business is variously defined as being either 50 or 100 employees.

Managing Converging Content in Organizations

Anne Honkaranta
University of Jyväskylä, Finland

Pasi Tyrväinen
University of Jyväskylä, Finland

INTRODUCTION

Content management is essential for organizational work. It has been defined as "a variety of tools and methods that are used together to collect, process, and deliver content of diverse types" (McIntosh, 2000, p. 1). Content management originates from document management. In fact, a great deal of contemporary content management system functionality has evolved from document management systems.

Documents are identifiable units of content, flexibly structured for human comprehension (Murphy, 2001; Salminen, 2003). They have traditionally been considered as containers for organizational content. *Document management* considers the creation, manipulation, use, publishing, archiving, and disposal of documents as well as the continuous development and design of these activities in organizational domains. In different domains, the requirements for document management differ accordingly. For example, manufacturing companies possess a bulk of technical drawings to be managed, and in e-government organizations, the document content may act as a normative reference that needs to be frozen and archived for long periods of time (Honkaranta, Salminen, & Peltola, 2005). Therefore document management in e-government is commonly split into two types: document management focusing on document production and the records management considering document repository management.

Research on document management in organizations has been carried out focusing on a multitude of issues, including document standardization (Salminen, 2003), document metadata (Murphy, 1998), document and information retrieval (Blair, 2002), the social role of documents for organizational groups (Murphy, 2001), as well as document engineering (Glushko & McGrath, 2005).

The wide selection of content management systems available has evolved mainly from document management systems (Medina, Meyers, Bragg, & Klima, 2002). They combine into single systems various functionalities developed separately in domains such as library sciences, text databases, information retrieval, and engineering databases. The essential features of document management systems cover:

- Library services and version management
- Management of user roles and access rights
- Text retrieval based on metadata and full-text search
- Support for document life-cycle and related workflows
- Management of *metadata*, as information about documents
- Multi-channel publishing for a multitude of devices and print

A survey on content management systems revealed that many of the systems still have a monolithic and closed architecture and their ability to adopt proprietary encodings is scarce (Paganelli & Pettenati, 2005). Contemporary content management systems' support for access management and for customizing workflows for integrating content into organizational processes may be modest. For example, the popular Microsoft SharePoint Server (http://www.microsoft.com/sharepoint/default.mspx) only assigns access rights to folders, not to individual files or units within the files. Content management software may include limited functionality for the design and management of an organization's Web site. The applicability of the document management approach and the systems for content management have been limited due to an orientation towards using documents as the only unit for managing content. As a consequence of this approach, long documents are difficult to browse through, portions of document content are difficult to reuse in other documents, and long documents are inconvenient for Web delivery (Honkaranta et al., 2005). At least two recent approaches on content management which aim at complementing these weaknesses can be identified. These are Web content management and the use of structured documents in the form of XML.

BACKGROUND

The Web Content Management (WCM) approach focuses on Web content publishing. A great deal of research efforts (e.g., McIntosh, 2000; Boiko, 2002; Murugesan & Ginige,

2005) are targeted specifically on Web content management. One focus in the approach is the reuse of content blocks, enforced either by an extensive use of metadata (Boiko, 2002) or by adopting a single-sourcing approach and XML (Rockley, Kostur, & Manning, 2003). The underlying approaches and the conceptual base used can be traced back to electronic publishing (e.g., Boiko, 2002; Rockley, Kostur & et al., 2003) and to database-oriented approaches (e.g., McIntosh, 2000). Technology-driven development and the growing adoption of open source software, such as Plone (http://plone.org/foundation/) and eZPublish (http://ez.no/products/ez_publish) are also characteristic to the Web content management approach. Therefore many researchers like Murugesan and Ginige (2005) call for more disciplined and more method-based development and maintenance for WCM and Web application development.

The conceptual base for the novel approach is inconsistent and immature (Grossniklaus & Norrie, 2002). The content life-cycle may involve different phases which are dealt with concepts and terms that are not yet stabilized. There are also differences in the content workflow. For example, according to McIntosh (2000, p.1), a content life-cycle consists of three main phases; 1) content assembly, 2) content production, and 3) content delivery. However, Boiko (2002) utilizes concepts such as content acquisition, aggregation and metatorial processing. The lack of a concise conceptual base may hinder requirements elicitation and cause communicational breakdowns between system analysts and the people in an organization.

The WCM approach focuses on managing the content delivered on the Web, while the content management approach manages the content right after its creation regardless of its (possibly multiple different) publishing channels. The Web may be just one additional channel for publication from the content management system perspective. Therefore the organization whose Web site is primarily meant for delivering textual and multimedia content rather than as an application interface should not only consider content management on the Web, but content management as a whole. Yet the Web as a delivery channel—just as any other—sets unique requirements for content presentation and organization. While document-based content management typically considers the content as an object to be presented via reader or editor software resembling a paper print, the WCM approach considers content units as a portion of Web site multi-frame layout. For defining content combinations and their positioning on the Web site, the WCM systems utilize *templates* containing placeholders for content units to be inserted.

Structured documents, such as XML (Bray et al., 2006), separate the content, its logical structure and visual layout from each other within documents by using markup delimiters. The logical structure is described by a schema such as a *document type definition* (DTD) or a *XML schema*. A schema defines the markup vocabulary and the structure for a class of XML documents. A great deal of contemporary research and utilization of XML for organizational content management has focused on the data-oriented use of XML, such as developing service-oriented architectures (SOAs), Web services, and markup languages for data exchange, such as HL7 for e-Health. For content management in organizations the structured documents provide means for document and data interoperability and unified and simplified maintenance procedures, and a standard format for data exchange between organizations. Although the tradition of structured documents is long, contemporary research on using XML (not XHTML) as a format for organizational content has remained scarce except for the field of electronic publishing (Fahrenholz-Mann, 1999) and utilization of XML in e-government (Salminen, 2005). Some other pieces of research on XML documents consider, for example, document type schema design (Jauhiainen & Honkaranta, 2006; Maler & El Andaloussi, 1996).

The benefits of using structured documents and related technologies have lately been recognized and adopted by both content management and WCM approaches, although the use of XML poses multiple challenges. There are systems and tools for managing XML documents as files or within databases. However, the support for XML in content management systems is varying or under development. Albeit many interoperability problems in systems and in service integration have been solved with XML, the hot topic is how to take advantage of the enhanced XML and custom schema support for document interoperability in new office software using XML as its native document format, such as Open Office (http://www.openoffice.org/) and Microsoft Office 2007 (http://msdn.microsoft.com/ office/understanding/xmloffice/tools/default.aspx). In addition, developers lack knowledge about research findings and practical experience on adaptations and implementations of domain-specific XML and related technologies in real-life organizations. This forms a novel and essential line of research for organizational content management.

CONVERGENCE OF CONTENT TYPES AND ORGANIZATIONAL WORK

We may identify at least two kinds of convergence taking place in organizational content management. First, the management of content is deeply intertwined with organizational work. Second, content as we know it is becoming exceedingly complex as it converges with different logical and physical entities to be managed.

Convergence of Organizational Work and Content Management

Despite there perhaps being one software for business (or workflow) process management and another for content management, the content and related organizational activities form a seamless, unified stream of actions from the user perspective. Yet, the requirements for managing business processes and content differ and consist of dissimilar entities. This article explores the components of content management and their relationship to organizational work, and the convergence of content types and metadata for content management.

The features of content management and its intertwined nature with organizational work are discussed via a framework consisting of the four components of content management: content, technology and systems, roles and processes (Honkaranta & Tyrväinen, 2005). Figure 1 illustrates the aforementioned framework for content management.

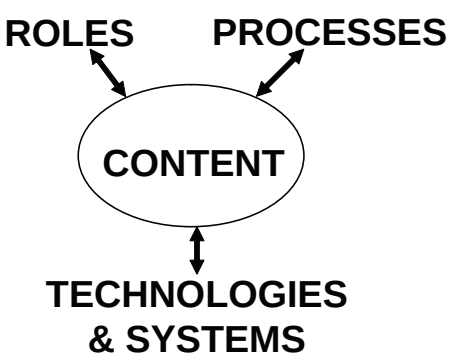
As presented by many researchers, the roles, processes, technologies and systems and content form a consistent whole in organizations. Therefore the components of the framework shown in the figure are interrelated. A change in one component will impact all other components of the framework. For example, adopting a content management system will impact the publication processes, the roles of the people, and the content units used (Honkaranta et al., 2005). A change in content form—such as transformation from paper to digital—may trigger the establishment of entirely new processes and roles in the organization (Eriksen & Ihlström, 2000).

For content management, people's *roles* should be separated with regard to content management development vs. operational roles. From the business process (operational) perspective a person may act as a manager, purchaser, accountant, and so on. From the content management perspective, the roles are attached to the content life-cycle. Thus, there are only a few roles to be considered. A person may act as a creator, modifier, viewer, signer, reviewer, publisher, and destroyer related to a content unit.

The operational business *processes* may be divided into two kinds: there are main processes related to the core of the organization's business and supporting processes. Traditionally, the core business processes have been supported by strategic information systems tailored for the organization, while the support processes have used standard systems. The technology for content management needs to be tailored to support the management of digital content in the main processes of an organization, where most of the communication volume appears (Tyrväinen, Kilpeläinen, & Järvenpää, 2005). As the business process consists of organizational activities, the "content process" concerns the activities leading to the change of content unit *state* during its life-cycle. These activities and states are typically similar to the roles discussed above, and allow few options (the following list has a notation of activity/state of a content unit): to create/a draft, to modify/a version, to review/a reviewed, to accept/an accepted, to publish/a published, to archive /an archived, to dispose/a disposed unit of content.

The *technology* of organizational content management includes standards, architectures, technologies, tools, and applications. Contemporary content management systems may be roughly divided into three categories: platform systems, horizontal systems, and vertical systems. Relational and XML databases and other generic *platforms* provide the base onto which content management applications and functionalities may be built on by custom software development projects. *Horizontal systems* are common-purpose document and content management systems, which already provide a base for managing content units as well as metadata and related processes and workflows. *Vertical systems* are systems that provide metadata and functionality related to the management of specific content units or for specific business processes. Examples of vertical systems are customer relationship management (CRM), supply chain management (SCM), and product data management (PDM) systems, as well as

Figure 1. Framework for organizational content management



patient information systems with specialized functionalities related to their subject area.

Convergence of Content Sources and Logical and Physical Content Units

The management of organizational content deals with the complexity of identifying and designing logical, physical and processable content units. *The logical units of content* are those identified by people according to their comprehension. *The physical units of content* to be managed may include a (virtual) folder of files, a file, or a field in a database. For example, a Web page containing text and multimedia files forms a (virtual) folder from the content management system perspective. The physical units of content may further contain *processable units of content,* such as XML elements.

The logical and physical content units in organizations may be analyzed by their *grain size* and *granularity* (Tyrväinen, 2003). The grain size of a logical content unit may vary from a single processable content element to content *aggregation* as a collection of documents. For example, a pension-system administrating organization may provide an aggregation of directives and guidelines related to the specific type of pension as a Web site folder for its customers (Honkaranta et al., 2005). A content unit considered as "a document" may be produced as *an assembly* of existing and novel content units, acquired from multiple content sources. For example, a budget of an organization may consist of various existing units of content—such as budgets of individual departments—which are combined with new content to form the budget of the whole company. While the grain size of the content units is increasing, the granularity is decreasing (Tyrväinen, 2003).

The amount of *metadata* related to the content increases along the number of the content units when the size of the managed unit decreases. Metadata is typically defined as "the sum total of what one can say about any information object at any level of aggregation" (Gilliland-Swetland, 1998). Commonly people associate metadata with content description for retrieval. It has almost become a norm to adopt a commonly used metadata standard, such as Dublin Core (1999), into a content management system. The metadata standard adopted defines the elements by which the content is described. Content may then be searched for and retrieved using the combination of metadata element names and their values specific to an instance content unit. Adoption of a metadata standard typically involves making organization-specific adjustments (e.g., Päivärinta, Tyrväinen, & Ylimäki, 2002).

A content management system utilizes metadata for a multitude of purposes. For example, a WCM system relies on metadata for automated publishing workflow and a CM system for the whole content workflow support. The role of metadata is increasingly essential as the sophisticated CM systems rely on metadata in virtually every aspect of content management: from access right management and workflow support to content creation and retrieval. Salminen (2005) has proposed categorizing metadata into three classes. Contextual metadata (such as metadata about user roles and access privileges) provides information about the context in which content units are created and used. Structural metadata provides information about the content units' relationships with respect to others (i.e., about the "has relationship," "is-a-part-of"—kind of hierarchical and non-hierarchical constructions), and semantic metadata describes the content with logical terms for search and retrieval.

With regard to content unit grain size, the WCM has a tendency to manage smaller units of content than those managed by content management systems. This means that WCM systems require extensive metadata for content assembly from smaller units of content and their management. Additional metadata also supports the reuse of content units but requires either much more manual work or a higher level of automation supported by sophisticated computerized management systems.

FUTURE TRENDS

The converging organizational content is produced from multiple heterogeneous data sources and delivered to multiple channels. Currently the Web dominates the research and will soon become the main delivery channel for content as well. Content creation includes the convergence of diverse systems, such as process and workflow management, content management, text and multimedia content production software, and Web Services, as well as the convergence of differing content types. As digitalization continues, we will witness an ever-increasing mix of combinations of speech, text, databases, spreadsheet data, and multimedia across and within the content units. Mobile and other handheld devices will gain popularity as secondary or perhaps also as alternative delivery channels into the Web. Since the Web as a delivery channel forced the use of smaller units of content, the new delivery channels may require the use of content units with an even smaller grain size than those used in the WCM, along with varying content formats and multiple variations of the content. For example, an organizational memorandum may be presented as text on the Web; the text may be automatically summarized by a natural-language processing system for mobile browsers, or transformed into speech for a mobile phone as requested by the user.

As the content convergence continues, the analysis and design of logical units of content in organizational settings becomes more complex. The theory of genres as prototypical models for communication (Yates & Orlikowski, 1992) provides a promising approach for identifying and analyzing logical content units in organizations. Thus far, genres

have been operationalized, for example, for identifying the content units in an organization and gathering metadata on them (Karjalainen, Päivärinta, Tyrväinen, & Rajala, 2000), as well as for analyzing the digitalization of organizational content (Tyrväinen et al., 2005).

Convergence of content and organizational work requires that process and workflow management, as well as other organizational systems, need to integrate with content management in a tighter and more sophisticated manner than before. There are a number of possibilities for technical integration of systems, most prominent of them being the utilization of Web services and service-oriented architectures allowing each system to be encapsulated from others and yet to interoperate. However, the system integration for content management requires that the metadata about content, activities, and businesses and operation logic should also be integrated for a consistent whole.

Metadata will be at the heart of research and development of content management. Extensive use of metadata is required for systems integration, supporting the workflows, and managing the ever-smaller units of content with varying forms. Convergence of enterprise taxonomies, corporate or business-level ontologies and metadata specifications across and in between organizations is required for the interoperability of systems and user groups.

Previously, organizations have commonly relied on standard metadata specifications for their semantic metadata, and on a set of system-specific or randomly defined metadata for other kinds of metadata. These standards may be appended by flexibly-built user-group developed folksonomies (Guy & Tonkin, 2006). A bundle of new and old technologies may be adopted to fulfill the requirements for advanced metadata management. Text databases have utilized text mining based on natural language processing, and text mining combined with ranking has been utilized in Web search engines. These technologies have emerged into organizations in the form of personal or desktop search engines, such as Google Desktop Indexing Software (http://desktop.google.com/) and Microsoft Desktop Search Engine (http://search.msn.com/ docs/toolbar.aspx?t= MSNT bar_CONC_About-SearchingYour Computer.htm). The CM systems will need to adapt to new kinds of hybrid retrieval modes combining metadata standard vocabularies and text processing. As people in organizations often need to find knowledgeable people instead of specific content, or they wish to look up resources by knowledgeable "authorities", the organizational content search may also be combined with metadata about persons or their resources. The aforementioned needs call for additional solutions, such as FOAF (Friend-of-a-Friend; a format for describing persons and their features), or joint book marking.

CONCLUSION

Content management has evolved from document management. Novel streams of research on the area focus on Web content management (WCM) and the utilization of structured documents in the form of XML documents. These approaches have not yet been consolidated into a uniform research area.

Characteristic to contemporary content management is a shift towards using units of content with varying grain sizes. A unit of content to be managed may be broader, similar, or smaller than a traditional document. Another focus of contemporary CM systems is the support for Web publishing. The Web as a publication channel is, however, different from document- or paper-based delivery. Web delivery enforces the use of content units smaller in grain sized than documents. The user interface is also different: instead of a document view, the WCM uses a site template which combines several units of content into a specific layout setting. Variance in content unit grain size and additional requirements for workflow support are reflected by an increasing variation and amount of metadata needed for managing and processing the content.

Content is deeply intertwined with organizational work. In the future, we may witness convergence of content units into new publishing channels such as mobile devices, and in ever-broadening formats, such as voice and new mixes of multimedia. Therefore, it may become difficult to identify the content units to be managed from the mix of publishing channels and media utilized for them. Research on content identification, analysis, and modularization will be needed to make sense of the content to be managed. Another avenue for further research is the management of new kinds of metadata for content management.

KEY TERMS

Content Aggregation (noun/verb)**:** A set of existing content units collected together for a specific use purpose. An aggregation may contain several versions of the same unit of content, and its creation may require human involvement.

Content Assembly (noun/verb)**:** A collection of existing or new units of content which may be manipulated to produce content for a publication or for a specific target audience. May be produced (semi-)automatically or involve manual processing. A portion of training content for specialists only may be an assembly.

Content Seeding: Adding identifiers and metadata to content units or their parts to enable computerized assemblies and aggregations on the content.

Content Unit: The object with which the management metadata is associated. May be "a document," "a file," "a component," or "a section of a document" among others.

Metadata: Data describing the content from the viewpoint of humans or computers. Metadata may describe the domain in which content is used, as well as collections, classes, units or processable portions of the content and content instances. Metadata enables content search, classification, and processing. Whereas humans may use and interpret metadata about documents, the metadata about the small units of content is primarily meant for computerized manipulation of content.

Template: A combination of static content, references to units of existing content, and program code for producing the content and navigation aids for a Web site.

Web Content Management: Management of content intended primarily for web delivery. Grain size of the content unit is typically smaller (e.g., a page or a paragraph) than that of documents.

Managing IS Security and Privacy

Vasilios Katos
University of Portsmouth, UK

INTRODUCTION

The concept of privacy has received attention for over a century now and its definition—let alone, understanding—has been profoundly challenging. This is primarily attributed to the "incompatible" and rich set of characteristics privacy comprises. As Brunk (2002) states very sharply, "Privacy is a matter of intellectual and philosophical thought and retains few tangible characteristics, making it resistant to simple explanation."

Perhaps the first scholarly work on privacy was that of Warren and Brandeis (1980), who introduced the highly abstractive yet popular definition of privacy as the "right to be left alone." As privacy was recognized as a right, it primarily existed within a legal context. Legislation for protecting one's privacy exists in many countries and in some cases at a constitutional level (see for example the Fourth Amendment of the U.S. Constitution).

It was soon realized in the information revolution era that privacy and information are somewhat coupled. More precisely, emerging privacy concepts and metrics relate to the intentional or unintentional information flows. However, when it comes to studying, using, and investing in information, security appeared to have a higher priority over privacy. Security and privacy seemingly operate under different agendas; privacy is about protecting one's actions in terms of offering anonymity, whereas security includes the notion of accountability which implies that anonymity is waived. Still, security is a vital component of an information system, as it is well needed in order to protect privacy.

This contradictory relation between security and privacy has caused a considerable amount of debate, political and technical, resulting in a plethora of position and research papers. Accepting that there may be no optimum solution to the problem of striking a balance between security and privacy, this article presents a recently developed methodology that could support policy decision making on a strategic level, thus allowing planners to macro-manage security and privacy.

BACKGROUND

A thorough overview on the economics of privacy is maintained by Acquisti (2008). The 1970s was a decade marked by economists and their aspirations to develop an economic model to "decrypt" the market forces. Although Hirshleifer (1971) introduced the value of information in relation to privacy in the early 1970s, economics tools were ported to the privacy domain in the late 1970s and early 1980s (e.g., Posner, 1978; Stigler, 1980). However in the 1980s the concept of information sharing and the Internet were showing signs of potential, only to be interrupted by the Morris Worm in 1988 (Seeley, 1989), and security was added into the agenda. Initially this was done in the expense of privacy. For the following years information security received substantial attention—if the members of the private sector were to invest in electronic communications and technologies, trust needed to be restored.

Formal treatment of information security was initially in the domain of cryptography, but soon expanded to access control models and intrusion detection systems. The security goals of confidentiality, integrity, and availability were defined. The escape from security being equivalent to confidentiality was soon realized in the domain of cryptography, which was enforced with Rivest's (1990) definition of cryptography which "is about communication in the presence of adversaries." As such, the adversary would not necessarily be interested in eavesdropping on a communication, but could elect to interrupt, modify, fabricate, or replay messages. Formally, this omnipotent adversary was initially captured in Dolev and Yao's (1981) threat model, spawning research into cryptographic protocols.

To date, the body of knowledge for information security has fairly matured. The security domains include both technical and organizational aspects. Standards and methodologies emerged—see for example BS 7799 and ISO/IEC 17799 (BSI, 1995a, 1995b), ISO 27001 (ISO, 2005, aligning with BS 7799 part 3), and CobiT (IT Governance Institute, 2007). It can be seen from the directions taken by these standardization efforts that information security management was becoming an isomorphism of risk management: understanding that there is no absolute security, controls need to be in place in order to diversify the risks of unauthorized disclosure (breach of confidentiality), unauthorized modification (breach of integrity), and denial of service (breach of availability), accepting that there is an amount of residual risk that will be present after employing the security controls.

Research on privacy followed at a much slower pace. It could be argued that a valid reason for this is that privacy is upper bounded by security; security needs to be in place in order to offer privacy. Indeed, some security technologies

such as cryptography were branded as privacy enhancing technologies (PETs), emphasizing the synergetic relationship between security and privacy. As the number of privacy violations and intrusions was steadily increasing in the 1990s (Acquisti, 2008), research on privacy gained momentum. Similar to the security goals stated earlier, the privacy criteria of unobservability, pseudonymity, unlinkability, and anonymity (ISO, 1999; Fischer, 2001) were introduced. With respect to the economics of privacy, the work by Laudon (1996), Varian (1996), Huang (1998), and Posner (1999) set precedence leading to research in the formal application of micro-economic techniques to analyzing privacy. Representative work on the formal application of micro-economics on privacy was published by Acquisti (2004; Acquisti, Dingledine, & Syverson, 2003), Otsuka and Onozawa (2001), and Ward (2001).

However, it was realized by Katos and Patel (2008) that a micro treatment of privacy would be applicable in establishing operational management procedures, yet it had major limitations when attempting to understand the challenges in balancing security and privacy when engaging in policy-making activities. The authors argued that a detailed (micro) view of privacy and security would make it virtually impossible to track or predict the outcome of a policy decision, and suggested that a higher-level—or aggregate—view should be adopted. In fact, Odlyzko (2003) conjectured that the privacy problem is intractable. An analogy could be drawn with the stock market environment: although trends could be established on a macro level for the performance of a certain market, the actual assessment and prediction of the micro variables (stocks) would be substantially more challenging, error prone, and less informing.

The following section presents a methodology developed as a response to the shortcomings of the micro views on security and privacy. The section summarizes the main points of the model. For a more detailed explanation, the reader is referred to Katos and Patel (2008).

A MACRO TREATMENT OF INFORMATION SECURITY AND PRIVACY

Initially we accept that there is no universally accepted, objective measure for privacy. As privacy applies not only to the data, but also to the user's actions as he or she interacts with any given system, we can consider a space of events that could be expressed by a set as follows:

$$A=\{stay\_home, go\_shopping, use\_credit\_card, mortgage\_application, \ldots\}$$

If a metric $p(\ )$ on privacy existed, mapping the above set into a formal range, we could argue that as a very basic requirement, the metric would be on an ordinal scale, for example:

$$p(stay\_home) \leq p(go\_shopping) \leq p(use\_credit\_card) \leq p(mortgage\_application)$$

This would be a minimum requirement for this hypothetical metric to be meaningful—or fulfill the representation condition as expressed in the area of measurement theory (Fenton & Pfleeger, 1998). It should be obvious that the exact initial level as well as change of privacy cannot be established. This is not only because privacy is qualitative and perhaps subjective, but also because we have no control or knowledge of all variables affecting it. For example, how many monitoring technologies (such as CCTV elements) have invaded our private space, and to whom is the captured data available? For how long? What is the quality of the captured data and therefore the likelihood of positive identification? What protection does the legal system provide against third-party enquiries to access the data? It can be seen that not only the number and diversity of these questions can be exceedingly high, but also answering them is challenging in principle.

Determining qualitative variables in uncertain and open problem domains has been a major topic of interest in the discipline of macroeconomics. The well-known so-called cross methodology has significantly contributed to the understanding of the market forces of supply and demand (Dornbush & Fischer, 1998; Branson & Litvack, 1981). The remainder of this section deals with porting these proven techniques to the domain of privacy and security.

Initially we need to classify the relevant technologies in two "markets": the security technologies and the adversarial technologies. By security technologies we mean those that intend to support the confidentiality of our private data, such as firewalls, antivirus tools, and so on. In other words, these are defensive technologies and primarily access control measures. By adversarial technologies we mean those technologies that are used for testing our security technologies. These are hacking tools, such as vulnerability scanners, exploits, security assessment frameworks. These offensive security mechanisms are required in order to be able to assess the security level of an IT infrastructure. A key differentiator is the purpose or intention of use of a certain technology. In the security technologies market, the technologies can only be used for benign purposes, whereas in the adversarial technologies market, the technologies can be used for either benign or malicious purposes. "Ethical hacking" for instance is the term used for capturing the benign use of the adversarial tools.

Against the above we can now proceed in defining the two markets. Figure 1 shows the security technologies market. The process for establishing the respective relations is as follows. Our objective is to determine the relationship between price and privacy (i.e., quadrant Q1) in this market. To do this, we need to define Q2, Q3, and Q4; then, Q1 will be defined as an equilibrium by attaching all assumptions (functions) to the other three quadrants.

Starting with Q2, we assume that there is an inverse relationship between the aggregate demand of the security technologies and price—that is, the lower the price of security technologies (P), the higher the quantity demanded of security technologies (SD).

The assumption captured in Q4 shows that there is a positive relationship between security technologies supply and level of privacy. Indeed, we support the view that there can be no privacy if there are no security technologies in place to protect the relevant personal information (i.e., privacy is bounded by security). Hence the supply for security technologies function SS = *g*(V) is rationalized by the fact that the more important (higher) privacy (V) is the higher quantity supplied of security technologies (SS) to keep privacy at high levels.

Quadrant Q3 reflects the economists' views who suggest that market forces and economic laws, if left alone, will eventually push security technologies demand to equilibrium with security technologies supply, regardless of their initial allocation. This is represented by the identity function SD=SS, or *f*(P) = *g*(V).

By attaching all three assumptions in Q2, Q3, and Q4, we can derive the curve in Q1. Consider price P_0, which corresponds to demand SD_0, which in turn matches supply SS_0, which in turn rests at privacy P_0. Similarly, consider the path for a different price P_1, leading to demand SD_1, matching supply SS_1, resulting in privacy P_1. The two variable pairs (P_0,V_0) and (P_1,V_1) define the two points of the privacy-price curve A_0 and A_1 respectively. If this is done for the infinite number of (P,V) pairs, we eventually obtain curve SS-SD.

A similar line of reasoning is followed for the adversarial technologies market. Although Q2 and Q4 remain the same as in the security technologies market, the attention should be drawn to Q3, which in this case is substantially different (see Figure 2). More specifically, Q3 captures the assumption relating to the use or intention of the technology. Assuming that an adversarial system may be used either for benign or for malicious purpose, SS*=SM+SB would denote the total number of systems used, where SM is the total number of systems used for malicious purposes and SB is the number of systems used for benign purposes. The line drawn in Q3

Figure 1. The security technologies market

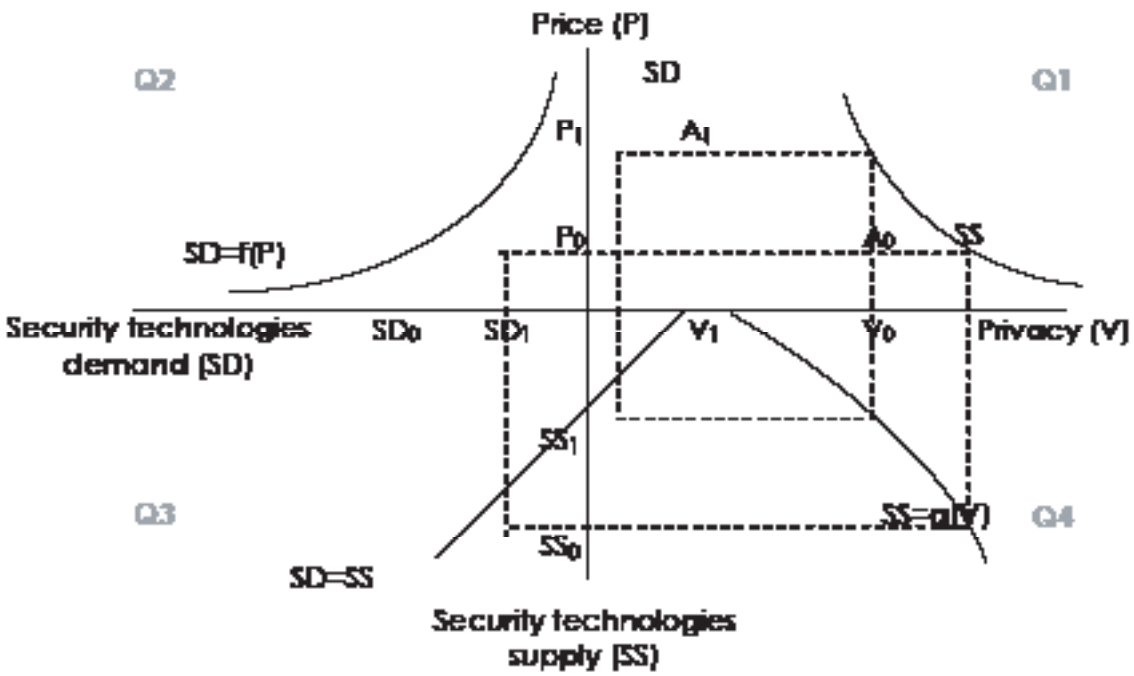

Figure 2. The adversarial technologies market

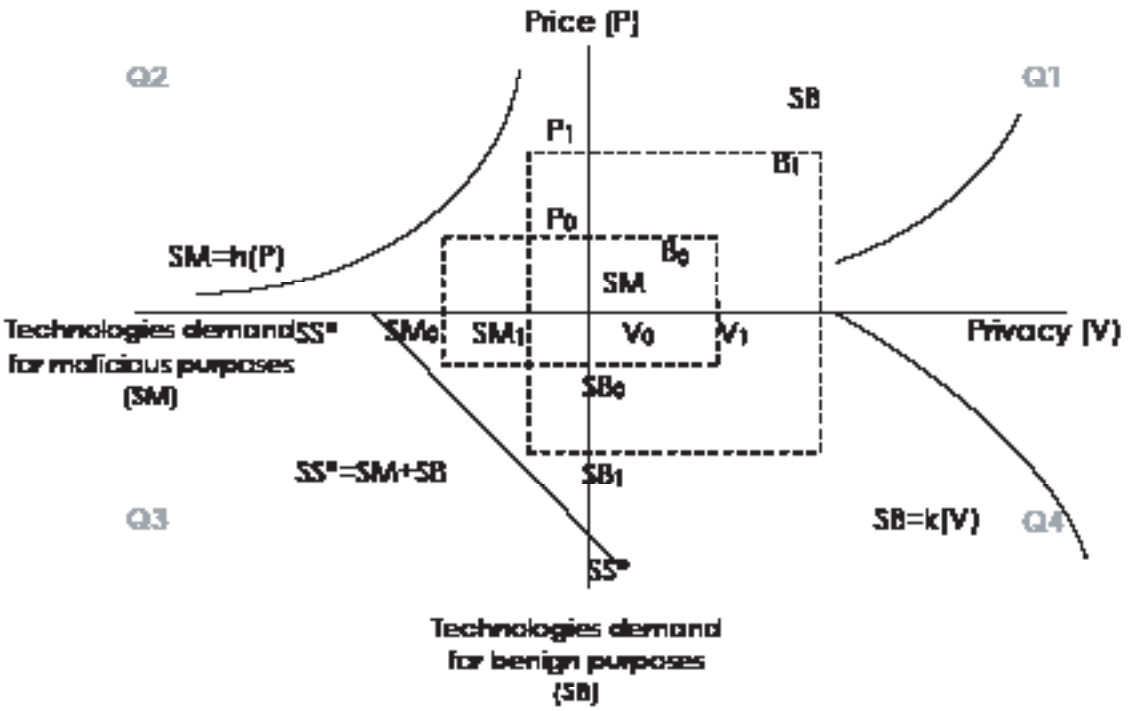


shows this as a constraint, and any point on this line sets the proportion between malicious and benign systems: due to the geometric nature of the -45º line, the two components of demand always add up to the total supply on each axis, so that the -45º line directly represents the equilibrium condition. Any point on this -45º line gives a demand for a malicious purposes technologies component plus a demand for a benign or privacy-enhancing security technologies component, which just add up to the total security technologies supply.

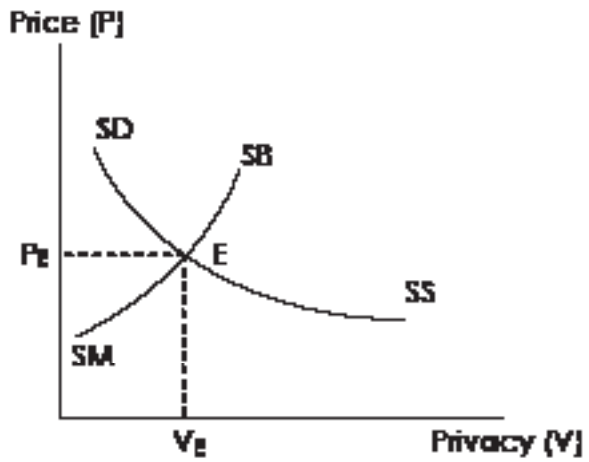
Following the process of identifying the (P,V) pairs by equating all assumptions in Q2, Q3, and Q4, we obtain the positively sloped SM-SB curve in Q1, which represents the technologies of the adversary market.

So far we have derived two pieces of geometric equipment. One gives the equilibrium pairs of P and V in Figure 1, that is, the SD-SS curve in the security technologies market, and the other gives the equilibrium pairs of P and V in Figure 2, that is, the SM-SB curve in the technologies of the adversary market. By placing these two curves on the same quadrant shown in Figure 3—that is, by solving the two equilibrium equations $f(P) = g(V)$ and $SS^* = h(P) + k(V)$ simultaneously—we can find the single (P, V) pair that gives equilibrium in both markets. This is shown as the equilibrium point $E(P_E, V_E)$ of intersection of the SD-SS and SM-SB curves in Figure 3.

Alone, this "snapshot" of the expected level of privacy is not very helpful, as we have still not escaped from the need to objectively measure privacy. However, the benefits of this method can be realized if we performed a comparative statics exercise.

Consider for example the case where a government decided to update a regulatory system by introducing stricter laws to hacking, that is, the malicious use of adversarial technologies. In this case, we can accept that the demand for security technologies for malicious purposes decreases, as indicated in Figure 4 by a right offset of the demand curve, from position $SF = h(P)$ to position $SF=h'(P)$. As a result it is shown, following the dashed lines in Figure 4, that curve SF-SG shifts to the right to position SF´-SG´ and thus the equilibrium point moves along the SD-SS curve from point E to point E´. Comparing points E and E´ (comparative statics), it is seen that the equilibrium price decreases from level PE to PE´ and privacy increases from level VE to level

Figure 3. The equilibrium

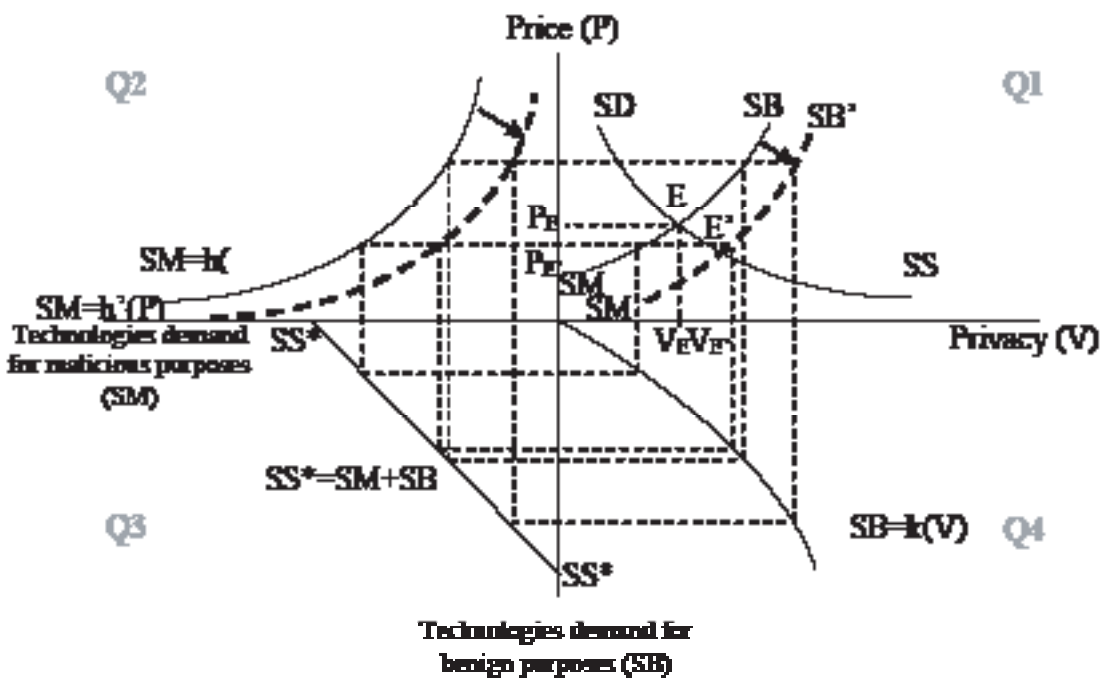


VE´. In other words, under the assumption of exogenously fixed supply of security technologies, the introduction of a stricter regulatory system results in a reallocation of security technologies demand between fraud and privacy-enhancing purposes (decreasing for malicious purposes and increasing for benign purposes), in lower levels of prices for security technologies, and correspondingly in higher levels of privacy. Intuitively the response from this model is correct. Although the model does not contribute to any knowledge on the objective and actual level of privacy (and price), it equips policymakers with enough information to allow them to make informed decisions on modifying or introducing new privacy and security policies.

FUTURE TRENDS

The macro view of security and privacy presented above seems to be a promising tool towards understanding the apparently complex and dynamic relationship between security and privacy. As this tool has been ported from the

Figure 4. The new equilibrium, following an introduction of a strict law against hacking



discipline of macroeconomics, its limitations and drawbacks are well known and have also been inherited. It is expected therefore that new models will be developed to overcome these problems.

It seems unreasonable to attempt a creation of an objective privacy metric, or measure privacy by absolute means. On the contrary, specialized hypothesis testing tools capable of running *what if* scenarios and simulators measuring privacy and security in a differential manner appear to be more realistic and result in a greater added value in managing security and privacy. Such an approach would provide adequate research space for a formal treatment of security and privacy.

CONCLUSION

The symbiotic yet apparently contradictory relationship between security and privacy has posed many challenges to the already rich in terms of characteristics concept of privacy. Starting from abstract and straightforward definitions of privacy, formal micro economic tools were introduced, arriving at a macro treatment in analyzing security and privacy. Nowadays strategic-level decision making is performed on a regular basis, affecting security, privacy, and their balance. It would be imperative therefore to work towards developing a tool for enabling policy planners to make informing decisions on societal, legal, and technological aspects influencing the delicate balance of security and privacy, and this article advocated a tool for doing so.

KEY TERMS

Access Control: All security processes and technologies that are responsible for determining and managing legitimate user access to data and system resources.

Adversarial Technologies: The technologies used in offensive security, such as hacking, penetration testing, and so forth.

Anonymity: The privacy goal of the inability to identify a user's identity when that user is performing an action or using a resource of a given system.

Pseudonymity: The privacy goal of hiding a user's identity by disguise, through the use of a pseudonym.

Side Channel: The unintentional flow of information through a probabilistic communication channel which facilitates information inference (or leakage).

Unlinkability: The privacy goal of allowing a user to perform multiple actions without others being able to link these actions together.

Unobservability: The privacy goal of allowing a user to perform an action or use a system resource without others being able to observe that the resource is being used.

Managing Organizational Knowledge in the Age of Social Computing

V. P. Kochikar
Infosys Technologies Ltd., India

INTRODUCTION

Technology, since the days of the Industrial Revolution, has been used by large corporations, such as factories and the railways, to great advantage. Starting around the end of the 19th century, technology began to be used directly by the consumer, but remained essentially a means of satisfying a *personal* need, such as lighting or listening to music. In the past decade, as technologies such as e-mail, Web, Weblogs (blogs), Wikis, and instant messaging have become pervasive, the way technology is used by individuals has changed—it has increasingly been put to use to meet *social* needs, such as interaction, sharing, and networking. This new paradigm of technology use, and the technologies that have enabled it, may be termed social computing.

By its very nature, social computing facilitates the sharing and leveraging of knowledge residing within a community of people. In this article, we discuss how social computing can act as the primary mechanism that enables the management of knowledge within an organization.

BACKGROUND: THE DISCIPLINE OF KNOWLEDGE MANAGEMENT

There are several ingredients that go into organizational success, and leveraging assets well is one of these. As intangible assets represent a rising proportion of total assets, they have come to represent an important area of management focus. The discipline of *knowledge management* (KM) thus encompasses the organizational activities directed toward the assimilation, dissemination, harvest, and reuse of knowledge. In simpler terms, KM is the answer to the question, "How can the organization update and use its knowledge more effectively?" (Kochikar, 2000).

Some of the world's most successful organizations, be they corporate, academic, or government, invest considerably in KM, and substantial benefits have been reported across industries (Berkman, 2001; Frappaolo, 2006; Kochikar & Suresh, 2005).

Knowledge Management Review magazine's survey of 400 global corporations revealed that the following are key objectives of KM programs (KM Review, 2002):

a. Increasing organizational communication
b. Gaining competitive advantage
c. Increasing collaboration among employees
d. Improving customer relationships
e. Raising efficiency
f. Innovating
g. Learning from mistakes and successes
h. Capturing and retaining tacit knowledge

Using the framework of Nahapiet and Ghoshal (1998), these objectives can be classified as improving *financial capital* (b, e); improving *social capital* (a, c, d); and improving *intellectual capital* (f, g, h).

Each organization must fashion a KM strategy that takes cognizance of its unique competencies, aspirations, and business context. Mechanisms for organizational KM typically take the form of setting up strongly engineered governance mechanisms, focusing on four key aspects: people, processes, technology, and content (see, e.g., Kochikar, Mahesh, and Mahind, 2002).

As an exemplar, Infosys Technologies (*NASDAQ: INFY*) has had a KM program since 1999, which aims to *empower every employee with the knowledge of every other employee*. Key elements of the KM architecture include the *Knowledge Currency Unit* scheme, a comprehensive mechanism for reward, recognition, and measurement of KM benefits; *KShop*, the corporate knowledge portal built in-house; and the *knowledge hierarchy*, a four-level taxonomy of over 2000 subject areas that constitute knowledge in the Infosys context (Kochikar et al., 2002).

For more on KM and its organizational uses, see work by Davenport and Prusak (1998), Drucker, Garvin, andLeonard (1998), Nonaka and Ichijo (2006), and Nonaka and Takeuchi (1995).

BACKGROUND: SOCIAL COMPUTING COMES OF AGE

Social computing is the name given to a slew of technologies that collectively allow people to pool their knowledge, keep in touch with, and interact better with others who belong to their community.

The stellar rise in the popularity of e-mail in the 1990s (the number of users skyrocketed from a few thousand at the beginning of that decade, to several hundred million at the end of it) clearly provides a pointer to the potential that social computing has—people are eager to take up technologies that will help them meet their social needs better. For example, there are as of May 2006 a total of 39 million blogs worldwide, with 75,000 being added each day (Klein, 2006). In an academic/research sense, social computing is a relatively new field—a fact reflected in the relative paucity of books and research papers in the reference section of this article.

What has spurred this gain in the importance of social computing? While there are several reasons, two in particular stand out:

- The steady march of advances in computing that have put more computing power in the hands of the users, allowing them to use it to achieve ends that they truly consider useful;
- Network effects as encapsulated in Metcalfe's Law: As the number of users of a particular technology that supports interaction or networking increases, the benefits perceived by all users accelerate significantly, causing even more users to adopt the technology.

Technologies that commonly go by the name of social computing include e-mail,instant messaging (IM), blogs, wikis, podcasting, and really simple syndication (RSS). They also include Web sites or portals supporting a variety of social interactions (examples include Yahoo!, Myspace, Flickr, del.icio.us).

A key sign of the coming of age of a new technology bubbling up from the masses is large corporations taking note of that technology. In the common view, technology diffuses by a "trickle-down effect," that is, a new technology first finds use within large corporations and then, as it becomes more affordable, trickles down to smaller businesses and finally becomes inexpensive enough to be used by the individual consumer. While such a top-down view is valid, it hardly represents the sole mechanism of technological diffusion. Equally, technology diffuses bottom-up too (Kochikar, 2006). The Internet was for decades used almost exclusively by researchers, then by academics, and subsequently (in the early 1990s) by individuals for publishing information using personal Web sites and so forth. Even when business uses were discovered for the Internet, it was small startups such as Amazon that leveraged it best—large corporations were in many ways the last to embrace the Internet. The same pattern can be seen with e-mail, instant messaging, gaming (which began with children and teenagers and is now finding uses in business such as for strategy formulation), and several other technologies. Other examples can be found in Kochikar (2006), which enumerates a few simple pointers for foreseeing emerging technologies that are "below-the-radar." Thus, large corporations must routinely monitor technologies that have not yet become visible on the corporate radar—that is, in use with small businesses, researchers, or individuals—or else they may miss an important source from where new technologies emerge. Social computing represents precisely such a "below-the-radar" technology.

Social computing is now beginning to find uses within large corporations and has elicited considerable enthusiasm from early adopters (BusinessWeek, 2006; McAfee, 2006).

SOCIAL COMPUTING: A NEW BACKBONE FOR ORGANIZATIONAL KM

Two key principles of social computing (or social software) are that

- It is highly participatory, or allows rich interaction between diverse and possibly dispersed members of a community, and
- It is evolutionary, or supports means for constant updating by the members of the community.

Together, these two characteristics indicate a mechanism for the collaborative creation and updating of content that constantly moves in such a direction as to better reflect the knowledge, beliefs, opinions, and/or aspirations of the community. This is precisely the goal of organizational KM—leveraging the combined knowledge of the organizational community.

To wit, a great deal of what has been learned and practiced by KM thinkers and practitioners over the past few years is finding expression now in the traction that social computing is getting. There has been recognition that social computing technologies can facilitate a new approach to KM. Say Caldwell and Linden (2004, p. 1):

Personal knowledge networking and social networks give individual knowledge workers direct control over the enterprise's intellectual capital and enable a new 'grassroots' approach to knowledge management. KM can happen without a lot of explicit governance.

While conventional KM systems often act as an additional "layer" on top of existing business processes and require people to devote time specifically for creating shareable content, or making existing content shareable, social computing technologies are more organic and integrate naturally into people's work habits or social needs. Harvard Professor Andrew McAfee writes (McAfee, 2006, p. 21):

There is a new wave of business communication tools including blogs, wikis and group messaging software—which may be dubbed, collectively, Enterprise 2.0 — that allow for more spontaneous, knowledge-based collaboration. These new tools may well supplant other communication and knowledge management systems with their superior ability to capture tacit knowledge, best practices and relevant experiences from throughout a company and make them readily available to more users.

Social computing technologies can help in a variety of organizational knowledge-sharing needs, such as

- Sharing useful materials, viz., documents, presentations, plans, and best practices
- Expressing opinions, reaching out, and getting feedback
- Finding experts in a specific domain
- Learning—sharing lessons learned, tips, and tricks
- Forming communities of like-minded individuals interested in a common activity, or sharing a common area of expertise; for example, a community dedicated to innovative product design may be formed
- Pooling knowledge about a product's market potential
- Finding products and services by means such as collaborative filtering

We illustrate with two or three sample technologies.

Wikis, which are one major component of social computing technologies, can find the following uses in the corporate activity of managing knowledge:

1. **Collaborative Publishing:** Creating documents that need input from multiple authors and reviewers, for example, user documentation for a product.
2. **Capturing Evolutionary Learning:** Creating and maintaining documents or reference material that change often and need to reflect knowledge being acquired on an ongoing basis. Examples include
   - Capturing tips and tricks on how to use a particular technology product or platform
   - Recording experiences of working in, or selling to, a new country
3. **Communication on Shared Concerns, Issues:** Providing a single location where a group of people can pool their views, opinions, and ideas on a concern that is common across the group, for example, how a new initiative can be designed to deliver results efficiently.

Blogging, another archetypal social computing technology, is essentially a "one-to-many" means of communication, while wikis are "many-to-many." Thus, while blogging can fulfill to a degree the three classes of use outlined previously, the quintessential nature of wikis, viz., the ability to capture multiple voices and multiple experiences easily and effectively, is absent. On the other hand, the ability to achieve more personal and individualistic ends, such as projecting one's expertise in a particular area, or enhancing one's credibility as an authoritative commentator on a specific topic or subject, is strongly supported by blogging.

A technology not commonly included in the list of social computing technologies is that of prediction markets. Since these are a mechanism for collecting and aggregating the opinions of a large number of people and making the output useful to the entire community, they can be seen as a form of social computing technology. And since diverse people form their opinions of the outcome based on the knowledge/expertise available to them, these markets, at a fundamental level, form a mechanism to bring together knowledge from across the organization—a goal fully consonant with that of KM. Sure enough, these are used at, for example, Microsoft (Kaihla, 2006) and Google (Google, 2005) to predict product launch dates by aggregating opinions of a large community of developers. Employees from across the company contribute knowledge and opinions, which are aggregated into a forecast by the market (Google, 2005). Eli Lilly Co. uses prediction markets to forecast the success of candidate drugs in the research pipeline (Giles, 2005). Interestingly, prediction markets have been found to be enormously accurate—often more so than conventional forecasting methods (Wolpers & Zitzevitz, 2006).

Can a social computing-based KM approach support KM programs at high maturity? Perhaps what social computing technologies do best within the organizational context is to allow content and human interaction to come together judiciously in carrying out organizational tasks. Referring to the five-level knowledge management maturity model (KMM) (Kochikar, 2000), one finds that two key result areas (KRAs or building blocks) at the highest levels of KM maturity—level 4 (Convinced) and level 5 (Sharing)—are *Content Enlivenment*, where content can be said to be truly "enlivened" with human expertise, and *Expertise Integration*, the notion that appropriate expertise is available to help understand content and tailor it to specific need. Kochikar (2000) states that,

Expertise integration represents the highest level of maturity of the sharing process, as true sharing requires a judicious mix of synchronous and asynchronous mechanisms, to achieve significant gains with optimal utilization of experts' time.

Social computing technologies, by acting as a mechanism to stitch together content and human interaction, facilitate both content enlivenment and expertise integration admirably, and are thus fully capable of supporting KM programs at high maturity.

CAVEATS

Most social computing technologies, by their very nature, involve the members of a community directly accessing and modifying content. Thus, they assume a certain degree of access to, and comfort with, computers, and so organizations/groups where the members do not meet this requirement may not find this technology very productive.

Accountability for content is an issue to be addressed. Accountability is direct in the case of some technologies such as blogging, as a blog typically is written by one person. However, with the appropriate security and auditing mechanisms, accountability can be very high with technologies that allow collaborative content creation, such as wikis, too.

Social computing also takes away a significant degree of responsibility, and hence control, from centralized corporate groups and puts it in the hands of a broader community. It thus engenders a mindset change in organizational governance, without which it may be difficult to absorb effectively.

Also, since a key tenet of social computing is trust, a culture of transparency is important.

FUTURE TRENDS

Considerable work is going into getting social computing technologies to better support various aspects of organizational knowledge sharing. One key area of focus is studying how groups and organizations "remember," and attempting to build systems to support various types of structured online activity such as design. The socially translucent system approach to KM, predicated on the notion that knowledge is discovered, shared, and used in a social context, is perhaps representative of the direction in which organizational KM systems will evolve (IBM, 2006).

Projects such as Cyc (http://www.cyc.com/) and MIT's Open Mind Project (MIT, 2006) also typify approaches for better organizing human knowledge and making machines more "aware," albeit in a societal rather than organizational context. However, the principles are valid in the organizational context, and likely to gain acceptance for managing organizational knowledge.

The Economist Intelligence Unit (Economist, 2006) identifies knowledge management as one of the five trends that will shape business and economy in the coming 15 years. However, in the era of social computing, corporate knowledge management systems will grow "lighter," ceding some of the hitherto centralized responsibility to the community.

CONCLUSION

In the final analysis, social computing is emblematic of the steady power shift that technology itself embodies—from governments, large institutions, and organizations to communities and the individual. Nobody decides on behalf of the user—the user decides what works. This stunningly simple principle is what has made social computing a phenomenon so powerful that it can be termed a profound social mega trend.

As this article illustrates, social computing is increasingly finding use in corporate environments, and is in the process of gaining traction as a mechanism for KM. This can only be a positive development, as ultimately the most effective way of ensuring that content represents what users want is to put the users in charge of managing it.

KEY TERMS

Collaborative Filtering: A technique for producing recommendations that are likely to meet an individual's taste, by looking at the preferences of "like-minded" other people.

Intangible Assets: Organizational assets that do not have any physical manifestation, or whose physical measures have no bearing on their value. The following is a typical list of intangible assets:

- fragmented knowledge residing with individuals, or encapsulated in artifacts such as documentation and software code;
- codified and classified knowledge residing in repositories;
- unique systems, processes, methodologies, and frameworks that the organization follows;
- "formalized" intellectual property such as patents, trademarks, and brands; and
- relationships and alliances that the organization may have shaped (Kochikar, 2002).

Intellectual Capital (IC): The "stock" of knowledge that exists in an organization, that can be used for generating value for stakeholders (Bontis, Crossan, & Hulland 2002).

Knowledge Currency Units (KCU): A mechanism defined at Infosys Technologies to convert all knowledge-sharing activities to a common denominator, in order to enable their measurement in quantitative terms.

Knowledge Management (KM): The gamut of organizational processes, responsibilities, and systems directed toward the assimilation, dissemination, harvest, and reuse of knowledge (Kochikar, 2000).

Metcalfe's Law: The utility of a network rises in proportion to the square of the number of its users. This means that as more users get connected into a network, the marginal utility perceived by new users increases dramatically (Metcalfe, 1996).

Prediction Markets: Speculative markets that can aggregate the opinions of a large number of users regarding the outcome of a particular event (Wikipedia, 2006).

Social Capital: The resources available through and derived from the network of relationships possessed by an individual or social unit within an organization (Nahapiet & Ghoshal, 1998).

Managing Relationships in Virtual Team Socialization

INTRODUCTION

The traditional organizational workplace is dramatically changing. An increasing number of organizations are employing workers who are physically and geographically dispersed and electronically dependent on each other to accomplish work (Gibson & Cohen, 2003; Griffith, Sawyer, & Neale, 2003). Recent technological advances, combined with more flexible job design, have helped increase the number of people working in distributed environments. Hence, more employees are working individually and on teams that seldom, if ever, meet face to face. These virtual employees have the same work responsibilities as traditional employees in addition to the challenge of operating within the dynamics of these newly designed mediated workplaces.

Rapid developments in communication technology and the increasing influence of globalization and efficiency on organizations have significantly accelerated the growth and importance of virtual teams in contemporary workplaces. Virtual teams are becoming more commonplace because of the possibilities of a more efficient, less expensive, and more productive workplace. Additionally, distributed teams are less difficult to organize temporal organizational members than traditional co-located teams (Larsen & McInerney, 2002; Lurey & Raisinghani, 2001; Piccoli & Ives, 2003).

Although there are apparent advantages of organizing work virtually, the challenge for new member integration lies in the fact that team members must communicate primarily through communication technology such as electronic mail, telephone, and videoconferencing or computer conferencing. This increased dependence on technology as a medium of communication significantly alters the way new members are socialized to work teams. Additionally, team members' ability to use complex communication technologies varies across individuals. This variation potentially may lead to inter- and intra-group conflict, as well as creating organizational work ambiguity, which refers to the existence of conflicting and multiple interpretations of a work issue (Miller, 2006). This article addresses the challenges of virtual team socialization with regard to newcomer assimilation and how newcomer encounter is an embedded process of virtual team assimilation.

BACKGROUND

Effective communication is central to organizational and team socialization. The way individuals are socialized in a team may determine his or her success within the team and the successful achievement of organizational and team goals. Team socialization and the communication practices associated with newcomer integration have been researched extensively (e.g., Brockmann, & Anthony, 2002; Lagerstrom & Anderson, 2003) since Jablin (1982) first explored this multilayered process. Socialization occurs when a newcomer of a team acquires the knowledge, behavior, and attitudes needed to participate fully as a member of that team. Jablin (1987) framed the stages of socialization as anticipatory socialization, organizational assimilation (encounter and metamorphosis), and organizational exit. Although there is an abundance of literature on traditional organizational socialization, research on virtual team socialization is beginning to emerge (Ahuja & Galvin, 2003; Picherit-Duthler, Long, & Kohut, 2004; Long, Kohut, & Picherit-Duthler, 2004).

NEWCOMER ASSIMILATION IN VIRTUAL TEAMS

Organizational assimilation is perhaps the most important, yet complicated, stage of virtual team socialization. Assimilation concerns the ongoing behavioral and cognitive processes of integrating individuals into the culture of an organization (Jablin, 1982). Assimilation is a dual-action process that consists of planned and unintentional efforts by the organization to "socialize" employees, while at the same time the organizational members attempt to modify their work roles and environment to coincide with their own

individual values, attitudes, and needs. Jablin (1987) suggests that organizational roles are negotiated and socially constructed by actively and reactively communicating role expectations by both the organization and its members. Newcomers typically enact this negotiation through information-seeking tactics.

Organizational culture also informs how newcomers are assimilated in virtual teams. Socialization is one of the most important processes by which organizations communicate their culture (Cheney, Christensen, Zorn, & Ganesh, 2004). While each member entering the organization learns the values, beliefs, and practices of the organization, they simultaneously shape the organization through their "reading" of those values. Because the spirit of virtual teams focuses on innovation, change, dynamic structure, and participant diversity, we should expect newcomers to be able to do more to shape the culture of their virtual team with their own values, beliefs, and practices than in the traditional team structure.

Organizational encounter as a phase of socialization is a time for newcomers to learn behaviors, values, and beliefs associated with their jobs and organizations (Schein, 1988). By entering a new situation, newcomers want to clarify their situational identity through their work roles (Berlew & Hall, 1966; Feldman, 1976), or through securing approval of others (Graen & Ginsburgh, 1977; Katz, 1978; Wanous, 1980). To reduce uncertainty, newcomers often search for information that allows them to adjust by defining the expectations of others and orienting their behavior to the behavior of others.

The speed that virtual teams form demands that workers deal with change rapidly. Although research on teamwork suggests that teams function optimally after they have worked together for a period of time, virtual teams may not have the luxury of establishing working relationships over an extended period of time (e.g., Furst, Blackburn, & Rosen, 1999; Mark, 2001). Hence, it is vital for newcomers to quickly establish and develop relationships with others in the work setting, especially with peers and supervisors (Jablin, 2001).

Among other things, organizational relationships provide newcomers with support that facilitates the learning process and reduces stress and uncertainty associated with adjusting to a new work environment (Jablin, 2001). Much of the research on relationship development in the organizational encounter stage focuses on information seeking and information giving (e.g., Boyd & Taylor, 1998), learning behaviors and attitudes through exchange activities (e.g., Comer, 1991), technical or social information (Comer, 1991; Morrison, 1995), and regulative and normative information (e.g., Galvin & Ahuja, 2001). Evidence suggests that formal and informal socialization practices may affect the level of organizational commitment (Berlew & Hall, 1966; Buchanan, 1974), longevity in the organization (Katz, 1978; Wanous, 1980), and satisfaction and feelings of personal worth (Feldman, 1976). In fact, Gibson and Gibbs (2005) propose that a supportive communication climate, defined as an atmosphere that encourages open, constructive, and honest and effective interaction (p .4), often enables innovation.

The next section examines the three central areas of relationship building in virtual teams: peer relationships, supervisory relationships, and mentoring relationships.

Peer Relationships

Working with others on a team may be problematic. Several questions arise when working with others in this context. Do individuals meet the expectations the team has of them? Are they easy to get along with? Are they competent? Peers help newcomers integrate disjointed pieces of information (Van Maanen, 1984) and communicate subtle values and norms that may not be explicitly expressed by their supervisors. Newcomers have more contact with coworkers, and as a consequence, more opportunities to share information with them and develop relationships (Jablin, 2001; Comer, 1991; Teboul, 1994). Sias and Cahill (1998) proposed a variety of contextual factors, including shared tasks and group cohesion (e.g., Fine, 1986), physical proximity (e.g., Griffin & Sparks, 1990), lack of supervisor consideration (Odden & Sias, 1997), and life events outside the workplace, as well as individual factors, such as perceived similarity in attitudes and beliefs as well as demographic similarity (Adkins, Ravlin, & Meglino, 1996; Duck, 1994; Glaman, Jones, & Rozelle, 1996; Kirchmeyer, 1995), that may affect the development of relationships with peers.

Trust is a key factor in developing close relationships. However, due to the lack of physical proximity and the reliance on communication technologies, our understanding of trust in virtual teams is different from the trust in traditional teams. Piccoli and Ives (2003) define team trust as the belief that an individual or group makes good-faith efforts to behave in accordance with any commitments both explicit and implicit. Cummings and Bromley (1996) further define trust as honesty in whatever negotiations preceded the commitment as well as not taking excessive advantage of another even when the opportunity is available (Cummings and Bromley, 1996). Meyerson, Weick, and Kramer (1996) coined the term "swift trust" to describe how virtual teams develop a different type of trust than in traditional teams. Due to the highly interdependent nature of task orientation of the team, newcomers develop trust more quickly. Team members are able to develop trust in the relationships on the basis of shared tasks rather than on the basis of similar demographics and/or physical proximity found in traditional teams (Jarvenpaa & Leidner, 1999).

However, swift trust is not enough to develop close peer relationships. Team members face a number of challenges including: technological mistrust by both newcomers and established members, intuitive fear of the misuse of archived

communication (e.g., e-mail trails), and the difficulty of sharing personal or non-work-related issues. Thus, virtual newcomers may be unable or unwilling to take advantage of the informal organizational development that appears central to organizational socialization in traditional teams. This clearly inhibits the development of close peer relationships in virtual teams, which in turn may inhibit constructive team cohesion. Similarly, opportunities to understand organizational politics are greatly reduced by the inherent dispersed nature of virtual teams. Unless the communication among team members is open, power alliances may form that foster certain behaviors such as social loafing, domination, and the formation of cliques to occur. Groups or individuals are alienated by these behaviors and may differ in their responses based on location or functional role. The outcome is the same — limited effectiveness of the team, low commitment, low loyalty, and mistrust. Other sources of information such as supervisors and mentors may prove more helpful in recognizing and adapting to political nuances.

Supervisor Relationships

Supervisors are important for assimilating newcomers to organizations by helping build a shared interpretive system that is reflective of assimilation (Berlew & Hall, 1966; Feldman, 1976; Graen, 1976; Kozlowski & Doherty, 1989; Ostroff & Kozlowski, 1992; Schein, 1988). Supervisors who frequently communicate with newcomers serve as a role model. These supervisors filter and interpret formal downward-directed management messages, have positional power to administer rewards and punishments, are a central source of information related to job and organizational expectations as well as feedback on task performance, and are pivotal in the newcomer's ability to negotiate his or her role (Ben-Yoav & Hartman, 1988; Jablin, 2001). According to Staples, Hulland, and Higgins (1998), workers who learn their communication practices by modeling their managers' behaviors have greater self-efficacy, better performance, and more positive job attitudes.

The supervisor-subordinate relationship is more important in virtual teams than in traditional teams due to the dislocated nature of the virtual structure (Long et al., 2005). The supervisor-subordinate relationship is complicated by the absence of a physical communication context that characterizes most traditional teams. The supervisor's coordination of virtual team activities is more difficult because of the distinct nature of technological feedback (synchronous vs. asynchronous), the lack of robust spontaneous information exchange between supervisor-subordinate, and the obvious reduction of face-to-face verbal and nonverbal communication cues. On the other hand, some findings suggest that assessment of team member contributions may be more accurate in virtual rather than face-to-face environments. For example, Weisband and Atwater (1999) found that ratings of liking contributed less bias to evaluations of contribution for virtual groups than face-to-face groups. Similarly, Hedlund, Ilgen, and Hollenbeck (1998) found that leaders of computer-mediated teams were better able to differentiate quality of decisions compared to leaders in face-to-face teams.

Regardless of whether the supervisor is part of the team or not, the effective supervisor-subordinate relationship depends in large part on whether the organization uses a traditional approach to managing the virtual team. In traditional teams, often supervisor-subordinate relationships are characterized by hierarchical embedded roles in responsibilities, more formalized rules, procedures, and structures (McPhee & Poole, 2001). However, in virtual teams there is a loosening of the rules and responsibilities in the supervisor-subordinate relationship. The virtual setting reduces tangible cues that distinguish the status and/or hierarchy of the team members. Thus, the supervisor-subordinate relationships in a virtual team rely more on co-orientation, which facilitates the socialization process more effectively. Mentoring relationships is also important to newcomers' adjustment to socialization efforts.

Mentoring Relationships

When discussing relationship building as part of the assimilation process, mentoring relationships is an important aspect. Mentors facilitate newcomer organizational adjustment by offering advice, support, and if appropriate, coaching behaviors to accomplish goals. Wigand and Boster (1991) suggest that "mentoring speeds up socialization into the work role, encourages social interaction, provides an opportunity for high-quality interpersonal interactions, and enhances identification with and commitment to the organization" (p. 16).

Mentoring relationships are formal and informal. Formal mentoring is a "deliberative pairing of a more skilled or experienced person with a lesser skilled or experienced one, with the agreed upon goal of having the lesser skilled or experienced person grow and develop specific competencies" (Murray & Owen, 1991, p. xiv). Several scholars (e.g., Allen, McManus, & Russell, 1999; Heimann & Pittenger, 1996; Seibert, 1999) acknowledge that newcomers who participate in formal mentoring relationships in traditional organizations realize greater benefits than those who do not have formal mentoring. Specifically, participation in formal mentoring increases the newcomers' understanding of various organizational issues and increases their level of organizational and job satisfaction.

Informal mentoring relationships develop naturally at the discretion of the mentor and protégé, and exist as long as the parties involved experience sufficient positive outcomes (Jablin, 2001). Newcomers who are informally mentored are privileged to information not directly associated with the job role or organizational tasks. This indirect communication includes organizational power and politics, involved

career-related support, "inside" information about various organizational issues, and increased social interaction outside of the workplace. As trust, commitment, and identification in the virtual team develops for both the newcomer and more experienced workers, informal mentoring will naturally occur. Virtual teams are more effective when communication barriers such as role uncertainty, task ambiguity, and tacit norms of the team are dismantled.

Organizations benefit when they recognize the value of both formal and informal mentoring relationships. Acknowledging the positive impact mentoring has on newcomer assimilation in a traditional team arrangement leads us to assume that mentoring will have similar impact on virtual team assimilation. However, due to the structural challenges of virtual teams, organizations should consider both formal and informal mentoring programs as tools to socialize newcomers to virtual teams.

In summary, virtual teams face an uncertain, but promising future. The socialization process of team members can become an enigma when building virtual teams. The next section outlines future trends in newcomer assimilation in virtual team socialization.

FUTURE TRENDS

Three interrelated relational aspects of virtual team assimilation are important to note when attempting to predict future trends in this emerging field of study. First, growing interest in virtual team socialization will lead to an accelerated interest in how trust is developed and maintained in virtual team relationships. Trust is a major factor influencing the cohesiveness among virtual team members (Sarker, Valacich, & Sarker, 2003). Instrument development and validation is of central concern as virtual teams become a ubiquitous aspect of organizational life. Scholars and practitioners both have a vested interest in fully developing this aspect of virtual team scholarship, as more individuals will work in this new organizational configuration and become more dependent upon the work of others in their virtual team. Working remotely clearly has its benefits, but opportunities will only be maximized when trust is fully realized among all organizational citizens, especially virtual team members.

Second, focused attention should be given to the amount of social contact individuals experience via mediated communication with their peers and supervisors. As workers become increasingly more isolated because of the flexibility technology affords them (e.g., telecommuting, flex hours), managers should be proactive in ensuring that many of the social components characteristic of working in traditional "brick-and-mortar" workplaces—the characteristics that keep individuals socially satisfied and committed to the organization—are transferred to the new dislocated work environment. Several scholars have suggested that the informal organization is equally, if not more powerful than the formal organization (e.g., Rogers & Kincaid, 1981; Monge & Contractor, 2001; Monge & Eisenberg, 1987). In order to maintain a consistently committed and talented workforce, deliberate attention should be earmarked to foster the intangible social relational aspect of virtual team functioning.

Finally, managers and scholars should work in tandem to fully realize the opportunities and potential for virtual mentoring. Networking and building informal coalitions and communities with others within and outside of their employing organization is a key strategy for upward mobility for individuals, especially minority organizational members (Bell & Nkomo, 2001; Parker, 2003). As more individuals are hired and socialized to work in more virtual team-based structures, it is critical that organizational leaders leverage the power of mentoring as a means to create a more committed workforce and reduce job transfers and turnover. Establishing a protégé and mentor relationship is critical, as technological uncertainty and task ambiguity increase due to the erosion of traditionally rich media forms such as face-to-face communication. Implementing formal and informal mentoring programs is certainly a future trend in virtual team socialization.

CONCLUSION

Organizations are turning to virtual teams as a way to remain competitive in an environment characterized by globalization, mergers, acquisitions, and dependence on information technologies. A great deal of attention is paid to how to provide adequate virtual team infrastructure such as hardware and software components. However, little attention has been devoted to the "human-structure" of virtual team organizing. Future research and organizational attention should focus on the methods of assimilating newcomers in virtual teams. This communication process is as important as the technology selected to accomplish work.

Some aspects of virtual team assimilation are similar to traditional team assimilation, but many are not congruent. Staples and Webster (2007) posit that the distinction between traditional and virtual teams is no longer needed, as all types of teams are characterized by varying degrees of virtuality. The primary difference is that virtual team members are typically more reliant on information technology as the medium for communicating, and virtual team members are more likely to be isolated from the rest of their team — hence, the importance of examining how virtual team members build relationships in this new organizational structure. Communication in peer, supervisor, and mentoring relationships is vital in optimizing organizational functioning, yet little attention is focused on these important relationships in the virtual team environment. In addition to the traditionally studied outcome variables such as costs, productivity,

and effectiveness, organizations should also be mindful of the importance of issues related to the internal team and interpersonal communication processes that embody and constitute organizations.

Effective virtual team assimilation, just like traditional team assimilation, fosters loyalty, commitment, trust, and potentially greater cohesiveness with the team. Virtual team socialization is a shared relational responsibility for the newcomer, the supervisor, and the organization. If little concern is given to building the relationships, then the long-term stability of the virtual team may be threatened.

KEY TERMS

Co-Located Team: A traditional team that shares a common goal and works toward that goal in a face-to-face, same-office environment.

Formal Mentoring: A deliberate pairing of a more skilled or experienced person with a lesser skilled or experienced one, with the agreed-upon goal of having the lesser skilled or experienced person grow and develop specific competencies.

Informal Mentoring: The non-assigned pairing of an experienced person who respects, guides, protects, sponsors, promotes, and teaches a younger, less experienced personnel member who develops naturally at the discretion of the mentor and protégé, and persists as long as the parties involved experience sufficient positive outcomes.

Organizational Assimilation: The processes by with individuals become integrated into the culture of an organization.

Newcomer Encounter: A time for newcomers to learn behaviors, values, and beliefs associated with their jobs and organizations.

Socialization: The process in which that member of a team acquires the knowledge, behavior, and attitude needed to participate fully as a member of the team.

Swift Trust: A type of trust that develops quickly on the basis of shared tasks rather than on the basis of similar demographics or physical proximity.

Virtual Team: A group of geographically and organizationally dispersed workers brought together across time and space through information and communication technologies.

Managing the Integrated Online Marketing Communication

Călin Gurău
GSCM – Montpellier Business School, France

INTRODUCTION

This chapter investigates the particularities of integrated marketing communication in the online environment. The study starts from the premise that the specific characteristics of the Internet transform the application of IMC principles from an alternative option to an absolute requirement for online organizations. Based on the analysis of the specific characteristics of the online environment and audiences, and on the primary data collected through face-to-face interviews with 19 marketing or communication managers of UK consumer retail firms, this article explores the opportunities and requirements for implementing integrated online marketing communication, proposing a theoretical model of that can be adopted by *Internet-active organizations.*

BACKGROUND

In the last 10 years, the concept of *integrated marketing communication* (IMC) has achieved notoriety and legitimacy both in the academic and in the professional environment (Schultz & Kitchen, 2000). This situation is proved by the numerous studies and debates centered on the subject of IMC (Cornelissen & Lock, 2001; Gould, 2004; Percy, Rossiter, & Elliott, 2001; Schultz & Kitchen, 2000).

The emergence and the development of IMC has been determined by a number of evolutionary trends in the areas of:

- *Marketing*—The increased fragmentation and segmentation of markets, relationship marketing, and direct marketing (Durkin & Lawlor, 2001; Eagle & Kitchen, 2000).
- *Information Technology*—The development of new communication technologies and database applications (McKim, 2002).
- *Communication*—Increased fragmentation of media audiences, multiplicity, and saturation of media channels (Smith, 2002).

From this perspective, the new paradigm of IMC can be represented as a strategic answer to the social and business conditions of the postmodern society (Proctor & Kitchen, 2002), which forced marketing organizations to move beyond functionally driven, internally focused approaches to marketing and communication (Cornelissen, 2003).

The concept of IMC was defined in many different, often contradictorial ways (Duncan, 2002; Shimp, 2000). The integration of marketing communication procedures was considered a result of centralized management, centralized budgeting, or message similarity across all communication channels, while other authors emphasized the integration of all the elements of the promotional mix in a coherent strategy (Pickton & Broderick, 2001). Many definitions emphasize that the integration of marketing communication should not be understood as a simple uniformity of the message transmitted across different channels (Kitchen, Brignell, Li, & Jones, 2004), but rather as the complex coordination and management of the information transmitted though complementary channels in order to effectively present a coherent image of the organization to the targeted audiences.

Beverland and Luxton (2005) argue that one of the main effects of IMC is the development of brand trust and credibility. Proctor and Kitchen (2002) emphasize that in the last 10 years there has been a significant move away from line branding towards corporate brand. The main reason is the desire to amortize communication across the entire portfolio as the cost of designing and supporting individual brands continues its upward curve. Board members and executives have come to realize that a major portion of shareholder value is brand equity, which requires careful development and management (Laczniak, 2005). In a fragmented and highly competitive marketplace, coherent images and messages lead to a greater impact on the perception and attitudes of targeted audiences (Moriarty, 1997). The integrated marketing communication effort can ensure that brand messages are strategically consistent and new communication technologies are effectively used to facilitate profitable interactions with customers and other stakeholders.

Despite the recognized impact of the Internet on integrated marketing communication, very few studies have investigated the specific requirements and opportunities for IMC in the online environment (Durkin & Lawlor, 2001), and the relation between IMC and customer relationship management (Grőnroos, 2004; Johnson & Schultz, 2004; Schultz, 2003).

This article attempts to investigate the particularities of implementing integrated marketing communication in an

online environment. The study considers that the specific characteristics of the Internet transform the application of IMC principles from an alternative option to an absolute requirement.

RESEARCH METHODOLOGY

In the first stage of this research project, a series of secondary sources of data have been accessed in the first instance, in order to collect general information about the evolution of the IMC concept, Internet characteristics, online communications, and online audiences.

In the second stage of data collection, a series of semi-structured interviews have been conducted with marketing or communication managers of Internet-active UK retailing firms. Using the contact information provided on their Web sites, 50 UK retailers specialized in consumer products (food, drinks, cosmetics, clothes, shoes) were contacted by phone or e-mail and invited to participate in this study. Twenty-four of these firms responded favorably, but only 19 interviews could be organized because of time restrictions in the interviewees' program. The face-to-face interviews took place from February to May 2006, and lasted between 40 and 60 minutes. The topics of discussion included the concept of integrated marketing communications, the opportunities and challenges created by the Internet concerning the corporate communication model, and the specific strategic model that can enhance the online marketing communication process. The analysis of the primary data was done manually, considering the limited number of interviews performed and the exploratory nature of the study.

THE IMPACT OF INTERNET TECHNOLOGY ON MARKETING COMMUNICATIONS

The rapid development of the Internet in the last 15 years has had a profound impact on traditional marketing paradigms and practices. But, most importantly, the Internet has changed the classical communication procedures, because of three specific and co-existent characteristics that differentiate it from any other communication channel:

- *Interactivity*—The Internet offers multiple possibilities of interactive communication, acting not only as an interface, but also as a communication agent (allowing a direct interaction between individuals and software applications).
- *Transparency*—The information published online can be accessed and viewed by any Internet user, unless this information is specifically protected.
- *Memory*—The Web is a channel not only for transmitting information, but also for storing information—in other words, the information published on the Web remains in the memory of the network until it is erased.

The networked world has increased exponentially the number of available channels of communication. We get messages from more different media: e-mail, voicemail, faxes, pages, cell phones, interoffice memos, overnight courier packages, television (with hundreds of channels), radio, Internet radio, and so forth. As a result, the media that used to provide an efficient channel of communication for practitioners have now become only noise that most of the audiences have learned to filter out. On the other hand, the *networked environment* provided the audiences with a new model, one in which they no longer accept every message a communicator wants to push to them, but they rather pull the information that suits their interests and needs. In the networked environment, information must be available where audiences can find it, and it needs to be customized or customizable (Rowley, 2001, 2004).

Therefore, in comparison with the traditional customer, the Internet user has more control over the communication process and can adopt a more proactive attitude, expressed by the capacity to:

1. easily search, select, and access information (using search and meta-search engines, intelligent agents, etc.);
2. contact online organizations or other individuals (using e-mail, chat, or discussion forums); and
3. express their opinions/views in a visible and lasting manner (creating and storing online content).

Taking advantage of the various online resources requires strategic thinking that recognizes that all these aspects of the networked world coexist. They must be coordinated to achieve specific, measurable objectives consistent with the goals of any marketing communications effort.

THE MEANING(S) OF INTEGRATED ONLINE MARKETING COMMUNICATION

The lack of a unifying definition for integrated marketing communication is one of the main barriers for the development and the practical application of this concept. One possible explanation of this theoretical crisis is the multitude of possible coexistent meanings for the IMC concept. This assumption might also be true in the case of Internet communication.

In order to identify the meaning(s) of integrated online marketing communication, the interviewees have been asked

Table 1. The practical meanings of integrated online marketing communication

Meaning	Frequency	Percentage
Combination of communication modes (one-to-one, one-to-many, many-to-many)	19	100
Integration of information types (text, sound, image)	19	100
Consistency of messages transmitted through the online communication mix (coherent meaning)	19	100
Integration of marketing and PR communication functions in the messages provided online	19	100
The coordination of the process—message conception, transmission, feedback reception, and analysis—in a closed loop	18	94.7
The direct connection of the corporate information system with the Internet	19	100
Coordination of internal, external, and internal-external flows of information	17	89.4
The integration of online marketing communication with the communication conducted through traditional channels	17	89.4
The consistency of the corporate message at global/international levels	11	57.8

to freely express the issues related with this concept in their practical activity. The responses have been semantically analyzed; the categories of meaning that have been identified are shown in Table 1.

As can be seen for all respondents, integrated online marketing communication represents a multi-faceted phenomenon, which comprises issues related to the message, the communication function, the management of information, and the specific mix of channels used for corporate communication. On the basis of these answers, the synergies and the challenges raised by the Internet are discussed in more detail in the following two sections.

INTERNET-BASED COMMUNICATION SYNERGIES

Internet technologies allow online-active organizations to implement three main communication synergies:

1. *The integration and coordination of communication modes*: The organizations can combine one-to-one (e-mail), one-to-many (list-based e-mail messages, Web pages), and many-to-many (discussion forums) communication in the online environment. This synergy increases the flexibility of the integrated communication approach, providing opportunities both for the personalization and the integration of messages (Rowley, 2001, 2004).
2. *The integration and coordination of various types of information* (Azzone, Bianchi, & Noci, 2000): The recent advances in information and communication technologies (broadband) allow organizations to transmit or receive a complex combination of information in the form of text, sound, and images (static and/or dynamic). This synergy has a direct effect on the complexity and clarity of the communication, enhancing the capacity of the organization to tailor its messages to the specific needs and requirements of various audiences.
3. *The integration and coordination of complex information flows between the organizational intranet and the Internet:* Organizations are now able to implement advanced software applications that connect their marketing and management information systems with the online environment, and to coordinate automatically the communication with various audiences (Basu, Poindexter, Drosen, & Addo, 2000). This capability has a powerful impact on multiple aspects of the communication process:
   - the capacity to capture and register automatically customer data (demographic or behavioral) and customer feedback;

- the capacity to analyze automatically the information collected about audiences, to a level of segmentation and detail that allows the implementation of one-to-one marketing communication; and
- the capacity to use the existing databases in order to automatically launch and coordinate highly targeted communication campaigns (automatic e-mail responses, automatic e-mail campaigns, personalized event marketing, promotional news, and newsletters).

INTERNET-BASED COMMUNICATION CHALLENGES

The online environment creates not only opportunities, but also challenges for the marketing communication process. The transparency of the Web makes online information available to all audiences, and reinforces the need for consistency in the planning, design, implementation, and control of online marketing communication (Hart, Neil, & Ellis-Chadwick, 2000).

On the other hand, since they are sharing the same channel and audiences, the marketing and the PR messages published on organizational Web sites are becoming more integrated (Ashcroft & Hoey, 2001). The corporate Web site is usually structured on various information categories, such as organizational profile, activity, products and services, financial reports, and other information for investors, job vacancies, contact, and related links.

The variety and multiplicity of information, sources, and interpretations available online raises an important challenge related to the management of the corporate image and identity. The voice of the corporation cannot be considered anymore as the dominant message, but only as a component in a mosaic of communication activities. The meaning is not simply transmitted, but must be negotiated separately with each online audience. The message needs to be adapted to the specific level of understanding and interpretation of each public, but on the other hand must express the same core organizational values, in order to display a coherent organizational image (Grőnroos, 2004). The various competing messages transmitted by other organizations, pressure groups, governmental agencies, or individuals must be taken into account and accommodated in such a way as the resultant effect to be favorable for the company.

The international dimension of the Internet creates another specific problem for communication practitioners. Complex choices must be made and implemented in terms of the communication strategy and tactics. If the company attempts also to reach foreign audiences, the message needs to be adapted to the cultural specificity of the overseas public. This raises important questions regarding the possibility of integrated online marketing communication in the global context.

A new strategic model must be adopted by any organization that attempts to present a coherent corporate identity in the online environment. The integrated marketing communication is the primary instrument to achieve this objective. However, the implementation of the IMC concept will have to accommodate the specific characteristics of the Internet, using the technological capabilities of the new medium to solve the specific challenges raised by the online environment and audiences.

A MODEL FOR IMPLEMENTING INTEGRATED ONLINE MARKETING COMMUNICATION

Based on the analysis of the specific characteristics of the online environment, applications, and audiences, a tentative model of integrated online marketing communications is proposed in this study. The model was designed and then refined as a result of the direct interaction and debate with 19 marketing or communication managers directly responsible for the online communication strategy of their companies.

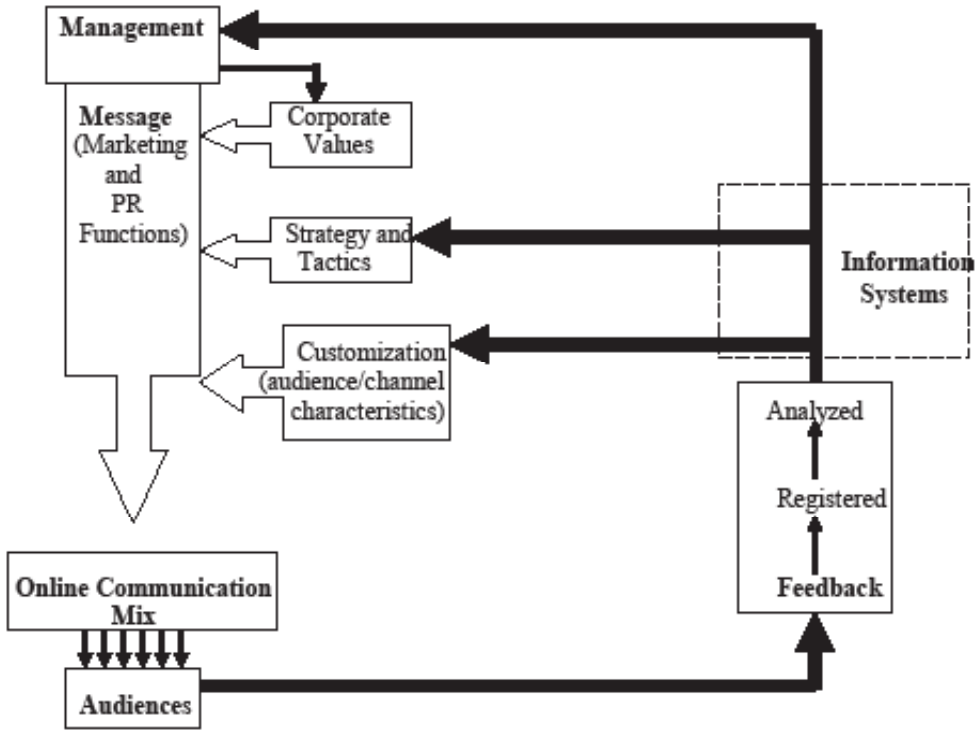
The messages sent by the company to its online audiences must be transformed/adapted in a three-stage process. First, the message should respect and integrate the core corporate values of the organization. Second, the message must be adapted in relation to the strategic and tactical objectives pursued through the online communication campaign. Third, the message should be transformed considering the specific characteristics of the targeted audience/channel. In the case of online communication, although the Internet can be considered as the main channel of communication, there are, in fact, various online applications or modalities of communication that can be combined and used as an online communication-mix (e-mail, chat, Web site, discussion forums, etc.). The online communication channels vary in terms of their degree of transparency, interactivity, memory, and selectivity, and these dimensions should be taken into account when establishing the proper *communication mix* for each targeted audience.

This process of message adaptation will preserve a flexible balance between continuity and customization, the consistency of the adapted communications being determined by the integration of the corporate core values in the structure of each message.

The respondents have also confirmed the tendency to integrate marketing and PR communication functions in the messages transmitted online, although there have been different opinions regarding the intensity of this integration.

On the other hand, the interactive dimension of the Internet forces the firm to adopt a more proactive attitude

Figure 1. A model of integrated online marketing communication



in searching, registering, and analyzing the direct and the indirect feedback transmitted by the targeted audiences—or even in some cases by all categories of relevant audiences connected to the Internet (considering the transparency and the memory of the Internet, even untargeted audiences can read and react to some of the online corporate messages).

The use of the feedback information collected and analyzed by the firm should represent a highly reactive process. The online environment is very dynamic, and any delay of an appropriate reaction to the messages sent by audiences can represent missed opportunities or aggravated situations. The company should therefore use the conclusions of the feedback analysis in order to define and better refine the strategic objectives of its communication campaigns, and the customization of the messages to audience/channel characteristics.

The feedback analysis is also transmitted to the company management, which can decide, if necessary, to modify the corporate core values in order to respond better to the market's requirements. However, this change should not be very frequent, in order to preserve the long-term coherence of corporate communications in line with the desired corporate image.

The respondents also emphasized the importance of an efficient information system that collects, selects, registers, and analyzes online input (feedback), and then acts directly on the adaptation of corporate communication strategy and tactics, as well as on the customization of online messages. In some cases, campaign management applications can use the feedback received directly and automatically for a more effective online message customization. On the other hand, the corporate information system represents the necessary basis for enhancing the customer relationship management capabilities of the firm (Grőnroos, 2004; McKim, 2002). The level of detail of customer-related data stored and analyzed by the internal information system defines the level of personalization that can be applied by the firm in its online communication and marketing campaigns. In fact, the modern database and campaign management applications permit the implementation of effective one-to-one marketing communication in the online environment.

FUTURE TRENDS

The rapid development of online communication tools requires a continuous adaptation and change of perspective from marketers. Search engines, newsgroups, blogs, discussion forums, advergames, and shared virtual reality environments create new opportunities and challenges for transmitting personalized messages to the online target audience. In these circumstances, the use of the company Web site as the main platform for integrating the online marketing communication must be complemented by the creative use of additional online communication facilities.

These new online applications permit a creative combination of above- and below-the-line communication methods, using a combination of text, images, and sound in order to transmit relevant messages to the target audience. On the other hand, in comparison with the corporate communication diffused through the company Web site, many of these online communication tools are open and interactive, outside the control of the company. In these conditions, online marketers should design and implement a formal process of technological and competitive intelligence comprising the following procedures:

- identifying the new online communication tools and evaluating their potential in relation to the targeted audiences;
- realizing a regular survey of the communication strategies applied online by competing firms;
- mapping the main online communication tools in terms of their effect on the corporate image;
- integrating the new online communication tools in the marketing communication portfolio of the firm; and
- assessing the performance of the new online communication tool and making corrections for increase efficiency and effectiveness.

CONCLUSION

This exploratory study has attempted to identify the major changes determined by the development of Internet technology in the area of marketing communications. The online environment raises a series of opportunities and challenges for communication practitioners.

The audiences become more fragmented and proactive, but, on the other hand, the company has the possibility to combine various modes and categories of information in a complex message. Online applications also permit the enterprise to collect, register, analyze, and use customer data and feedback for better targeting online audiences and customizing its messages.

In fact, the specific characteristics of the Internet are making the implementation of integrated online marketing communication both inevitable and efficient for an online organization. The transparency, interactivity, and memory of the Internet force the organization to adopt a proactive-reactive attitude in online communication, and to combine consistency and continuity with flexibility and customization.

These characteristics can be integrated by designing and implementing a specific model of integrated online marketing communication. The message communicated online should be first infused with the core corporate values, then adapted to the online strategy and tactics of the organization, and finally customized for a specific combination of target audience/online channel. The selection of the appropriate communication-mix needs to take into account the characteristics of the targeted audiences, but also the degree of transparency, interactivity, memory, and selectivity of each online channel.

The use of advanced online applications to collect customer data and feedback information is paramount for the success of the online communication campaign. Because of the high interactivity of the Internet, the communication process has become a real-time dialogue (Grőnroos 2004) that forces the company to quickly analyze the response of the audience to its messages and to restructure dynamically its message to the new circumstantial situation. Integrated online marketing communication is not an isolated and self-sufficient concept, but represents the main instrument for an effective implementation of online customer relationship management campaigns.

A number of important issues relevant for the implementation of online integrated marketing communication have not been addressed because of space and methodology limitations. These areas can represent the subject of future research projects investigating: the management process of integrated online marketing communication, the criteria used for selecting and combing various channels in the online communication mix, the relation between the organization and Web advertising agencies, or the challenges raised by the general integration and coordination of online and off-line (tradition) communication.

KEY TERMS

Communication Mix: The combination of various communication methods used by a company to transmit messages to its publics.

Customer Relationship Management (CRM): The procedures, methodologies, and tools that help businesses manage customer relationships in an organized and effective way.

Integrated Marketing Communication (IMC): A management orientation that integrates the use of various marketing communication methods such as advertising, sales promotion, public relations, and direct marketing in order to send a coherent and consistent message to its publics.

Marketing Communication: The messages and the related media channels used by a firm to communicate with its market.

Online Communication Channel: Online application (e-mail, chat, discussion forum, etc.) used by firms to communicate with its publics.

Public Relations Communication: The messages and the related media channels used by a firm to communicate with various publics, in order to develop a positive and coherent corporate image.

Target Audience: A clearly defined demographic group for which the company develops and transmits various communication messages.

Marketing Vulnerabilities in an Age of Online Commerce

Robert S. Owen
Texas A&M University, Texarkana, USA

INTRODUCTION

This article provides an overview of strategic and tactical threats to the marketing efforts of businesses engaged in online marketing activities. Marketing-related assets that are vulnerable to attack include networking and hardware resources, human resources, information resources, promotion resources, and brand equity and customer good will. Vulnerable areas that an organization should protect include its core network and computing infrastructure, its internal social infrastructure, domain name registrations related to its branding, and branding exploits on external social networks. Although hacks of networking and hardware resources are of concern, the focus of this article is on encouraging marketing managers and strategists to consider a wider variety of external and internal threats.

BACKGROUND

While the Internet has provided new opportunities for businesses and marketing, it has also created new vulnerabilities to attack. An organization's existing brand name can be taken hostage or destroyed via the online activities of third parties; opportunities to penetrate an online market with a new brand name can be diminished or eliminated by the actions of external third parties. Customer good will can be destroyed by the online activities of competitors or disgruntled customers. Technical, financial, and human resources can be diluted or consumed by the online activities of third parties. Confidential internal information can be compromised by employees who use e-mail and social networking Web sites for nonmission or personal uses.

This article attempts to outline such emerging strategic and tactical threats to online marketing efforts. While technical support people tend to focus on threats to hardware and networks, little guidance exists for marketing managers who should be interested in a wider variety of issues that can affect an organization's products, promotion, distribution, and costs (which affect pricing). "Scholarly" discussion on the subject is almost nonexistent, so this article attempts to compile, categorize, and discuss the sorts of issues that are starting to emerge in the popular press.

STRATEGIES AND TACTICS FOR ATTACK

The following are emerging strategies and tactics that have been enabled by online activities.

Fishing for Information

There are three basic ways to gain access to information within an organization: through exploits of the networking infrastructure, through exploits of the human social network, and through human mistakes. Networking exploits to obtain internal information could include system scans and probes, account and root compromises, packet sniffing, and malicious programming (cf. NIAC, 2004). A survey of 700 organizations by the Computer Security Institute and the U.S. Federal Bureau of Investigation found that unauthorized access amounted to $31.2 million in annual losses, and theft of proprietary information amounted to $30.9 million (Gordon, Loeg, Lucyshyn, & Richardson, 2005).

Attempts to fish for information do not have to be aimed directly at scanning and probing a networking system from the outside environment. A remote access Trojan is a hidden piece of malicious software that is attached to another seemingly innocent software application, such as a cute electronic greeting card or a more serious looking Excel spreadsheet (Vamosi, 2004). When these executable applications (greeting card, screen saver, spreadsheet, etc.) are opened, the Trojan is silently released to begin, say, covertly scanning files or logging keystrokes to be silently sent to another organization. These can be injected into an organization's computer if an employee opens an infected e-mail message or if an employee brings work that was infected on an online home computer. Once inside the organization, the Trojan can attach itself to internal applications that are exchanged, such as when employees exchange internal e-mail with executable attachments.

Microsoft employees, for example, reportedly received an infected e-mail which released a Trojan inside the Microsft organization; this in turn disguised itself as the Notepad text editor and sent information to a remote computer in Asia, with stolen passwords then used to gain access to the source code of Microsoft products (Thurrott, 2001). Attempts to

fish for information can be targeted to individual high-level executives, not just the organization as a whole. For example, an individual who opens an Excel spreadsheet attached to an e-mail message could unknowingly be installing a malicious program that now scans that person's files for information that is sent back to the criminal hacker (cf. Miller, 2003).

Information can be released through the mistakes or ignorance of employees. Members of the British Computer Society were sent a customer satisfaction survey that mistakenly contained the e-mail addresses of all recipients in the "to" field, allowing recipients to see the addresses of all other members (Oates, 2007). Information can also be obtained through simple employee ignorance. For example, employee names and e-mail addresses can be harvested through the use of chain e-mail (also known as a chain letter). Chain e-mail relies on social engineering, whereby one employee receives an e-mail message, for example, describing a cute lost puppy looking for a good home, and feels compelled to forward it to others within and outside of the organization. As each recipient forwards the seemingly harmless message to several others, a name and address list can be accumulated in each forward. This list can then be harvested when the chain letter eventually makes its way back out of the organization to the perpetrator; this allows a competitive intelligence researcher to find out who is employed by the organization, to find out who are partners or affiliates with the organization, or to find out who are the less-careful employees who are more likely to open e-mail of malicious intent. One of the more well-known incidents is the "Richard Douche Free CD" chain letter, in which the perpetrator offered a free CD to anyone who forwarded it to others with a CC to the perpetrator (Hoaxbusters, undated a).

Another way to harvest e-mail addresses is to send a message that contains a single unseen one pixel image tag. If the e-mail is received and opened, the hidden link accesses an external server and a record that this is a live e-mail address is made. The sender merely needs to guess at e-mail addresses and to use a subject line that is either motivating (social engineering) or appears to be official business in order to get a recipient to open it. The simple method of implementing this tactic is described by Voicenet Communications (undated). Organizations can use e-mail clients that block images, but this in turn creates problems for marketers (e.g., suppliers and other business partners) who send e-mail with legitimate product images (cf. Popov & McDonald, 2004).

Disruption and Consumption of Network and Hardware Resources

Disruption and consumption of networking and computing resources can temporarily inhibit an organization from conducting online commerce (cf. CERT, undated). Gordon et al. (2005) reported that annual business financial loss due to virus attacks were $42.8 million for 700 survey respondents, while denial of service (DOS) attacks were costing $7.3 million. Costs associated with attacks include not only the cost of defence, but also include the cost of lost business. After launching World Series online-only ticket sales, the Colorado Rockies baseball team received a malicious attack of 8.5 million hits. With their online resources swamped, they were forced to stop sales after only two hours and 500 tickets sold (Sports Illustrated, 2007).

In addition to shutting down an organization's Web site server, an organization's e-mail server could be swamped or crashed, temporarily disrupting communications with customers, suppliers, business partners, and employees. A former employee was convicted after crashing the server of a UK-based insurance company by swamping it with five million e-mail messages (BBC News, 2006). More difficult to trace, forged e-mails that contain hundreds of nonexistent recipient addresses in the "copy to" fields can cause some e-mail servers to then forward duplicate messages with huge attachments to those hundreds of e-mail addresses. Even if the recipient name is nonexistent, the server receiving those e-mails can be swamped to the point of crashing. Researchers tested the mail servers of all Fortune 500 companies and found that 30% could be used to make this kind of attack (Knight, 2004).

Disruption and Consumption of Human Resources

British mobile phone retailer Phones 4U started a ban on the use of e-mail on the belief that this would save each employee 3 hours per day. The company moved to communicating via phone and its internal intranet (Thomas, 2003). Deliberately flooding an organization with bogus e-mail messages can consume substantial amounts of recipient time as well as computing resources. Deliberately flooding an organization with electronic greeting cards, chain e-mail, and other such tactics that rely on social engineering can cause employees to waste time with activities that are not related to work. These could cause the organization to quit trusting e-mail or even to quit using e-mail communications altogether; if e-mail attacks are spoofed (faked) to appear to be from a particular business partner, an unscrupulous competitor might be able to cause the receiving organization to block incoming communications from that competitor.

Disruption of Promotion Strategies

These attacks are used to consume a competitor's promotion budget, to discourage a competitor from investing in online promotion activities, or to trick an organization into believing that its online marketing tactics are working better than actual performance. Traffic aggregation is the use of

a domain name, often multiple domain names, to redirect visitors to another Web site (cf. Marsan, 2002). When Web designers build a Web site, they might promise immediate traffic (visitors) to the Web site. Visitors to the client's Web site had believed they were going to some other Web site, but that Web site instead redirected them to the client Web site. A hit log might show a lot of visits to the client's Web site, but these redirected visitors did not end up at the Web site by choice or interest. Through traffic aggregation, the client organization is tricked by the Web site designer into believing that its marketing investment is generating legitimate Web site interest when it is not doing so.

Competitive click fraud is used to either drive up a competitor's online advertising budget, used to either deplete the competitor's promotion budget or to discourage the competitor from advertising online (cf. Claburn, 2005; Lee, 2005). With this tactic, one competitor can repeatedly click on another competitor's online advertising, driving up the advertising competitor's costs in pay-per-click advertising pricing. The competitor can also bid up the prices for pay-per-click rates, discouraging the advertising competitor from even advertising at all. Affiliate click fraud (Stricchiola, 2004) can also drive up an organization's pay-per-click costs, but in this case, the fraud is from advertising hosts rather than from competitors. Although done for financial gain by the advertising host and not necessarily to harm the advertising organization, this is still an external threat to the conduct of online commerce.

Damage to or Disruption of Branding Strategies

These attacks cause a loss of brand equity, customer good will, or brand penetration opportunities. A chain e-mail campaign, for example, is sometimes started to deliberately damage the reputation of a person or firm (Hoaxbusters, undated b). In one chain e-mail, an article is attributed to the popular American radio personality Paul Harvey to give it some level of credibility. The article purports to be providing "facts" which suggest that U.S. Senator Hilary Rodham Clinton, wife of former U.S. president Bill Clinton and a presidential candidate herself as this article is being written, was associated with the defence of Black Panther members accused of tortuous murders in 1969; Ms. Clinton, however, was merely a college student at the time (Snopes, 2005). This chain e-mail has the potential to damage not only the Senator and presidential contender's political reputation, but also the reputation of the radio personality Paul Harvey.

Domain names that attract traffic (visitors) have value and so are attractive to domain name grabbers whose activities can damage a brand name or the reputation of an organization. Domain grabbers register a domain name as it expires in order to capture its traffic. In some cases, the domain is allowed to expire accidentally, but in many cases, it is allowed to expire because the owner believes that it is no longer needed. The Catholic Diocese of Brooklyn, New York, for example, abandoned a domain name that was difficult to remember after registering a new one. It was later embarassed to find that the old name was being used as a host for adult content because it was still attracting traffic (Hardy, 2001). Domain name squatters register a domain name that has value in generating interest, and therefore traffic to the name. San Francisco mayor Willie Brown found his name on multiple domains, used by detractors to drive traffic to content that was unfavorable to the mayor (Learmonth, 1999).

Domain typosquatters register a mistyped variant of a brand name to gain traffic of people who had attempted to visit a Web site associated with the name (cf. Sullivan, 2000). Spoofing is done when someone registers and uses a domain name that is deceptively similar to a trademark or organizational name, potentially harming the brand or organizational name. The domain name irs.com looks very much like it would be the official Web site for the U.S. tax agency, Internal Revenue Service, which is instead located at irs.gov. Problems faced by users of the spoof Web site could ultimately reflect badly on the real organization. In an interesting twist, traffic that might go to the spoof irs.com is stolen by the typosquatter wwwirs.com (the typosquatter is getting visitors who had left out the dot after typing "www").

Social networking and consumer rating/complaint Web sites can also be harmful to an organization's marketing efforts. Phoney pages on the social networking Web site MySpace that purport to be posted by famous business people often contain malicious misinformation (Petrecca, 2006). U.S. presidential candidates Hilary Clinton and Barack Obama were both cast in unflattering roles in anonymously sponsored advertisements that appeared on YouTube (Fox News, 2007). Consumer rating and complaint Web sites, such as Epinions, RateItAll, PlanetFeedback, and My3Cents, can contain unflattering or false information about an organization or brand. Organizations also need to be concerned about unflattering or false information that is posted on forums, blogs, and personal Web sites (cf. Dozier, 2006). Urban legends, as in the chain e-mail which falsely describes Senator Clinton as having defended tortuous murderers, can be spread through social engineering.

FUTURE TRENDS

Due to online commerce, an organization's information resources, computing and human resources, promotion resources, and brand reputation are increasingly more vulnerable than was once the case. Organizations have much control over most of the strategic and tactical points that are outlined above. For example, information leakage and

lost productivity associated with social engineering could be halted altogether; employees could be prohibited from opening executable e-mail attachments even from colleagues if not mission-related, from exchanging mission-unrelated e-mail such as chain e-mail, and from conducting any online activities that are not mission-related. Organizations can dilute spoofing activities by maintaining their own spaces at social networking Web sites such as MySpace and by maintaining, by registering typosquatted and other variations on the domain names associated with new brands. Threats to branding and marketing will continue (and possibly worsen) if organizations do not become more proactive in protecting marketing assets depends on how well these threats can be publicized.

CONCLUSION

Marketing managers and strategists should monitor (and protect) the following:

- Monitor the Core Infrastructure for system probes, scans, and such; monitor for e-mail that is not related to mission-related activities; monitor for the installation of software applications that are not mission-related.
- Monitor the Internal Social Infrastructure for employee mission-unrelated activities that include the exchange of electronic greeting cards, the exchange of chain e-mail, personal e-mail activities, and visits to mission-unrelated Web sites; monitor employees for taking work outside of the physical and virtual confines of the organization; monitor employees for bringing any work or personal activities into the organization.
- Monitor External Social Infrastructures, consumer rating sites, and public forums for the spread of urban legends, unflattering information, and false information; maintain an organizational presence on social networking spaces such as MySpace and YouTube.
- Monitor Internal and External Domain Name Registration to ensure that names associated with organizational brands are not hijacked, grabbed, squatted, typosquatted, or spoofed.
- Monitor Online Promotion Exploits from competitors and online advertising affiliates; monitor potential attempts to siphon Web site visitors via traffic aggregation techniques.

KEY TERMS

Chain E-Mail, Chain Letter: An e-mail letter that directs recipients to forward multiple copies of the same letter to others.

Click Fraud: Clicking on an online advertisement link for the premeditated purpose of causing a pay-per-click advertiser to pay for the click without the intent to take any other actions (such as buy a product).

Domain Name Grabbing: Registering an abandoned or lapsed domain name immediately after it is released by a registrar.

Domain Name Squatting: Registering a trademark, an organization's name, or person's name as a domain name with the intention to profit from traffic to an unrelated Web site or by reselling the domain name back to the person or organization.

Exploit: An action that takes advantage of weaknesses or vulnerabilities in software or hardware.

Social Engineering: Manipulating people through their natural trust or desire to help in order to trick them into divulging information or performing actions.

Spoofing: Pretending to be the owner of a trademark or organization name; registering and using a domain name that is deceptively similar to a trademark or organization name. This could be through transposing words or inverting a phrase.

Traffic Aggregation: Using a domain name, often multiple domain names, to drive traffic (visitors) to one Web site.

Trojan: A malicious program that is hidden within a seemingly useful and harmless program. Also known as a Trojan horse.

Typosquatting: Registering and using a domain name that is a misspelled variation of a trademark or organization name.

Urban Legend: A story that contains some measure of truth or fact but is embellished with misinformation and repeatedly passed from person to person.

Measurement Issues in Decision Support Systems

William K. Holstein

University at Albany, State University of New York, USA

INTRODUCTION

The past decade has seen tremendous progress in systems for information support–flexible and adaptable systems to support decision makers and to accommodate individual needs and preferences. These model- or data-driven or hybrid decision support systems (DSS), now often called business intelligence (BI) systems, incorporate diverse data drawn from many different internal and external sources. Increasingly, these sources include sophisticated enterprise resource planning (ERP) systems, customer relationship management (CRM) systems, data warehouses and other enterprise-wide systems that contain vast amounts of data and permit relatively easy access to that data by a wide variety of users at many different levels of the organization. Decision support, DSS and BI have entered our lexicon and are now common topics of discussion and development in large, and even in medium-sized, enterprises. Now that DSS is well established, attention is turning to measurement and the metrics that populate such systems.

BACKGROUND

Decision-making as we know it today, supported by computers and vast information systems, is a relatively recent phenomenon. But the concept has been around long enough to permit the methods and theories of decision-making to blossom into "a plethora of paradigms, research schools, and competing theories and methods actively argued by thousands of scientists and decision makers worldwide" (Robins, 2003).

Early computer systems focused primarily on accounting and financial data. It is said that information systems are about transforming data. We could say that early systems transformed data into aggregated or summarized data – for example, wage rates, hours worked, benefits and tax data, and so forth transformed into departmental or corporate payroll reports.

In the mid-1960's, the development of the IBM System 360 and rapidly proliferating competitive systems from other vendors ushered in the era of Management Information Systems (MIS). Applications quickly moved beyond finance and accounting data and into operations. Transaction processing systems began to generate order, usage, and customer data that could be analyzed with (what quickly became quite sophisticated) models. The transformation of data into information became commonplace. For example, data on sales and usage, costs, supplier lead times and associated uncertainties were transformed into reorder points, safety stocks, and comprehensive inventory management and production scheduling systems.

Despite the broader reach of MIS, such systems are characterized by highly structured, infrequent reports, often with standard formatting. Frequently, because it was "easier" (for the IT staff), each manager in a given function, for example, marketing, received the same voluminous report – even though a manager of activities in Japan could not careless about data relating to New Jersey. Despite the tremendous advance of MIS over previous-generation systems, contemporary MIS systems draw most of their data from enterprise resource planning (ERP) systems that contain mostly internal data on transactions, and therefore suffer from many of the same problems as older systems (an internal, historical, and financial focus).

Decision support systems "evolved from the theoretical studies of organizational decision making done at the Carnegie Institute of Technology during the late 1950s and early '60s and the technical work on interactive computer systems, mainly carried out at the Massachusetts Institute of Technology in the 1960s" (Keen & Scott Morton, 1978; Power, 2003). By the end of the 1970's, it was clear that model-based decision support had become a practical, useful tool for managers.

A 1970 article by John Little of MIT clarified the concept of decision support. In a 1979 paper he provided a definition that is paraphrased here:

A coordinated collection of data, systems, tools, and techniques along with requisite software and hardware, by which an organization gathers and interprets relevant information from the business and environment and turns it into a basis for action.

Another useful definition of a DSS is:

Interactive computer-based systems designed to couple the intellectual resources of individuals with the capabilities of the computer to utilize data and models to identify and solve semi-structured (or unstructured) problems and improve the quality of decisions (paraphrased from Gorry & Scott Morton, 1989)

In these two definitions, we see some important concepts–gathering and interpreting relevant information (related to the decision at hand, not just to transactions), using the intellectual resources of managers, and providing information that can be used as the basis for action. The "new idea" here was that managers need more than information, they need decision support. If provided with good data, and models and tools to transform the data into useful information, their effectiveness will improve.

As the field has evolved, the term *Business Intelligence* has come to be used for the types of systems that were previously referred to as DSS. A simple definition of business intelligence fits well with the DSS definitions given earlier: "Technologies that help companies make better business decisions" (www.orafaq.com/glossary).

METRICS OF BUSINESS AND MANAGEMENT PERFORMANCE

The definition of decision support, or the capturing of business intelligence, is supporting managers who are running the business. Increasingly, it refers to supporting middle-level managers who rely on a mix of internal and external data that is steadily tilting towards external data on customers, markets, competitors, and the political, regulatory and economic environment. If we define the process of *control* as tasks undertaken by middle- and lower-level managers to *ensure that plans come true*, we see clearly the role of data and information in decision support: managers use data and convert it into information to *monitor* the implementation of plans to ensure that strategic goals are met. If the monitoring indicates that plans will not be fulfilled, corrective *action* must be taken *in time* to ensure that the plan is in fact met. If the information from a decision support system cannot serve as the basis for action (i.e., cannot first help the decision-maker to decide to do something, and then help to decide what to do) the information will not be used and the system will therefore be useless.

The keywords in the previous paragraph that lead to action are *monitoring* and *in time*. Monitoring is the management function that is the primary target for DSS implementation. Timeliness is crucial; advance warning without enough time to steer around the iceberg, or to make the necessary changes to ensure that strategic plans are successful, is not the kind of decision support that managers seek.

In recent years, we have seen the emergence of *operational business intelligence*, the same concept as the older BI and DSS, but focused on shorter-term, operational decision-making.

Operational BI most differs from BI for management and control purposes in both the level of detail required and in the timeliness of the data. Operational BI may involve accessing a transaction system directly or through a data warehouse that is updated in near real-time multiple times throughout the day. Business intelligence for management and control purposes may also be in near real time, but can also be based on weekly or monthly data (Howson, 2008).

As we think about supporting management decision-making, we must think of how managers work at decision-making. What they do is easy to describe (despite the fact that it is fiendishly difficult to do it): managers abhor irregularities and plans that do not come true, yet they thrive on exceptions. They look for things that do not fit, that look funny, and that are out of line. Then they ask why. Much of their time is spent trying to answer that simple question and searching for actions that will make perceived problems disappear and bring things back to "normal expectations".

Examples of the "whys" that plague managers of large companies include:

- Why is it that Cadillac does not attract younger buyers?
- Why did the PC manufacturers who dominated the market in the 1990's lose so much share to Dell Computer?

Shorter-term examples include:

- Why did that ad campaign not work? (Think of Infiniti's ad campaign when the brand was introduced in 1989-90 – the ads never showed the car and while considered creative, it started the brand on an also-ran trajectory that to this day, has not caught up with its Japanese and European luxury-car rivals.)
- Where are the bottlenecks in our supply chain?
- What can we do to fix a supplier who is behind on delivery of a critical component? (Think of the current problems of the Airbus A380 and the Boeing 797).

For each of these questions, one can imagine a manager who is conjuring the question as a response to a perceived exception that needs to be "fixed".

- Which Cadillac sales manager thinks that the product is not attractive to young buyers?

- What ad manager thinks the campaign failed?
- What Boeing manager wants to contemplate dropping a supplier and finding another one immediately?

And yet, in all cases, the exception is obvious and something has to be done.

We cite this process and these questions to focus clearly on metrics of business performance and management performance. Measurement and metrics are the tools for identifying exceptions. Exceptions, in turn, drive management to seek and find actions that will deal with the exceptions and achieve strategic goals. But think for a moment about traditional metrics; the Cadillac manager knows how to measure the average age of Cadillac buyers. But how does the manager measure the potential attractiveness to younger buyers of a proposed new model? How does the manager measure the potential attractiveness of a proposed advertising campaign? How does the manager measure the potential attractiveness of a proposed discount or rebate program? This is where judgment, experience, and intuition come into play – and these are precisely the areas where managers need decision support.

In the current environment, measurement must be related to business matters, business strategies and goals – the stuff that managers deal with in their everyday environment. They are trying to formulate and monitor plans that reflect the strategic mission and goals of the business, that is, accomplish strategic tasks. They need IT that can add value to the business in ways that they can clearly understand.

We turn now to implementation issues surrounding these ideas and suggest some guidelines for DSS development incorporating new metrics.

IMPLEMENTATION GUIDELINES

Breadth in Measurement

A first guideline, as we have discussed, is that breadth in measurement (beyond financial and accounting measures) is important. The ideas behind the Balanced Scorecard (Kaplan & Norton, 1992) should be understood and implemented in decision support systems; breadth, however, does not imply complexity.

Consider the following quote – it may be true since it does not say "*only* three things" – and it fits the point here: "The ability of companies to boost profits depends on three things: how high they can lift their prices, how much they can increase output per worker, and how fast wages are rising" (Mandel, 2002).

The ability to raise prices, often described as "pricing power", is related to many different metrics and measures. Some of these measures are "hard", such as ROI, return on capital employed, turnover, profitability of other divisions, products and services, and capital structure; but many are not. Examples are "soft" metrics such as customer perception of the company's value proposition, features and benefits of products and services, embedded technology, total quality (not just product quality), competitive position in the marketplace, relationship with customers, suppliers, and workers. Increasing worker productivity involves similarly complex metrics.

Simplicity

A second guideline is simplicity. Metrics must be easy to understand and communicate. They must relate to relevant activities and tasks, and be "drivable", that is, managers must be able to use the measures to determine (drive) actions that will affect future results. The following quote makes this point very effectively and provides some detail on what the metrics should accomplish:

…Companies need an 'organizational magnifying glass' – something that focuses the work of employees so everyone is going in the same direction. Strong leaders do this. However, … they need more than just the force of their personality and experience to focus an organization. They need an information system that helps them clearly and concisely communicate key strategies and goals to all employees on a personal basis every day (Eckerson, 2005).

Selectivity

Our third suggestion relates to simplicity: DSS designers must avoid the impulse to measure everything. The focus must be only on the most important metrics from the user's (the decision maker's) point of view. Metrics should be built in hierarchies, with more details for lower-level managers, and fewer, more summarized measures for higher-level managers. Here is another quote from the previous source that emphasizes the importance of not only focus, but focusing on only the most important tasks:

The system should focus workers on tasks and activities that best advance the organization's strategies and goals. It should measure performance, reward positive contributions, and align efforts so that workers in every group and level of the organization are marching together toward the same destination. In short, what organizations really need is a performance dashboard that translates the organization's strategy into objectives, metrics, initiatives, and tasks customized to each group and individual in the organization (Eckerson, 2005).

Research and Learning

Fourth, DSS design should emphasize data and data collection, not just for reporting, evaluation and auditing, but for research and learning, for finding exceptions, for learning the root causes of exceptions and for exploring alternative courses of remedial action. "Research" is perhaps a strange term to use in the context of management practice, but research, in the best sense of the term (investigate, study, explore, delve into, examine) is required to find, first, meaningful measures of exceptions (*deviations* in the following quote) and, then, their causes.

Feedback is essential for control of any system. Without the feedback provided by sight, sound and touch, we humans would not be able to identify threatening or favorable situations and there would undoubtedly be fewer of us on the planet. The same is true for companies. When managers don't have timely and meaningful feedback, companies fail to recognize opportunities and become much more vulnerable to hazards that can threaten their existence.
The feedback provided by performance measures gives managers better control over their areas of responsibility, whether it is a department, a plant, or a division. With measures in place, deviations in performance are detected earlier, enabling managers to step in and minimize the damage or make the most of the opportunity. Performance measures also prevent managers from getting blind-sided with bad news (Kados, 1998).

Benchmarking

As a fifth guideline, we cannot overemphasize the importance of benchmarking against credible external targets. Indeed, without a firm connection to good external benchmarks (best practice, best-of-class indicators) companies can fall victim to *manumation*, simply automating old, outdated, manual processes. A formula for manumation has been around for years:

OP + NT = EOP
(**Old Processes** plus **New Technology** equals **Expensive Old Processes)**

Benchmark analysis can identify problems and suggest solutions and can serve as an excellent idea bank for new metrics. Benchmarks or comparatives are important because metrics need anchor points for comparison. Without a benchmark for "normal" or "best in class", how can you gauge results?

Simple benchmarks might include your own past performance, current goals, customer expectations for things like order-to-delivery time, percentage defects, or on-time delivery. In particular, you should know how you compare to others in your industry and leaders in your functional area. Be sure to think carefully about which comparatives will lead to valid conclusions and sensible action.

In some industries and functions, there are a growing number of highly useful benchmarks from trade associations, consulting companies and other organizations. An example of a widely used set of metrics is the Supply Chain Council's Supply Chain Operations Reference (SCOR) model (Supply-Chain Council, 2004). SCOR allows companies to objectively measure their supply chain practices and compare them against benchmark standards gathered from the more than 700 manufacturing and related companies that are members of the Supply Chain Council. The SCOR model groups supply chain functions into five process categories: Plan, Source, Make, Deliver, and Return. Metrics at each level of the model are supported by progressively more detailed metrics for processes at lower levels.

The following quote highlights the importance of metrics to support process change when new factors, such as Web-enabled processes, are introduced:

Updating performance metrics for Web-enabled supply chain operations became important the day your company migrated from an information-only Website to one with interactive customer capabilities. Whether you're tracking customer orders or collaborating with partners on products and processes, your new business dynamics likely don't fit the old criteria, and you may need to update your basic supply chain performance measurements to match an advanced level of attainable objectives (Schultz, 2001).

Benchmarking is useful beyond performance measurement. It can help to answer the "why"? when exceptions are identified. For example, is a manufacturer's frequent late delivery an inventory-level issue? Or is it caused by slow order-reaction-time on the part of one or more of the supply chain's participants? Benchmarking can help to target on the exact answer, which can then lead to needed adjustments.

Time

As a sixth and final guideline, we suggest careful consideration of collapsing time. Speeding up of business processes and reaction times has become almost a cliché, but time is the most important element in many new metrics to support decision-making. Consider this example from the previously quoted article:

If I said today that I need 30 percent more of something, how fast can my suppliers, and their component suppliers, deliver that? [Only] Part of the answer is in manufacturing lead time, [The other, equally important] part is administrative lead times – getting the information, sharing it, and synchronizing it.

FUTURE TRENDS

Pulling together what we have stated thus far, we see a situation that precludes significant progress in the development and implementation of decision support systems unless:

- New metrics that focus more clearly on business and management performance are developed and implemented, and
- More attention is given to metrics that focus on monitoring strategic activities, or activities that will have an important effect on the outcomes of strategic initiatives and high-level company goals.

The latter is particularly important. Without wishing to denigrate the importance of support for very-short-term operational decisions, the real prize is in supporting longer-term, more strategic decisions. This also means gathering and interpreting data and information from the lowest levels of the organization (the "front lines") and processing vast amounts of current information in a timely manner. Stated otherwise, it means taking advantage of supporting operational people responsible for short-term performance, but also making it the basis or platform for support for more long-term, strategic decisions.

A good example of this need is captured in the following quote from a recent book on dashboards, graphical interface displays of DSS data (Alexander, 2007):

…(many companies have) one dominate business, with smaller but different business units in the portfolio. Managers have a tendency to apply a single business model, expecting similar rations and performance across the businesses, which can result in dysfunctional decisions and missed opportunities. ... For example, there may be an opportunity to build a business based on the current product line, but requiring lower pricing and therefore lower costs. Managers may pass on this opportunity because of lower expected gross margins. However, it is possible that this product line may require lower levels of selling, general, and administrative spending and inventory. This may result in returns approximating or even exceeding the levels achieved by the high-end business.

This example raises interesting and provocative questions for systems designers: How can the elements of a "business model" be incorporated in a DSS or BI system, but not so deeply ingrained that it prevents good thinking about alternatives to the model? How can data from one business be "modeled" differently to see the effects of a different approach to the business? And how can that different model form the basis for a different system to support decision-making?

Early work at MIT focused on "Critical Success Factors" or "Key Performance Indicators" as the basis for metrics in information systems (Rockart, 1979; Rockart & Treacy, 1982). These metrics were defined to ensure successful competitive performance for the organization. They were incorporated in reports, and backup systems provided the ability to drill down to underlying detail, budget information, plans and objectives, competitive information, news, and more to determine the "drivers" of the success factors. More recently, the Balanced Scorecard and other initiatives have made it clear that traditional MIS systems and business metrics rely too heavily on financial and accounting measures (Kaplan & Norton, 2006). Today, the issue of metrics is very active with performance management systems, digital dashboards and cockpits and scorecards to drive organizational performance measurement and management down to the individual level in order to support alignment with business strategies (Akpan, 2007; Power, 2003).

Financial measures tend to be hard, historical, and internal, rather than soft (including judgmental data and estimates that, while "inaccurate", are vital to future planning), future-oriented (and therefore, by definition, "soft") and external (related to the customer, the market and the environment). We see, therefore, that an important question in the future of metrics in decision support systems and business intelligence is not just *what* to measure, but *how* to measure, and *in which areas of the business* to seek meaningful metrics.

CONCLUSION

The earlier quote about a 30% increase in output (Schultz, 2001) deftly summarizes much of what we have discussed. We see a clear exception – the need to increase output by 30%, quickly–and the immediate following need to organize the required information internally, and then to communicate that information externally to suppliers and on to their suppliers.

The key element in the processes that are involved here is time, not cost. So, first, metrics to ensure that these processes are working properly will be drawn largely from nonfinancial data, including a large slug of temporal (relating to time) data.

Next, there is a pressing need to focus only on the most important, but not necessarily the most obvious, issues and to collect relevant data to support understanding of how the task will be accomplished. Much of the learning will be based on intensive communication, with suppliers and their suppliers, probably much of it will be Web-based.

Previous benchmarking outside the organization with suppliers and processes would be highly valuable at this point–indicating who can perform and who cannot, who can respond quickly, who has people that we know and can trust.

Summarizing our implementation guidelines for the development of metrics for decision support or business intelligence systems:

- Think beyond ROI and payback metrics for IT investments (Renkema, 2000)
- Measurement for business and management performance is more important
- Think beyond financial measures
- Focus only on the most important, but not necessarily obvious, issues and collect relevant data to support exploration, analysis and understanding
- Benchmark outside the organization and build relevant knowledge to support change, and
- Do it fast, and make it possible for users of the system to work quickly as well.

KEY TERMS

Decision Support System (DSS): Decision support systems couple the intellectual resources of individuals with the capabilities of the computer to improve the quality of decisions. [They comprise] a computer-based system for management decision makers who deal with semi-structured problems (Gorry & Scott Morton, 1989).

Business Intelligence (BI): The process of gathering information in the field of business. Information is typically obtained about customer needs, customer decision making processes, the competition, conditions in the industry, and general economic, technological, and cultural trends. Business intelligence is carried out to gain sustainable competitive advantage, and is a valuable core competence in some instances. The term was first used by Gartner and popularized by analyst Howard Dresner. It describes the process of turning data into information and then into knowledge. The intelligence is claimed to be more useful to the user as it passes through each step (http://explanation-guide.info/meaning/Business-intelligence.html)

Hard Data: Historical, usually accurate, data, often from transaction processing systems.

Soft Data: Judgmental, qualitative data, often from external sources; any data involving the future.

Actionable Information: Information that can be used as the basis for a decision, or for taking action, usually to change something.

Metric: A predetermined measure that will be used as the basis for a measurement process. For example, percentage of customer calls answered within one minute.

Benchmark: A standard, usually from outside sources and usually representing the best, or better than average, performance against which an activity's metric is compared. For example, world-class competitors have 35 defects per unit within the first 6 months; we have 85.

Measurement: The process of determining values representing performance, or the results of the process. For example, the measurement process is now started, or the measurement was 35 days.

Balanced Scorecard: An approach for measuring business and management results that goes well beyond financial metrics. Several "perspectives" are suggested, for example financial, customer, internal processes and learning and innovation (Kaplan & Norton, 1992).

Measuring Collaboration in Online Communication

Albert L. Ingram
Kent State University, USA

INTRODUCTION

Collaboration has become a key concept in the workplace, in research laboratories, and in educational settings. Companies want members of different departments located far apart to work together. Various government agencies try to establish collaborative relationships with private organizations. Academics and corporate researchers collaborate with far-flung colleagues to produce new knowledge. Students at all levels of our educational system are increasingly being asked to learn collaboratively. In addition, more work is being done online. Businesses communicate over the Internet, and increasing numbers of educational experiences are being delivered at a distance. Virtual high schools, traditional and for-profit distance education institutions, and colleges and universities are all among the current users of the Internet in education.

In all of these situations—educational and non-educational, face-to-face, and online—several questions need to be addressed. First, what is collaboration? The word is sometimes used as if everyone already understands what it means, but we can find a variety of different definitions in the literature. Second, when we form groups to collaborate, how do we know when they have done so? Is it possible to measure the extent to which collaboration has occurred in a given group and setting? Third, what actions and conditions enhance the collaboration that does take place? And finally, does collaboration work? That is, do groups that are more collaborative produce better results or learning than groups that are less collaborative?

This brief article will not attempt to answer all these questions, but it will concentrate on a specific issue: What methods can be used to determine whether, and how much, collaboration has occurred in online groups in various settings? We will explain our preferred definition of collaboration, based on previous research, and then discuss some of the implications of these ideas for online collaboration and for research into that issue.

BACKGROUND

Collaboration can be generally described in a variety of ways, but perhaps a typical definition is "working in a group of two or more to achieve a common goal" (McInnerney & Roberts, 2004, p. 205). Such a general definition, however, does not tell us how reliably to identify when collaboration has taken place or, assuming that there can be degrees of collaboration, how much of it is going on. To make such measurements, we need an operational definition of collaboration. Recently, Hathorn and Ingram (2002) proposed such a definition. They maintained that collaboration consists of at least three key ingredients: interdependence (Johnson, Johnson & Smith, 1998), a product that is achieved through genuine synthesis of information and contributions from all members (Kaye, 1992), and independence from a single leader (Laffey, Tupper, Musser & Wedman, 1998). In education, this would likely be independence from the class instructor. In other settings, it would mean relative independence from supervisors or others who might otherwise control the process too tightly.

Under this definition, collaboration contrasts sharply with what can be called a *cooperative* way of working. In this characterization, cooperation occurs when a group agrees to divide the work among them, with each taking part of the project. The final product, then, is the sum of separate contributions from each member, rather than being a true synthesis as in a good collaborative effort (Hathorn & Ingram, 2002; Ingram & Hathorn, 2004; Dillenbourg, Baker, Blaye & O'Malley, 1996).

Hathorn and Ingram (2002) operationalized their definition by looking at ways of measuring each of the three components of collaboration. Positive interdependence occurs when group members share information and test their ideas on one another. When individuals in a collaborative group work toward their common goal, they often achieve things that would not have been possible individually (Henri, 1992; Kaye, 1992). Synthesis occurs as the group attains new insights as a result of working together (Henri, 1992; Kaye, 1992). Finally, independence requires that the group function on its own without too much centralized direction (Laffey et al., 1998). Otherwise, it is a directed project, not a collaboration among equals.

MEASURING COLLABORATION

In the literature we can find a variety of ways to measure collaboration that have been used by teachers and researchers. In general, these break down into a few major categories: teacher or leader observations, student and participant self-ratings and self-reports, and quantitative analysis of discussion transcripts. Here we look briefly at each of these in turn.

Teacher/Leader Observations

Sometimes an instructor or a team leader can have a very good "feel" for how well a group is collaborating. By scrutinizing the team in action and examining the products that result from the group work, these observers can often tell who is participating fully and contributing to the results, and who is not. Frequently, however, teachers and others may assume that simply putting people into groups automatically results in high-quality collaborative work. This assumption is false: good collaboration requires many factors, and casual observations may not reveal what is really going on. In many cases, online collaborative groups can be easier to observe than face-to-face groups, because all the conversations may be recorded automatically, depending on the software and systems used.

Student and Participant Self-Ratings and Self-Reports

In many instances, members of groups may know how well they are working together. For instance, a frequent complaint of students doing group work for classes is the uneven distribution of the workload. Finding ways to get clear and reliable self-reports from students and other participants in collaborative groups can lead to better understanding of how the groups operate. There is a danger in this, however, because group members may not have a clear understanding of what it means to collaborate effectively. This is especially true if they have never experienced high-quality collaboration themselves. Many groups, especially in education, seem to prefer a "divide-and-conquer" cooperative strategy that appears to them to be collaborative. In fact, it lacks both the interactions and synthesis necessary for good collaboration, because each member of the group works on just part of the whole project. Therefore, in order both to increase the actual collaboration among group members and to improve the reliability and validity of the self-reporting, it is necessary to teach people the characteristics of good collaboration, how to recognize those characteristics, and how to produce them.

Quantitative Measures

Finally, we look at quantitative measurements of whether collaboration has occurred and of its extent. One approach was taken by Wilczenski, Bontrager, Ventrone, and Correra (2001). They measured the behaviors in a group that facilitated and detracted from the collaboration, under the assumption that groups with more facilitative behaviors would be more collaborative. The study showed that groups exhibiting more facilitative behaviors did better on several measures.

Hathorn and Ingram (2002; Ingram & Hathorn, 2004) also took a quantitative approach. Based on the definition of collaboration cited above, they developed measures of its three main components: interdependence, synthesis of contributions, and independence. Specifically, they applied these concepts to asynchronous threaded discussions, although the same ideas could be useful in other contexts as well (e.g., synchronous online chats). They relied on close and detailed content analysis of the discussions themselves (Silverman, 1993). Rourke, Anderson, Garrison, and Archer (2001) noted that a key step is to develop a way of coding the discussions to illuminate the questions one wants to answer. Hathorn and Ingram (2002; Ingram & Hathorn, 2004) developed such a system for the construct of collaboration, noting the inadequacy of many previous schemes for analyzing online collaboration specifically.

In order to use these measures, one needs complete transcripts of the discussions. Online textual discussions are especially useful in this regard since the transcripts are usually kept automatically in both synchronous and asynchronous discussions. Conceivably, the actual medium of communication could be instant messaging/chat, e-mail (including listservs), threaded discussion boards, or other text-based systems, as long as the technology can keep complete logs of the discussions. In Hathorn and Ingram's (2002) system, coding is based on "statements" made in the discussions. Statements are sentences or complete ideas within sentences that represent individual idea units. A single message can contain just one statement or numerous statements on a variety of topics. Indeed, a single sentence can contain multiple statements.

Interdependence is identified using several criteria. First, it requires roughly equal participation among all members. Without that, it is difficult to see how the members can be meaningfully interdependent. Participation is measured primarily by the number of messages and/or statements contributed by each group member. The count of statements is probably a more accurate measure of actual participation than number of messages, sentences, or words would be. It is unlikely in any group that the members participate exactly equally by any measure, so the requirement for good collaboration is that there be at least roughly equal participation. A simple test for this is a chi-square analysis on the participation of the group members. If the test shows significance,

it is likely that the members were not participating equally enough for the group to be considered collaborative.

Beyond simple participation, we can measure interdependence by looking at interactions among the group members. In particular, Hathorn and Ingram (2002) focused on direct participation in the substantive discussion (as opposed to off-task comments and other such contributions). The patterns of discussion that indicate actual interaction are threads where different participants refer, explicitly or implicitly, to one another's comments. The minimum length of such a thread that would indicate true interaction is three statements: an initial comment, a response to that comment, and a synthesizing response. The more such threads (and longer ones) appear in a discussion, the more interaction there is and, all other things being equal, the more collaboration is taking place. A useful technique at this point is to diagram the discussion, using the statement as the unit. Each statement appears in a separate box, and lines connecting them show the patterns. It is important not to diagram the messages, because in our experience these do not reflect the substantive patterns that are revealed by the statement-level analysis.

Next, the question of synthesis arises. True collaborations result in products that cannot be identified as resulting from individual efforts. This can be measured in two ways. First, the patterns of interactions noted above include the necessity for synthesizing responses, so that was the first and more detailed measure of synthesis. The other measure focused on the final group product and whether it was written by an individual or the entire group.

Finally, independence from a central authority can be measured by examining both the basic participation of the group members in relation to the instructor and the number of interactions that take place without the instructor's or leader's participation.

Thus, in this quantitative view, the extent of collaboration is revealed by conducting a close content analysis based on the transcripts of the online discussions. Measuring the three elements of collaboration depends on several key pieces of data: overall participation based on the number of statements made by each individual, the types of statements they make (on-task, off-task, and others), and the patterns of interaction, represented especially by the basic unit of collaboration consisting of comment-response-synthesis. The nature of the actual product developed by the group is also important.

Measuring Collaboration in the Real World-An Example

Jim is project manager for a medium-sized information technology firm. His team is scattered around in several locations and needs to work together using a variety of different technologies. Specifically, his supervisor expects him to ensure that they are collaborating well in spite of the distance, the different time zones, and other obstacles. Naturally, the most important concern for Jim and his supervisor is the quality of the work. So far, this has been acceptable, but not outstanding. Jim thinks his team can do better if they learn to collaborate more effectively.

Being a systematic sort of person, Jim decides to approach the problem carefully. So far, simply exhorting the team to do better has not worked, so he wants to find out where they might be failing to collaborate well. To do that, he needs some data about their current efforts. One advantage he has is the fact that much of the work done by the team is online and text based; frequently there is an automatic record kept of the conversations that people have. For example, the team's private collaborative Web site includes a threaded discussion board where everyone can read all the messages and contribute to the conversation. In addition, all documents produced by the team are stored in the online repository in their space. Finally, there is the opportunity for synchronous chats among members while they are working on specific pieces of the project. Jim has decided to record and archive those chats for future use.

Jim's first step in deciding whether his team is collaborating productively is to scan the communications that they have made. At first glance, it looks as if they are all participating and making contributions, although he did not read everything in detail. He decides to try something else before he goes through that lengthy chore.

First, Jim sends an e-mail to everyone in the team asking them to assess the level of collaboration in the team and to e-mail him back by Friday. Very quickly he receives numerous questions about how he defines collaboration, what the request means, and so forth, so he decides to try another approach. This time, Jim does a little research about what is meant by collaboration and sends a more specific e-mail message to the group. Now, instead of asking a global question, he asks people to rate whether the members of the team participate roughly equally and respond well to one another, whether they synthesize each other's contributions, and whether they work independently of the leader. (That last one is tricky for team members, since Jim *is* the leader.)

This time, people are able to answer, and the responses are interesting. In general the team thought they were participating equally and responding to each other. They had mixed views on whether their resulting products were really the result of synthesizing ideas from many sources within the group. They all agreed (tongue in cheek?) that they could get along without Jim for most of their work.

Now Jim has a choice. Is the information he received from the group enough to make decisions about the direction he needs to take? One possibility is that he could arrange to train his team on collaborative techniques, especially using online technologies. Training can be expensive, though, and Jim does not relish taking people away from their jobs for the time it would take. If the team would benefit, then he

believes it would be worth it. He is still not sure that they will (or will not) gain enough from such training.

Perhaps the self-reports of his team members are good enough for Jim to make the decision. If the stakes are high enough, however, Jim might want to look further. In that case a more detailed content analysis might pay off. His team members might overestimate the extent to which they respond to each other's message. Often an online discussion proceeds more as a series of monologues than as a true collaborative conversation. Sometimes what seems to be a synthesis of ideas is really one person dominating the group. Or perhaps the team is not as independent of Jim as they think. If Jim can pinpoint more specific problems with their collaborative skills, then it is more likely that he can arrange to have them trained in the relevant skills. In turn, that could lead to more tangible benefits from the collaborative team structure that he has developed than he is seeing now. He will not really know until he finds a way to measure the actual collaboration taking place.

FUTURE TRENDS

Online collaboration is likely to become even more important in the future for education, research, business, and other fields. In many of these areas, it will be important to ensure that groups working online are actually collaborating. Often in job settings working groups are composed of people with different knowledge and skill sets. If they do not truly collaborate, then their products (reports, designs, and other substantive materials) may be incomplete and substandard. In educational settings group work may produce high-quality learning outcomes primarily in groups that collaborate, rather than those using a less effective "divide-and-conquer" strategy in which group members learn only the pieces that they work on.

One indication of the trend toward more online collaboration is the increasing number of software packages aimed at improving the efficiency and effectiveness of online collaboration. For example, Groove *(www.groove.net)* is inexpensive peer-to-peer software designed specifically for small groups and containing a variety of tools beyond basic synchronous and asynchronous discussion capabilities. Convea *(www.convea.com)* is similarly inexpensive Web-based software designed for much the same purpose. Such packages are increasingly under scrutiny as collaborative tools (Ingram & Parker, 2003; Ingram, Pretti-Frontczak & Parker, 2003).

These trends mean that we need more and better ways to assess the presence, amount, and nature of online collaborative processes. Such measures will be useful in research, in education, and in practical application. Which measures are used depends on the questions being asked and on the purposes to which the assessment will be put. Some measures are extremely subjective and not firmly grounded in theory and previous research. Others may rely too heavily on the untutored impressions of participants. On the other hand, one drawback of a detailed quantitative approach such as the one we outlined here is the time it takes to complete. An approach being pursued by the present author and his colleagues is using the detailed research approach to develop better surveys of team members that will allow the identification of good and poor collaboration more quickly and efficiently. Such tools would have wide applicability.

CONCLUSION

This article has discussed several ways that collaboration in small online working groups might be measured. The need for such measurements seems clear: high-quality work in a variety of fields demands good collaboration. In turn, managers, researchers, educators, and others need to be able to identify the presences, amount, and nature of the collaboration that does or does not take place in different circumstances.

All of the measurement methods discussed here have strengths and drawbacks. Some are quick and easy to use but may give misleading results. Others are precise and based on some of the best research available, but demand significant effort and time to implement. One direction for future research and practice may be to develop measurement tools that are both accurate and quick.

KEY TERMS

Asynchronous Discussion: Online discussions that occur independent of time and space. Participants do not have to be online simultaneously, and can read and contribute to the conversation on their own schedules.

Collaboration: Occurs when small groups of people work together toward a common goal in ways that produce new products and knowledge that are unlikely to be developed by individuals. Three essential elements of collaboration are interdependence, synthesis, and independence.

Cooperation: Cooperative groups work together on group projects in ways that do not necessarily result in high-quality interaction, and new products and knowledge. A typical cooperative strategy is to divide up the work among the members and stitch the various contributions together at the end of the project.

Independence: The independence of a group from a central authority, such as an instructor or manager, ensures that the group can truly collaborate among themselves and produce results that are unique and new.

Interaction: Interaction among members of a group is necessary to produce collaboration. It can be measured by examining the give-and-take nature of the discussion threads.

Interdependence: Interdependence among members of a small group is a necessary element of collaboration. It means that group members could not produce the results they did without one another.

Participation: The most basic requirement of collaboration; it may be measured by the number of postings made and read or by the number of statements contributed to a discussion.

Synchronous Discussion: Occur when all participants are online and actively involved in the discussion at the same time.

Synthesis: Occurs when the final product of a group effort includes information and other elements from all members in such a way that individual contributions are difficult or impossible to identify.

Metrics for the Evaluation of Test-Delivery Systems

Salvatore Valenti
Università Politecnica delle Marche-Ancona, Italy

INTRODUCTION

Most solutions to the problem of delivering course content supporting both student learning and assessment nowadays imply the use of computers, thanks to the continuous advances of information technology. According to Bull (1999), using computers to perform assessment is more contentious than using them to deliver content and to support student learning. In many papers, the terms computer-assisted assessment (CAA) and computer-based assessment (CBA) are often used interchangeably and somewhat inconsistently. The former refers to the use of computers in assessment. The term encompasses the uses of computers to deliver, mark, and analyze assignments or examinations. It also includes the collation and analysis of data gathered from optical mark readers. The latter (that will be used in this paper) addresses the use of computers for the entire process, including assessment delivery and feedback provision (Charman & Elmes, 1998).

A typical CBA system is composed of the following.

- Test-Management System (TMS) - that is, a tool providing the instructor with an easy-to-use interface, the ability to create questions and to assemble them into tests, and the possibility of grading the tests and making some statistical evaluations of the results
- Test-Delivery System (TDS) - that is, a tool for the delivery of tests to the students. The tool may be used to deliver tests using paper and pencil, or a stand-alone computer on a LAN (local area network) or over the Web. The TDS may be augmented with a Web enabler used to deliver the tests over the Internet. In many cases, producers distribute two different versions of the same TDS: one to deliver tests either on single computers or on a LAN and the other to deliver tests over the WWW (World Wide Web). This is the policy adopted, for instance, by Cogent Computing Co. (2004) with CQuest LAN and CQuest Net.

The TMS and TDS modules may be integrated in a single application as, for instance, Perception developed by Question Mark Computing (2004), or may be delivered as separate applications as it occurs for MicroTest and MicroGrade developed by Chariot Software Group (2004).

BACKGROUND

The interest in developing CBA tools has increased in recent years thanks to the potential market of their application. Many commercial products, as well as freeware and shareware tools, are the result of studies and research in this field made by companies and public institutions.

Thus, for instance, 42 quiz software products are referenced by the Soft411 (2004) directory, 23 by the Educational Software (2004) directory, and 8 by Assessment System Co. (2004). Moreover, it must be noted that almost all course management systems (Edutools, 2004) provide facilities for CBA. This noteworthy growth in the market raises the problem of identifying a set of criteria that may be useful to an educational team wishing to select the most appropriate tool for their assessment needs. The literature on guidelines to support the selection of CBA systems seems to be very poor since no other up-to-date papers are available on the Internet apart from the works by the author and his colleagues (Valenti, Cucchiarelli, & Panti, 2002a, 2002b).

The purpose of this paper is to provide a framework for the evaluation of a test-delivery system.

METRICS FOR THE EVALUATION OF A TDS

Three main functional modules roughly compose a TDS: a student interface, a question-management unit, and a test-delivery unit. Therefore, our framework for the evaluation of a TDS is defined in terms of criteria that may support the evaluation of each functional module and other criteria for the evaluation of the whole system, as shown in Table 1.

The evaluation of the interface is a qualifying aspect for the evaluation of a CBA system and obviously for a TDS. This becomes dramatically true if we take into account the fact that neither the teacher nor the students involved in the use of a TDS necessarily have a degree in computer science, nor may be interested in acquiring skills in this field. According to Nielsen and Molich (1990), the interface must be easy to learn, efficient to use, easy to remember, error free, and subjectively pleasing. Some further criteria that may be adopted to evaluate the usability of the interface are summarized in the following list.

Table 1. Metrics for the evaluation of a TDS

Issue		Metrics
Component Level	Interface	Friendly GUI (graphical user interface)
	Question Management	Types of Questions
		Question Structure (retries, tutorial building)
	Test Management	Help and Hints
		Restricted Availability
		Grading
System Level		Security
		Survivability
		Communication

- speak the users' language (multilinguality and multiculturality)
- be accessible
- provide feedback
- provide clearly marked exit points

The question-management unit of a TDS can be evaluated with respect to its ability to provide

- multiple attempts at solving a question (retries),
- feedback and tutorials on the topic covered by the questions, and
- capabilities for the inclusion of multimedia in questions.

The ability of providing retries may be of great importance for self-assessment since it is useful to improve the knowledge of the student whilst reducing the need for providing feedback and/or tutoring. On the other hand, the impossibility to change the answer to a question during an examination is often perceived as unfair by the students (Valenti et al., 2002b). It is worth outlining that allowing multiple attempts at question answering may affect the use of adaptive systems whenever item presentation depends on previous responses.

The feedback may be provided after each question (this solution being preferable for self-assessment), after a set of questions covering a given topic, or at the end of the test, and can be based on the overall performance. Furthermore, the feedback may be used to indicate the correctness of the answer, to correct misconceptions, or to deliver additional material for deepening and/or broadening the coverage of the topic assessed by the question. Tutorials represent an extended approach to provide additional information to the students. The existence of some facility to ease inclusion of tutorials in the TDS represents an important feedback aid. As an example, Perception provides explanation-type questions that may be used for "information screens, title pages, or to display large bodies of text" (Question Mark Computing Ltd., 2004).

The use of questions incorporating multimedia, such as sound and video clips or images, may improve the level of knowledge evaluation. This aspect may be of great importance, for example, in language assessment, where the comprehension of a talk or a movie can be assessed by recurring to multimedia only. The use of multimedia can raise issues related to portability and interoperability since it may require special hardware and software, both for the server delivering the questions and for the client used by the students. Furthermore, it may raise the costs for the adopted solution. These issues may not represent a problem whenever a Web-enabled TDS is selected since the nature of the World Wide Web is inherently multimedial. In this case, the choice of standard plug-ins for the most common browsers may reduce risks of portability and of interoperability. Since most plug-ins used to grant access to multimedia sources are usually free of charge, their use may not interfere with cost problems.

Among the issues taken into account to evaluate the test-management unit of a TDS, we have identified the ability to

- provide help and hints,
- make tests available at a given time, and
- allow scoring procedures.

The capability of a TDS to provide directions about the completion of the test and hints that usually are related to the contents of the questions represents a further measure of the ease of use of the application from the student's point of view.

Tests can be made either available or unavailable at a specified date and time. This allows test designers to specify exactly when people can access a test. It should be possible to leave out either or both restrictions to provide maximum flexibility. This lends itself nicely to the computer-lab set-

ting where students are required to complete an online test during a specified time frame on a specified day.

Obviously, any software for assessment should be able to compute student grades. Furthermore, grades must be delivered as feedback to the course coordinator, to the instructor, and to the students. Each of these categories of stakeholders may require a different kind of feedback on the grades associated with a test. For instance, a student needs to know where he or she stands with respect to other students and to the class average besides his or her own individual and cumulative grades. This need raises obvious concerns about privacy that may be faced through the security facilities provided with the assessment tool.

Among the issues taken into account to evaluate a TDS from a systemic point of view, we have selected

- security,
- survivability, and
- communication with other software.

There is a wide range of security issues related to the use of TDSs. In more detail, many concerns on the security of the availability of the test material, on the HTML (hypertext markup language) code that implements testing, and on the access-control privileges do exist. With respect to security concerns about the test material and its HTML code, it must be outlined that while commercial programs usually implement encrypting approaches, a lot of issues are raised by freeware. In fact, most freeware applications rely either on Perl/CGI (common gateway interface) or on JavaScript. In particular, since a CGI program contains an executable code, the use of CGI-based applications is the equivalent of letting the world run a program on the server side, which is not the safest thing to do. Therefore, there are some security precautions that need to be implemented when it comes to using CGI-based applications. The one that will probably affect the typical Web user is the fact that CGI programs need to reside in a special directory so that the server knows to execute the program rather than just display it to the browser. This directory is usually under direct control of the webmaster, prohibiting the average user from creating CGI programs. On the other hand, the assessment program cannot be completely hidden whenever using a JavaScript code that runs on the client side of the application, so a "smart" student can access the source, discovering the right answer associated to each question. Some sophisticated techniques can be used to partially overcome this problem (Cucchiarelli, Panti, & Valenti, 2000).

The ability of a TDS to perform under adverse conditions (i.e., survivability as discussed in Valenti et al., 2002a) is of great importance. In particular, no termination procedures should result in any loss of data. To ensure this, both student and system files should be updated after each transaction so that no data is lost if the test is terminated because of machine or power failure. The possibility of providing examination printouts may further enforce the survivability of the system. Furthermore, after a crash, the system should be able to restart from the point of termination with all aspects of the original status unchanged, including the answers already given and the clock still displaying the time remaining.

Communication with other existing software may be very useful both for exporting answers and for calling external applications. Furthermore, this feature is required to allow the integration of a TDS with a TMS distributed by different producers. Exporting answers is usually performed through test files and data-conversion utilities. This may be useful to customize the reports generated by the application or whenever an in-depth analysis is needed to evaluate the results obtained. Moreover, many available TDSs enable the calling of a program as a block within a question. The called program returns a score in points that may be added to the test score. This may be useful for assessing abilities that cannot be evaluated through the basic question-answer paradigm of most assessment tools.

Finally, some tools allow external applications to be called at the very end of the test phase for printing certificates for all users who pass the test, for the electronic submission of the answer file to a central location for analysis and evaluation, and for the storage of the results in a file to be accessed by a user program (Question Mark Computing Ltd., 2004).

FUTURE TRENDS

The software-evaluation process is a very complicated task because many, often contradictory, attributes have to be taken into account. Issues such as selection of appropriate attributes, creation of their hierarchy, assignment of relative weights to them, and application of a sound decision-aid methodology arise frequently both for nonexperienced and skilled users. Therefore, a first step toward providing support for the evaluation of test-delivery systems could be the construction of a Web site listing all the available software on the market, providing an independently reviewed, objective source of information to help educators in making the best decision for their institution. A further step in this direction could be the implementation of a decision support system to be used as an (semi) automated aid for helping the educator in selecting the most appropriate criteria and constructing the evaluation model.

CONCLUSION

In this article we have discussed a framework that may be useful in assisting an educational team in the selection of a TDS. Three main functional modules roughly compose a TDS: a student interface, a question-management unit,

and a test-delivery unit. Therefore, we decided to organize our framework by identifying some metrics to support the evaluation of the functional modules and other metrics to support the evaluation of the system as a whole.

KEY TERMS

Computer-based Assessment: addresses the use of computers for the entire process of assessment including production, delivery, grading, and provision of feedback

CGI: CGI is the acronym for common gateway interface. A CGI program is any program designed to accept and return data that conforms to the CGI specification. CGI programs are the most common way for Web servers to interact dynamically with users. The program could be written in any programming language including C, Perl, Java, or Visual Basic.

HTML: HTML is the acronym for hypertext markup language, the authoring language used to create documents on the World Wide Web. HTML defines the structure and layout of a Web document by using a variety of tags and attributes. HTML is derived from SGML, although it is not a strict subset.

JavaScript: a scripting language developed to enable Web authors to add dynamic content to sites. Although it shares many of the features and structures of the Java language, it was developed independently. It is supported by recent browsers from Netscape and Microsoft.

Multiculturality: the term used to address the measures now being taken to provide graphical user interfaces with ad hoc icons and texts according to the cultural heritage of the user

Multilinguality: the term used to address the measures now being taken to provide graphical user interfaces with features for internationalization, that is, support of the character sets and encodings used to represent the information being manipulated, and presentation of the data meaningfully

Test-Delivery System: a tool for the delivery of tests to students. The tool may be used to deliver tests using a stand-alone computer on a local area network or over the World Wide Web.

Micro and Macro Level Issues in Curriculum Development

Johanna Lammintakanen
University of Kuopio, Finland

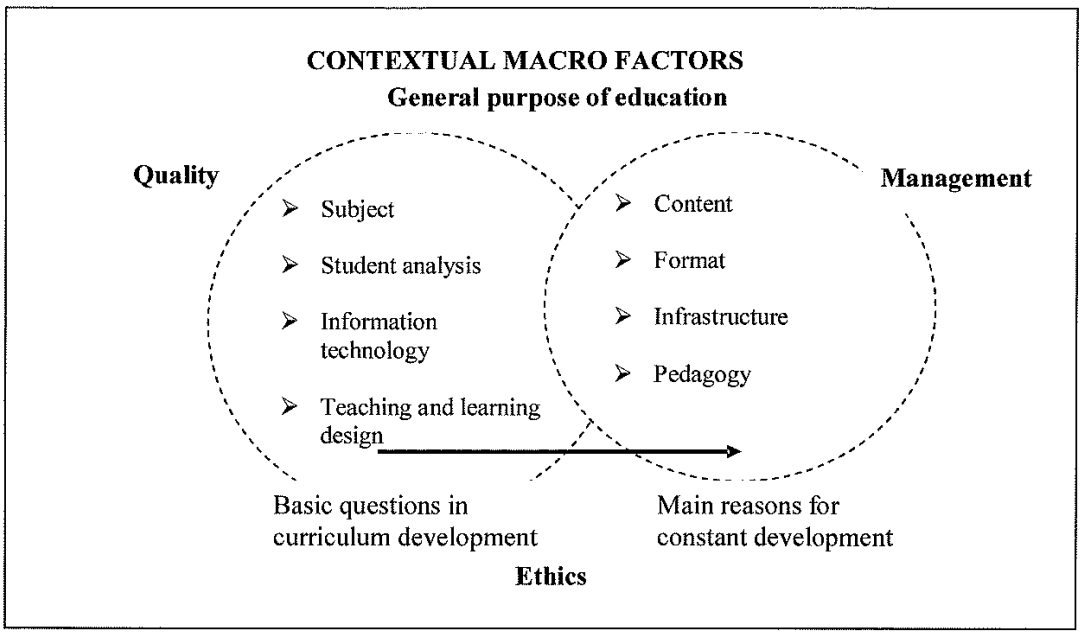
Sari Rissanen
University of Kuopio, Finland

INTRODUCTION

It is a well-known fact that an educational paradigm shift occurred in the course of the last decade, with a move from traditional to Web-based education at various educational levels (Harasim, 2000; Karuppan, 2001; Kilby, 2001). Web-based education (WBE) has advanced from the delivery of educational content to Web-based sites with interactive functions (Carty & Philip, 2001). Concurrently, new innovative kinds of pedagogical experiments have shifted the paradigm from teaching to learning (Pahl, 2003). However, there is a greater need for innovation in the area of pedagogy rather than that of technology (Littig, 2006). Indeed, educators have realized, as summarized by Armstrong (2001), that good Web-based educational theory and good educational theory are one and the same, the only difference being that WBE transcends the barriers of space and time.

The paradigmatic shift has occurred in both global education (including developing countries) and corporate training. The key impetus for this shift may vary in these areas, but the role of knowledge and intellectual capital, coupled with the needs of organizations and individuals to learn more rapidly, are apparent as the driving forces for WBE (e.g., Bell, Martin, & Clarke, 2004). The growth of WBE has been part of planned educational policy, but at the same time, good international or national experiences have also supported its growth. Furthermore, the cash crises in the western university sector (Bell et al., 2004) and the endeavors towards more coherent and cohesive educational systems and degrees, especially in the European context (Littig, 2006), can be identified as the other galvanizing factors for this shift.

Figure 1. Curriculum development as a continuous process



Aim and Structure of this Article

The aim of this article is to pursue the discussion of some essential micro- and macro-level issues in Web-based curriculum development, mainly at the level of higher education (see Figure 1). It was fairly often the case initially that the main concerns in curriculum development were related to students, the subject, new technology, and pedagogical issues. Curriculum development, however, must be seen as a *process* due to these issues, which are constantly evolving. Moreover, curriculum development does not happen in a vacuum—hence the two parts of the article. The first part focuses on the above-mentioned issues, while the second part presents a summary of the general purpose of education, ethics, quality, and management as important contextual concerns in WBE curriculum development.

Curriculum Development in Web-Based Education at the Micro Level

Web-based education, and curriculum development in particular, has taken a step forward in recent years. However, while a substantial body of research has concentrated on this new teaching medium, the results have been mixed and have shown no significant improvement in learning over traditional methods. In addition, the need for systematic and scientific knowledge remains, especially with regard to the effects and outcomes of WBE (Karuppan, 2001; Orr & Bantow, 2005).

Previous studies have shown that technology affects learning in many ways. Pedagogical choices, the design of the course Web site, and the interaction possibilities, for example, have different kinds of effects on learning outcomes (Romanov & Nevgi, 2006). One challenge is to integrate curriculum, technology, community, and learning in a manner that supports student motivation, self-regulation, and retention in WBE (Fisher & Baird, 2005). Unfortunately, technical matters and narrowly defined subject areas still receive the most emphasis from e-learning developers (Littig, 2006).

The identification of potential users and the analysis of their needs form the basis for curriculum development (Karuppan, 2001; Lammintakanen & Rissanen, 2003), but a stronger focus is needed more than ever before on learners and their needs (Littig, 2006). Moreover, Web architecture and learning materials should support the student's particular learning style in order to facilitate learning (Karuppan, 2001; Graff, 2006), while expectations concerning the technology dictate that it should be easy to access and easy to navigate at no extra cost to the learner.

Consideration of the expected level of learning is an important aspect in curriculum development. In other words, the course can be based on the assumption that learning is a process *for* acquiring information. However, the course can also be based on the assumption that learning is a process *of* acquiring information and processing experience, in which the learner selects and constructs useful and appropriate knowledge (Littig, 2006). Careful evaluation is needed during the curriculum development stage on whether or not the chosen technology supports teaching strategies that encourage active involvement and critical thinking, and fosters relationships between learners (Armstrong, 2001).

Curriculum development is time intensive and requires adequate financial and human resources in order to develop tightly organized courses. Web-based learning forces teachers to become course designers who make decisions based on their understanding of the probable needs, expectations, and behaviors of students on their own campuses. The role of tutor is a multi-faceted one, requiring organizational and management skills as well as the ability to motivate and encourage student interaction and facilitate learning and group processes (Packham, Jones, Thomas, & Miller, 2006).

Table 1. The factors of change promoting curriculum development (Pahl, 2003)

Content	The course subject evolves Changes in content to improve the material
Format	Changes in • Staff • Student body (qualifications, numbers, mode of learning) • Timetable (where and when the course takes place) • Syllabus (the content and organization of the course) • Curriculum (level, extent, prerequisites) • Legal and/or financial environment
Infrastructure	Improvements in hardware technology Systems and language technology face constant minor changes Learning devices are developing
Pedagogy	Knowledge acquisition, modeling of and access to educational knowledge Active learning in terms of engaging the student through interactive systems Collaborative learning supportive systems Autonomous learning Evolving instructional design

Previously, the challenges of curriculum development focused merely on the lack of both students' and staff members' skills, attitudinal problems, and suitable equipment for WBE. Maintenance aspects have been neglected in the design and development of new technologies. In fact, while in the previous stage, the main concerns were with regard to planning processes (i.e., how to begin with WBE); nowadays, important issues concern the how up to date the curriculum is and how to develop it further. In addition, online teachers' professional development has also become one of the topics of research (see Vrasidas & Zembylas, 2004).

Curriculum development can be based on students' evaluations, experiences of others, as well as previous studies. On the basis of previous research, Young and Norgard (2006), for example, summarized that the following areas are important for student satisfaction in an online course: interaction among students and the tutor, consistent course design across courses, the availability of technical support, and the flexibility of online courses compared to traditional learning and teaching. However, factors also exist that require us to develop the curriculum. Pahl (2003), for example, has provided a summary of both internal and external reasons why the curriculum needs to be constantly evolved (see Table 1). The evolvement of the design of a Web-based course can be affected by four dimensions; content, format, infrastructure, and pedagogy.

FUTURE TRENDS

The Macro Context of Curriculum Development

The previous section describes WBE curriculum development from the micro-level perspective. However, some existing and, concurrently, future challenges that have not yet been mentioned have become more important during the curriculum development process. These themes have been summarized into four interrelated categories: (1) the general purpose of education, (2) ethical and legal issues, (3) quality assurance and accreditation, and (4) managerial and organizational issues. These challenges became apparent in part from the literature and in part from practical experiences (e.g., Alexander, 2001; Kilby, 2001; Roffe, 2002), and concern both national and international curriculum development, since a more global perspective in design and courseware provision is expected (Kilby, 2001; e.g., MIT Open Courseware, in Potts, 2003; Bell et al., 2004).

The General Purpose of Education

The mass of information is growing rapidly and lifelong learning has been widely accepted at the societal level. However, critical analyses concerning how WBE fulfills the general purpose of education are rare. The theoretical literature of education shows that education has many other functions than the mere transfer of information. Bell et al. (2004) state that universities are not only "credentialing institutions or knowledge delivery mechanisms" (factors which remain the focus of major online and distance schools), but they also provide hugely beneficial learning communities in which students learn how to "be." This can mean, for instance, learning how to learn, or how to learn complex social strategies that cannot be learned in a virtual classroom. One of the crucial issues is how to combine the general purposes of education (e.g., sophisticated people acting in a civilized nation) and WBE education.

Ethical and Legal Issues

One interesting ethical issue concerns what happens to different cultures if education is globalized via Web-based learning. How, for example, do different countries maintain their identity, language, and culture in a globalized world? WBE solutions make it easily possible to assemble students from different socio-economical, political, and ethnical backgrounds. While this can bring added value for the learning and professional development (e.g., Akar, Öztürk, Tuncer, & Wiethoff, 2004), it may also cause some deep problems if the education is not carefully planned and supported by the tutors. Features of the WBE environment (e.g., effective communication, suitable instructions), for instance, may be interpreted and accepted more or less depending on the social and cultural background of the students (e.g., Lum, 2006). In addition, the faceless environment could, at its worst, facilitate student harassment if there is no supervision and proper norms and rules. In fact, from the ethical perspective, the students' privacy and confidentiality—and their respectful and dignified treatment on the Web-based environment—are imperative (Armstrong, 2001).

Web-based education provides good opportunities to make use of the many information sources available via the Internet (Jefferies & Hussain, 1998). The problem is, however, the quality of knowledge: how to cull information and how to avoid the use of misinformation (Calvert, 1998). At their worst, Web-based learning environments enhance fabrication, falsification, and plagiarism, all of which lead to copyright considerations.

Quality Assurance and Accreditation

Quality is a crucial concern in WBE: there are no common quality standards for course design, delivery, and evaluation, nor is there is an accreditation system. Some institutions and countries (such as the United Kingdom) have developed quality assurance protocols that demonstrate that the online programs are of equal quality to those delivered by traditional

methods (Roffe, 2002). As an example, the Massachusetts Institute of Technology (MIT) offers a standardized process for course modeling and encourages extending collaboration and interdisciplinary teaching. MIT Open Courseware is open and available all over the world (Potts, 2003). From the students' point of view, one important issue concerns how the courses can be accepted as part of the curriculum, how different educational institutes recognize the courses offered from other institutions nationally and internationally.

Managerial and Organizational Issues

The tradition of individualism in teaching remains part of the organizational culture at different educational institutions. At best, the organizational culture can support both Web-based curriculum development and joint teaching. The allocation of both human and technical resources and a clear strategic decision from managers are requirements for faculty development and the incorporation of WBE into the curriculum (Carty & Philip, 2001). It is essential that the organization and its managers have a positive attitude to WBE, as well as time and resources, and that they promote its implementation (e.g., Alexander, 2001; Lum, 2006). The promotion of WBE may threaten the status quo of the organization. Enuku and Ojugwu (2006), for instance, have noticed that the fear of change may be due to change in the routine at work, or fear of being left behind or replaced by others who have the relevant pedagogical and technological skills. These and other fears held by staff members and managers emphasize the management of change as a crucial factor in the promotion of WBE.

The managerial approach to guiding teaching and curriculum development work is, however, not yet very visible in various educational organizations. The study by McPherson and Nunes (2006) summarizes the critical success factors for WBE implementation from the leadership, structural, and cultural perspectives in higher education. Familiarity with the organizational culture, structure, corresponding, and potentially conflicting strategies is held as important before rushing into the design, development, and implementation of WBE solutions. In addition, human issues in terms of participation, information, training, and communication, as well as stakeholder involvement, are fundamental when engaging in WBE initiatives.

CONCLUSION

In conclusion, there is no consistent paradigm for WBE, rather there are multiple ways of making use of the Web in education, and these will vary depending on the subject being taught and the needs of the learner. Curriculum development requires a great deal of competence and effort from different stakeholders. Furthermore, both micro- and macro-level issues must be taken into account in Web-based education. Therefore, motivation and commitment to long-term WBE development strategies are needed at the personal, organizational, national, and global levels. In addition, Web-based education appears to support cultural cohesion and more rapid transfer of information. The attention of current research has tended to focus mainly on micro-level issues, while the more general aspects and impacts of Web-based education remain less studied. However, both technological and pedagogical competencies of different actors, as well as the body of research, are constantly evolving, and therefore, more promising outcomes of Web-based education will be achieved.

KEY TERMS

Computer and Information Literacy: The abilities to perform computer operations at a skill level high enough to meet the demands of the society, and to use the tool of automation in the process of accessing, evaluating, and utilizing information (Carty & Philip, 2001).

Cultural Differences: Not limited simply to differences in ethnicity or nationality; refers to patterns of thought, attitudes, and behaviors that vary according to the level of sameness shared by distinct groups (Lum, 2006).

Learning Style: The way in which individuals acquire and use information, strategies to process information in learning, and problem-solving situations (Karuppan, 2001).

Learning Tools: Tools included in Web-based learning environments for managing the course and geared to facilitating student learning in the environment.

Web-Based Education (WBE): Differs from traditional classroom teaching in two essential elements — physical distance and time — allowing the learner more flexibility. The most basic form of WBE is to deliver syllabi, lecture notes, reading materials, and assignments via the Internet. The more advanced level includes computer conference facilities, a help desk, linkage of conferencing and Web page assignment, testing and course management tools, and evaluation (Karuppan, 2001).

Web-Based Learning Environment: A specially developed program using Internet technology for the design and development of teaching and learning purposes. Trademarks include, for example, WebCT, WebBoard, Top Class, and Virtual-U.

Web-Based Misinformation: Describes information found on the Internet that does not fit normative patterns of "truth" — that is, it is incomplete, out of date, confused, or offers low consensus "knowledge" (Calvert, 1998).

Migration of Legacy Information Systems

INTRODUCTION

In recent years, the accelerated competition in the global marketplace rendered the corporate environment more volatile than ever. The businesses are heavily relying on technological advancements to deliver a vast array of initiatives across a variety of industries. The firms' main partner in this increasingly complex and unpredictable journey is considered to be their information systems. Although the relevant industry offers an unprecedented rate of technological innovations, nevertheless there are cases where the information systems carry significant baggage from the past (Kelly, Gibson, Holland, & Light, 1999). There are aged systems that often form the central hub of the information flow within the organisation and are responsible for consolidating information about the business (Bisbal, Lawless, Wu, & Grimson, 1999; Sommerville, 2001) and thus they are called *mission-critical legacy information systems*.

The term "Legacy", according to the Oxford Dictionary, refers to any long-lasting effect of an event or process. The Legacy System describes an old system that remains in operation within an organisation. These systems often represent a massive, long-term business investment. Ulrich (1994) defined them as "stand-alone applications built during a prior era's technology, but they are perhaps more widely understood as software systems whose plans and documentation are either poor or non-existent" (Connall & Burns, 1993). Bennett (1995) referred to the legacy systems as, "large software systems that we do not know how to cope with but that are vital to the organisation", while Brodie and Stonebraker (1995) as "any information system that significantly resists modification and evolution to meet new and constantly changing business requirements". Finally, O'Callaghan (1999), drawing on the characteristics of legacy systems, described them as "a large system delivering significant business value today from a substantial pre-investment in hardware and software that may be many years old. Characteristically, it will have a long maintenance tail. It is, therefore, by definition a successful system and is likely to be one that is, in its own terms, well engineered. It is a business critical system which has an architecture which makes it insufficiently flexible to meet the challenges of anticipated future change requirements."

Legacy systems as a subject area is often overlooked in favour of areas such as new technology developments and strategic planning of information technology. In this context, the following sections present an overview of the legacy information systems problems in terms of their scale and definition. The legacy system issues include the required man-effort and costs of maintaining and evolving existing systems and the current methods of migrating complex legacy systems to new technology. It is shown that legacy systems present a critical area of study in both software engineering and business information systems. Taking into account that the role of technology is not merely supportive but affects the way enterprises conduct their business, it is shown that it is outdated to consider the migration process as the simple replacement of aged or problematic hardware and software. Thus, the migration should be approached as a planned change process that first and foremost requires an understanding and a methodology that covers the range of issues and organisational entities involved.

BACKGROUND

Legacy Information Systems

O'Callaghan (1999) refers to the adoption of an informational culture within the organisations in which "point solutions" were developed due to the widespread use of computer technology over several decades. There are cases where different divisions of the same organisation have developed individual applications in order to meet their perceived needs

in an application-by-application basis (O'Callaghan, 1999). In a similar way, there are applications in the same company that are running on different operating systems. Subsequently, such "point solutions", according to O'Callaghan (1999), became subject to localised optimisation, and uncontrolled maintenance, exacerbating the position further (Zou & Kontogiannis, 2002). These applications are unambiguously hard to maintain, improve, and expand because there is a general lack in their understanding. In addition, integration with newer systems may also be difficult because new business software may use completely different technologies (Wu, Lawless, Bisbal, Grimson, Wade, O'Sullivan, & Richardson, 1997). Due to the aforementioned reasons, there is a significant number of software engineers and practicing managers that consider the legacy systems to be potentially problematic (Bisbal et al., 1999).

On the other hand, according to Brodie and Stonebraker (1995), legacy systems do not always fit this stereotype. They propose that if a system was recently developed but cannot be readily modified to adapt to the constantly changing business requirements, then such a system can be regarded as a legacy system. Similarly, Randall (1999) stresses that "Legacy" is not just a problem encountered by organisations with aging mainframes and dated software, it is an issue from the moment a computer system becomes an integral part of any organisation's work (Randall, 1999).

The common rule is that if the legacy systems cannot support the business requirements, the business will not be able to remain competitive for long (Brodie & Stonebraker, 1995). Both a significant budget and person-hours will be monopolised by legacy systems maintenance. De Palma and Woodring (1993) referred to over 40% of the IT costs within an organisation being spent on maintaining its legacy systems, while Brodie and Stonebraker (1995) considered that the process of keeping these systems running takes 80-90% of the IT budget. Slee and Slovin (1997) gave an estimation in the area of 80% just for the routine maintenance activities.

Migration of Legacy Information Systems

The common sense solution to the legacy problem is migration. The definition of a successful information system migration according to Brodie and Stonebraker (1995) is as follows: "it begins with a mission-critical legacy system of a significant size in full operation and it ends with a fully operational, mission critical target application (or applications components) that replaces the essential aspects of the original legacy system." This involves replacing the problematic hardware and software, including the interfaces, applications, and databases that compose an information system infrastructure. Brodie and Stonebraker (1995) claim that legacy information system migration involves starting with a legacy information system and ending with a comparable target information system. This target system is significantly different from the original, but it contains substantial functionality and data from the legacy system.

The target system must be built using technological advancements in place of the legacy technology. For practical reasons, the target system may contain legacy components for which there is no adequate justification for their migration. According to Bisbal et al. (1999) the essence of legacy system migration is to allow the organisations to move their legacy systems to new environments, retaining the functionality of existing information systems without having to completely redevelop them.

In recent years, a significant number of organisations have initiated large-scale migration projects in order to improve their operations performance and to be compatible with the latest technological advancements. Particularly, the introduction of the Web browser technology, the so-called first-wave of the Internet (Dreyfus, 1998), forced the organisations to undertake migration projects in order to exploit the benefits of the shared information resources (Zou & Kontogiannis, 2002). Afterwards, the convergence of the Web and the distributed-object technologies extended the information Web-based applications to the services-based worldwide applications which was referred to as the Internet's second-wave (Dreyfus, 1998), and where the provided services and the content were distributed over the Internet (Zou & Kontogiannis, 2002). Moreover, the object-oriented technologies provided some valuable tools for the realisation of the services-based Web due to their inherent properties of encapsulation, polymorphism, and specialisation. In addition to the object orientation as a design paradigm, n-tier object computing was gradually being adopted by organisations as the preferred architecture for distributed applications because it allowed for the clear separation of business logic, representation logic, and back-end services (Zou & Kontogiannis, 2002).

Considering the case where the stakeholders of a large organisation (for instance, in the banking sector) have decided to maintain organisation's competitive edge and achieve conformation to the requirements posed by the need for flexibility and the minimization of time to market, the migration of company's legacy systems towards a new operating Web-based environment will be a considerably effective system evolution strategy. The strategic objectives will focus on leveraging the existing legacy software assets while minimising the risks involved in implementing from scratch its large scale mission-critical legacy applications (Umar, 1997). Thus, following the new era of distributed component-based applications, the organisation will face pressures to evolve its existing system (for instance, a large mainframe) in response to its customer expectations. The transformation from the mainframe computer to a multi-tier architecture will force the migration engineers to separate the integration logic and the legacy services to be stored in the middle-tier and the back-end tier, respectively. This architec-

ture will enable lightweight and thin clients to interact with servers in a fully customisable way. The component-based development will be based on the concepts of modularity, structured design, and object-orientation. The migration engineers and the practicing managers will emphasise on the design of the information systems in terms of well-defined modules that will be accessible to other modules through well-defined interfaces.

Current Migration Approaches

Each migration project could address the areas of reverse engineering, business reengineering, data transformation application development, human computer interaction, and testing (Ulrich, 2002). A generic process of legacy systems migration may include distinct phases (Bisbal et al., 1999) such as the Justification of the Migration process; the Understanding of the Legacy System; the Development of the Target System; the Testing and the Cut-Over (actual Migration). Within each task, general software and system engineering techniques can be applied.

Regarding the crucial phase of the actual migration process, various software engineers propose different methodological approaches.

Brodie and Stonebraker (1995) describe two strategies for migration: Cold Turkey and Chicken Little. The main drawback of the Cold Turkey strategy is the probable failure because the system will be written essentially from scratch. In that case, the risk level is high due to the fact that the development and evolution of the new system usually last for many years, in which the factors that affect the system may change. Chicken Little is a better strategy, according to Brodie and Stonebraker (1995), as it separates the migration process into step, and faces each one with a different aspect. Gateways play a significant role in the Chicken Little process.

The Butterfly methodology is being developed as part of the MILESTONE project (Wu et al., 1997). During the migration, the methodology eliminates the need for system users to simultaneously access both the legacy and target systems and, therefore, to keep consistency between these two heterogeneous information systems. The Butterfly methodology is based on the assumption that the data of the legacy system is logically the most important part of the system and that, from the viewpoint of the target system development, it is not the ever-changing legacy data that is crucial, but rather its semantics or schema(s). Thus, the Butterfly methodology separates the target system development and data migration phases, thereby eliminating the need for gateways.

BUSINESS "LEGACY" AND MIGRATION AS A BUSINESS CHANGE PROCESS

According to Laudon and Laudon (1998), today's business environment has been altered by the three powerful worldwide changes, namely, the emergence of globalisation; the transformation of industrial societies and economies into knowledge and information-based economies; and the transformation of the business enterprise whereby organisations are moving away from a hierarchical, centralised structure to become decentralised. The presence of business legacy within organisations can be identified by examining how they operate in their environment (Kelly et al., 1999).

Figure 1. Major activities in legacy system migration (Bisbal et al., 1999)

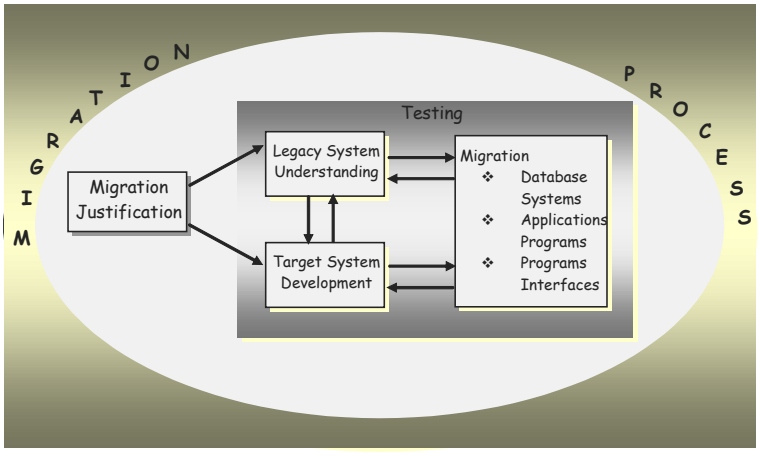

Figure 2. Chicken Little 11-step[1] strategy (Brodie & Stonebraker, 1995)

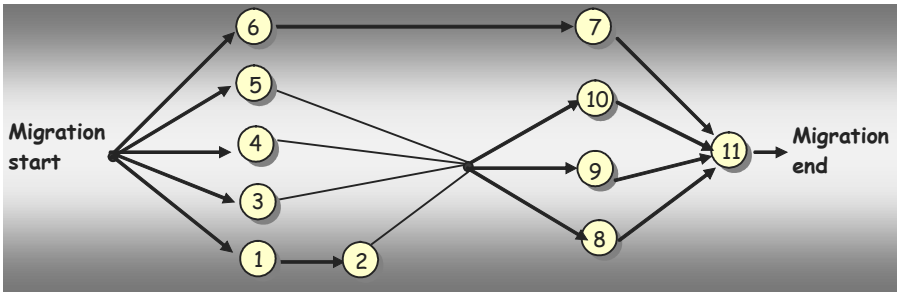

Figure 3. The Butterfly methodology (Wu et al., 1997)

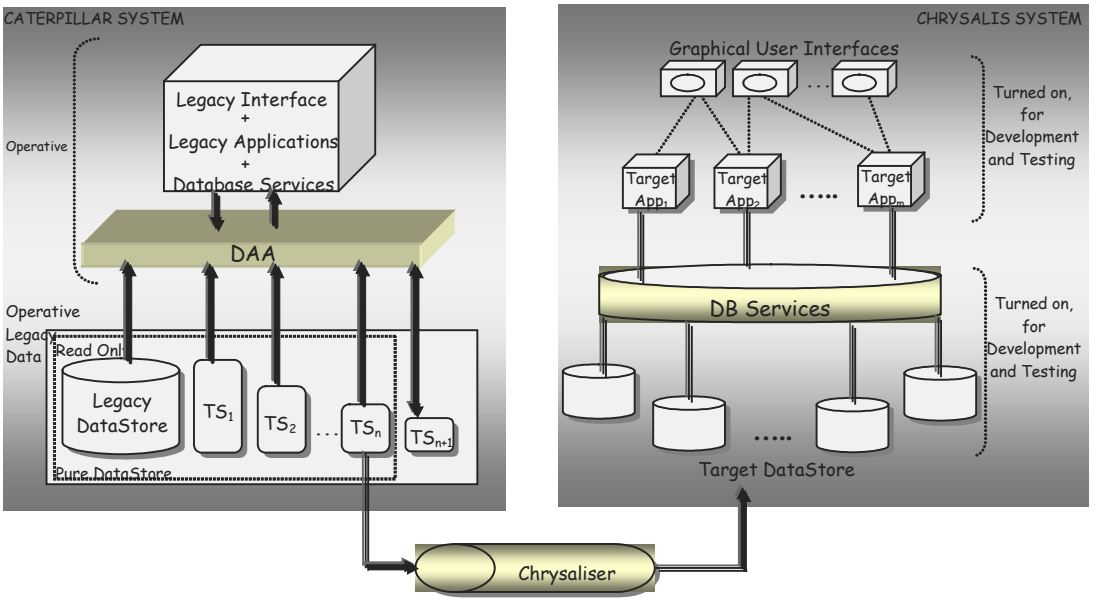

Kelly et al. (1999) refer to the typical components of "business legacy" as the way firms perceive their business, their organisational structure, and the way that they perceive the market within which they operate. Moreover, the business objectives and the organisational strategy can be part of this "business legacy" as well as the way work is organised such as workflows and business processes (Kelly et al., 1999). In this context, the "business legacy" is embedded in the legacy information systems, and it is the inter-relatedness of business and information systems legacy that makes either business or systems change a very complex process.

In this context, Stamati, Kanellis, Stamati, and Martakos (2004) consider the fact that although the legacy migration is being viewed as the replacement of aged or problematic hardware and software, including applications, interfaces, and databases that compose an information system infrastructure, it does not take into account the role of technology today which is not merely supportive but pervades every aspect of the way enterprises conduct their business. Their position is that migration must be implemented as a planned change process that first and foremost requires an understanding of the range of issues and organisational entities involved (Stamati et al., 2004).

In this case, the main underlined hypothesis is that migration is a process which entails business change, and it is more than just the movement or reorganisation of database systems, application programs, and program interfaces. The consideration of these physical systems is only the informational view of migration. However, from a business perspective, migration must also account for the broader impact to

business change which occurs from the organisational and operational viewpoints.

The motivation for any migration process is the transition from an initial organisation situation A, which is unsatisfactory in some aspect, to a desired situation B where the problem is treated. Possible causes to such change include perceived opportunities, threats, or strategic decisions, including for example the opportunities offered by new technologies, the treatment of inefficient business processes, the increased customer demands, the globalisation of markets, or the decision to move to a different operating platform (Kavakli & Loucopoulos, 2004).

FUTURE TRENDS

Recent methodologies consider business requirements as "the process of transforming the need for organisational change into a requirements specification which can then serve as a framework for making the necessary change into the organisational domain" (Pohl, 1996). Considering the aforementioned hypothesis for a migration process, it should be stressed that the actual business structures and practices should be considered as a domain of potential change and new design. Thus, business requirements should be considered as a central part of any migration activity within a business environment (Kavakli & Loucopoulos, 2004). Migration requires cooperation and understanding between the business management and technology management. Once business management has determined its goals, technology management must seek ways to modify the technology to support these goals.

Migration, therefore, should not be an undirected process but a purposive activity driven by organisational change goals. Its effectiveness should depend on being able to make good decisions about what migration goals to pursue, on selecting the appropriate strategies for achieving the desired goals, and on guiding the application of the chosen strategies.

CONCLUSION

The concept of migration has shifted in order to include both organisational change as well as change in computer systems that enable such enterprise change. Such a movement has led to the emergence of new definitions that put emphasis on a broader process of migration, and include the cognitive, social, and technical context of migration. These definitions are based on the premise that the replacement of a software system in the organisation inevitably brings change in the way work is organised. In a similar manner, any organisational change should be reflected in the software system requirements. Therefore, migration is concerned both with the design and implementation of a new software system and the management of change in the business systems that might be supported by it.

KEY TERMS

Component Architecture: A notion in object oriented programming where components of a program are completely generic. Instead of having a specialised set of methods and fields they have generic methods through which the component can advertise the functionality it supports to the system into which it is loaded.

Distributed Programming: The kind of programming that supports objects distributed across a network.

Gateway: A software module that is placed between other software modules. One of its roles for instance, is to simulate the old information system, while it is migrated, so it is still visible to the old user interfaces and application modules. Another role may be the transformation of the target information system in order for it to be visible to the old user interfaces, and the old legacy information system to be visible to the new user interfaces.

Mainframe: A machine designed for batch rather than interactive use, though possibly with an interactive time-sharing operating system retrofitted onto it.

N-Tier (or Multi-Tier) Architecture: This means splitting a system into more than just a client layer and a database layer. The server in this case refers to a custom written thing. The server then takes care of the business logic, and gets and returns the raw data to one or more database servers.

Object-Oriented Programming: The use of a class of programming languages and techniques based on the concept of an object which is a data structure encapsulated with a set of routines, called methods, which operate on the data. Operations on the data can only be performed via the methods, which are common to all objects that are instances of a particular class.

Reengineering: The examination and modification of a system to reconstitute it in a new form and the subsequent implementation of the new form.

Web Services Definition Language: An XML format for describing network services as a set of endpoints operating on messages containing either document oriented or procedure-oriented information. The operations and messages are described abstractly and then bound to a concrete network protocol and message format to define an endpoint. Related concrete endpoints are combined into abstract endpoints (services).

ENDNOTE

[1] S1: analyse the legacy information system, S2: decompose the legacy information system structure, S3: design the target interfaces, S4: design the target applications, S5: design the target database, S6: install the target environment, S7: create and install the necessary gateways, S8: migrate the legacy database, S9: migrate the legacy applications, S10: migrate the legacy interfaces, S11: cut over to the target information system.

Mobile Ad Hoc Network Security Vulnerabilities

INTRODUCTION

Mobile ad hoc networks inherently have very different properties from conventional networks. A mobile ad hoc network (MANET) is a collection of mobile nodes that are self configuring (network can be run solely by the operation of the end-users), capable of communicating with each other, establishing and maintaining connections as needed. Nodes in MANET are both routers and terminals. These networks are dynamic in the sense that each node is free to join and leave the network in a nondeterministic way. These networks do not have a clearly defined physical boundary, and therefore, have no specific entry or exit point. Although MANET is a very promising technology, challenges are slowing its development and deployment. Nodes in ad hoc networks are in general limited in battery power, CPU and capacity. Hence, the transmission ranges of these devices are also limited and nodes have to rely on the neighboring nodes in the network to route the packet to its destination node. Ad hoc networks are sometimes referred to as multi-hop networks, where a hop is a direct link between two nodes.

MANET has many important applications, including battlefield operations, emergency rescues, mobile conferencing, home and community networking, sensor dust and so forth.

Due to limited memory and computational power, nodes in MANETs have limited services and security provision. Unlike wired networks which have a higher level of security for gateways and routers, ad hoc networks have characteristics such as dynamically changing topology, weak physical protection of nodes, no established infrastructure or centralized administration and high dependence on inherent node cooperation. The routing protocols used in the current generation of mobile ad hoc networks, like Dynamic Source Routing (DSR), and Ad hoc On Demand Distance Vector Routing Protocol (AODV), are based on the principle that all nodes will cooperate, but dynamic and cooperative nature of MANETS presents substantial challenges to this assumption (Johnson, Maltz, & Broch, 2001; Perkins & Royer, 1999). Without node cooperation in a mobile ad hoc network, routes cannot be established, and packets cannot be forwarded. As a consequence, access control mechanisms, (similar to firewalls in wired networks) are not feasible. However, cooperative behavior, such as forwarding other node's messages, cannot be taken for granted because any node could misbehave. Misbehavior means deviation from regular routing and forwarding protocol assumption. It may arise for several reasons, non-intentionally when a node is faulty or intentionally when a node may want to save its resources. Cooperation in mobile ad hoc networks is a big issue of consideration. To save battery, bandwidth, and processing power, nodes should not forward packets for others. If this dominant strategy is adopted, the outcome is a nonfunctional network when multi-hop routes are needed, so all nodes are worse off. Without any counter policy, the effects of misbehavior have been shown to dramatically decrease network performance. Depending on the proportion of misbehaving nodes and their strategies, network throughput could decrease, and there could be packet losses, denial of

service or network portioning. These detrimental effects of misbehavior can endanger the entire network.

Wireless ad hoc networks are vulnerable to various attacks. These include passive eavesdropping, active interfering, impersonation, modification of packets and denial-of-service. Intrusion prevention measures, such as strong authentication and redundant transmission, can be used to tackle some of these attacks. However, these techniques can address only a subset of the threats, and moreover, are costly to implement due to the limited memory and computation power on nodes. We can identify two types of uncooperative nodes: faulty or malicious and selfish. Faulty or malicious behavior refers to the broad class of misbehavior in which nodes are either faulty and can therefore not follow a protocol, or are intentionally malicious and try to attack the system. Selfishness refers to no cooperation in certain network operations. In mobile ad hoc networks, the main threat from selfish nodes is dropping of packets (black hole), which may affect the performance of the network severely. Faulty, malicious and selfish nodes are misbehaved nodes.

ROUTING IN MANETs

Dynamic Source Routing is a popular routing protocol for ad hoc networks and was proposed for MANET by Johnson, Maltz and Broch (2001). In DSR, nodes do not store route to different nodes but they are discovered as they are needed. This type of routing is called R*eactive* routing and protocols used in this are called R*eactive* P*rotocols* (e.g., DSR, AODV, etc.). DSR works as follows: Nodes send out a ROUTE REQUEST (RREQ) message, all nodes that receive this message put themselves into the source route and forward it to their neighbors, unless they have received the same request before. If a receiving node is the destination, or has a route to the destination, it does not forward the request, but sends a REPLY (RREP) message containing the full source route. It may send that reply along the source route in reverse order or issue a ROUTE REQUEST including the route to get back to the source, if the former is not possible due to asymmetric links. After receiving one or several routes, the source selects the best (by default the shortest) route, stores it, and sends messages along that path. The better the route metrics (number of hops, delay, bandwidth, or other criteria) and the sooner the REPLY arrives at the source, the higher the preference given to the route and the longer it will stay in the cache. Because route to the destination is put into the packet, it is called source routing.

Attacks on DSR

There are a number of attacks possible on DSR protocol because there is no security measure and it assumes honest coordination of nodes among them and to protocol. A few attacks are outlined in this section and others are discussed in detail in the cited references.

- Dropping of packets by a node takes into account the following scenarios-Drop all packets not destined to it or perform only partial dropping. Partial dropping can be restricted to specific types, such as only data packets, or route control packets that contain it or packets destined to specific nodes.
- Avoid sending a ROUTE ERROR when having detected an error, to prevent other nodes from looking for alternative routes.
- By sending forged routing packets, an attacker can create a so-called black hole, a node where all packets are discarded or all packets are lost.
- Attempt to make routes that go through one appear longer by adding some virtual nodes to the route. Thus, a shorter route will be chosen, avoiding this node.
- Modify the nodes list in the header of a ROUTE REQUEST or a ROUTE REPLY to misroute packets and to add incorrect routes in the route cache of other nodes.
- Decrease the hop count (TTL) when receiving a packet, so that the packet will never be received by the destination. This attack could be detected by the previous node in route by enhanced passive acknowledgment.
- Initiate frequent ROUTE REQUEST to consume bandwidth and energy and to cause congestion.
- Send route replies with a time not proportional to the length of the route. This can give more priority to long routes, thus attracting routes to the attacker, or less priority to short routes, thus avoiding the attacker.

Listed above are some frequent attacks possible on DSR operating without any security measurements.

INTRUSION DETECTION SYSTEMS

Intrusion detection systems (IDS), especially those which are reputation-based, are a new paradigm and are being used for enhancing security in different areas. These systems are lightweight, easy to use and are capable to face a wide variety of attacks as long as they are observable. Among these mechanisms, some of the popular ones are CORE, CONFIDANT, OCEAN and SAFE.

Reputation-Based IDS

Reputation-based IDS do not rely on the conventional use of a common secret to establish confidential and secure communication between two parties. Instead, they are simply based on each other's observations (Buchegger & Le Boudec, 2005). To be more precise, every node in the network moni-

tors the packet emission of its neighboring nodes and derives a reputation value for them. If any misbehavior is detected, this information is broadcasted to the neighboring nodes in order to help them to protect themselves against this fraud (Buchegger & Le Boudec, 2003). Different architectures using the reputation concept for securing packet forwarding have been proposed so far (Resnick & Zeckhauser, 2002). The reputation herein is simply bound to how "good routers" the nodes are. Monitoring the packet loss carried out by the neighborhood is one of the main tasks of these reputation-based systems (Marti, Giuli, & Baker, 2000). The monitoring operation was implemented in CORE and CONFIDANT using a packet overhearing technique based on the promiscuous mode.

Issues Being Addressed

There are few basic problems in MANET that need to be kept in mind while designing any security solution. First, it is often very hard to differentiate intrusions and normal operations or conditions in MANET because of the dynamically changing topology and volatile physical environment. Second, mobile nodes are autonomous units that are capable of roaming independently in unrestricted geographical topology. This means that nodes with inadequate physical protection can be captured, compromised, or hijacked. Third, decision-making in ad hoc networks is usually decentralized and many ad hoc network algorithms rely on the cooperative participation of all nodes. Most ad hoc routing protocols are also cooperative in nature and hence can be easily misguided by false routing information (Yau & Mitchell, 2003).

It is observed that without countermeasure the effect of misbehavior dramatically decreases network performance. Intrusion prevention measures, such as authentication and encryption, can be used as the first line of defense against attacks in MANETs. However, even if these prevention schemes can be implemented perfectly, they still cannot eliminate all attacks, especially the internal or insider attacks. Also, they are costly to implement on mobile nodes from the point of view of limited computation power and energy needed. Another possible solution to this problem is similar to the concept of economic incentives, but the problem with them is that they need a centralized banking system and tamper proof hardware, and a more basic question is who will pay and how much ?

Architecture and Working Principle of Reputation-Based IDS

Reputation-based systems are used for enhancing security in ad hoc networks as they model cooperation between the nodes which is inspired from our social behavior. As in our daily life, when we meet somebody for the first time, we build a reputation about him or her from our personal (firsthand) and some body else's (secondhand) experience. Reputation-based systems are built on this principle. Such systems are used to decide who to trust, and to encourage trustworthy behavior. Resnick and Zeckhauser identify three goals for reputation systems (Resnick & Zeckhauser, 2002):

- To provide information to distinguish between a trustworthy principal and an untrustworthy principal,
- To encourage principals to act in a trustworthy manner, and
- To discourage untrustworthy principals from participating in the service the reputation mechanism is present to protect.

Watchdog and *Path-rater* are some essential components of any Reputation-based Intrusion detection System (Buchegger & Le Boudec, 2004). Complementing DSR with a watchdog increases throughput of mobile ad hoc networks. Misbehavior Detection and Reputation Systems may or may not be distributed. Here, fully distributed means whether information regarding one's reputation is immediately propagated in the whole network or not. In the latter case, nodes are fully dependent on their own personal view about other nodes reputation and behavior.

Distributed IDS protocols either rely only on firsthand information or on positive secondhand information. CONFIDANT and CORE fall into this category. Some basic problems with this approach of global reputation systems are:

- Every node has to maintain O(n) reputation information where n is number of nodes in network.
- Extra traffic generation in reputation exchange.
- Extra computation in accepting indirect reputation information (secondhand information), especially Bayesian Estimation.
- Security issues in reputation exchange such as reputation data packets can be modified.

CONFIDANT, proposed by Buchegger and Le Boudec, detects misbehaving nodes by means of observation or by ALARM signals from neighborhood (Buchegger & Le Boudec, 2002). CONFIDANT aggressively informs nodes in neighborhood about misbehavior of the malicious node. The weight-age of ALARM warning signal depends upon the level of trust that is believed by receiving node. CONFIDANT uses Bayesian Estimation for various measures and calculation of trust and reputation and thus IDS become complex. Each ad hoc running a CONFIDANT system comprises of a:

- *Monitor,* for observation purpose,
- *Reputation Manager,* for calculating reputation of other nodes,

- *Trust Manager,* for calculating level of trust to a particular node, which is used in calculating weightage of ALARM from that node, and
- *Path Manager,* for update path information in route cache as the reputation of neighborhood nodes changes. For example, Deletion of paths containing malicious node, selection of path from various available path option on particular situation and so forth.

CONFIDANT is vulnerable to false accusation if trusted nodes lie or if several liars collude.

Michiardi and Molva (2002) proposed a mechanism called CORE, to enforce node cooperation in mobile ad hoc network. In this mechanism, reputation is a measure of someone's contribution to network operations. Members that have a good reputation can use available resources while members with a bad reputation, because they refused to cooperate, are gradually excluded from the community. CORE defines three types of reputation:

1. Subjective reputation is a reputation value which is locally calculated based on direct observation.
2. Indirect reputation is secondhand reputation information which is established by other nodes.
3. Functional reputation is related to a certain function, where each function is given a weight as to its importance. For example, data packet forwarding may be deemed to be more important than forwarding packets with route information, so data packet forwarding will be given greater weight in the reputation calculations.

CORE reputation values range from positive (+1), through null (0), to negative (-1). CORE suffers from the problem of unwanted consequence of good reputation, where a good node may even wish to decrease its reputation by behaving badly to prevent its resources from being overused. The CORE mechanism assumes that every node will use the same reputation calculations and will also assign the same weights to the same functions. This is a potentially inappropriate assumption in heterogeneous ad hoc networks, where devices with different capabilities and roles are likely to place different levels of importance on different functions depending upon CPU usage, battery usage and so forth. One can take advantage of this situation and may perform only those functions which have higher preferences in calculating reputation.

A second type of IDS is one that solely depends upon the firsthand observation for reputation maintenance. Nodes make routing decision based on only the direct observation of its neighbor's node. This eliminates most of the trust manager complexity but in highly mobile ad hoc network it might not be appropriate to only depend solely upon personal observation. But also using secondhand information can significantly accelerate the detection and subsequent isolation of malicious nodes in mobile ad hoc networks.

OCEAN by Bansal and Baker relies exclusively on firsthand observations for ratings and avoids indirect (secondhand) reputation information. In OCEAN, the rating of each node is initialized to Neutral (0), with every positive action resulting in an increment (+1) of the rating, and every negative action resulting in a decrement (-2) of the rating (Bansal & Baker, 2003). Once the rating of a node falls below a certain faulty threshold (-40), the node is added to a faulty list. The faulty list represents a list of misbehaving nodes. If the rating is below the faulty threshold, the node is added to the faulty list. This faulty list is appended to the route request by each node broadcasting it to be used as an avoid list. A route is rated good or bad depending on whether the next hop is on the faulty list. In addition to the rating, nodes keep track of the forwarding balance with their neighbors by maintaining a chip count for each node.

OCEAN's approach is to disallow any secondhand reputation exchanges. Routing decisions are made based solely on direct observations of neighboring nodes behavior. This eliminates most trust management complexity. The basic problem with OCEAN is that it does not take secondhand information that can significantly improve detection of malicious nodes. Also, authors only consider individual bad behavior, not collusion of nodes.

CONCLUSION

Mobile ad hoc networks have a number of significant security issues which cannot be solved alone by Intrusion detection systems. Physical security of nodes is another very important issue. Reputation systems are used to establish trust and encourage trustworthy behavior and cooperation among nodes. In this article, we have critically examined the existing systems and outlined their strength and shortcomings.

KEY TERMS

Ad Hoc Network: A mobile ad hoc network (MANET) is a kind of wireless ad hoc network, and is a self-configuring network of mobile routers (and associated hosts) connected by wireless links—the union of which form an arbitrary topology.

Bandwidth: Bandwidth is a measure of frequency range and is typically measured in hertz. Bandwidth is related to channel capacity for information transmission.

Denial of Service (DoS): Is an attempt to make a computer resource unavailable to its intended users. Typically, the targets are high-profile Web servers where the attack is aiming to cause the hosted Web pages to be unavailable on the Internet. It is a computer crime that violates the Internet proper use policy as indicated by the Internet Architecture Board (IAB).

Firewalls: A logical barrier designed to prevent unauthorized or unwanted communications between sections of a computer network.

Gateway: A computer or a network that allows or controls access to another computer or network.

Intrusion Detection System (IDS): Is used to detect many types of malicious network traffic and computer usage that can't be detected by a conventional firewall.

Promiscuous Mode: Refers to a configuration of a network interface wherein a setting is enabled so that the interface passes all traffic it receives to the CPU rather than just packets addressed to it, a feature normally used for packet sniffing.

Routers: A router acts as a junction between two or more networks to transfer data packets among them.

Reputation: As a socially transmitted belief (i.e., belief about belief) concerns properties of agents, namely their attitudes toward some socially desirable behavior, be it cooperation, reciprocity, or norm-compliance.

Terminal: In the context of telecommunications, a terminal is a device which is capable of communicating over a line.

INTRODUCTION

This chapter offers a state-of-the-art review in mobile ad hoc networks (MANETs). It first introduces the history of ad hoc networks, explaining the ad hoc network concept and referring to the main characteristics of these networks and their fields of application.

It then focuses on technologies and protocols specific to ad hoc networks. Firstly, it refers to relevant proposals targeting the PHY/MAC layers. Secondly, it discusses the different routing protocol proposals for ad hoc networks according to the category to which they belong. Finally, it includes an overview of the different protocols proposed for ad hoc networks at the transport layer. The chapter concludes with some remarks on future trends in these networks.

BACKGROUND

The history of wireless networks dates from the 1970s. In fact, radio communications and computer networks were first combined by the University of Hawaii, in 1971, in an experimental network named ALOHANET. That network offered bidirectional communications following a star topology, and its purpose was to allow communicating with US mainland. During the 1980s, the technology was improved, and towards the end of the 1990s, interest on wireless networks reached a peak, mainly due to the fast growth of the Internet.

Nowadays we can split existing wireless networks into different categories according to their scope and size. Wireless wide area networks (WWANs), such as GSM and UMTS (Ojanpera, T. & Prasad, R., 1998), usually cover hundreds of kilometers and use private frequency bands. Such networks are usually owned and maintained by telecommunications providers, and their purpose is to offer services in a country or a region of it. Wireless metropolitan area networks (WMANs), such as WiMax (IEEE 802.16 WG, 2004), typically have a range of a few kilometers, and can operate over both private and public frequency bands, so that both telecommunication companies and private users can take advantage of them. Wireless local area networks (WLANs), such as WiFi (IEEE 802.11 WG, 1999), usually cover areas between a few tens of meters up to a kilometer. They typically use public frequency bands so that users can freely install and use them. At the lower end, we have wireless personal area networks (WPANs), such as Bluetooth (IEEE 802.15 WG, 2005), which also use free frequency bands that are used to replace cables within a very limited area around a single user (few meters).

This chapter focuses on recent developments in terms of infrastructure-less wireless networks, more commonly known as ad hoc networks, that extend WLAN technologies to offer more flexible solutions. All nodes within an ad hoc network provide a peer-level multihopping routing service to allow out-of-range nodes to be connected. Unlike a wired network, nodes in an ad hoc network can move freely, thus giving rise to frequent topology changes.

Such a network may operate in a stand-alone fashion or be connected to the larger Internet. An ad hoc architecture has many benefits, such as self-reconfiguration and adaptability to highly variable characteristics, namely, power and transmission conditions, traffic distribution variations, and load balancing. However, those benefits come with many challenges. New algorithms, protocols, and middleware have to be designed and developed to create a truly flexible and decentralized network.

In terms of applications, ad hoc networks offer the required flexibility to adapt to situations where no sort of infrastructure is available. Examples of such situations are army units moving inside hostile territories, or organized teams, such as firemen, performing rescue tasks. In general, mobile ad hoc networks can be used on all those situations characterized by lack of fixed infrastructure, peer-to-peer communication, and mobility support.

TECHNOLOGIES AND PROTOCOLS FOR AD HOC NETWORKS

A. PHY/MAC Layer Technologies

Throughout the past few years, novel solutions for MAC/PHY layers have been sought in the wireless ad hoc networking field. In particular, there have been several proposals targeting the MAC layer (Kumar, Raghavan, & Deng, 2006).

Despite the many proposals available, very few have made it to the market. Nowadays, almost every ad hoc network relies on IEEE 802.11 technology (IEEE 802.11 WG, 1999), which defines both physical and MAC layers. Since this standard has gained much relevance, we now offer more details about it.

In 1997, IEEE group 802.11 was created. The purpose was to create a technology for wireless local area networks operating on ISM (industrial, scientific, and medical) frequency bands. With that purpose, a MAC layer and three different physical layers were defined, operating at 1 and 2 Mbit/s:

- Infrared (IR) – baseband
- Frequency hopping spread spectrum (FHSS) – 2.4 GHz band
- Direct sequence spread spectrum (DSSS) – 2.4 GHz band

In December 1999, the IEEE 802.11a standard was completed, proposing a different technique for the physical layer named orthogonal frequency division multiplexing (OFDM). This technology was able to offer up to 54 Mbit/s on the 5 GHz band. A year later, in January 2000, the IEEE 802.11b standard was completed, consisting basically of an extension to the original standard, offering up to 11 Mbit/s on the 2.4 GHz band. Only in July 2003 was the IEEE 802.11g standard completed, offering 54 Mbit/s speeds on the 2.4 GHz frequency band. Recently, the 802.11n group is proposing higher speed extensions to the standard, targeting data rates above 300 Mbit/s.

Concerning 802.11's MAC layer, its main functions are reliable data delivery, fair access to the wireless media, and data protection. Moreover, it is responsible for a correct operation in noisy, unreliable environments.

The 802.11 standard offers two different medium access mechanisms:

- Distributed coordination function (DCF), a mandatory access mechanism based on CSMA/CA. (*carrier sense multiple access with collision avoidance*).
- Point coordination function (PCF), optional, based on a polling method to support services with time restrictions.

Since the latter only applies to access points, in ad hoc networks, the DCF must be used instead. Despite that the ad hoc mode proposed by the IEEE 802.11 standard did not specifically target multihop ad hoc networks, it is widely used and offers relatively good performance.

B. Routing Protocols

A routing protocol is required when a packet must go through several hops to reach its destination. It is responsible for finding a route for the packet and making sure it is forwarded through the appropriate path.

Routing techniques used can be divided into three families: *distance vector* (Bellman, 1957; Ford & Fulkerson, 1962), *link state* (Dijkstra, 1959), and *source routing* (Estrin, Li, Rekhter, Varadhan, & Zappala, 1996).

Internet routing protocols, based on these techniques, generate periodic control messages, a procedure that is not adequate for a large mobile network with long routes since it would result in a large number of control messages. Reducing routing overhead is critical for mobile nodes since CPU use, as well as radio transmissions and receptions, would cause batteries to be quickly depleted.

We will now present different routing protocol proposals for MANETs that are currently available. We have organized them into three groups: proactive, reactive, and other strategies, being that the latter embraces all those that do not fall under the former two categories.

Proactive Routing Protocols

When using proactive routing protocols, all the nodes (routers) periodically exchange routing information, with the aim of maintaining a consistent, updated, and complete network view. Each node uses the exchanged information to calculate the costs towards all possible destinations. That way, if a destination is found, there will always be a route available towards it.

The main advantage of proactive routing schemes is that there is no initial delay when a route is required. On the other hand, these are usually related to a greater overhead and a larger convergence time than for reactive routing techniques, especially when mobility is high. To increase the performance in ad hoc networks, both *link-state* and *distance vector* algorithms were modified. Examples of routing protocols using *distance vector* techniques are the *destination-sequenced distance vector* (DSDV) (Perkins & Bhagwat, 1994) and the *wireless routing protocol* (WRP) (Murthy & Garcia-Luna-Aceves, 1996). Examples of *link-state* based protocols are the *optimized link state routing* (OLSR) (Clausen, Jacquet, Laouiti, Muhlethaler, Qayyum, & Viennot 2001), and the *topology broadcast reverse path forwarding* (TBRPF) (Bellur & Ogier, 1999).

Reactive Routing Protocols

Reactive routing does not depend, in general, on periodic exchange of routing information or route calculation. Therefore, when a route is required, the node must start a route discovery process. This means that it must disseminate the route request throughout the network and wait for an answer before it can proceed to send packets to the destination. The route is maintained until the destination is unreachable or until the route is no longer necessary. By following this strategy, reactive routing protocols minimize the resource consumption by avoiding the maintenance of unused routes. On the other hand, the route discovery process causes a significant startup delay and causes a considerable waste of resources. If the network is wide enough, the overhead will be similar or superior to that achieved with proactive routing protocols.

The most common routing algorithms found among reactive routing protocols are *distance vector* and *source routing*. Examples of reactive routing protocols are the *ad hoc on-demand distance vector* (AODV) (Perkins & Royer, 1999), the *dynamic source routing* (DSR) (Johnson, Maltz, & Hu, 2004), and the dynamic on-demand routing protocol (DYMO) (Chakeres & Perkins, 2008).

Other Strategies

There are other strategies proposed for the design of routing protocols. There are, for instance, hybrid solutions, such as the *zone routing protocol* (ZRP) (Pearlman & Hass, 1999), which uses both reactive and proactive concepts. Some protocols are based on *clustering* and hierarchical architectures, such as the *distributed mobility-adaptive clustering* (DMAC) (Basagni, 1999) and the *cluster-based energy saving algorithm* (CERA) (Cano, Kim, & Manzoni, 2003).

The LAR protocol (Ko & Vaidya, 1998) tries to avoid the flooding associated with route discovery by using GPS information so that only those nodes on a certain geographic area between source and destination must retransmit route requests.

Finally, *power aware routing* (PAR) (Singh, Woo, & Raghavendra, 1998) is a solution that intends to improve the power consumption by taking into account the battery lifetime, selecting those routes that minimize the energy consumption of the system.

C. Transport Protocols

The transmission control protocol (TCP) is perhaps the most important and widely used transport protocol in the Internet. Most applications, such as Web, mail, SSH, and peer-to-peer file exchange, depend on it for the reliable delivery of data on an end-to-end basis.

Since TCP was designed for the Internet environment, it is prone to suffer from poor performance in wireless networks, especially in mobile ad hoc networks. The main reasons have to do with packet losses and node mobility.

In the Internet environment, the physical media is very reliable, and the path traversed by packets is typically the same throughout the duration of a connection. So, losses are usually related to congestion. TCP's congestion control mechanisms act upon packet losses to regulate the data rate, being quite effective for the Internet. Contrarily to wired media, wireless transmission are prone to frequent bit errors due to fluctuations in signal-to-noise ratio (SNR), multipath and shadowing effects, and so forth. Such errors are not related to congestion, and so, should not receive a similar treatment at the transport layer.

Mobile ad hoc networks suffer from frequent topology updates that require highly adaptive routing protocols, as referred previously. Route maintenance, though, is not instantaneous, and often causes large groups of packets to be delayed and/or lost. This occurrence is not related to congestion either and, therefore, should also receive a differentiated treatment.

Due to the aforementioned problems, specific transport layer proposals for ad hoc network environments are available in the literature. They can be grouped into three different categories:

- Solutions that propose improvements to the TCP protocol
- TCP-aware cross layer solutions
- Transport protocols specific to ad hoc networks

In terms of solutions proposing improvements to the TCP protocol, the most relevant work in the field is ELFN (explicit link failure notification) (Holland & Vaidya, 1999). This solution mitigates the route discovery problem through explicit link failure notification from network nodes to the TCP sender. The sender then enters a hold state, periodically probing the network to assess if the path has been reestablished. When a new path is available, the TCP agent returns to its previous state (before the path was lost), hence, improving resource usage.

Concerning TCP-aware cross-layer solutions, the most relevant work in the field is the Atra framework (Anantharaman & Sivakumar, 2002). This proposal basically consists of three mechanisms, two at the routing layer and one at the MAC layer, that cooperate to improve the performance of TCP. At the MAC layer, there is a mechanism that predicts route failures to improve routing tasks. At the routing layer, it includes a mechanism, symmetric route pinning, to reduce the frequency of route failures. It also includes a proactive mechanism that informs all interested nodes about failing links, improving global performance.

Finally, in terms of protocols specific to ad hoc networks, the most relevant proposal in the field is the ad hoc transport protocol (ATP) (Sundaresan & Anantharaman, 2003). This protocol consists of a complete redesign of the transport layer for optimum performance in ad hoc network environments. Its main characteristics are the use of rate-based transmissions instead of TCP's sliding windows paradigm, a quick start mechanism, a delay-based congestion indicator, and a feedback mechanism from receiver to source that includes SACK (selective acknowledgements) blocks similar to those proposed in TCP-SACK (Mathis, Mahdavi, Floyd, & Romanow, 1996).

FUTURE TRENDS

The field of mobile ad hoc networks is still under intensive research. New application areas are emerging, such as vehicular ad hoc networks (VANETs), that rely on ad hoc connections between vehicles to improve road safety. The sensor networks area is also strongly related to ad hoc networks, and a merge of some of the ideas and solutions employed is prone to occur. Wireless mesh networking (WMN) is an area also intimately related to mobile ad hoc networks; the former are characterized by minimal or no mobility compared to the latter.

Concerning improvements to the MAC layers, the IEEE 802.11e standard represents an important enhancement to the MAC layer to offer quality of service (QoS) support. In the future, we expect to see MAC layer solutions that further improve QoS traffic discrimination at this layer.

In terms of routing, a merge of independent solutions is required to offer a protocol that takes into consideration issues such as power consumption, security, anonymity, QoS, as well as the physical and MAC layers used.

For the transport layer, a cross-layer solution specific to ad hoc networks offering efficient support to both best effort and real-time traffic is still one of the missing points. Since these networks are very prone to errors, enhancements to the transport layer are also expected to include advanced error correction techniques that completely avoid retransmissions up to a certain loss rate.

CONCLUSION

Mobile ad hoc networks are a field under intensive research due to their flexibility and lack of requirements in terms of infrastructure. Currently, several solutions are available for the different network layers involved, physical, MAC, routing, and transport, both in terms of theoretical and real-world implementations of protocols and technologies. Despite the ongoing efforts, there is still much room for improvement, since the performance of these networks is typically poor compared to other wireless technologies, such as UMTS, WiMax, and so forth.

In years to come, and with the advent of novel applications requiring these networks (e.g., VANETs), it is expected that this type of network will become widely adopted by the industry, resulting in the deployment of new products and solutions that rely on ad hoc networks to offer a set of functionalities and services that no other technology is able to offer. Once the technology becomes mature, it can be adopted also for critical missions, such as rescue, disaster, and military scenarios.

KEY TERMS

Distance Vector: Routing technique that maintains a table for the communication taking place, and employs diffusion (not flooding) for information exchange between neighbors. All the nodes must calculate the shortest path towards the destination using the routing information of their neighbors.

Link State: Routing protocols, based on this technique, maintain a routing table with the full topology. The topology is built by finding the shortest path in terms of link cost, cost that is periodically exchanged among all the nodes through a flooding technique.

MAC Layer: The medium access control layer is a protocol layer embedded within the link layer that is responsible for coordinating the access to a shared medium according to a set of rules.

Node: In the context of mobile ad hoc networks (MANETs), it usually refers to a mobile terminal, such as a PDA, laptop, smartphone, or other device with wireless communication capabilities that participates in the networks both as a traffic generator and traffic forwarder.

Source Routing: Technique where all the data packets have the routing information on their headers. The route decision is made on the source node, which avoids routing loops entirely.

SSH: Secure shell is a protocol that allows accessing a remote computer in a secure manner by employing cryptographic techniques. Usually, the term refers also to the client/server tools that support this protocol.

VANET: Vehicular ad hoc network, consisting of a network of vehicles, moving at a relatively high speed, that communicate among themselves with different purposes, being the main purpose that of improving security on the road.

Mobile Agent Authentication and Authorization in E-Commerce

Sheng-Uei Guan
National University of Singapore, Singapore

INTRODUCTION

With the increasing worldwide usage of the Internet, electronic commerce (e-commerce) has been catching on fast in a lot of businesses. As e-commerce booms, there comes a demand for a better system to manage and carry out transactions. This has led to the development of agent-based e-commerce. In this new approach, agents are employed on behalf of users to carry out various e-commerce activities.

Although the tradeoff of employing mobile agents is still a contentious topic (Milojicic, 1999), using mobile agents in e-commerce attracts much research effort, as it may improve the potential of their applications in e-commerce. One advantage of using agents is that communication cost can be reduced. Agents traveling and transferring only the necessary information save the bandwidth and reduce the chances of network clogging. Also, users can let their agents travel asynchronously to their destinations and collect information or execute other applications while they can disconnect from the network (Wong, 1999).

Although agent-based technology offers such advantages, the major factor that is holding people back from employing agents is still the security issues involved. On the one hand, hosts cannot trust incoming agents belonging to unknown owners, because malicious agents may launch attacks on the hosts and other agents. On the other hand, agents may also have concerns on the reliability of hosts and will be reluctant to expose their secrets to distrustful hosts.

To build bilateral trust in an e-commerce environment, the authorization and authentication schemes for mobile agents should be well designed. Authentication checks the credentials of an agent before processing the agent's requests. If the agent is found to be suspicious, the host may decide to deny its service requests. Authorization refers to the permissions granted for the agent to access whichever resource it requested.

In our previous work, we have proposed a SAFER (Secure Agent Fabrication, Evolution & Roaming) architecture (Zhu, 2000), which aims to construct an open, dynamic and evolutionary agent system for e-commerce. We have already elaborated agent fabrication, evolution, and roaming in Guan (1999, 2001, 2002), Wang (2001), and Zhu (2001). This article gives an overview of the authentication and authorization issues on the basis of the SAFER architecture.

BACKGROUND

Many intelligent agent-based systems have been designed to support various aspects of e-commerce applications in recent years, for example: Kasbah (Chavez, 1998), Minnesota AGent Marketplace Architecture (MAGMA) (Tsvetovatyy, 1997), and MAgNet (Dasgupta, 1999). Unfortunately, most current agent-based systems such as Kasbah and MAGMA are serving only stationary agents. Although MAgNet employs mobile agents, it does not consider security issues in its architecture.

D'Agents (Gray, 1998) is a mobile agent system, which employs the PKI for authentication purposes, and uses the RSA (Rivest, Shamir, & Adleman, 1978) public key cryptography (Rivest et al., 1978) to generate the public-private key pair. After the identity of an agent is determined, the system decides what access rights to assign to the agent and sets up the appropriate execution environment for the agent.

IBM Aglets (Lange, 1998; Ono, 2002) are Java-based mobile agents. Each aglet has a globally unique name and a travel itinerary (wherein various places are defined as context in IBM Aglets). The context owner is responsible for keeping the underlying operating system secure, mainly protecting it from malicious aglets. Therefore, he or she will authenticate the aglet and restrict the aglet under the context's security policy.

Ajanta is also a Java-based mobile agent system (Karnik, 1999, 2001, 2002) employing a challenge-response based authentication protocol. Each entity in Ajanta registers its public key with Ajanta's name service. A client has to be authenticated by obtaining a ticket from the server. The Ajanta Security Manager grants agents permissions to resources based on an access control list, which is created using users' Uniform Resource Names (URNs).

iJADE (intelligent Java Agent Development Environment) (Lee, 2002) provides an intelligent agent-based platform in the e-commerce environment. This system can provide fully automatic, mobile and reliable user authentication.

Under the public key infrastructure (PKI), each entity may possess a public-private key pair. The public key is known to all, while the private key is only known to the

key owner. Information encrypted with the public key can only be decrypted with the corresponding private key. In the same note, information signed by the private key can only be verified with the corresponding public key (Rivest, 1978; Simonds, 1996). The default algorithm that generates the key pairs is the digital signature algorithm (DSA), working in the same way as a signature on a contract. The signature is unique, so that the other party can be sure that you are the only person who can produce it.

MAIN THRUST OF THE ARTICLE

This article presents an overview of the architecture based on SAFER (Secure Agent Fabrication, Evolution & Roaming) (Zhu, 2000) to ensure a proper authentication and authorization of agent. Here, the public key infrastructure (PKI) is used as the underlying cryptographic scheme. Also, agents can authenticate the hosts to make sure that they are not heading to a wrong place. According to the level of authentication that the incoming agent has passed, the agent will be categorized and associated with a relevant security policy during the authorization phase. The corresponding security policy will be enforced on the agent to restrict its operations at the host. The prototype has been implemented with Java.

Design of Agent Authentication and Authorization

Overview of the SAFER Architecture

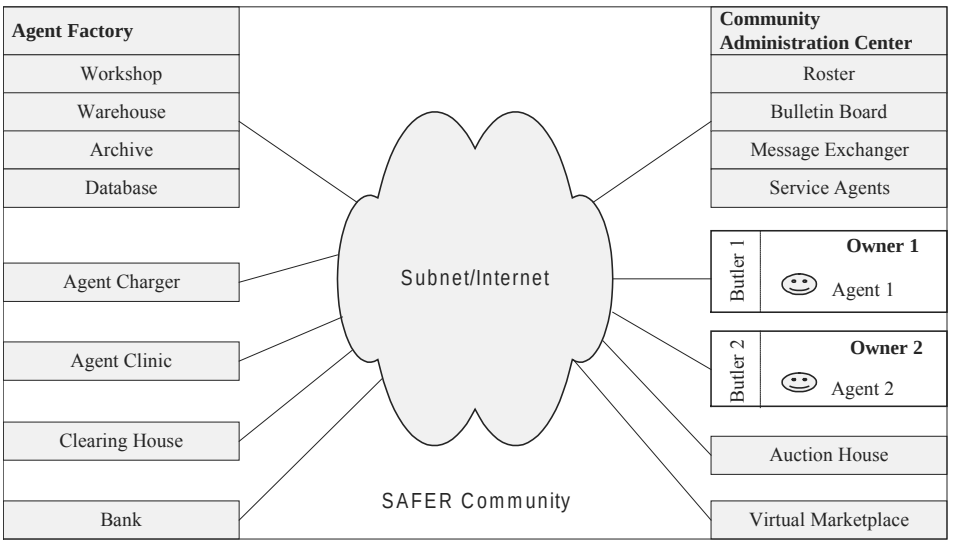
The SAFER architecture comprises various communities and each community consists of the following components (see Figure 1): Agent Owner, Agent Factory, Agent Butler, Community Administration Center, and so forth. The Agent Owner is the initiator in the SAFER environment, and requests the Agent Factory to fabricate the agents it requires. The Agent Butler is a representative of the Agent Owner authorized by the owner to coordinate the agents that are dispatched. Owner can go offline after dispatching his or her agents, and thereafter the butler can take over the coordination of the agents. The Agent Factory fabricates all the agents. This is the birthplace of agents and is thus considered a good source to check malicious agents. The Community Administration Center (CAC) is the administrative body, which has a roster that keeps the data of the agents that are in the community. It also collects information, such as addresses of new sites that agents can roam to.

Agent Structure and Cryptographic Schemes

In SAFER, mobile agents have a uniform structure. The agent credentials (hard-coded into the agent (Guan, 2000, 2001)) are the most important part of the agent body and are immutable. This part includes FactoryID, AgentID, Expiry Date, and so forth. The Agent Factory then signs this immutable part. When the receiving host accepts an agent, it can verify with the Agent Factory's public key whether the agent's credentials have been modified. The mutable part of the agent includes the Host Trace, which stores a list of names of the hosts that the agent has visited so far. Upon checking, if any distrusted host is found, a host may decide not to trust this agent and impose a stricter security policy on it.

In SAFER, the main cryptographic technology used is the PKI. The public keys are stored in a common database

Figure 1. SAFER architecture



located in CAC, where the public has read access, but no access to modify existing records.

Authentication Process

Authenticating Host

Before roaming to the next host, it is the duty of the agent to authenticate the next host to make sure that the host it is visiting is a genuine one. A hand-shaking method is devised to authenticate hosts. The agent sends its request to a host, asking for permission to visit. The host will sign on the agent's request message with its private key and send it back to the agent. The agent can then verify the host's identity by extracting the host's public key from the common database and authenticating the signature. If the authentication is successful, then the agent is communicating with the genuine host and starts to ship itself over to the host.

Authenticating Agent

Authentication of an agent involves two major steps: 1) to verify the agents' credentials, and 2) to verify the mutable part of the agent, checking whether it has been tampered with by anyone in its roaming process.

The authentication procedure is shown in Figure 2. Firstly, the agent will be checked for its expiry date. If it has not expired, its host trace will be examined to see if it has been to any distrusted host. If the agent passes these two tests, the final test is to check the trustworthiness of the factory that has manufactured it.

Authorization Process

After the host accepts an agent, it has to determine what resources the agent is allowed to access based on the level of authentication that the agent has passed. Four levels of authorization have been designed, with level 1 being the strictest and level 4 the most lenient. Level 1 authority is given to agents that the host does not have much trust in. An agent that passes all levels of authentication and is deemed to be trusted may be awarded the level 4 authority. Table 1 shows the four policies and the restrictions imposed on each policy. The permissions can be customized to meet the requirements of different hosts. Here, AWT stands for Abstract Window Toolkit (AWT), which allows our programs to create a Graphical User Interface (GUI) to interact with the users.

Implementation

Implementation of agent authentication and authorization was done using the Java programming language. The Java Security API and the Java Cryptography Extension were widely used

Figure 2. Authentication & authorization procedure

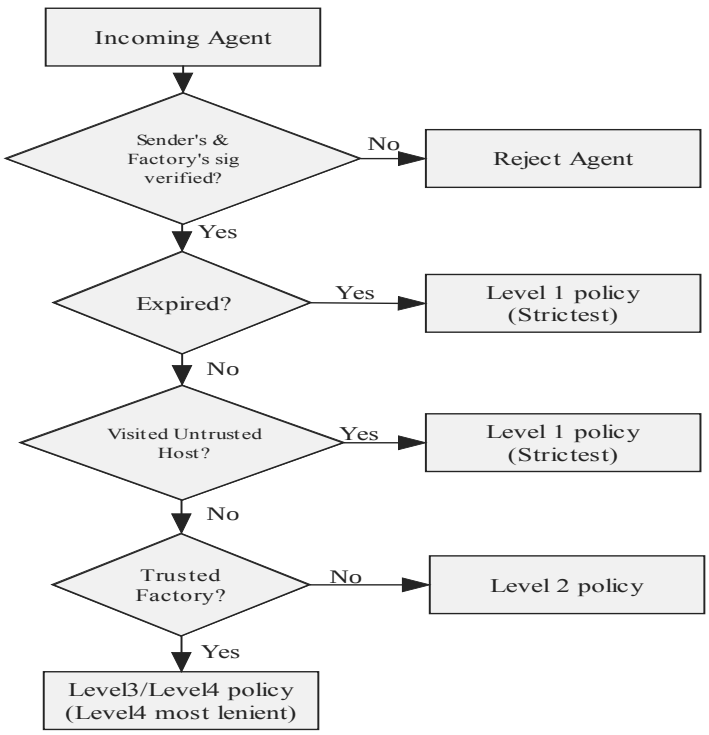


Table 1. Definition of the various security policies

Level of leniency	Policy name	Permissions
Level 4 (Most lenient)	Polfile.policy	FilePermission (Read, write)
		AWT Permission
		Socket Permission (Accept, Listen, Connect)
		Runtime Permission (create/set SecurityManager, queuePrintJob)
Level 3	Pol1.policy	FilePermission (Read, write)
		AWT Permission
		Socket Permission (Accept, Listen, Connect)
		Runtime Permission (create SecurityManager, queuePrintJob)
Level 2	Pol2.policy	FilePermission (Read only)
		AWT Permission
		Socket Permission (Accept, Connect)
		Runtime Permission (create SecurityManager)
Level 1 (Most Strict)	Pol3.policy	FilePermission (Read only)
		No AWT Permission
		No Socket Permission
		No Runtime Permission

in the implementation. The graphical user interfaces were designed using the Java Swing components.

Discussions

We do not intend to compare our prototype with mobile agent systems such as D'agents and Aglets on detail benchmarks, as the focus of our approach is on the security issues in the context of e-commerce applications. Here, we present our features in comparison to related work, and discuss the advantages and limitations of our system in the following subsections.

Our approach has some features that are similar to the related systems discussed in the second section. For example, the authentication mechanism is based on PKI. The authorization mechanism is implemented using the Java security manager and some user-defined security policies. The major features of our approach lie in the method of authorization. Some agent systems authorize agents based on a role-based access control list and some are based on the identity of the agent. The SAFER system is different in that it allocates a different security policy based on the identity of the agent and the level of authentication it has passed.

Advantages of Our Infrastructure

Storage of Keys

One of the principal advantages of the prototype implemented is that there is no sending of keys over the network. This enhances the security of the system since it is impossible that keys can get intercepted and replaced.

The database storage of the public keys also allows an efficient method of retrieval of keys. This facilitates the verification of all previous signatures in the agent by the current host. For example, the owner may want to verify the signatures of all the previous hosts that the agent has visited. Instead of having all these hosts append their public keys to the agent (which may be compromised later), the owner can simply retrieve the keys from the database according to the hosts' ID.

Examining the Agent's Host Trace

Every host is required to sign on the agent's host trace before it is dispatched to the next destination. The IDs of the hosts visited are compared with the distrusted host list that each host would keep. If a distrusted host were found, the host would then take special precautions against these agents by imposing a stricter security policy on its operations.

Automation of the Authentication and Authorization Process

The beauty of this system is that it can be automated or run manually when the need arises. In the automatic configuration, when an agent is sent over, the host will do the authentication and assign an appropriate security policy to the agent. If the execution is successful, the host signs the agent and adds its identity on the host trace, before sending it out to the next host. In the manual configuration, all the authentication and authorization procedures need prompting from the host owner. The advantage is that the host has more control on what methods to authenticate and what authorization level and policy to enforce on the agent.

Limitations of Our Infrastructure

Pre-Determined Security Policies

In the current design, the agent is assigned to the security policy based on the authentication process. Having pre-determined security policies may be stifling to the operations of an agent. It would be useless if the agent is denied the read access but instead granted other permissions that it does not need. The limitation here is an implementation choice because the mechanism to customize the permission for each agent has not been developed. Pre-determined security policies are simpler to implement for large-scale systems.

Difficulty in Identifying a Malicious Host

The current implementation does not have a way of identifying the host that is causing the attacks on the agent. The agent owner can only detect that certain information has been tampered with, but does not know which host exactly caused the disparity.

FUTURE TRENDS

The implementation of the prototype has provided a basic infrastructure to authenticate and authorize agents. We are improving our approaches and implementation in two aspects. Firstly, to make the system more flexible in enforcing restrictions on agents, a possible improvement is to let the agent specify the security policy that it requires for its operation at the particular host. It is desirable to have a personalized system with the agent stating what it needs and the host deciding on whether to grant the permission or not. Secondly, the protection of agents against other agents can be another important issue. The authentication and authorization aspects between communicating agents are similar to that of host-to-agent and agent-to-host processes. We are designing certain mechanisms for this type of protection.

CONCLUSION

The advantages of employing mobile agents can only be manifested if there is a secure and robust system in place.

In this article, the design and implementation of agent authentication and authorization are elaborated. By combining the features of the Java security environment and the Java Cryptographic Extensions, a secure and robust infrastructure is built. PKI is the main technology used in the authentication module. To verify the integrity of the agent, digital signature is used. The receiving party would use the public keys of the relevant parties to verify that all the information on the agent is intact. In the authorization module, the agent is checked regarding its trustworthiness and a suitable user-defined security policy will be recommended based on the level of authentication the agent has passed. The agent will be run under the security manager and the prescribed security policy.

KEY TERMS

Agents: A piece of software, which acts to accomplish tasks on behalf of its user.

Authentication: The process of ensuring that an individual is who he or she claims to be.

Authorization: The process of giving access rights to an individual or entity.

Cryptography: The act of protecting data by encoding them, so that they can only be decoded by individuals who possess the key.

Digital Signature: Extra data appended to the message in order to authenticate the identity of the sender, and to ensure that the original content of the message or document that has been sent is unchanged.

Java: A high-level programming language similar to C++ developed by SUN Microsystems.

Private Key: That key (of a user's public-private key pair) known only to the user.

Public Key: The publicly distributed key that if combined with a private key (derived mathematically from the public key), can be used to effectively encrypt messages and digital signatures.

INTRODUCTION

The rapid expansion of information and the high demand for timely data delivery have triggered the development of a large number of wireless information systems that enable users to access data from anywhere at anytime. These applications must face three major challenges: the limited bandwidth of wireless medium, intermittent network connectivity, and the fact that portable devices have limited CPU power, memory, and energy sources. Traditional distributed system design methods, such as the client/server-based computational model, cannot meet the aforementioned challenges very well. In contrast, a relatively new distributed system design paradigm, the mobile agent-based computation model, provides natural solutions to these problems. In this article, we will introduce the concept of mobile agent-based computing, review some examples of existing agent-based information systems, and discuss security issues that are related to them.

BACKGROUND

An *agent* is a computer program that acts autonomously on behalf of a person or organization (Lange & Oshima, 1998). A *mobile agent* is an agent that can move through the heterogeneous network autonomously, migrate from host to host, and interact with other agents (Gray, Kotz, Cybenko, & Rus, 2002). Agent-based distributed application design is gaining prevalence because it provides a single framework that allows a wide range of distributed applications to be implemented easily, efficiently, and robustly.

Mobile agents have many advantages (Lange & Oshima, 1998). We only highlight some of them that are closely related to distributed information system design.

- **Support Disconnected Operation:** Mobile agents can roam the network and fulfill their tasks without the owner's intervention. Thus, the owner only needs to maintain the physical connection during submission and retraction of the agent. This asset makes mobile agents desirable in the mobile computing environment where intermittent network connection is often inevitable.
- **Balance Workload:** By migrating from the mobile device to the core network, the agents can take full advantage of the high bandwidth of the wired portion of the network and the high computation capability of servers/workstations. This feature enables mobile devices with limited resources to support functions beyond their original capability.
- **Reduce Network Traffic:** Mobile agents' migration capability allows them to handle tasks locally instead of passing messages among the data sources. This implies fewer messages and, consequently, reduced chances for loss of messages and the overhead of retransmission.

One should note that the agent-based computation model also has some limitations. For instance, the overhead of mobile agent execution and migration can sometimes overshadow the performance gain obtained by reduced communication costs. In addition, the ability to move and execute code fragments at remote sites could introduce serious security implications.

MAIN THRUST OF THE CHAPTER

Mobile Agent-Based Information Systems

Papastavrou, Samaras, and Pitoura (2000) proposed the DBMA-Aglet Framework for World Wide Web distributed database access. The system uses mobile agents, between the client and the server machine, as a means of providing

database connectivity, processing, and communication. The DBMS-Aglet Multidatabase Framework is an extension of the DBMS-Aglet Framework that can perform parallel execution over multiple databases. In this framework, a coordinator DBMS-Aglet is responsible for creating and dispatching multiple DBMS-Aglets to different data sources. Finally, the coordinator DBMS-Aglet compiles the results and returns it to the client. The authors claimed that the DBMS-Aglet Framework allows the aglet to be portable, light, independent, autonomous, flexible, and robust.

Vlach, Lana, Marek, and Navara (2000) implemented a system called Mobile Database Agent System (MDBAS). The system intends to integrate heterogeneous databases under one virtual global database schema to transparently manage distributed execution. The MDBAS aims to preserve local autonomy and execute distributed transactions using the two-phase commit protocol. Based on the experiences gained in the development of MDBAS, the authors claimed that mobile agent technology will play an important role in the software industry in a short time.

Babaoglu, Meling, and Montresor (2002) proposed a Java-based multi-agent system, called Anthill, which is a framework for peer-to-peer (P2P) application development, deployment, and testing. Anthill adopts the concept of swarm intelligence (Kennedy & Eberhart, 2001), where there is no central coordination of activity and the collection of simple agents of limited capability achieves intelligent collective behavior. Performance evaluation of Anthill was done by using 10,000 queries collected from the Internet. Simulation results confirm that the performance of the system, in terms of the success rate for each search request and the number of hops necessary for the first reply to a search request, improves over time because of the learning and adaptive capabilities of agents.

The VIPAR (Virtual Information Processing Agent Research) system is a multi-agent system that uses agents and ontology to automatically monitor and manage newspaper articles in a manner comparable to humans (Potok, Elmore, Reed, & Shelton, 2003). It includes 13 information agents that manage 13 different newspaper sites. Results show that VIPAR can efficiently handle information gathering, analysis, and summarization tasks that are critical to the Virtual Information Center (VIC) at the U.S. Pacific Command. The deployment of such a system can drastically reduce the cost of these labor and resource intensive processes.

MAMDAS stands for Mobile Agent-based Mobile Data Access Systems (Jiao & Hurson, 2004). Its design aims to alleviate two major difficulties in large-scale mobile data access systems: heterogeneity and mobility of data sources and/or users. Experimental results have shown that under the same underlying multi-database configuration, the mobile agent-based computation mode can achieve better performance and robustness than the traditional client/server-based model. In addition, the authors also pointed out that, from a software engineering point of view, the use of mobile agents can significantly improve modularity and reusability and simplify the management of large complex systems. Therefore, the authors believe that mobile agent-based programming is an excellent solution to distributed information system design.

Spyrou, Samaras, Pitoura, and Evripidou (2004) also share the view that mobile agent technology has great potential in wireless computing applications. The authors proposed a general framework for dynamically configuring applications through the deployment of mobile agents. They believe that the use of mobile agents enhances the applicability of different software models to mobile wireless computing, and it makes applications more light-weight and tolerant to intermittent connectivity. The proposed framework was illustrated through a wireless Web-based data access application. Their simulation results show that, in the wireless environment, for average size transactions, the deployment of mobile agents provides a performance improvement of approximately a factor of 10.

Security Issues

Despite the advantages that mobile agents have demonstrated in building flexible distributed information systems, the success of mobile agent-based systems will depend on the development of robust security defense mechanisms. Due to the mobility and autonomy of mobile agents, designing such security mechanisms is a challenging task.

Within the scope of security, three key issues have been identified for mobile intelligent agent systems (Chess, 1998):

- Protection of the agent against malicious hosts;
- Protection of the host against malicious agents;
- Protection of the network communication.

Ideas from the distributed computing and operating systems can be borrowed to address the second issue (Farmer, Guttman, & Swarup, 1996; Greenberg, Byington, & Harper, 1998), and techniques such as the Secure Socket Layer (SSL) can resolve the third problem. However, protecting agents against malicious hosts is a new and difficult problem that is specific to mobile agents. In the following subsections, we will first summarize the security threats in mobile agent-based systems and then, briefly review solutions that have been proposed in the literature for both host and agent protection.

Security Threats in Mobile Intelligent Agent Systems

Types of attacks are often categorized as follows: damage, denial of service, unauthorized access, harassment, masquerade, and repudiation. These attacks may be launched by

mobile agents against hosts, by hosts against mobile agents, and among mobile agents.

Definition 1: Damage Attack is defined as destruction or subversion of a host's files, configuration, hardware, or of a mobile agent or its mission.

A mobile agent can launch damage attacks to a host by tampering with the services that the host provides, such as destroying the agent execution environment. A host can damage a mobile agent by modifying its code, providing wrong execution results, or simply by erasing the agent.

Definition 2: Denial of Service attack is defined as partially or completely impeding one or more computer services, or a mobile agent's access to some resources or services.

Malicious mobile agents can overload a host by constantly consuming CPU time, memory, or network connections. An overloaded host may fail to provide services to all other mobile agents. From the point of view of protecting the agents, a hostile host may refuse to execute or transport the agent and thus launch a denial of service attack against the mobile agent.

Definition 3: Unauthorized Access attack is defined as illegal or undesired access or removal of data from a host or a mobile agent.

A mobile agent may access and steal private information from the host. It may also use covert channels to transmit data in a hidden way that violates a host's security policy. Similarly, a host may observe or illegally copy secrets carried by mobile agents. Encryption may help alleviate the problem, but unfortunately, some information must be decrypted during execution.

Definition 4: Harassment attack is defined as annoying people with repeated attacks.

Some examples of this type of attack include mobile agents displaying unwanted messages on the host monitor, or hosts tracing a mobile agent and attempting to discover sensitive information about the agent's owner.

Definition 5: Masquerade attack is defined as one party disguising its own identity or claiming a false identity in order to deceive the other party.

A masquerading agent may pose as an authorized agent in order to gain access to services or resources to which it is not entitled. One agent host may masquerade as another in an effort to deceive a mobile agent. An agent may masquerade as another agent in order to lure the victim agent to communicate with it and, therefore, obtain information.

Definition 6: Repudiation attack is defined as one party participating in a transaction or communication, and later claiming that the transaction or communication never took place.

Repudiation may occur because of a misunderstanding or may be an intentional attack. One way to prevent this type of attack is to maintain records/logs that can help resolve any dispute.

Protection of the Host Against Malicious Agents

Techniques that protect the host include: authenticating credentials, access control, code verification, limitation techniques, and audit logging (Greenberg et al., 1998).

a. **Authenticating Credentials:** A mobile agent is digitally signed by one or more parties using one of a number of algorithms, such as a digital signature algorithm. By examining the signatures, a host can discover whether the agent has been tampered within transit. Note that forgery, cryptanalysis, theft of cryptographic keys, or poor implementation can compromise cryptographic techniques.
b. **Access Control:** After a mobile agent's identity is authenticated, a reference monitor is used to restrict the information, system resources, and services that the mobile agent is allowed to access and use. Some mobile agent systems put a restriction on the number of times an object can be accessed. The reference monitor consults a security policy to determine whether or not to grant permission to mobile agents based on their level of authorization as shown by their credentials.
c. **Code Verification:** A code verification program scans the mobile agent's binary image and determines if the mobile agent is a valid program. If illegal instructions are found, the code verification program will not invoke the execution layer. This technique protects hosts by protecting their execution layers that are vulnerable to subversion or sabotage by mobile agents executing within them.
d. **Limitation Techniques:** Time, range, and duplication limits are three limitation techniques that control the persistent survivability of mobile agents. Time limits control the amount of time that a mobile agent system allows a mobile agent to run in an execution layer. Range limits determine the number of destinations or network "hops" that a mobile agent is permitted to visit. Duplication limits regulate the number of times that a mobile agent can be transmitted or be cloned—a

large number of mobile agent clones can swamp the hosts on a network.

e. **Audit Logging:** An audit trail of the mobile agents' activities is kept so that after abuse is detected, the responsible party can be identified and called to account. Based on when the log is examined, auditing techniques can be classified into two categories: passive and active. Passive techniques perform a posteriori analysis and bring security violations to the auditor's attention. Active approaches, on the other hand, perform analysis in real time. Once a violation is detected or suspected, the intrusion detection system alerts the auditor and may take immediate measures for system protection.

Protection of the Agent Against Malicious Hosts

Mobile agent protection techniques can be categorized into two groups: fault tolerance based and encryption based techniques (Greenberg et al., 1998). Techniques based on fault tolerance aim to make mobile agents robust in unpredictable environment, thus protecting them from malfunctioning hosts, intermittent network connectivity, and so forth. Techniques based on encryption hide the mobile code or sensitive information so that it cannot be recognized and thus will be less likely to be stolen or misused.

Fault-tolerant based techniques include replication, persistence, and redirection.

- **Replication:** This technique ensures a mobile agent gets to its destination eventually. When traveling on a network, a mobile agent is replicated at each host for the purpose of fault masking. One obvious drawback of this approach is that it introduces a large amount of overhead in creating and storing the replicas.
- **Persistence:** This technique utilizes the temporary storage (hard disk) on the host to store the mobile agent and its execution state. In the case of host failure, the copy of mobile agent and its execution information persists in the storage. When the host restarts, it can reload the mobile agent from the temporary storage and resume services. Although this improves the mobile agent's tolerance to host failures, it may cause unwanted duplications if the mobile agent is already replaced by the sender assuming the agent is destroyed or forgotten.
- **Redirection:** Redirection refers to the mobile agent's capability of finding available paths around damaged hosts or network to accomplish a mission.

Encryption-based techniques mainly include append-only data logs, trail obscuring, code obfuscation, encrypted data manipulation, and state appraisal functions.

- **Append-Only Data Logs:** This scheme (Karnik & Tripathi, 2001) uses a combination of a digital signature and public key cryptographic primitives to ensure that data can only be appended to the log, and there is no way that data can be removed or modified without the owner being able to detect it. In addition, a host cannot observe data appended by the previous hosts.
- **Trail Obscuring:** This technique constantly modifies the mobile agent's binary image to make it hard to identify by pattern matching. It prevents hosts that are colluding in an attempt to track a specific agent from succeeding.
- **Code Obfuscation:** This is a method to obscure a mobile agent's code to make it hard to reverse engineer. This technique deters theft or subversion, but not destruction.
- **Encrypted Data Manipulation:** This technique encrypts the data carried by a mobile agent in a way that allows it to be manipulated while still encrypted (Sander, 1997). This allows the mobile agent to carry data that cannot be read by a host, but the host can still inspect the mobile agent's code through code verification. This technique was extended later by Lee, Alves-Foss, and Harrison (2004).
- **State Appraisal Functions:** While roaming the network, a mobile agent's execution state may change; a portion of its contents cannot be encrypted and is therefore vulnerable to subversion. State appraisal functions are used to ensure that a mobile agent's unencrypted dynamic data is not tampered with.

FUTURE TRENDS

The success of existing mobile agent-based information systems and the rapidly emerging new agent-based applications have led us to believe that the agent-based paradigm will become a prevalent solution to many distributed applications, especially in the mobile computing environment. We also note that applicability and security always go hand-in-hand. Security in mobile agent-based systems is especially difficult to achieve because mobile agents and hosts have a conflict of interest: Techniques that protect agents may pose potential threats to hosts, and measures that secure hosts may endanger mobile agents. Current mobile agent security solutions are far from being mature. Future research is required to properly address these issues.

CONCLUSION

Extensive research has been conducted to explore the potential of mobile agents in designing large distributed information systems and e-commerce systems. Mobile agents have also been utilized in network management and network intrusion detection tasks. Because mobile agents are distributed and intelligent in nature, it is envisioned that they are suitable for a broad range of future technologies such as semantic Web and sensor network management. This article is intended to provide an overview of applications of mobile agents in distributed information system design and security problems and solutions that are pertinent to them. We believe that if the challenges of agent security can be properly addressed, agent-based applications will proliferate in the near future.

KEY TERMS

Agent: A computer program that acts autonomously on behalf of a person or organization.

Damage Attack: Defined as destruction or subversion of a host's files, configuration, or hardware, or of a mobile agent or its mission.

Denial of Service Attack: Defined as partially or completely impeding one or more computer services, or a mobile agent's access to some resources or services.

Harassment Attack: Defined as annoying people with repeated attacks.

Masquerade Attack: Defined as one party disguising its own identity or claiming a false identity in order to deceive the other party.

Mobile Agent: An agent that can move through the heterogeneous network autonomously, migrate from host to host, and interact with other agents.

Repudiation Attack: Defined as one party participating in a transaction or communication, and later claiming that the transaction or communication never took place.

Mobile Commerce and the Evolving Wireless Technologies

INTRODUCTION

The mobile phone industry has experienced an explosive growth in recent years. The emerging markets such as China, India, and Brazil contribute this growth. In China, the number of mobile subscribers has already surpassed the number of fixed landline phone subscribers. In Korea and Japan, there is an explosion of mobile and wireless services. The United States are joining too and there were 207.9 million subscribers in 2005 (CTIA, 2006). Mobile e-commerce (m-commerce) makes business mobility a reality; mobile users could access the Internet at any time, from anywhere with handheld devices or laptop. A 3G enabled smart phone enables you to access a wide range of services anywhere and anytime. For example, you can send and receive e-mail, make cinema and restaurant reservations and pay for them, check real train time, look at digital maps, download music and games, and also browse the Internet. Mobile and wireless services are ranging from mobile communication networks to wireless local area networks. The service provided by mobile communication systems has achieved huge success as mobile and wireless communication technologies are converging at fast speed. We will study mobile and wireless communication in relation to mobile phones. Hence, m-commerce is defined as electronic commerce carried out in handheld devices such as smart phone through mobile and wireless communication network.

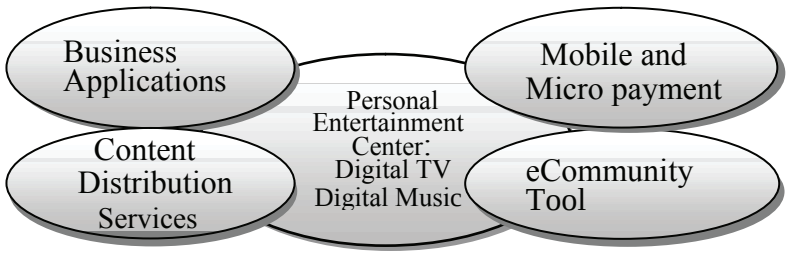
BACKGROUND

E-commerce was once characterized by e-marketplaces, online auction systems that act as the intermediary between buyers and sellers. Now it is evolving toward social network in which users take the control on the contents. Social networks such as YouTube (http://www.youtube.com) enable participants to share life experiences by posting video clips taken by mobile phones especially. The integration creates rich user-generated contents. At the same time, m-commerce also undergoes the evolution too. Many new business models have been established around the use of mobile devices. Mobile devices have the characteristics of portability, low cost, more personalization, GPS (global positioning system), voice etc. The new business models include micro payment and mobile payment, content distribution services, business services, and personal multimedia entertainment center (see Figure 1). Because of their existing customer base, technical expertise, and familiarity with billing, mobile telephone operators are the natural candidates for the provision of mobile and micro payment services. Micro payment involves small purchases such as vending and other items. In other words, the mobile phone is used as an ATM card or debit card. Consumers can pay for purchases at convenience stores or buy train tickets using their mobile phones.

Content distribution services are concerned with real time information, notification (e.g., bank overdraft), and using positioning systems for intelligent distribution of personalized information by location (e.g., selective advertising of locally available services and entertainment). Real-time information such as news, traffic reports, stock prices, and weather forecasts can be distributed to mobile phones via the Internet. The information is personalized to the user's interests. By using a positioning system, users can retrieve local information such as restaurants, traffic reports, and shopping information. Content distribution services with a greater degree of personalization and localization can be effectively provided through a mobile portal. Localization means to supply information relevant to the current location of the user. Users profiles such as past behavior, situation, and location should be taken into account for personalization and localized service provision. Notification can be sent to the mobile device too. Mobile network operators (MNOs) have a number of advantages over the other portal players (Tsalgatidou & Veijalainen, 2000). First, they have an existing customer relationship and can identify the location of the subscriber. Second, they have a billing relationship with the customer while the traditional portal does not. MNOs can act as a trusted third party and play a dominant role in m-commerce applications.

In addition, the mobile phone has become a personal entertainment center. A wide range of entertainment services are available, which consist of online game playing, ring tones download, watching football video clips, live

Figure 1. M-commerce applications



TV broadcasting, music download, and so on. Unsurprisingly, adult mobile service and mobile gambling service are among the fast growing services. Juniper Research Inc. estimates that worldwide revenue from adult mobile content will jump from US$500 million in 2004 to $2.5 billion in 2009 (Korzeniowski, 2005). In the market of mobile games, Juniper Research estimates that annual revenues will have passed the $3 billion mark by the end of 2006. It also acts as a community tool to generate a lot of revenue from SMS (short message service). SMS broadcasting is an ideal communication tool in community.

M-commerce also has a great impact on business applications, especially for companies with remote staff. Extending the existing enterprise resource planning (ERP) systems with mobile functionality will provide remote staff, such as sales personnel, with real-time corporate and management data. Time and location constraints are reduced and the capability of mobile employees is enhanced. Also it makes paperless office a reality so that off-site engineers or salesmen don't need to carry loads of paper such as delivery note to their clients. The logistic related business also benefits from the use of mobile inventory management applications. One interesting application is "rolling inventory" (Varshney & Vetter, 2002). In this case, multiple trucks carry a large amount of inventory while on the move. Whenever a store needs certain items/goods, a nearby truck can be located and just-in-time delivery of goods can be performed. M-commerce offers tremendous potential for businesses to respond quickly in supply chains.

CHALLENGES IN M-COMMERCE

M-commerce has a number of inherent complexities as it embraces many emerging technologies: wireless technologies, handheld devices, software, wireless protocols, and security (Ojanperä, & Prasad, 2001). These technologies have rapid product cycles and quick obsolescence. M-commerce, which is more complex than e-commerce, faces a number of challenges.

Economic Aspect

The delay in 3G mobile network operators (MNO) is in implementing their systems infrastructure. The success of m-commerce in Japan changes the concept of "free" Internet to "paid" Internet. Users are willing to pay for the service. MNOs anticipate a huge profit in taking control of the backbone of m-commerce—the wireless infrastructure. In addition, MNOs also play a dominant position in providing m-commerce applications. This has created an unreasonably high expectation from the services. Big companies in Europe such as Deutsche Telecom, France Télécom, Spain's Telefónica, and the UK's Vodafone spent an estimated US125 billion to US150 billion on 3G licenses (Garber, 2002). Many of them are burdened with high debts. In Europe, 3G was slowly rolled out in 2004 and the number of users was less than 1 million after a huge price cut campaign. As a result, MNOs are reluctant to build the infrastructure of 3G (e.g., O2 in UK).

Social Aspect

With the exception of Korea and Japan, there is a lack of interest in 3G mobile phone. The Western European market has reached saturation point, where mobile possession rate is close to 100% in some countries. In addition, mobile users have "upgrade fatigue" (i.e., they are reluctant to upgrade their mobile phones). In 2002, the mobile phone business pushed very hard on picture messaging, which required new expensive handsets. The response was poor. The mobile revenue mainly comes from the voice calls and SMS messaging. Recently, Apple iPod is a big success. It transforms the music industry and shows that consumers are willing to pay for download music. In 3 GSM world Congress 2005, mobile phone operators are unveiled to team up music companies and mobile phone manufacturers to offer digital music download and play in mobile phone. MNO hopes that they can attract the customers to use their network to download music.

Standards Aspect

The market for handheld devices is quite different from the personal computer (PC) market. For instance, Nokia, the handset manufacturer, not only produces handset hardware but also develops the Symbian software (the operating system (OS) of mobile phone) together with other handset manufacturers such as Motorola and the handset manufacturers have closed relationship with MNOs. The OS standards are under the control of handset manufactures and MNOs.

Technologies Aspect

Security is a major issue. Mobile communications offer users many benefits such as portability, flexibility, and increased productivity. The most significant difference between wired networks and mobile communication is that the airwave is openly exposed to intruders. The intruder eavesdrops on signaling and data connections associated with other users by using a modified mobile phone. In addition, their small size, relatively low cost, and mobility means that they are likely to be lost or stolen. Sensitive information such as the "private-key" is thus vulnerable (Karygiannis & Owens, 2002). A 3G mobile device, when connected to an IP network, is in the "always-on" mode. Both this "always-on" mode and bluetooth's "on" mode make the device susceptible to attack. Moreover, it also provides the opportunity to track a user's activity, which may be a violation of privacy.

Furthermore, handheld devices have many inherent limitations. Technological developments will increase the computing power and storage in handheld devices. However, insufficient battery life and power consumption will impede the potential growth of m-commerce even when 3G is widely available. At present, the battery life is very short (e.g., 2-4 hours for surfing). Fuel cells may be the answer to treble the power of a mobile phone. However, the liquid is inflammable, commercial viability is in doubt. Furthermore, the small screen is another limitation. The screen of a mobile phone is 7cm*5cm, which poses difficulty when surfing the Web. A low power, inexpensive, high-resolution color display would seriously increase the growth of m-commerce.

FUTURE TRENDS

Technology has historically advanced in waves of disruption. It is the same in the telecommunications. The disruptive technologies are Wi-Fi, WiMax, mesh networks, and powerline broadband. WiFi (wireless fidelity) allow users to surf the Internet while moving, are proliferating at astonishing speed on a global scale. Worldwide retail chains like Starbucks and McDonald offer wireless Internet access to their customers. It offers a fast and stable connection; the data rate is several times faster than 3G. The WiFi is an important, new, and disruptive technology to mobile telephone technology and it may be a watershed for all other m-commerce investment by telecom and content providers in the world of the mobile Internet (Lamont, 2001). In making use of this technology, mobile phone manufacturer Nokia and wireless network manufacturer Cisco have been working together closely to produce the Wi-Fi phone. In the future, the tariff of accessing the mobile Internet will be reduced to budget price.

WiMax (worldwide interoperability for microwave access), a low cost wireless broadband connection in wide area network (WAN) starts the rollout. It will offer an opportunity for new mobile phone operators to enter the industry at a small fraction of the cost. As the mobile and wireless technologies are converging, the competition will be keen. The low cost wireless mesh network competes in the market. It is a peer-to-peer wireless communication system that allows two user devices to communicate directly without routing through a central switch. End user devices in a mesh network not only send their data but also act as routers or repeaters, relaying signals for other devices. Powerline broadband has the potential to make an impact too. It is a technology delivering high-speed Internet access into electrical outlets via common electrical grid (Buvat, 2005). The transmission rates are currently better than DSL (digital subscriber line)/cable. It is important for MNOs to embrace those technologies in order to maintain the competition.

CONCLUSION

As the mobile and wireless technologies are evolving rapidly and sophisticated mobile phones becomes affordable, the mobile commerce will become part of our daily life. The mobile Internet is ideal for particular applications and has useful characteristics that offer a range of services and content. The widespread adoption of mobile commerce is fast approaching. In business, the mobile computing is changing the logic of business; businesses have to implement effective strategies to capture and retain increasingly demanding and sophisticated customers. Business needs to think critically about how to integrate mobile Web to wired Web.

KEY TERMS

3.5G: It is based on a technology called, HSDPA (high-speed downlink packet access). It will be upwardly compatible with 3G W-CDMA systems, but will enable more than 10X the peak data rate and more than 6X the capacity of initial 3G systems.

Global System for Mobile Communications (GSM): It is a world standard for digital cellular communications using narrowband TDMA (time division multiple access). It is the standard most commonly used in Europe and Asia, but not in the United States.

i-Mode: It is the packet-based service for mobile phones offered by Japan's leader in wireless technology, NTT DoCoMo. The i-mode protocol uses compact HTML (cHTML) as its markup language instead of WAP's wireless markup language (WML) to provide mobile phone voice service, Internet, and e-mail.

Short Message Service (SMS): It has grown very rapidly and is very popular in Europe. SMS messages are two-way alphanumeric paging messages up to 160 characters that can be sent to and from mobile phones

The Third Generation (3G): It will bring wireless transmission speeds up to 2Mbps, which permits high-quality wireless audio and video. It comprises three primary standards: W-CDMA (wide-band code division multiple access), CDMA2000, and TD-CDMA (time division CDMA).

The WAP: A standard for providing cellular phones, pagers, and other handheld devices with secure access to e-mail and text-based Web pages.

Wi-Fi (Wireless Fidelity): It is a popular term for 802.11b, a wireless local area network (WLAN) specified by the Institute of Electrical and Electronic Engineers (IEEE) and is based on the Ethernet protocol and CSMA/CA (carrier sense multiple access with collision avoidance) for path sharing. Wi-Fi supports a range of about 150 feet and data rates up to 11mbps.

WiMax (worldwide interoperability for microwave access): It is called 802.16 in industry standard, a wireless broadband connection in wide area network(WAN). It offers fast wireless data communications over distance up to about 30 miles.

Wireless Application Protocol (WAP): It is an open, global specification that empowers mobile users with wireless devices to easily access and interact with information and services instantly.

Mobile Commerce Technology

Jyh-haw Yeh
Boise State University, USA

INTRODUCTION

With the introduction of the World Wide Web, electronic commerce has revolutionized traditional commerce and boosted sales and exchanges of merchandise and information. Recently, the emergence of wireless and mobile networks has made possible the admission of electronic commerce to a new application and research subject—mobile commerce, which is defined as the exchange or buying and selling of commodities, services, or information on the Internet through the use of mobile handheld devices. With services provided by mobile commerce, consumers may use the microbrowsers on their cellular phones or PDAs to buy tickets, order meals, locate and book local hotel rooms, even write contracts on the move.

In just a few years, mobile commerce has emerged from nowhere to become the hottest new trend in business transactions. NTT DoCoMo's i-mode (2003) is by far the most successful example of mobile commerce. Introduced in February 1999, i-mode has attracted over 36 million subscribers worldwide. With i-mode, cellular phone users can easily access more than 62,000 Internet sites, as well as specialized services such as e-mail, online shopping and banking, ticket reservations, and personalized ringing melodies that can be downloaded for their phones. The i-mode network structure not only provides access to i-mode and i-mode-compatible contents through the Internet, but also provides access through a dedicated leased-line circuit for added security. i-mode users are charged based on the volume of data transmitted, rather than the amount of time spent connected. In Spring 2001, NTT DoCoMo introduced its next-generation mobile system, based on wideband CDMA (W-CDMA), which can support speeds of 384Kbps or faster, allowing users to download videos and other bandwidth-intensive content with its high-speed packet data communications.

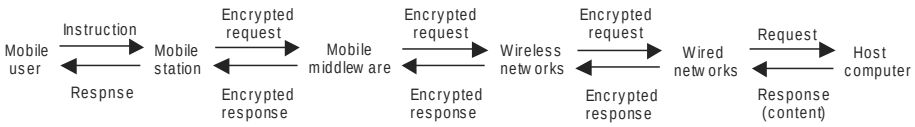
BACKGROUND

A mobile commerce system is very complex because it involves such a wide range of disciplines and technologies. In general, a mobile commerce system can be divided into six components: (1) mobile commerce applications, (2) mobile stations, (3 mobile middleware, (4) wireless networks, (5) wired networks, and (6) host computers.

To explain how these components work together, the following outline gives a brief description of a typical procedure that is initiated by a request submitted by a mobile user:

1. *Mobile commerce applications:* A content provider implements an application by providing two sets of programs: client-side programs, such as a user interface on a microbrowser, and server-side programs, such as database accesses and updating.
2. *Mobile stations:* Mobile stations present user interfaces to the end users, who specify their requests on the interfaces. The mobile stations then relay user requests to the other components and display the processing results later using the interfaces.
3. *Mobile middleware:* The major purpose of mobile middleware is to seamlessly and transparently map Internet contents to mobile stations that support a wide variety of operating systems, markup languages, microbrowsers, and protocols. Most mobile middleware also encrypts the communication in order to provide some level of security for transactions.
4. *Wireless networks:* Mobile commerce is possible mainly because of the availability of wireless networks. User requests are delivered to either the closest wireless access point (in a wireless local area network environment) or a base station (in a cellular network environment).
5. *Wired networks:* This component is optional for a mobile commerce system. However, most computers (servers) usually reside on wired networks such as the Internet, so user requests are routed to these servers

Figure 1. Flowchart of a user request processed in a mobile commerce system



using transport and/or security mechanisms provided by wired networks.

6. *Host computers:* This component is similar to the one used in electronic commerce, which includes three kinds of software. User requests are generally acted upon in this component.

To better illustrate the above procedure, Figure 1 depicts a flowchart showing how a user request is processed by the components in a mobile commerce system (Leavitt, 2000).

MOBILE COMMERCE SYSTEMS

Since each component in a mobile commerce system is large enough to be a research area by itself, only elements in components that are specifically related to mobile commerce are explained in this article. Related research on mobile commerce systems can be found in the article by Varshney, Vetter, and Kalakota (2000).

Mobile Commerce Applications

The applications of electronic commerce are already widespread; mobile commerce applications not only cover these but also include new ones. For example, some tasks that are not feasible for electronic commerce, such as mobile inventory tracking and dispatching, are possible for mobile commerce. Table 1 lists some of the major mobile commerce applications (Gordon & Gebauer, 2001; Sadeh, 2002), along with details of each.

Mobile Stations

A mobile station or a mobile handheld device, such as a personal digital assistant (PDA) or Web-enabled cellular phone, may embrace many of the features of computers, telephone/fax, e-mails, and personal information managers (PIMs), such as calendars and address books, and networking features. A mobile station differs from a PC or notebook due to its limited network bandwidth, limited screen/body size, and mobility features. The limited network bandwidth prevents the display of most multimedia on a microbrowser, while the limited screen/body size restricts the mobile stations of today to either a stylus or keyboard version. Table 2 lists some major mobile station specifications, although several table entries may be incomplete as some of the information is classified as confidential due to business considerations.

Table 1. Major mobile commerce applications

Mobile Category	Major Applications	Clients
Commerce	Mobile transactions and payments	Businesses
Education	Mobile classrooms and labs	Schools and training centers
Enterprise resource planning	Resource management	All
Entertainment	Games/images/music/video downloads and online gaming	Entertainment industry
Health care	Accessing and updating patient records	Hospitals and nursing homes
Inventory tracking and dispatching	Product tracking and dispatching	Delivery services and transportation
Traffic	Global positioning, directions, and traffic advisories	Transportation and auto industries
Travel and ticketing	Travel management	Travel industry and ticket sales

Table 2. Specifications of some major mobile stations

Vendor & Device	Operating System	Processor	Installed RAM/ROM	Input Methods	Key Features
Compaq iPAQ H3870	MS Pocket PC 2002	206 MHz Intel StrongARM 32-bit RISC	64 MB/32 MB	Touchscreen	Wireless email/Internet
Handspring Treo 300	Palm OS 3.5.2H	33 MHz Motorola Dragonball VZ	16 MB/8 MB	Keyboard/ Stylus	CDMA network
Motorola Accompli 009	Wisdom OS 5.0	33 MHz Motorola Dragonball VZ	8 MB/4 MB	Keyboard	GPRS network
Nokia 9290 Communicator	Symbian OS	32-bit ARM9 RISC	16 MB/8 MB	Keyboard	WAP
Nokia 6800	Series 40			Keyboard	Innovative keyboard integration
Palm i705	Palm OS 4.1	33 MHz Motorola Dragonball VZ	8 MB/4 MB	Stylus	Wireless Email/Internet
Samsung SPH-i330	Palm OS 4.1	66MHz Motorola Dragonball Super VZ	16 MB/8 MB	Touchscreen/ Stylus	Color screen
Sony Clie PEG-NR70V	Palm OS 4.1	66 MHz Motorola Dragonball Super VZ	16 MB/8 MB	Keyboard/ Stylus/ Touchscreen	Multimedia
Sony Ericsson T68i			800KB	Keyboard	Multimedia Messaging Service
Toshiba E740	MS Pocket PC 2002	400 MHz Intel PXA250	64 MB/32 MB	Stylus/ Touchscreen	Wireless Internet
Sony Ericsson Z1010			32MB	Keyboard	MP3, MMS, WAP2.0

Mobile Middleware

The term middleware refers to the software layer between the operating system and the distributed applications that interact via the networks. The primary mission of a middleware layer is to hide the underlying networked environment's complexity by insulating applications from explicit protocol handling disjoint memories, data replication, network faults, and parallelism (Geihs, 2001). Mobile middleware translates requests from mobile stations to a host computer and adapts content from the host to the mobile station (Saha, Jamtgaard, & Villasenor, 2001). According to an article in *Eurotechnology* entitled Frequently asked questions about NTT-DoCoMo's i-mode (2000), 60% of the world's wireless Internet users use i-mode, 39% use WAP, and 1% use Palm middleware. Table 3 compares i-mode and WAP, the two major kinds of mobile middleware.

Wireless Networks

Network infrastructure provides essential voice and data communication capability for consumers and vendors in cyberspace. Evolving from electronic commerce (EC) to mobile commerce (MC), it is necessary for a wired network infrastructure, such as the Internet, to be augmented by wireless networks that support mobility for end users. From the perspective of mobile commerce, wireless networks can be categorized into wireless local area networks (WLANs) and wireless cellular networks.

WLAN technologies are suitable for office networks, home networks, personal area networks (PANs), and ad hoc networks. In a one-hop WLAN environment, where an access point (AP) acting as a router or switch is a part of a wired network, mobile devices connect directly to the AP through radio channels. Data packets are relayed by the AP to the other end of a network connection. If no APs are

Table 3. Comparisons of WAP and i-mode

	WAP	i-mode
Developer	WAP Forum	NTT DoCoMo
Function	A protocol	A complete mobile Internet service
Host Language	WML (Wireless Markup Language)	CHTML (Compact HTML)
Major Technology	WAP Gateway	TCP/IP modifications
Key Features	Widely adopted and flexible	Highest number of users and easy to use

available, mobile devices can form a wireless ad hoc network among themselves and exchange data packets or perform business transactions as necessary. Many WLAN products are available on the market. In general, Bluetooth technology supports very limited coverage range and throughput. Thus it is only suitable for applications in personal area networks. In many parts of the world, the IEEE 802.11b (Wi-Fi) system is now the most popular wireless network and is used in offices, homes, and public spaces such as airports, shopping malls, and restaurants. However, many experts predict that with much higher transmission speeds, 802.11g will replace 802.11b in the near future.

Cellular system users can conduct mobile commerce operations through their cellular phones. Under this scenario, a cellular phone connects directly to the closest base station, where communication is relayed to the service site through a radio access network (RAN) and other fixed networks. Originally designed for voice-only communication, cellular systems are evolving from analog to digital, and from circuit-switched to packet-switched networks, in order to accommodate mobile commerce (data) applications. Currently, most of the cellular wireless networks in the world follow 2G or 2.5G standards. However, there is no doubt that, in the near future, 3G systems with quality-of-service (QoS) capability will dominate wireless cellular services. The two main standards for 3G are Wideband CDMA (WCDMA), proposed by Ericsson, and CDMA2000, proposed by Qualcomm.

Host Computers

A host computer processes, produces, and stores all the information for mobile commerce applications. This component is similar to that used in an electronic commerce system because the host computers are usually not aware of differences among the targets, browsers or microbrowsers they serve. It is the application programs that are responsible for apprehending their clients and responding to them accordingly. Most of the mobile commerce application programs reside in this component, except for some client-side programs such as cookies. Usually this component contains three major elements: a Web server, a database server, and application programs and support software.

FUTURE TRENDS

It is estimated that 50 million wireless phone users in the United States will use their handheld devices to authorize payment for premium content and physical goods at some point during the year of 2006. This represents 17% of the projected total population and 26% of all wireless users (The Yankee Group, 2001). Mobile commerce is an effective and convenient way to deliver electronic commerce to consumers from anywhere and at anytime. Realizing the advantages to be gained from mobile commerce, many major companies have begun to offer mobile commerce options for their customers in addition to the electronic commerce they already provide (Over 50% of large U.S. enterprises plan to implement a wireless/mobile solution by 2003, 2001).

However, without secure commercial information exchange and safe electronic financial transactions over mobile networks, neither service providers nor potential customers will trust mobile commerce systems. Mobile security and payment are hence crucial issues for mobile commerce. Security issues span the whole mobile commerce system, from one end to the other, from the top to the bottom network protocol stack, from machines to humans. For example, in WAP, security is provided through the Wireless Transport Layer Security (WTLS) protocol (in WAP 1.0) and IETF standard Transport Layer Security (TLS) protocol (in WAP 2.0). They provide data integrity, privacy, and authentication. One security problem, known as the "WAP Gap" is caused by the inclusion of the WAP gateway in a security session. That is, encrypted messages sent by end systems might temporarily become clear text on the WAP gateway when messages are processed. One solution is to make the WAP gateway resident within the enterprise (server) network (Ashley, Hinton, & Vandenwauver, 2001), where heavyweight security mechanisms can be enforced.

In an IEEE 802.11 WLAN, security is provided by a data link level protocol called Wired Equivalent Privacy (WEP). When it is enabled, each mobile host has a secret key that is shared with the base station. The encryption algorithm used in WEP is a synchronous stream cipher based on RC4. The ciphertext is generated by XORing the plaintext with a RC4 generated keystream. However, recently published literature has discovered methods for breaking this approach (Borisov, Goldberg, & Wagner, 2001; Fluhrer, Martin, & Shamir, 2001; Stubblefield, Ioannidis, & Rubin, 2002). The next version, 802.11i, is expected to have better security.

Payment on mobile commerce systems is another issue. Although the Secure Electronic Transaction (SET) protocol (SET Secure Electronic Transaction Specification, Version 1.0, 1997) is likely to become the global standard in the domain of electronic commerce over the Internet, a WAP client device normally does not have sufficient processing and memory capability to utilize SET software. A "thin" SET wallet approach (Jin, Ren, Feng, & Hua, 2002) has thus been proposed to adapt the SET protocol for WAP clients. Under the "thin" SET wallet model, most of the functionality of current "fat" SET wallets is moved to the wallet server. To support a SET payment, a WAP client installed with only a "thin" wallet securely connects with a wallet server, which communicates with other SET entities. When SET purchase requests arrive from the "thin" wallet, the wallet server takes over the responsibility of routing requests and managing digital keys and certificates.

CONCLUSION

The emerging wireless and mobile networks have extended electronic commerce to another research and application subject: mobile commerce. A mobile commerce system involves a range of disciplines and technologies. This level of complexity makes understanding and constructing a mobile commerce system an arduous task. To facilitate this process, this article divided a mobile commerce system into six components, which can be summarized as follows:

- Mobile commerce applications: Electronic commerce applications are already broad. Mobile commerce applications not only cover the existing applications, but also include new applications, which can be performed at any time and from anywhere by using mobile computing technology.
- Mobile stations: Mobile stations are limited by their small screens, limited memory, limited processing power, and low battery power, and suffer from wireless network transmission problems. Numerous mobile stations, such as PDAs or Web-enabled cellular phones, are available on the market, but most use one of three major operating systems: Palm OS, Microsoft Pocket PC, and Symbian OS. At this moment, Palm OS leads the market, although it faces a serious challenge from Pocket PC.
- Mobile middleware: WAP and i-mode are the two major kinds of mobile middleware. WAP is widely adopted and flexible, while i-mode has the highest number of users and is easy to use. It is difficult to predict which middleware will be the eventual winner in the end; it is more likely that the two will be blended somehow at some point in the future.
- Wireless and wired networks: Wireless communication capability supports mobility for end users in mobile commerce systems. Wireless LANs and cellular networks are major components used to provide radio communication channels so that mobile service is possible. In the WLAN category, the Wi-Fi standard with 11 Mbps throughput dominates the current market. It is expected that standards with much higher transmission speeds, such as 802.11g, will replace Wi-Fi in the near future. Compared to WLANs, cellular systems can provide longer transmission distances and greater radio coverage, but suffer from the drawback of much lower bandwidth (less than 1 Mbps). In the latest trend for cellular systems, 3G standards supporting wireless multimedia and high-bandwidth services are beginning to be deployed. WCDMA and CDMA2000 are likely to dominate the market in the future.
- Host computers: Host computers process and store all the information needed for mobile commerce applications, and most application programs can be found here. They include three major components: Web servers, database servers, and application programs and support software.

An important trend for mobile commerce is enhancing mobile security mechanisms and payment methods. Mobile commerce systems can prosper only if information can be securely exchanged among end systems (consumers and vendors). Security issues (including payment) include data reliability, integrity, confidentiality, and authentication and are usually a crucial part of implementation in wireless protocols/systems. Solutions are updated frequently, due to the lack of a comprehensive wireless security infrastructure and standard. A unified approach has not yet emerged.

KEY TERMS

i-mode: the full-color, always-on, and packet-switched Internet service for cellular phone users offered by NTT DoCoMo.

Mobile Commerce: the exchange or buying and selling of commodities, services, or information on the Internet (wired or wireless) through the use of mobile handheld devices.

SET: the Secure Electronic Transaction (SET) protocol is a technical standard designed to provide security for payment transactions among cardholders, merchants, payment gateways, and certification authorities in Internet.

Third Generation (3G): wireless system that can provide fairly high-speed (384 Kbps) packet-switched wide-area wireless Internet access to support multimedia applications.

Wi-Fi: IEEE 802.11b (Wi-Fi) is a wireless local area network standard. It operates in an unlicensed radio frequency band at 2.4 GHz and provides data access at 11 Mbps.

Wired Equivalent Privacy (WEP): a data link-level protocol that provides security for the IEEE 802.11 WLAN standards. The encryption algorithm used in WEP is a stream cipher based on

Wireless Application Protocol (WAP): an open, global specification that allows users with mobile devices to easily access and interact with information and services instantly

Mobile Location Services

George M. Giaglis
Athens University of Economics and Business, Greece

INTRODUCTION

The term "mobile era" as a characterization of the 21st century can hardly be considered an exaggeration (Kalakota & Robinson, 2001). Mobile phones are the fastest penetrating technology in the history of mankind, and global mobile phone ownership has surpassed even the ownership of fixed phones. Mobile applications, despite potentially being very different in nature from each other, all share a common characteristic that distinguishes them from their wire-line counterparts: they allow their users to move around while remaining capable of accessing the network and its services. In the mobility era, *location identification* has naturally become a critical attribute, as it opens the door to a world of applications and services that were unthinkable only a few years ago (May, 2001).

The term "mobile location services" (MLS) [or "location-based services (LBS), as they are sometimes also referred to] has been coined to group together applications and services that utilize information related to the geographical position of their users to provide value-adding services to them (Rao & Minakakis, 2003). This article provides a concise introduction to the major types of MLS and also introduces the reader to the most important positioning technologies that render the provision of MLS possible. Finally, the article also introduces a number of issues that are critical for the future of MLS, including privacy protection, regulation, and standardization.

CATEGORIES OF MOBILE LOCATION SERVICES

Mobile networks are quickly becoming ubiquitous. The ability to reach mobile phone users regardless of their location and, even more importantly, the ability to reach mobile phone users *based* on their location has created a new world of exciting and promising applications. While the possibilities for providing innovative MLS are limited only by one's imagination, we will outline the most important categories of such services in this section.

Emergency Management

Perhaps the clearest market application of MLS is the ability to locate an individual who is either unaware of his or her exact location or is not able to reveal it because of an emergency situation (injury, criminal attack, and so on). MLS are even applicable as a means of overcoming one of the most common problems of motorists, namely, the fact that, most often than not, they are unaware of their exact location when their vehicle breaks down. The ability of a mobile user to call for assistance and at the same time automatically reveal his or her exact location to the automotive assistance agency is considered one of the prime motivators for signing up subscribers to MLS (Hargrave, 2000).

Navigation Services

Navigation services are based on mobile users' needs for directions within their current geographical locations. The ability of a mobile network to locate the exact position of a mobile user can be manifested in a series of navigation-based services:

1. By positioning a mobile phone, an operator can let users know exactly where they are as well as give them detailed *directions* about how to get to a desirable destination.
2. Coupled with the ability to monitor traffic conditions, navigation services can be extended to include destination directions that take account of current *traffic conditions* (for example, traffic congestion or a road-blocking accident) and suggest alternative routes to mobile users.
3. The possibility to provide detailed directions to mobile users can be extended to support *indoor routing* as well. For example, users can be assisted in their navigation in hypermarkets, warehouses, exhibitions, and other information-rich environments to locate products, exhibition stands, and other points of interest.
4. Similarly, *group management* applications can be provided to allow mobile users to locate friends, family, coworkers, or other members of a particular group that are within close range and, thus, create *virtual communities* of people with similar interests.

Information Provision

Location-sensitive information services mostly refer to the digital distribution of content to mobile terminal devices based on their location, time specificity, and user behavior. The following types of services can be identified within this category:

1. *Travel services*, such as guided tours (either automated or operator-assisted), notification about nearby places of interest (for example, monuments), transportation assistance, and other services that can be provided to tourists moving around in unfamiliar surroundings.
2. *Mobile yellow pages* that provide a mobile user, upon request, with knowledge regarding nearby facilities.
3. *Infotainment services*, such as information about local events, location-specific multimedia content, and so on.

Advertising and Marketing

Mobile advertising is among the first trial applications of MLS, due to its promising revenue potential and its direct links to mobile-commerce activities. Furthermore, mobile advertising has gained significant attention because of the unique attributes, such as *personalization* (Kalakota & Robinson, 2001), that offer new opportunities to advertisers to place effective and efficient promotions on mobile environments. There are various mechanisms for implementing mobile advertising coupled with MLS. Examples of mobile advertising forms include *mobile banners*, *alerts* (usually dispatched as SMS messages), and *proximity-triggered advertisements*.

Tracking

Tracking services can be equally applicable to the consumer and the corporate markets. As far as consumers are concerned, tracking services can be utilized to monitor the exact whereabouts of, for example, children and elderly people. Similarly, tracking services can be effectively applied in corporate situations as well. One popular example refers to tracking vehicles so that companies know where their fleet and goods are at any time. A similar application allows companies to locate their field personnel (for example, salespeople and repair engineers) so that they are able, for example, to dispatch the nearest engineer and provide their customers with accurate personnel arrival times. Finally, the newfound opportunity to provide accurate product tracking within the supply chain offers new possibilities to mobile supply chain management (m-SCM) applications (Kalakota & Robinson, 2001).

Billing

Location-sensitive billing refers to the ability of a mobile service provider to dynamically charge users of a particular service depending on their location when using or accessing the service. For example, mobile network operators may price calls based on the knowledge of the location of the mobile phone when a call is made. Location-sensitive billing includes the ability to offer reduced call rates to subscribers who use their mobile phone when at their home, thereby allowing mobile operators to compete more effectively with their fixed telephony counterparts.

POSITIONING TECHNOLOGIES

The applications and services that were discussed in the previous section are based on underlying technological capabilities that enable the identification of the location of a mobile device, thereby making the provision of MLS possible. Positioning techniques can be implemented in two ways: *self-positioning* and *remote positioning* (Zeimpekis et al., 2003).

In the first approach (self-positioning), the mobile terminal uses signals, transmitted by the gateways/antennas (which can be either terrestrial or satellite) to calculate its own position. More specifically, the positioning receiver makes the appropriate signal measurements from geographically distributed transmitters and uses these measurements to determine its position. A self-positioning receiver, therefore, "knows" where it is, and applications collocated with the receiver can use this information to make position-based decisions, such as those required for vehicle navigation.

In the case of remote positioning, the mobile terminal can be located by measuring the signals travelling to and from a set of receivers. More specifically, the receivers, which can be installed at one or more locations, measure a signal originating from, or reflecting off, the object to be positioned. These signal measurements are used to determine the length and direction of the individual radio paths, and then the mobile terminal position is computed from geometric relationships.

Self-Positioning Techniques

Global Positioning System (GPS) and Assisted GPS (A-GPS): GPS is the worldwide satellite-based radio navigation system, consisting of 24 satellites, equally spaced in six orbital planes 20,200 kilometres above the Earth, that transmit two specially coded carrier signals: one for civilian use and one for military and government use (Djuknic & Richton, 2001). The system's satellites transmit navigation messages that a GPS receiver uses to determine its position.

GPS receivers process the signals to compute position in three dimensions—latitude, longitude, and altitude—with an accuracy of 10 meters or less. The main advantage of this technique is that GPS is already in use for many years. However, in order to operate properly, GPS receivers need a clear view of the skies and signals from at least three or four (depending on the type of information needed) satellites, requirements that exclude operation in indoor environments. As far as the A-GPS method is concerned, the mobile network or a third-party service provider can assist the handset by directing it to look for specific satellites and also by collecting data from the handset to perform location identification calculations that the handset itself may be unable to perform due to limited processing power. The A-GPS method can be extremely accurate, ranging from 1 to 10 meters (Giaglis et al., 2002).

Indoor Global Positioning System (Indoor GPS): This system focuses on exploiting the advantages of GPS for developing a location-sensing system for indoor environments. It should be noted that the GPS signal does not typically work indoors, because the signal strength is too low to penetrate a building (Chen & Kotz, 2000). Indoor GPS solutions can be applicable to wide space areas where no significant barriers exist. Indoor GPS takes into account the low power consumption and small size requirements of wireless access devices, such as mobile phones and handheld computers. The navigation signal is generated by a number of pseudolites (pseudo-satellites). These are devices that generate a GPS-like navigation signal. The signal is designed to be similar to the GPS signal in order to allow pseudolite-compatible receivers to be built with minimal modifications to existing GPS receivers. As in GPS, at least four pseudolites have to be visible for navigation, unless additional means, such as altitude aiding, are used (Giaglis et al., 2002).

Remote Positioning Techniques

Cell Identification (Cell-ID): The Cell-ID (or *Cell of Origin, COO*) method is the most widely used technique to provide location services and applications in second-generation mobile communication networks. The method relies on the fact that mobile networks can identify the approximate position of a mobile handset by knowing which cell site the device is using at a given time. The main benefit of the technology is that it is already in use today and can be supported by all mobile handsets. However, the accuracy of the method is generally low (in the range of 200 meters in densely covered areas and much lower in rural environments) (Giaglis et al., 2002).

Angle of Arrival (AOA): The basic idea is to steer in space a directional antenna beam until the direction of maximum signal strength is detected. In terrestrial mobile systems, the directivity required to achieve accurate measurements is obtained by means of antenna arrays (Sakagami et al., 1994). Basically, a single measurement produces a straight-line locus from the base station to the mobile phone. Another AOA measurement will yield a second straight line, and the intersection of the two lines gives the position fix for this system.

Time of Arrival (TOA): Positioning information is derived from the absolute time for a wave to travel between a transmitter and a receiver or vice versa. This implies that the receiver knows the exact time of transmission. Alternatively, this approach might involve the measurement of the round-trip time of a signal transmitted from a source to a destination and then echoed back to the source, giving a result twice that of the one-way measurement. This does not imply synchronization between the transmitter and the receiver and is the most common means of measuring propagation time.

Differential Time of Arrival (DTOA): The problem of having precisely synchronized clocks at transmitter and receiver is solved by using several transmitters synchronized to a common time base and measuring the time difference of arrival at the receiver. More specifically, each DTOA measurement defines a hyperbolic locus on which the mobile terminal must lie. The intersection of the hyperbolic loci will define the position of the mobile device.

CRITICAL ISSUES RELATED TO MLS

Further to the business and technological aspects of mobile location services discussed above, a number of other critical factors will also ultimately determine their successful application in mobile communication networks. Such issues include the need to protect sensitive personal information of individuals, as well as the role of regulation and standardization initiatives in establishing the right climate for market rollout and healthy competition.

Privacy Protection

According to Nokia (2001), “of all the challenges facing mobile location service providers, privacy is undoubtedly the biggest single potential barrier to market take-up" (p. 9). For example, mobile advertising based on a user’s location is a sensitive issue and has to be provided only with the explicit consent of the user.

However, even in such a case, the likely exchange of information between third parties (for example, network operators and advertising agencies) may hamper the privacy of user’s personal data. To ensure commercial success of mobile location services, user trust must be ensured. A

clear prerequisite of the trust-building mechanism is that the control over the use of location information is always on the hands of the user, not of the network operator or the service provider.

Regulation and Standardization

The role of regulatory and policy-making bodies is substantially enhanced in the case of mobile location services. It is not surprising that the initial boost to the market has come from such bodies (the US FCC mandate for emergency services) and that the European Commission has had a very active role in the development of the market on the other side of the Atlantic.

Standardization can also be a serious success or failure factor for any new technology, and mobile location services are not an exception to this rule. A number of bodies worldwide are working toward defining commonly accepted standards for the mobile industry, but prior experience has shown that standardization efforts may have a regional, rather than a global, scope. For example, the presence of incompatible standards for second-generation mobile telephony in Europe and the Americas has created considerable problems for users and the industry alike. Worldwide efforts to define universal standards for third-generation systems provide a more optimistic view of the future; however, the danger of incompatibility and technological "islands" remains. To this end, a number of standardization initiatives are underway, sometimes initiated by the industry. For example, Ericsson, Motorola, and Nokia, have joined forces to establish the *Location Interoperability Forum (LIF)*, with the purpose of developing and promoting common and ubiquitous solutions for mobile location services.

The importance of standardization becomes even more evident when we think of what can be termed as *the paradox of mobile location services*. Although these services are by definition local, any given user will most probably need them when in a nonlocal environment. We can envisage tourists outside the familiar surroundings of their local residences relying on MLS to obtain assistance and directions, and companies also utilizing MLS to track their goods in distant lands. To be useful to their users, mobile location services must, therefore, be provided in a location-independent and user-transparent fashion. From a standardization and technological point of view, this requirement poses a difficult problem: *service portability* and *roaming* issues have to be resolved in order for MLS to be compelling to users (UMTS, 2001).

KEY TERMS

Angle of Arrival (AOA): A positioning technology in which the mobile network sends directional antenna beams

to locate a mobile device at the intersection of the directions of maximum signal strength.

Assisted Global Positioning System (A-GPS): A variation of the *global positioning system (GPS)* in which the mobile network or a third-party service provider assists the mobile handset in determining its geographical position (either by directing it to look for specific satellites or by collecting data from the handset to perform location identification calculations that the handset itself may be unable to perform due to limited processing power).

Cell Identification (Cell-ID): The Cell-ID method is the basic technique to provide location services and applications in second-generation mobile communication networks. The method relies on the fact that mobile networks can identify the approximate position of a mobile handset by knowing which cell site the device is using at a given time.

Differential Time of Arrival (DTOA): A positioning technology in which several transmitters (synchronized to a common time base) are used to measure time differences of arrival at the receiver and, hence, determine the receiver's geographical position.

Global Positioning System (GPS): GPS is the worldwide satellite-based radio navigation system. The system's satellites transmit messages that a receiver uses to determine its own geographical position.

Indoor Global Positioning System (Indoor GPS): A variation of the *global positioning system (GPS)* for use in indoor environments, where the normal GPS signal does not typically work, because the signal strength is too low to penetrate a building. Indoor GPS navigation signals are generated by a number of pseudolites (pseudo-satellites) and are sent to pseudolite-compatible receivers that use the information to determine their own geographical positions.

Location-Based Services (LBS): A synonym for *mobile location services (MLS)* denoting applications that utilize the knowledge of one's geographical position to provide added-value services.

Location Identification: The ability of mobile hosts to determine the geographical location of wireless access devices.

Mobile Location services (MLS): Applications provided over a mobile network that utilize information related to the geographical position of their users to provide added value to them.

Time of Arrival (TOA): A positioning technology where information is derived from the absolute time for a wave to travel between a transmitter and a receiver or vice versa.

INTRODUCTION

A radio mobile-position system operates by measuring, processing, and storing physical quantities related to radio signals travelling between a mobile terminal and a set of transceivers, for example, satellites or Base Stations (BSs). Positioning techniques in cellular networks are of great importance for supporting emerging services that require a sufficient, precise estimation of the position of the mobile terminal (MT) associated with a number of given base stations. The ability to support position location within wireless networks provides network operators with valuable services, as well as users with a host of new applications. This includes navigation, location-based services, network management, and security applications. Nowadays in GSM networks, there is no specific algorithm included in the software to locate subscribers. The only possibility to locate a subscriber is accomplished by using *GPS* technology or special firmware.

An innovative development should be the design and implementation of certain location positioning techniques, as *Time of Arrival* (ToA) and *Angle of Arrival* (AoA), over the existing GSM network. Although there are already next generation networks in use nowadays (UMTS, GPRS, WLAN), and there also is extensive research towards the fourth generation cellular networks, GSM seems to be the most popular network so far. GPRS network is a data network over GSM platform and it exists only with GSM architecture. The reason is that GPRS uses the GSM air interface (Radio Network Part) and it only diverts in the core network where it transmits the data packets towards a different switch. UMTS, on the other hand, is a unique network supporting cellular and voice-data applications, and is the evolution of GSM towards IP applications. Although it could be implemented separately from GSM, most of the operators preferred to implement it in a GSM convergence mode towards the core network for eliminating the investment. As a result, in most countries GSM is the major network with full geographical coverage and network location positioning techniques are most implemented in a network environment with a satisfactory number of Base Stations.

BACKGROUND

In 1991, European Telecommunication and Standardization Institute (ETSI) accepted the standards for a new upcoming mobile, fully digital, and cellular communication network (Figure 1).

The purpose of positioning the mobile is to provide location-based services (LBS), including wireless emergency services (Porretta, Nepa, Manara, Giannetti, Dohler, Ben, & Aghvami, 2004). The handset based positioning techniques require that the existing handsets have to be redesigned in order to meet new requirements, while the network based positioning techniques need adjustments only at the Base Stations (BSs) or switching centers. Furthermore, with the first approach, the MT utilizes transmitted signals from the BSs to estimate its own position while with the second approach the BSs measure the transmitted signals from the MT and relay them to a central site for processing.

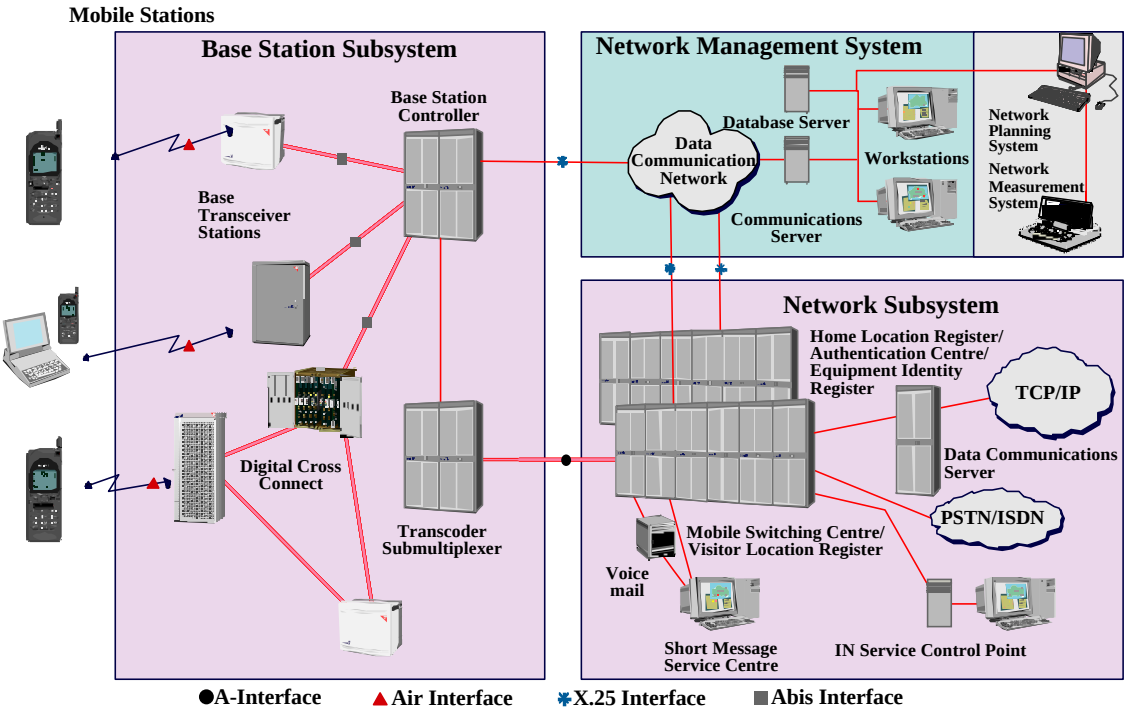
Handset-Based Mobile Positioning Technology

It is referred to as "handset based" because the handset itself is the primary means of positioning the user (Smith, 1991), although the network can be used to provide assistance in acquiring the mobile device and/or making position estimate determinations based on measurement data and handset based position determination algorithms (Kothris, Beach, Allen, & Karlsson, 2001). The representative techniques of handset based positioning technology are:

- **Enhanced Observed Time Difference (E-OTD)**

This technique is also encountered as handset based Time Of Arrivals and specially equipped handsets are required. Enhanced Observed Time Difference (E-OTD) technique operates by instating location receivers called location measurement units (LMU) at several places geographically dispersed in the radio coverage area of a cellular network.

Figure 1. GSM network architecture



- Global Positioning System (GPS)

Unambiguously, the main technology for the implementation of handset based positioning is the Global Positioning System (GPS) which has changed navigation and position forever. It is a universal system consisting of three interlocking segments: the space segment, the user segment, and the control segment. The space segment consists of 24 satellites each in its own orbit 20.000 km above the Earth which means that it takes 12 hours to orbit the Globe.

- Assisted Global Positioning System (AGPS)

GPS suffers position errors from satellite clock, satellite orbit, ephemeris prediction, ionospheric, and tropospheric delays, and so forth. In order to reduce these errors and correct the initial position estimation, additional information can be applied to GPS receivers. A substantial correction method is Differential GPS (DGPS). According to this method, a reference GPS receiver at a proper position is used to send correction data to the quested MT (Zhao, 2002).

Network Based Mobile Positioning Technology

It is called “network based” because the mobile network, in cooperation with network-based position determination equipment (PDE) is used to position the mobile terminal. It is also referred to as “unmodified handset” which means that there are no changes and, thus, additional cost for the subscribers in the mobile device. On the contrary, this technology requires changes in the infrastructure of the GSM elements.

- Fingerprint method

It is an implementation used mainly for indoor application (Pahlavan, Li, & Mäkelä, 2002), which makes use of

the multipath characteristics of the signal received at the Base Station in proportion to the handset position. During the implementation of the method a database, where the fingerprints of the received signals at the BS from each position in the cell area are stored, is created. Therefore, a received signal at the BS is matched with an entry and the BS estimates the location of the MT. The drawback of this method is its demanding implementation. As for each BS cell, extensive and accurate measurements are required for creating and updating the database. This is the reason why this method is used in indoor environments where the database has limited size.

- Doppler location method

It was proposed by N. J. Thomas, D. G. M. Cruickshank and D. I. Laurenson (2001). It requires a single BS and unmodified moving MTs. According to this approach, the position of the MT is calculated by using the Doppler shift related to each scatterer surrounding the BS. The advantages of the method are the implementation simplicity in addition to the signaling overhead, but the main disadvantage is the necessity for moving handsets.

- Cell of Origin (COO)

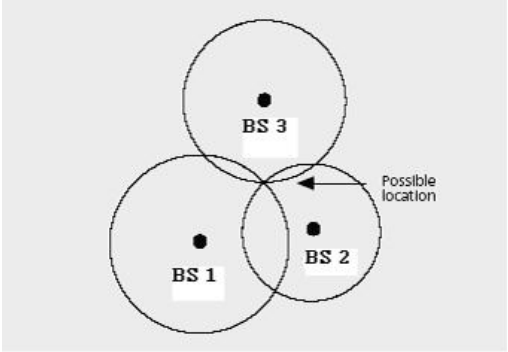
It is the easiest and the most natural technique to offer LBS because all mobile devices support this technology. According to the COO, the network uses the closer (to the handset) BS to identify the cell where the subscriber is. The accuracy depends upon the cell area and it can be up to 150 meters for an urban area. Moreover, depending on the radio architecture, the accuracy is approximately 150m – 5 Km in microcellular design, 500m – 150m in picocellular indoor or outdoor, or 35Km – 150m in macrocellular design.

TIME OF ARRIVAL POSITIONING TECHNIQUE

In the Time Of Arrival (TOA) technique, the location of the MT derives from measuring the time needed for a signal to travel from a number of BSs to the Mobile Terminal (MT). The equation $d = c \cdot t$ provides the distance of the MT from the BSs. Geometrically, the MT lies on a circle centerd at the BSs' location and radius the distance *d*. By using at least three BSs, the position of the MT is given by the intersection point of the three circles (Figure 2).

Due to measurement errors in time estimates, the circles do not intersect at a single point. In that case, location algorithms have been introduced in literature to resolve the problem (Chan & Ho, 1994). Moreover TOA method suffers from *non Line Of Sight* (nLOS) propagation which means that between the BS and the MT exist one or more obstacles.

Figure 2. The TOA method



In that case, the signal does not travel directly from the MT to the BS but it reaches the latter through reflections or diffractions on buildings, cars, other obstacles, and so forth. As a result, the signal takes a longer path in comparison to the direct path in LOS propagation. The typical location error caused by nLOS propagation in GSM networks has been calculated to approximately 400-700m. (Caffery & Gordon, 1998).

Several methods have been introduced to mitigate the location error caused by nLOS propagation. An effective one (Turin, Jewell, & Johnston, 1972), is to change the location algorithm taking into consideration that in nLOS, propagation the measured distance ct_{BS_i} is greater than the real one $c(t_{BS_i} - \Delta t)$ (Δt is the nLOS propagation error) and, therefore, the possible location of the MT lies inside the circle centred in BS's position. For the three BSs TOA

Figure 3. nLos Propagation error in TOA

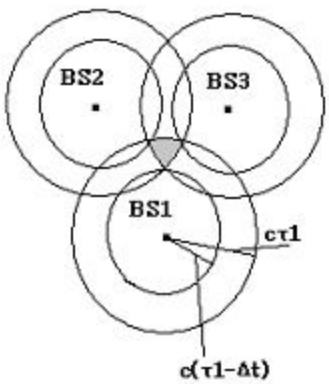


Figure 4. Location area for the three-TOA method

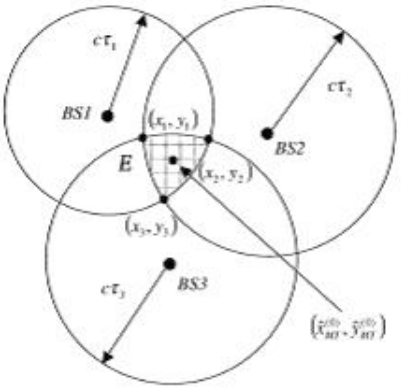

technique, the intersection of the three circles provides an area (feasible area in Figure 3) where the MT can possibly lie. An initial estimation of the MT location can be finding the center of the feasible area. In case of three BSs (Figure 4), supposing that the coordinates of the three points of intersection which set the feasible area E, are (x_1, y_1), (x_2, y_2), and (x_3, y_3) the coordinates of the center of the area E are (Porretta, et al., 2004):

$$(\hat{x}_{MT}^{(0)}, \hat{y}_{MT}^{(0)}) = (\frac{x_1 + x_2 + x_3}{3}, \frac{y_1 + y_2 + y_3}{3})$$

In several cases where the MT is quite close to one BS and the circles do not intersect, the feasible area is estimated as a circle around the adjacent BS. Furthermore, a position nearby that BS is chosen as the initial guess. In order to enhance the initial guess and minimize the location error, a non-linear least square solution can be introduced. According to this, for each BS used in location process, the following function is formed (Porretta, et al., 2004):

$$g_i(x,y) = ct_{BS} - \sqrt{(x - x_{BS_i})^2 + (y - y_{BS_i})^2}$$

The feasible area E can be appointed by the following inequalities:

$$E = \{(x,y) \mid g_i(x,y) \geq 0 \forall i = 1,.....N_{BS}\}$$
$$=> E = \{(x,y) \mid (x - x_{BS_i})^2 - (y - y_{BS_i})^2 \leq (ct_{BS_i})^2 \forall i = 1,.....N_{BS}\}$$

N_{BS} is the number of the BSs.

The next step is to form the following cost function (Porretta, et al., 2004):

$$G(x,y) = \sum_{i=1}^{N_{BS}} a_i g_i(x,y),$$

α_i are weights reflecting the signal strength as received at the i_{th} BS, *(i=1,…..N_{BS})*.

If no information about signal strength is available or not taken into account, it is possible to set $a_i = 1 \forall (i = 1,.....N_{BS})$. The location estimate is finally given by the couple *(x, y)* that minimizes the cost function inside the feasible region.

In order to mitigate even more, the Turin's (1972) cost function from location errors due to nLOS propagation, a weight coefficient ℓ_i is proposed. To implement the weight ℓ_i the network has to meet the following requirements:

- BS antenna arrays in order to measure the angle of the received signal.
- A *Geographical Information System* (GIS) available to the network operator.

Another requirement is the introduction of a *First Obstacle Distance Function*, FODF(θ), which is defined as the Euclidean distance between the BS and the nearest obstacle found along the azimuth direction identified by angle θ of the received signal. FODF derives from GIS. If FODF(θ)<ct (t is the time estimate) then the MT is in nLOS with the BS. If FODF(θ)>ct the BSi is in LOS and then $\ell_i = 1$. If one BS is in nLOS then $\ell_i = \frac{1}{10}$. If two BSs are in nLOS and $FODF_1(\theta)-ct_1 < FODF_2(\theta)-ct_2$ then $\ell_1 = \frac{1}{10}$ and $\ell_2 = \frac{1}{100}$. In that case, the proposed cost function follows:

$$G'(x,y) = \sum_{i=1}^{N_{BS}} \ell_i a_i g_i(x,y)$$

TOA IMPLEMENTATION IN GSM NETWORK: AN ENHANCEMENT TECHNIQUE

GSM standards specify with accuracy the procedures and messages in order to implement specific applications. The purpose of implementing a TOA positioning technique in GSM network is to intervene in the GSM network's infrastructure as little as possible. In the following, a number of interventions are proposed in both busy and *idle mode* of the subscriber's MT in order to implement TOA technique.

Idle Mode

At the idle mode, the implementation begins with a periodic Location Update signaling for the MT (Figure 5). The timing parameter is sent to the MT through Broadcast Control channel (BCCH). In due course, a paging signaling follows in order

Figure 5. GSM method for the calculation of TOA time estimates (Idle mode)

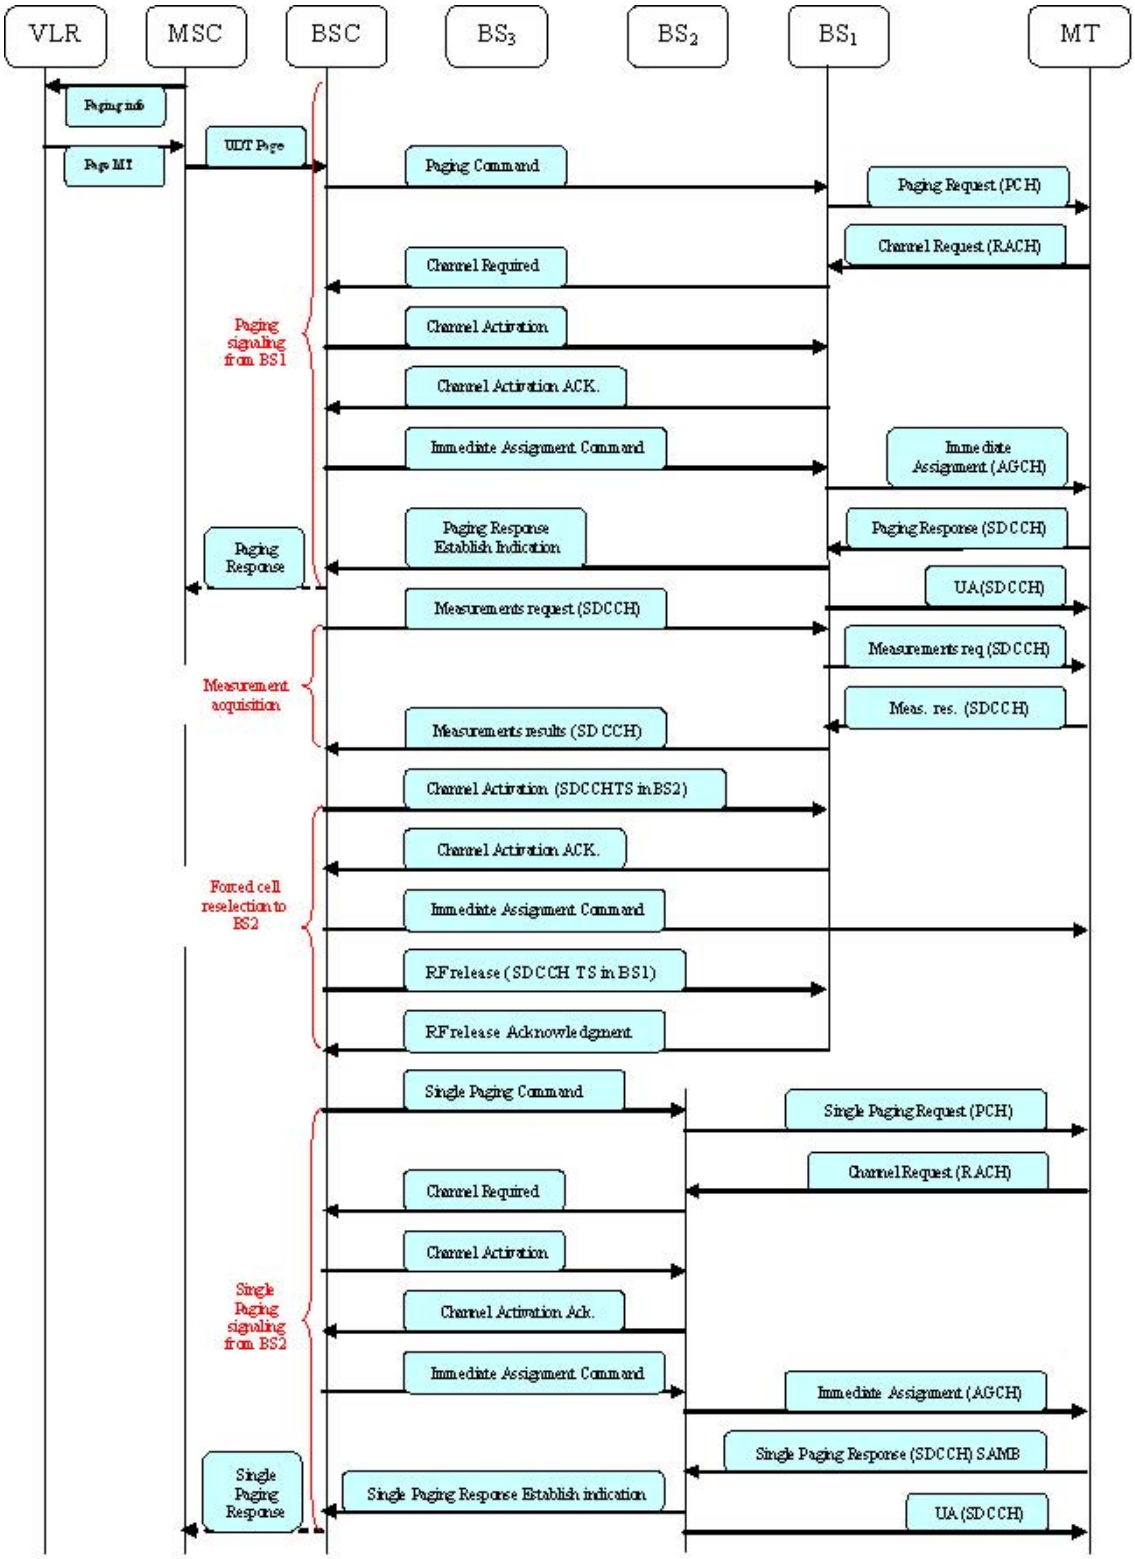

Figure 5. GSM method for the calculation of TOA time estimates (Idle mode) (continued)

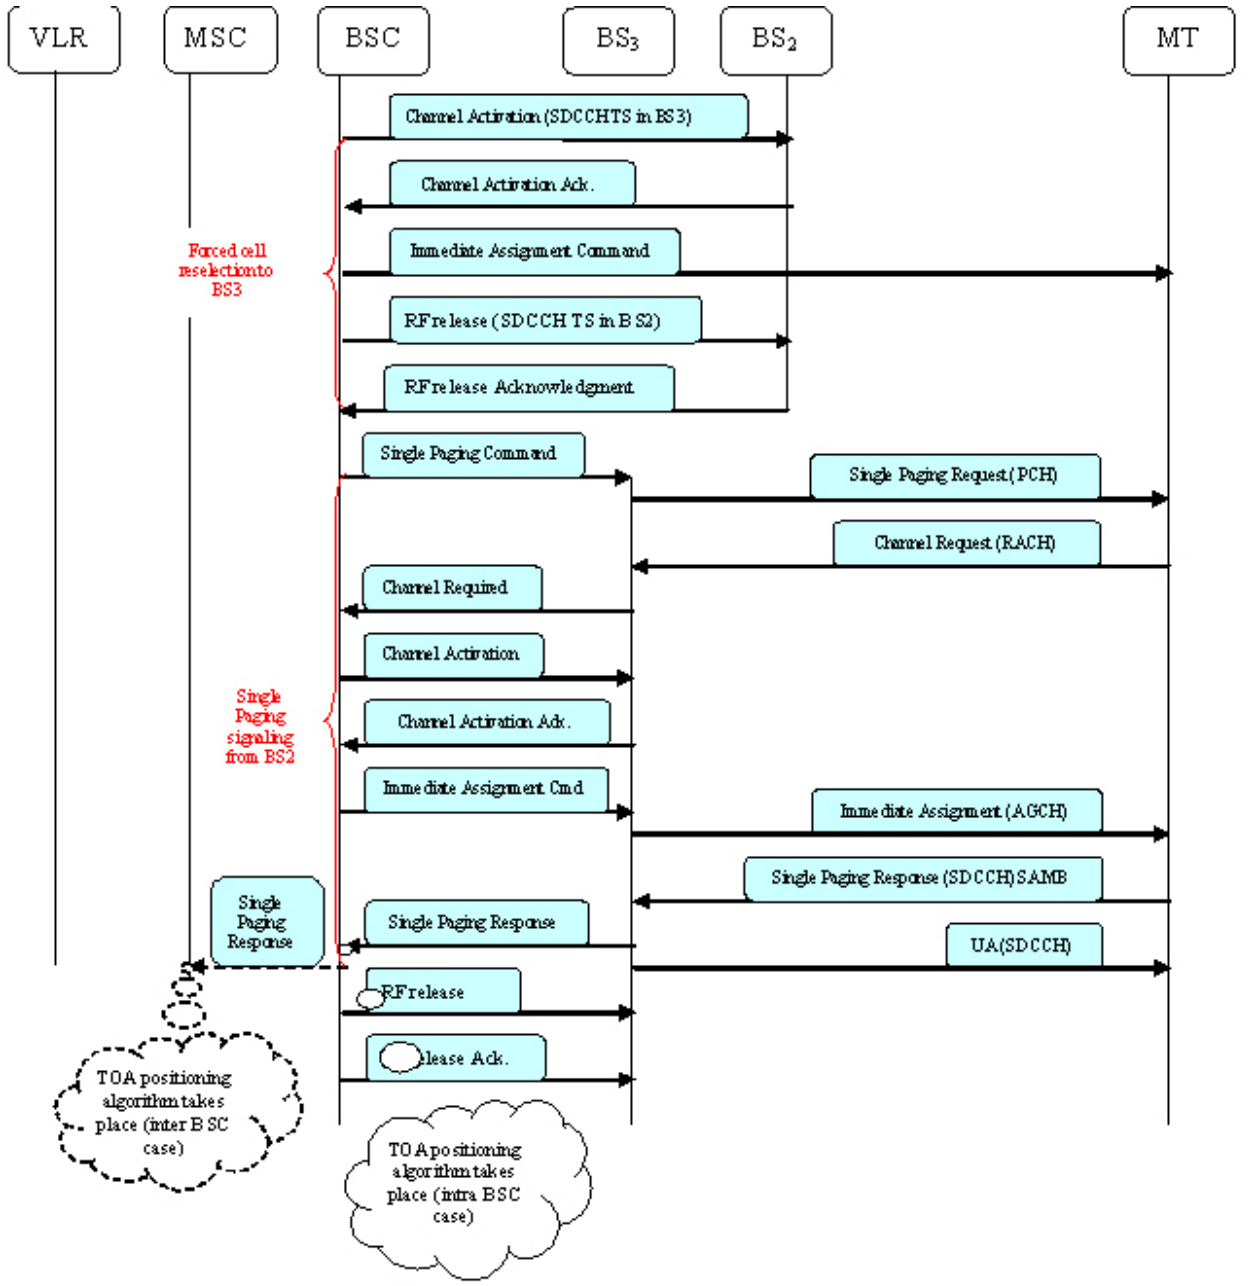
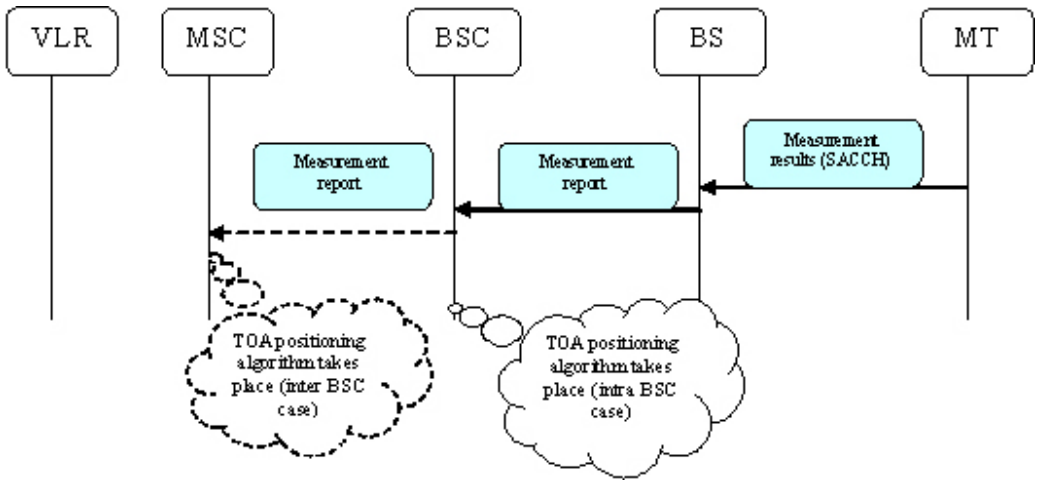


to obtain the Timing Advance from the serving BS. In case of Idle Mode condition, the MT keeps for itself measurements about the received signal power from the nearest and the 6 adjacent BSs. Furthermore, to obtain the Timing Advance from the other 2 BSs a new Paging Command message is introduced. After that, the MT is sequentially coordinated to each of the 2 selected BSs by utilizing a proposed Forced Cell Reselection procedure. Finally, the three time estimates are sent back to the BSC where the position estimation of the MT according to TOA algorithm takes place.

Figure 6. GSM method for the calculation of TOA time estimates (Busy mode)



Busy Mode

In the Busy mode scenario (Figure 6) the MT transmits to the serving BS measurements about the received signal power level and the Timing Advance from the serving and the adjacent BSs, two times per second. Every 21 frames in the air interface, a TimeSlot (TS), corresponds to idle mode where the measurements take place in the MT while a second corresponds to SACCH where the measurements are sent. As a result, for a list of seven BSs (six adjacent plus one serving), a time space of: $7 \times 21\, frames \times 0.577\, {ms}/{frame} = 84.82 ms$ is required. This can be translated to a location error of 1.16m for a mean value of the subscriber's velocity.

ANGLE OF ARRIVAL POSITIONING TECHNIQUE

In AOA –or Direction Of Arrivals (DOA) in some literature- the MT position is calculated by using the triangulation technique. According to AOA method, the angles of arrivals of a signal from the MT at a pair -or more- BSs are measured by using antenna arrays. The position of the MT is defined by the intersection of at least two directional lines of bearing (Figure 7).

A linear antenna array consists of a set of similar dipoles, having the same direction and transpiring by a current of the same pattern but differences in the amplitude or the phase. By changing the number or distances between the dipoles or the amplitude and the phase of the current transpiring each one of them, the appropriate radiation pattern in proportion to the application, can be succeeded. Therefore, the received signal from the MT is translated to a current pattern (phase, amplitude) at the antenna array and the BS is able to compute the signal's AOA.

Location errors occur in AOA technique by reason of nLOS propagation and multipath. Due to nLOS propagation, the reflected signal received at BS antenna array has different AOA than the direction of the MT. Moreover, even in LOS propagation, multipath, which means scattered signals near and around the BS, would still alter the measured AOA. Because of measuring limitations of the devices, the higher the distance between MT and BS, the more the precision of the method decreases.

Due to nLOS propagation and multipath, it is wiser in location estimation using the AOA method to utilize more than two BSs. In Figure 8, the three BSs approach is shown. An

Figure 7. The AOA method

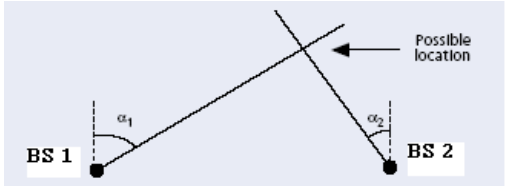


Figure 8. Three BTS AOA intersection area

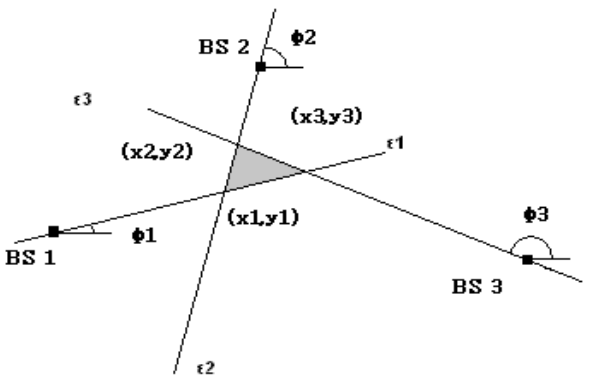

initial suggestion, introduced by the writers, for the solution to the positioning problem could be the following:

$$(\hat{x}_{MT}^{(0)}, \hat{y}_{MT}^{(0)}) = (\frac{a_1 \cdot x_1 + a_2 \cdot x_2 + a_3 \cdot x_3}{a_1 + a_2 + a_3}, \frac{a_1 \cdot y_1 + a_2 \cdot y_2 + a_3 \cdot y_3}{a_1 + a_2 + a_3})$$

where a_i are weights related to signal strength received at the BS_i. If no information about signal strength is provided, it is possible to set $a_i = 1$.

In addition, the writers introduce a further, more precise algorithm that is based on the minimization of a cost function for AOA. To be more specific, as the MT's location lies on a beeline determined by the AOA of the signal received at the BS and BSs' coordinates (Figure 8), the following function can be proposed:

$$f_i(x, y) = (y - y_{BS_i}) - \tan \mathrm{f}_i \cdot (x - x_{BS_i})$$

Where (x_{BS_i}, y_{BS_i}) are the coordinates of the BS_i and f_i the AOA of the signal received at the BS_i from the MT. The coordinates of the MT are those that minimize the following quadratic form (cost function):

$$F(x, y) = \sum_{i=1}^{N_{BS}} a_i \cdot l_i \cdot f_i^2(x, y)$$

where, l_i are factors reflecting whether the MT is in LOS with BS_i (l_i=1) or not (l_i=0). Using a Geographical Interface System (GIS) and the TOA of the signals received, BS can determine whether there is LOS propagation or not and, thus, give the appropriate value to l_i factor. If none, BS is in LOS with the MT then we give the value l_i=0 only to one BS with the greater |ct-FODF(φ)|. The reason for this criterion is that the greater the difference |ct-FODF(φ)| is, the more possible it is that the signal reaches the BS after many reflections. Suggesting that the antenna array in BS uses differential reception and more than one BS are in LOS with the MT then the location error can be reduced to 0m as the MT coordinates zero the cost function.

In Turin, et al. (1972) a single BS AOA technique using the TOA ate the MPCs impinging at the BS is introduced.

For macrocells, where the BSs are usually above roof level, or at least above the terrain, the scatter signals are located close to the BS. As a result, the received signals AOA follow a narrow spread distribution. On the other hand, for microcells where the BSs are placed below roof level and, thus, surrounded by local scatterers following a large spread distribution. To sum up, AOA technique is more appropriate for macrocells than for microcells.

FUTURE TRENDS

Combined techniques TOA-AOA are interesting since they should provide location accuracy in different environments (urban, suburban, city center, suburbs), and the network applications would be independent of the environment the subscriber is moving. There is also another technique, the *Power of Arrival* (POA) (Hata & Nagatsu, 1980), which is extremely useful in environments of city centers and generally in microcellular and picocellular networks. According to this technique, the signal strength received at the BS from the MT is measured and, by the use of a known mathematical propagation model, the path attenuation loss is determined. Several propagation models have been introduced such as the Free Space Loss model, the Plane Earth model EGLI model, LEE model OKUMURA model, ext. In all propagation models, path loss attenuation is computed by using the distance between BS and MT and the height of the MT's antenna.

Since the measured signal strength is translated to a distance estimate, the MT's position lies on a circle centered at the BS. As in TOA method, the MT's location derives from the intersection of more than one circle. Errors in POA method are caused by multipath fading and shadowing phenomena. Degradation of the signal strength received at the BS can be as high as 30-40 dB on the order of a half of the wavelength, due to multipath. A solution to this apart from low mobility MTs, could be the utilization of the average strength of a set of measurements. In case of shadowing, error can be reduced by using premeasured signal strength contours centered at the BSs . However, this solution suggests a constant physical topography and needs that contours are mapped out for each BS.

According to POA, a future profitable solution should be a combination of TOA-AOA-POA in a unique algorithm

to predict position in a GSM network and, moreover, the implementation of this new algorithm with new or modified messages in the existing software configuration.

CONCLUSION

GSM network is a worldwide standard for cellular applications. Although new cellular networks have been developed, GSM is still the first choice for subscribers due to its simplicity, and for operators due to its cost effectiveness in implementation and development. As subscribers increase in GSM networks and ask for more precise applications dependent in location accuracy, the cost of implementation elimination is of great importance for the operators. The network location solution seems to be most preferred since it only demands software solutions. The implementation of TOA and AOA algorithms in the standard messages and signaling of GSM network is very important since it leaves unaffected the main GSM network architecture and it only requires a new software release to include the new procedures and messages.

KEY TERMS

Base Station: The module that produces the cellular coverage through electromagnetic radiation.

Base Station Controller: The switch that controls all the Radio resource management in the core network part.

Busy Mode: The subscriber's mode when the mobile is activated and a dedicated traffic channel is reserved and used for the transmission of voice data.

Cell: The geographical area covered by electromagnetic radiation from a transmitter in the GSM frequency band.

Idle Mode: The subscriber's mode when the mobile is activated and it listens to the network.

Line Of Site (LOS): The direct physical path between the mobile terminal and the antennae of the Base Station.

Location Area Code: The code that specifies uniquely a cell in a large geographical area.

Microcell: The cell with a coverage area distance of 1Km to 5 Km.

Mobile Switching Centre: The switch that controls all the mobility management in the core network part.

nLOS: Non Line of Site. The indirect path between the mobile terminal and the antennae due to reflections and scattering.

Picocell: The cell with a coverage area distance of 100m to 1 Km.

Subscriber Identity Module (SIM): The portable database that is carries inside the mobile station.

Transceiver: The hardware element of the Base Station that produces the electromagnetic coverage in a cell.

Mobile Spatial Interaction and Mediated Social Navigation

Mark Bilandzic
Technische Universität München, Germany

Marcus Foth
Queensland University of Technology, Australia

INTRODUCTION

The increasing ubiquity of location and context-aware mobile devices and applications, geographic information systems (GIS) and sophisticated 3D representations of the physical world accessible by lay users is enabling more people to use and manipulate information relevant to their current surroundings (Scharl & Tochtermann, 2007). The relationship between users, their current geographic location and their devices are summarised by the term "mobile spatial interaction" (MSI), and stands for the emerging opportunities and affordances that location sensitive and Internet capable devices provide to its users. The first major academic event which coined the term in its current usage was a workshop on MSI (see http://msi.ftw.at/) at the CHI 2007 (Fröhlich et al., 2007).

Mobile spatial interaction is grounded in a number of technologies that recently started to converge. First, the development of mobile networks and mobile Internet technologies enables people to request and exchange specific information from anywhere at anytime. Using their handheld devices people can, for example, check the latest news, request recent stock exchange values or communicate via mobile instant messaging. The second enabler is global positioning technology. Mobile devices with integrated Global Positioning System (GPS) receivers—soon to be joined by the Russian Global Navigation Satellite System (GLONASS) and the European Galileo system—are aware of their current latitude and longitude coordinates and can use this data as value added information for context-aware services, that is, mobile applications that refer to information relevant to the current location of the user. A possible use scenario for such an information request would be, for example, "find all clubs and pubs in a radius of 500 meters from my current position." The focus of this work is to enrich the opportunities given by such location aware services with selected Web 2.0 design paradigms (Beer & Burrows, 2007; Kolbitsch & Maurer, 2006) toward mobile social networking services that are bound to specific physical places. User participation, folksonomy and geotagging are three design methods that have become popular in Web 2.0 community-platforms and proven to be effective information management tools for various domains (Casey & Savastinuk, 2007; Courtney, 2007; Macgregor & McCulloch, 2006). Applying such a design approach for a mobile information system creates a new experience of collaboration between mobile users, a step toward what Jaokar refers to as the Mobile Web 2.0 (Jaokar & Fish, 2006), that is, a chance for mediated social navigation in physical spaces.

BACKGROUND

Applications based on mobile spatial interaction can be classified into four different categories (Fröhlich et al., 2007): 1) Systems that facilitate navigation and wayfinding in geographic places: This category is, for example, represented by car navigation systems that assist the driver, for example, with interactive maps, arrows or spoken instructions providing directions to the address of destination (Baus, Krüger, & Wahlster, 2002; Kray, Elting, Laakso, & Coors, 2003); 2) Mobile augmented reality applications such as the head-mounted display (HMD) of virtual information added to objects in the physical world, (Bruce, Piekarski, Hepworth, Gunther, & Demczuk, 1998; Piekarski & Bruce, 2002); 3) Applications creating; or 4) providing access to information that is attached to physical places or objects: For such applications, geotagging, a method to attach latitude and longitude identifiers, enables information resources such as text, pictures or videos to be put into a specific geographic context (Torniai, Battle, & Cayzer, 2005).

In categories 3 and 4, which represent the fields relevant to our work, most of the previous studies focus on techniques that allow people to create or access locative information and share their personal stories, thoughts, experiences and knowledge about specific places. Lancaster University's GUIDE project, for example, is an electronic tourist guide that provides users with context-aware information, depending on their profile, interests and location (Cheverst, Davies, Mitchell, Friday, & Efstratiou, 2000). On the other hand, GeoNotes (Espinoza et al., 2001) and Urban Tapestries (West, 2005) allow mobile users to not only read but

also create spatially contextualised content. They can attach virtual sticky notes to particular latitude and longitude coordinates. Equipped with Wi-Fi-enabled personal digital assistants (PDA), users can then see other users' notes that were left behind in their current immediate surroundings. E-graffiti, a context-aware application evaluated on a college campus, detects each participating student's location on the campus and displays notes that were left behind by other students (Burrell & Gay, 2002). Just-for-Us (Kjeldskov & Paay, 2005) helps a group of friends in a city to identify an appropriate place to meet depending on their individual current locations, and the George Square project (Brown et al., 2005) focuses on location, photography and voice sharing functions to let on-site and off-site users collaboratively explore a city sight.

Besides the various use scenarios, the applications primarily differ in the interaction design of specific features (Tungare, Burbey, & Perez-Quinones, 2006), for example, access virtual post-its from remote places (Espinoza et al., 2001; West, 2005) vs. in-situ access (Burrell & Gay, 2002; Rohs, 2005), push (Espinoza et al., 2001; Kjeldskov & Paay, 2005) vs. pull services, expiration dates of the messages or private vs. public messaging (Burrell & Gay, 2002; Espinoza et al., 2001). However, not much work has yet been carried out on studying different interaction techniques between the information provider and information consumer of geographically contextualised content. The focus of our work is on evaluating direct and indirect interaction methods, such as phone calls, text messages and whiteboard messages that can be described and retrieved via folksonomy tags.

MOBILE SPATIAL INTERACTION AS AN ENABLER FOR MEDIATED SOCIAL NAVIGATION IN PHYSICAL SPACES

Our physical world holds certain characteristics that enable us to interpret what other people have done, how they behaved and where they have travelled. Sometimes, we can see traces on physical objects that provide hints about people's actions in the past. Footprints on the ground left by previous walkers can show us the right way through a forest, or in a library, for example, dog-eared books with well-thumbed pages might be worthwhile reading, as they indicate the popularity of the text. The phenomenon of people making decisions about their actions based on what other people have done in the past or what other people have recommended doing, forms part of our everyday social navigation. The concept of social navigation describes the "moving towards a cluster of other people, or selecting objects because others have been examining them" (Dourish & Chalmers, 1994).

Social navigation in its classic sense is often restricted to visible traces that were intentionally or unintentionally left behind by earlier navigators, and indicate a former interaction between them and an object in the physical world. While some previous work use social navigation as a design concept to enhance navigation and wayfinding in virtual spaces such as Web browsing or online shopping (Dieberger, 1995, 1997; Dieberger, Dourish, Höök, Resnick, & Wexelblat, 2000; Dourish & Chalmers, 1994; Erickson & Kellogg, 2000; Forsberg, Höök, & Svensson, 1998; Höök, Benyon, & Munro, 2003; Svensson, 2002; Svensson, Höök, & Cöster, 2005), a different approach is to leverage multimedia and virtual information spaces to enhance social navigation in the physical world, which we refer to as "mediated social navigation." The technical infrastructure comprising mobile Internet and global positioning systems paves the way for mediated social navigation using mobile phones. They enable users to add multimedia content to physical places or objects and overlay the real world with a virtual information space that can then be requested by mobile users (Burrell & Gay, 2002; Jaokar & Fish, 2006), and more specifically, create a mediated social environment. Such applications not only provide hints about what somebody has done at a specific place, but he or she can document this with text, photos, audio and video recordings. Such an infrastructure based on user generated content makes use of mediated social navigation to enable mobile users to effectively exchange local knowledge (Foth, Odendaal, & Hearn, 2007).

In our study, we explored the appropriateness of principles that guide the design of a mobile phone application to support social navigation in physical environments (Bilandzic & Foth, 2007a). Targeting the specific domain of public inner-city places, we have designed "CityFlocks," a mobile system enabling urban residents to leave digital annotations with ratings, recommendations or comments on any place or physical object in the city. Thus, CityFlocks turns residents into in-situ amateur journalists for the benefit of visitors or other residents who have questions or need navigational aid related to any place in the city. Furthermore, it provides two interaction alternatives to let people collectively share information about places in their city or neighbourhoods, one following a direct and the other an indirect social navigation approach (Dieberger, 2003; Svensson, 2002). The direct social navigation feature enables information seekers to set up a direct voice link with a local resident who has agreed to voluntarily provide local information to visitors and other residents. The indirect approach produces a dynamic list of virtual, location-based messages, authored and rated by local residents that provide information about the respective place. In order to retrieve a virtual message or an appropriate voice-link partner, CityFlocks provides a built-in search function based on the folksonomy concept. Folksonomy is a user-generated taxonomy, initially applied to categorise and retrieve Web content such as Web pages or photographs, using open-ended labels called tags (Vander Wal, 2007). For every entry users submit, they can attach a number of

tags to describe the comment and place they are submitting. Other CityFlocks users can then search for such tags to find the recommendations and places they are looking for. The underlying database is designed to allow users to request tags that other people have used to describe similar places. In doing so, one can use the community's collective intelligence to find related places. Similar to Amazon's (http://amazon.com) recommendation feature ("customers who bought this item also bought this item"), CityFlocks identifies correlations between the user generated tags to propose places that are related to one's initial search request.

FUTURE TRENDS

There are two major research fields regarding future MSI-applications: On the one hand enhanced positioning methods and technologies need to be further developed. New approaches embrace a seamless mix of various positioning technologies, such as GPS, Wifi-Fingerprinting (Taheri, Singh, & Agu, 2004) and Radio Frequency Identification (RFID) to ensure precise location awareness where a single technology on its own would fail, for example, GPS in indoor locations or Wi-Fi fingerprinting in rural areas.

The second research field deals with usability issues and the creation of appropriate interaction techniques for the various types and use scenarios of MSI applications. In our CityFlocks project, for example, we propose an innovative interaction type for end-user information systems (Bilandzic & Foth, 2007b) by combining Web 2.0 techniques such as geotagging, folksonomy or user-generated content with context-aware features and direct voice link capabilities on mobile phones. The outcomes provide valuable input into the process of designing future community-driven, mobile information systems. This study continues and expands our work in the area of urban informatics (Foth, 2006, 2008, in press; Foth & Hearn, 2007; Klaebe, Foth, Burgess, & Bilandzic, 2007). Only if designers manage to create intuitive and easy-to-learn interfaces, MSI applications might be adopted and used by the broad mass of users. However, there are some other critical factors such as privacy and social acceptance issues where further studies need to be carried out.

CONCLUSION

Originally, social navigation was restricted to visible interaction histories that were naturally left behind and thus relied on earlier physical interaction between people and the respective object. People interpret these hints as a message, recommendation, warning or just a note telling them something about the type of interaction the previous navigator had with the object. With a clever mix of modern mobile information and communication technology and a set of Web 2.0 technologies, social navigation methods can be enhanced in physical spaces (Höök, 2003). There is an emerging trend that takes advantage of the network connectivity of mobile phone users to create a mediated social environment where people who are interested in particular geographic locations can exchange information, personal opinions and experiences with the respective place. This would, for example, enable visitors of a new city to access the knowledge and experiences from local residents about inner-city facilities. This mind-shift in designing mobile services toward a high engagement of individuals has great potential to enhance peoples' experience when navigating physical spaces (Höök, 2003; Jaokar & Fish, 2006). Turning mobile phone users into in-situ journalist who can upload location-based ratings, comments and recommendations to a shared community platform will eventually form a huge social knowledge repository decentralising control over information about local services.

The idea of the proposed service targets a community-driven urban information service and is meant to provide an infrastructure to let residents become authors of information regarding their own neighbourhoods and make them available for interested people in the city, for example, visitors and tourists. This design approach proposes a new type of mobile information systems, providing the benefits of mediated social navigation to MSI applications. It leverages Web 2.0 techniques toward an effective collaboration between mobile users in order to enhance social navigation in physical spaces.

KEY TERMS

Mobile Social Navigation: The process of guiding activities aimed at determining our position and planning and following a specific route based on what other people have done or what other people have recommended doing, using mobile devices. First introduced by Dourish and Chalmers (1994), they describe social navigation as "moving toward a cluster of other people, or selecting objects because others have been examining them."

Local Folksonomies: In the context of the Web 2.0 discussion, a folksonomy (sometimes also known as a "tag cloud") is a user-generated taxonomy made up of key terms that describe online content. By assigning these freestyle keywords or so-called "tags," the semantics of various information resources can be described in a more flexible, decentralised, collaborative and participatory way than fixed categories allow for. The term has been coined by Thomas Vander Wal.

Geotagging: An approach which adds latitude and longitude identifiers as metadata to online content. It enables people to embed their information resources such as text, pictures or videos in a specific spatial and semantic context to augment the physical world with virtual information. Such a mediated social environment can help people navigate physical spaces by using location aware mobile devices.

Mobile Web 2.0: The suite of systems and mobile devices which either run existing Web 2.0 applications or re-appropriate according characteristics (tagging, user participation, mash-ups, personalisation, recommendations, social networking, collective intelligence, etc.) for the specific context of mobile use and mobile devices.

Context-aware Mobile Devices and Applications: Applications that react or provide information based on the user's context. The context is defined by a vector of selected data, for example, representing his/her current geographic location, emotional state, physical conditions (e.g. light, noise) or other variables that describe the user's current situation. Devices that run context-aware applications are usually equipped with sensors to perceive the environment or make assumptions via intelligent algorithms.

Local Knowledge: Knowledge, or even knowing, is the justified belief that something is true. Knowledge is thus different from opinion. Local knowledge refers to facts and information acquired by a person which are relevant to a specific locale or have been elicited from a place-based context. It can also include specific skills or experiences made in a particular location. In this regard, local knowledge can be tacitly held, that is, knowledge we draw upon to perform and act but we may not be able to easily and explicitly articulate it: "We can know things, and important things, that we cannot tell" (Polanyi, 1966).

Global Positioning System (GPS): A set of earth orbit satellites transmit microwave signals which can be received with so-called GPS-receivers. By comparing the timestamps of signals from different satellites, GPS-receivers can determine their geographic location. Each position can be described by a set of latitude and longitude coordinates.

Mobile Technology Usage in Business Relationships

Jari Salo
University of Oulu, Finland

INTRODUCTION

Business relationships have been studied for decades (Wilkinson, 2001). However, the literature has been criticized of the lack of focus on information technology (IT) usage within business relationships (Reid & Plank, 2000). As managers have started to employ digital tools such as the Internet, intranets, and extranets, buyer-seller relationship scholars have realized the need to focus on IT deployment within relationships. There is a growing body of research that focuses on the different types of technologies being employed such as electronic data interchange (EDI) (Naudé, Holland, & Sudbury, 2000), Internet-based EDI (Angeles, 2000), and extranet (Vlosky, Fontenot, & Blalock, 2000) and their influence on business relationships. Nevertheless, mobile technology usage within business relationships is a nascent field of scientific inquiry.

Besides buyer-seller relationship literature, mobile commerce (MC) (conducting commercial activities via mobile networks) literature also noticeably lacks academic research on business usage of mobile technology (Okazaki, 2005; Scornavacca, Barnes, & Huff, 2005). By combining these indications for further research from the buyer-seller relationship and MC fields it can be argued that there is a clear call for research in this area. Hence, I aim to bridge some aspects of the identified research gap. The research gap is filled in by discussing bonding within buyer-seller relationships to illustrate how mobile technologies create a novel bond in business relationships. It is acknowledged that some research on the adoption of mobile technology in the business context exists (see e.g., Kadyté, 2005).

The paper is organized as follows: First, a brief discussion of the background of business relationships, mobile technologies, and bonding is provided. Then, I highlight how mobile technologies are used within relationships with a case study. After that, future trends in this pertinent area are presented. The paper finishes with a concluding discussion.

BACKGROUND

Basically, it can be stated that both the popular as well as academic press has regularly indicated that the number of relationships that exist between buyers and sellers has decreased, but the amount of trade contracted within existing relationships has simultaneously increased. The fact remains that in many cases, it is not profitable to play dozens or even hundreds of competing suppliers or customers off against each other, but working directly with a few of them within a business relationship is profitable for all parties. This is because, as the number of possible partners increases so do the transaction costs. Thus, it is evident that existing business relationships are a vital area for research.

Within the business relationships domain there are multiple and overlapping fields of inquiry (Ritter & Gemünden, 2003) that have provided specific frameworks applicable to different types of problems. Here, I use the bonding discussion as it provides a means to evaluate changes occurring in business relationships. A bond can be seen as a building block for a relationship that is created through interaction between business parties. Academic literature to date has identified 10 bonds that are pertinent in business relationships: technical, time, knowledge, legal, economic, geographic, social, cultural, ideological, and psychological (Wendelin, 2004). Bonds have an important role in value creation and destruction in business relationships.

Social bonds were the starting point of studies focusing on bonding (McCall, 1970). Before a business relationship is built through business exchanges, there are many distances between the two interacting companies. Johanson and Wiedersheim-Paul (1975) identified social, cultural, technological, and time-related distances. For example, social distance measures the extent to which the actors are unfamiliar with each other's ways of thinking and working. Bonding is seen to reduce the distances. This paper focuses on technical bonds.

Technical bonds play a crucial role when business parties are interacting. For example, if company A produces mobile phones and company B is a supplier of components, over time company A and B will usually create interfacing processes in which, for example R&D teams can meet to plan how new products can be produced in the most effective way. Hence it might be the case that company B adjusts its production so that it is more suitable to company A or buy some machinery specifically to deliver the new subassembly to company A. This type of adaptation and mutual planning of the manufacturing process within the business relationship can be seen as one type of technical bonding that has a crucial role in the development of business relationships.

Technical bonds usually refer to connections in the manufacturing process (Wendelin, 2004); however, an exception to this view is provided by Perry, Cavaye, and Coote (2002). IT-based bonds are considered to be a subset of technological bonds. Bonding can have two opposing impacts depending on the context. It can either have a positive impact on a business relationship as it may enhance interfacing processes—this happens with mobile technologies in the business relationship of the Alpha-Zeta case study—or it can have a negative impact, as it may hinder cooperation with other parties. This can happen if a company has intensive bonding with directly competing companies. In the contract-based software development business for mobile phone manufacturers this may be the case.

Still, it can be stated that not all business relationships that managers engage their companies in are valuable and effective enough. Luckily, the current IT field provides many new applications that can be deployed interorganizationally to make existing business relationships even more valuable and profitable. One of these tools is mobile technology, more fashionably called the mobile solution. These mobile technologies provide a wide array of opportunities to enhance interorganizational processes. Here, I focus on wireless local area network (WLAN)-based infrastructure and personal digital assistant (PDA)-based mobile solutions.

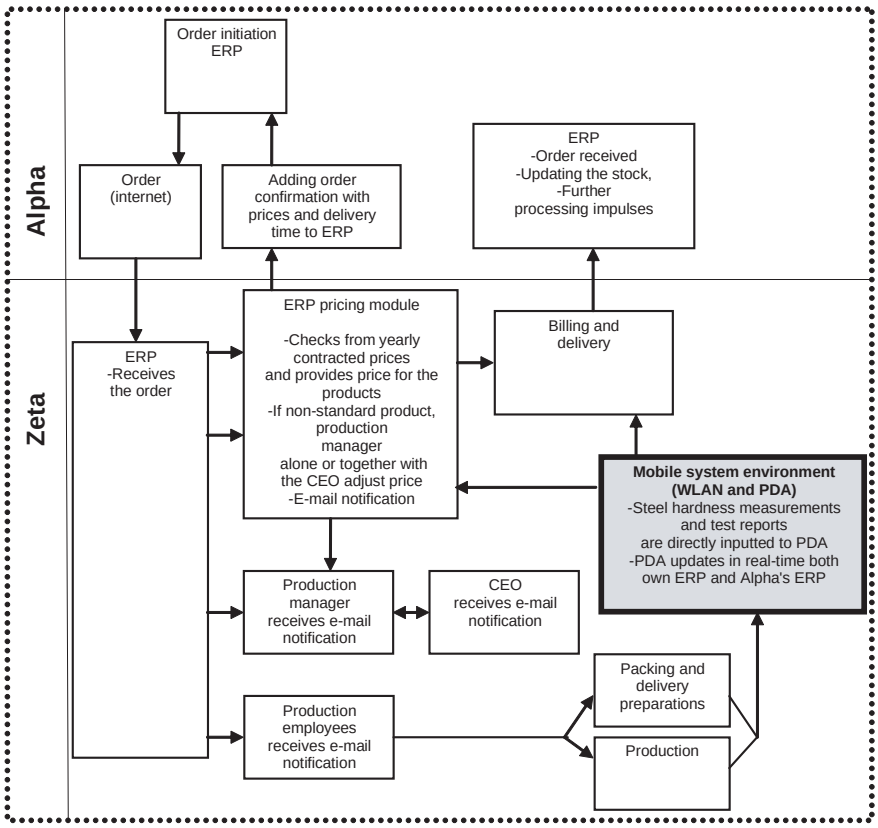
Currently, mobile technologies enable individual business people to check e-mails, place orders, and log in to company networks from the road (Aungst & Wilson, 2005). Some of the mobile devices are connected to Internet networks, such as wireless application protocol (WAP) phones, while others are unconnected, such as PDAs that are subscribed to services like Avantgo and Vindigo, which are unconnected services. More specifically, in a business context MC can be deployed internally or interorganizationally. Within an organization MC can be used to enhance selling activities in the form of sales force automation (SFA) (see Aungst & Wilson, 2005). Interorganizationally, MC can be used to mobilize customer relationship management (Sinisalo, Salo, Karjaluoto, & Leppäniemi, 2006) or it can be deployed with the help of WLAN or Wi-fi and smart devices (such as PDA, hybrid phones, Blackberries). WLAN deployed uses 802.11b standard, and it is connected to a local area network (LAN). MC and mobile technologies have been studied mainly from the consumers' point of view in recent years. The use of MC in relationships is studied even less and there are no studies, as far as I know, that employ empirical research. Based on this, it is essential to examine how mobile technologies can be employed to enhance order-delivery processes in a relationship.

DEPLOYMENT OF MOBILE TECHNOLOGIES IN THE ALPHA-ZETA BUSINESS RELATIONSHIP

In essence, methodological choices are guided by the purpose of research. The basic aim of this paper is to deepen and expand existing knowledge regarding business relationships and how mobile technology may be used to enhance those relationships. This goal calls for a case study method (see e.g., Yin, 1989), as a case study provides detailed and rich information of one focal phenomenon. More specifically, the case is a relationship that is composed of two companies interacting with each other. The perspective of both parties needs to be studied to be sure of the value of the findings (John & Reve, 1982). Based on thorough secondary information sources, I selected a business relationship from the steel industry. This industry was chosen as the empirical context because computerization has a long history in the industry and new technologies play a central role (Chaffey, 2004). Research on the usage of mobile technologies and solutions in the steel industry context is scarce. Therefore, it can be argued that the steel industry context is worth studying, especially when companies are employing novel mobile solutions to enhance their business. In this study, the steel mill is called Alpha and the steel workshop is labeled Zeta. To be more precise, the narrow context of the Alpha-Zeta business relationship is steel processing, that is, the hardening and marketing of steel plates and components. I used semistructured in-depth interviews that were transcribed and analyzed accordingly. I also used several additional sources of information such as documents, minutes of meetings, industry reports, and plant visits to validate research results (see e.g., Patton, 1987). The data triangulation employed here increases the validity and reliability of the research (Eisenhardt, 1989). The identities of the case study companies and the informants are not revealed for confidentially reasons.

The Alpha-Zeta business relationship is now 6 years old and is based on and developed from a previous 40-year business relationship that still exists between Alpha and Beta. Zeta was established to serve Alpha's needs by hardening steel qualities from 5mm up to 60mm. When the relationship was initiated, all activities related to the order-delivery process were manual, that is, handled physically. In brief, Alpha has relatively high IT skills and uses enterprise resource planning (ERP), customer relationship management (CRM), and supply chain management (SCM) systems as well as traditional office systems. At first Zeta had limited IT skills but managed to acquire and implement a small scale, first generation ERP system. Until 2004, almost the whole order-delivery process was digitized with the help of the ERP systems that were integrated over the Internet. From here on, I focus on the development and usage of mobile technologies.

Figure 1. Activities within the Alpha-Zeta business relationship after mobile solution adoption



The most recent technological addition to the relationship is the mobile technology discussed previously. The main idea is to use the mobile technology to speed up inventory control, test-report transmissions, and other nonroutine communications. In a technological sense the solution is based on WLAN infrastructure and employs handheld computers such as PDAs as wireless devices. The technology employed was acquired from a local mobile system developer that had provided some IT systems for Zeta earlier. Basically, the mobile solution renders paper-based and manual strength measurement reports obsolete and transforms these into a digital form that is easier to process for both parties in the relationship. Before this new technology was adopted, reports were first conducted by writing the required information down on paper, inputting this information to a system, printing the report, and then sending it to Alpha's administration who filed it. Now the mobile solution enables information to be input directly to a PDA which updates Zeta's ERP system and provides e-mail notification to Alpha about the new reports, which are essential for the documentation of the steel solutions delivered to customers. Furthermore, Alpha can now receive information about Zeta's hardening capacity, which is vital for generating new sales. Previously, a hardening capacity check was manual and information received by Alpha's sales department was usually too outdated to reliably act upon and thus information needed to be rechecked. Today, Alpha's employees, with access codes to Zeta's system, can retrieve information from the real-time database updated by Zeta's employees and the mobile solution. Figure 1 depicts the order-delivery process after implementing the mobile technology.

Figure 1 illustrates how the mobile technology employed is aligned with other technologies and how it has eased processes in the relationship. The benefits, in the form of faster information delivery which provides the means to sell more steel solutions, are enjoyed by both parties. Furthermore, the adoption of these novel technologies and the adaptations made a clear signal to Alpha that Zeta was willing to help in every way possible to make the business relationship more effective and efficient. Similarly, Alpha signaled to Zeta through increasing orders that the relationship was worth continuing.

FUTURE TRENDS

It is clear from current literature that future research will attempt even more than before to bridge the research void that exists concerning business usage of mobile solutions (Aungst & Wilson, 2005). Besides focusing on business usage of mobile solutions, specific emphasis will also be placed on the deployment of mobile solutions in business relationships (Salo, 2006). This is because all business organizations have a large number of relationships that need to be handled effectively. Thus, it is clear that IT-based systems such as mobile solutions will not render personal communication obsolete but those forms of communication will coexist and enhance communication in business and within business relationships.

Moreover, a wide array of different types of mobile solutions is applicable to business usage and business relationship usage. These systems might include Radio Frequency Identification RFID), mobile CRM (management of relationships via mobile gadgets), or mobile accessible SCM or ERP. It is evident that this topic merits further research from both MC and marketing viewpoints. In addition to academic studies more practical research is also needed to fully understand the nature of this emerging phenomenon.

CONCLUSION

This article provides insights into ways mobile technologies can be used to enhance existing processes in relationships. In addition to looking at MC literature this paper also provides ideas from a business relationship perspective. Basically, the paper identifies the emergence of mobile, technology-based bonds as a subset of technological bonds. Interestingly, technological bonds are usually perceived as manufacturing-related bonds but it can be seen here that mobile, technology-based bonds are based on communication via mobile devices. Mobile, technology-based solutions helped both companies to speed up inventory control, test-report transmissions, and other nonroutine communications. It also created more new sales possibilities as excess capacity became easier to identify and act upon. In general, this paper tackled some of the possible mobile technology benefits available from the adoption of technology into a business relationship.

Managerially this study has opened up a discussion on the possible usage of mobile technologies other than traditional e-business tools. This case illustrates how WLAN-based technology was used to effectively cut costs and streamline the order-delivery process as well as interfacing parts of that process. For managers interested in mobile solutions and how to proceed with ideas, a good reference point is an article by Aungst and Wilson (2005) in which they suggest 11 issues that should be covered when planning to adopt and use mobile solutions. The five most important ones are (1) coverage (WLAN or longer distance), (2) the mobile device platform, (3) the upgrade path, (4) the mobile application, and (5) issues with integration. Mobile technology such as m-ERP, mobile supply chain management, and WLAN-based internal systems provide novel tools to create leaner and meaner machines out of any organization that has the wisdom to grasp the mobile technology that will create the mobile future. Of course not all problems require a mobile solution but mangers ought to understand, and more importantly, recognize their problems and consider whether MC might provide a solution for their problems.

The main limitation of this paper is the exploratory and qualitative nature of the study. The second limitation is that only one business relationship in the steel industry context was studied. However, this study indicates that future studies should focus on how MC and mobile technologies are changing the logic of business relationships and how business relationships can excel in today's hypercompetitive landscape with the help of mobile systems. Future studies should employ a large scale survey about the usage of mobile technologies in business relationships to validate and broaden earlier findings.

KEY TERMS

Bond: Can be seen as a building block for a business relationship. Bonds are created through interaction between business parties.

Business Relationships: Relationships are created through the interaction between parties involved in exchange. Single acts and episodes, that is, the elements of interaction build the relationship over time. Satisfaction, commitment, and trust emerge as the distance between the parties is reduced. In due time, bonds are created on several levels of the relationship.

Mobile Commerce (MC): All commercial activities including sales and procurement that are conducted via mobile technology.

Mobile Technology: A form of information technology that can be used to mobilize various traditional activities. Includes sales force automation (SFA), mCRM, order pick-ups and other information and transaction flows between business parties.

Wi-Fi: 802.11.b based WLAN is often labeled Wi-Fi.

Wireless Local Area Network (WLAN): In short, a local area network without cables. Airwaves are used to transmit and receive data. The most commonly used WLAN is based on standard 802.11b.

Mobile Telecommunications and M-Commerce Applications

Clarence N.W. Tan
Bond University, Australia

Tiok-Woo Teo
Bond University, Australia

INTRODUCTION

This article presents an overview of prevailing trends and developments shaping mobile commerce (m-commerce) and the wireless economy. A review of wireless telecommunications infrastructure attempts to demystify the evolving technology landscape. Mobile Internet deployment and adoption demographics are highlighted, as are innovative wireless applications and current m-commerce issues.

BACKGROUND

The World Wide Web (WWW) and Web browser software brought mass market accessibility to the Internet. Riding on this ubiquity and reach is electronic commerce (e-commerce) in its many forms: inter-business dealing, intra-organization transactions and business-to-consumer trade, and so forth. E-commerce has witnessed impressive growth and continues to be a significant propellant of Internet progress. Participants have, however, hitherto been essentially tethered to fixed line connections. The development of novel wireless services and mobile adaptations of familiar applications (Ghini, 2000) is fueled by demand from increasingly nomadic users looking to access familiar online facilities, and the steady convergence of telecommunications and computing technologies (Messerschmitt, 1996).

Wireless telecommunications was conceived in the 1980s to carry voice, but has evolved to become data bearer, including Internet communications. The cellular telephone is now commonplace and more personal digital assistants (PDAs), hand-held computers and the like are sporting cellular radio connectivity. These devices form a sizable platform for deploying m-commerce applications. M-commerce refers to the ability to browse, interact with and make payment for goods and services directly from mobile terminals such as cell phones, PDAs and portable computers (Tan, 2002). Industry forecast statistics point to exponential growth in the sector:

- Worldwide shipment of Web-enabled wireless devices rose 796% in 2000 over 1999 and consumer transactions committed from such terminals will total US $1.8 trillion worldwide by 2005 (Source: Gartner Group).
- International wireless data market was expected to grow from 170 million to more than 1.3 billion subscribers between 2000–2004, equipping themselves with 1.5 billion wireless-capable handsets and other Internet appliances by end of 2004 (Source: Cahners In-Stat Group).
- Wireless Internet users in the Asia-Pacific region alone will rise 10-fold from 20 to 216.3 million between 2000–2007 (Source: Strategis Group).

As Internet and mobile communications converge, e-commerce evolves into m-commerce. The tremendous potential of "anytime" convenience and "anywhere" mobility in carrying out everyday online transactions will spur many unique mobile services yet.

TECHNOLOGY ROAD MAP

Early wireless telecommunications architecture in the late 1940s was modeled after television broadcasting. Tall, centralized transmitter towers provided radio coverage. Limitations like restricted user mobility and capacity, poor voice quality and high cost saw the introduction of new cellular technology in late 1970s—a superior architecture persisting to this day.

A cellular mobile communications system comprises a vast collective of low-power antenna subsystems, dispersed in small overlapping geographical units called cells. Individual cellular base stations provide local coverage and interconnect for a combined footprint that constitutes the wireless network. Modern implementations are typified by larger, sparse cells in rural areas and small, dense ones in metropolitan districts. The technology road map is demarcated by milestones corresponding to transmission bandwidth.

First Generation—1G: Analogue radio transmission characterized 1G cellular systems. The one-time de facto standard throughout the Americas and the Asia-Pacific was

the Advanced Mobile Phone Service (AMPS) introduced in the United States in 1983. Despite technical imperfections such as limited growth capacity, poor data transport and deficient transmission security, 1G systems maintained their popularity till the early 1990s. Improved derivatives of AMPS are still deployed in the remaining analogue cellular networks around the world today.

Second Generation—2G: Digital radio transmission heralded the 2G era. Information is digitized into a stream of computer binary coded data packets for transmission and reassembly at the receiving end. Two competing digitization schemes are Time Division Multiple Access (TDMA) and Code Division Multiple Access (CDMA). Better bandwidth utilization boosts network capacity, enhances coverage and improves voice quality. New service features such as data encryption, short text messaging, fax and data transmission can also be offered.

Launched commercially in 1991, the European developed, TDMA-based Global System for Mobile Communications (GSM) is the de facto international 2G standard today, with 863.6 million subscribers in 174 countries at end of May 2003 (Source: GSM Association, *http://www.gsmworld.com*). An American adaptation of GSM called PCS 1900 was launched in late 1995. CDMA-based networks began commercial operation in 1995 and are now the predominant standard in the Americas, Korea and Japan, with 164.1 million subscribers in 60 countries as at June 2003 (Source: CDMA Development Group, *http://www.cdg.org*).

Conventional fixed line Internet connectivity offers varying data rates:

- Up to 56 kbps (kilobits per second): Analog modem
- 64–128 kbps: Integrated Services Digital Network (ISDN)
- 256 kbps–1.5 Mbps (megabits per second): Optical fiber and Digital Subscriber Line (DSL)

In comparison, 2G data service provides 9.6–57.6 kbps throughput, with most network operators supporting only speeds no more than 14.4 kbps. This makes for poor overall user experience for consumers increasingly accustomed to higher-speed, broadband Internet access through fixed connections. Real-time multimedia applications such as live video are also impracticable on 2G architecture. Solutions better optimized for wireless data transmission are clearly needed to meet growing demand for quality mobile Internet access.

Second-and-a-Half Generation—2.5G: 2.5G systems extend 2G infrastructures for upgraded data throughput. New handsets, however, are required to tap the improvements and other added functionalities. The enhancement to GSM is called the General Packet Radio Service (GPRS). Capable of a theoretical maximum 171.2 kbps transmission, the average is 40–80 kbps deployed in practice. Like the Internet, GPRS networks are also based on the Internet Protocol (IP) standard, so GPRS terminals function just like other wired Internet sub-nodes with seamless access to familiar applications such as the WWW, e-mail, Telnet and FTP (File Transfer Protocol), and so forth. The first commercial GPRS service was inaugurated in the United Kingdom in June 2000. 2.5G CDMA technology is known as the IS-95B standard and offers ISDN-like data rates. Its first commercial debut in Japan in early January 2000 beat GPRS to market by some 6 months, and the 64 kbps throughput was superior to prevailing 2G GSM offerings.

While data speed boost is useful in time-sensitive applications like online transactions and credit authorization, there remain technical idiosyncrasies and transmission latencies detrimental to time-critical multimedia functions such as video decoding and playback. Hence, 2.5G is still not the ideal platform for deploying high quality, real-time video conferencing.

"2.75G": When wireless data rates approach those of conventional fixed line broadband connectivity, user experience will improve significantly and truly mobile Internet access would be a reality. Some have termed this stage of the road map loosely as "2.75G".

The Enhanced Data rates for Global Evolution (EDGE) standard is engineered as an extension to GSM technology and leverages past investments in TDMA and GPRS. Throughput of 384–553.6 kbps is theoretically possible and early EDGE-compatible handsets support rates in excess of 100 kbps. The world's first commercial EDGE service was deployed in the United States in July 2003. The equivalent evolution in CDMA technology is the CDMA2000 standards, providing network speeds from 144–614 kbps. From the first commercial service in Korea in October 2000, CDMA2000 subscribers have grown to number 54.1 million by June 2003 (Source: CDMA Development Group).

Third Generation—3G: Wireless broadband connectivity and industry standards harmonization characterize 3G systems. New handsets are again necessary to exploit multimedia capabilities and applications enabled by high-performance wireless networking at unprecedented 384 kbps–2 Mbps speeds.

More importantly, the vision is for 3G devices to roam seamlessly on enabled networks within a country and across continents, creating truly borderless mobile services. To this end, the International Mobile Telecommunications 2000 (IMT-2000) recommendations were promulgated in late 1999 with international participation. IMT-2000 prescribes how mobile service providers should evolve existing cellular networks towards full inter-network compatibility independent of underlying radio technologies. Disparate TDMA, CDMA, GSM systems and their derivatives will be accommodated. For example, under IMT-2000, GSM will evolve into the Universal Mobile Telecommunications System (UMTS) and employ a new transmission

technology called Wideband CDMA (W-CDMA). The first commercial UMTS 3G service was introduced in Japan in October 2001.

WIRELESS MESSAGING

SMS—Short Message Service: The Short Message Service is a wireless radio service for bidirectional transfer of alphanumeric messages of up to 160 characters each among mobile terminals in GSM and UMTS networks (European Telecommunications Standards Institute, 2002). Multiple text messages (up to 255) may be concatenated to form longer ones. Messaging is near instantaneous and operates on a store-and-forward scheme that guarantees delivery. Sent messages are routed to their destinations by an electronic intermediary in the cellular network called a Short Message Service Center, or SMSC (European Telecommunications Standards Institute, 2002). If the intended recipient is not immediately contactable, the message is stored for a stipulated time period to facilitate reattempted delivery. The SMSC can notify a message sender of the ultimate delivery success or failure via an SMS notice called a delivery report.

Introduced in 1991, SMS began as a supplement to voice calls, alerting subscribers to awaiting recorded messages. Its use has since grown to encompass notification services like paging alerts, new e-mail notice and calendar reminders; and information services like weather forecast, traffic watch, stock quotes, gaming results and horoscope readings, and so forth. Interpersonal communications still dominate SMS messaging volume by far today but SMS is also finding increasingly sophisticated uses in corporate applications such as job dispatch (Tan, 2002) and secure m-commerce transactions systems (Tan, 2003).

In 2002, an estimated 360 billion SMS messages were sent worldwide with some 30 billion sent monthly in December—double the rate 24 months ago (Source: GSM Association). The growth trend is expected to continue.

EMS—Enhanced Messaging Service: EMS is a minor extension to SMS whereby a mix of formatted text (e.g., bold, italics, etc.), simple animations, tiny pictures and short melodies can be included as message content. The specification provides for amalgamating multiple classic SMS messages to convey the increased EMS message complexity. Compatible handsets have been commercially available since 2001, but there has been a lack of full interoperability among different makes and models due to proprietary implementations of the EMS standard by manufacturers.

MMS—Multimedia Messaging Service: MMS is the latest generation wireless messaging standard that inherits the SMS store-and-forward schema and features improved security mechanisms for managing message encryption, authentication and privacy. MMS is devised to carry a full range of multimedia elements including text, audio clips, still pictures, animated images and full-motion video, all encoded using industry standard file formats (e.g., JPEG for photographs, MP3 for audio, MPEG for video, etc.). Such rich content increases message size and considerably more bandwidth is needed to deliver MMS messages expeditiously. Hence, the takeoff of MMS is only expected to dovetail on the rollout of 3G networks internationally. The world's first commercial MMS service was introduced in Hungary in April 2002.

INNOVATIVE APPLICATIONS

The sheer success of the mobile telephone as a consumer device is indisputable. Mobile phones have already outstripped conventional telephone subscriptions in many countries. As cellular telecommunications networks and the Internet converge, the spillover of Internet e-commerce will fuel m-commerce takeoff. Wireless broadband technology can be used to deploy not only mobile variants of existing Web-based applications, but also fundamentally new ones. This creates new value proposition for consumers and revenue streams for vendors. The true power of the mobile Internet lies in these innovative applications that will be spawned, some of which are listed next.

- **Location-based services (LBS):** LBS refers to the provisioning of value-added services to cellular subscribers based on the physical location of their mobile devices within the network. Potential applications: location-based call billing, emergency medical services, courier fleet tracking, proximity-based personalized marketing, locality information services like navigation and directory assistance, and so forth.
- **Mobile multimedia entertainment:** Higher bandwidth afforded by 2.5G and 3G networks creates new distribution channels for paid multimedia entertainment like computer games, music and video. For example, games can be downloaded wirelessly for play on enabled handsets or with other gamers on the network. Music and video vendors may stream content wirelessly on demand to mobile devices for instantaneous preview playback and subsequent purchase.
- **Wireless telemetry:** The facility for gathering data or remotely controlling devices over the footprint of a cellular network through two-way communication between remote equipment and a central facility. Potential applications: security alarm monitoring, climate control, meter readings and inventory status polling, and so forth.
- **Wireless electronic payment systems:** Cellular phones become secure, self-contained tools for instantly authorizing payment for goods and services wirelessly over the network. One example is the use

of SMS messages for making purchases at vending machines.

- **Telematics:** The integration of wireless telecommunications and in-vehicular monitoring and location systems will bring mobile Internet facilities, location-based services and multimedia entertainment to vehicle dashboards. Potential applications: online information services (e.g., traffic news, weather forecast, route assistance, etc.), target advertising based on vehicle locale and streaming media content, and so forth.
- **Wireless telemedicine:** Cellular telecommunications and wireless broadband multimedia technologies can deliver health care expertise and services remotely. Potential applications: remote monitoring of patients in ambulances and long-distant specialist teleconsultation for patients in remote regions.

CURRENT ISSUES

The realm of m-commerce is still in its infancy and to the extent that it bears roots in e-commerce, many technical, business, marketing and legal perspectives in m-commerce may be extrapolated from e-commerce ones. But as a fundamentally new business paradigm, m-commerce will elicit contentious issues of its own. A few have been highlighted as follows.

- **Wireless privacy:** Industry self-regulation and legislation are needed to guard against potential threat of undue surveillance and profiling, invasion to personal privacy and wireless spam resulting from abuse of location data gathered for provisioning LBS.
- **Wireless security:** Increased vigilance is necessary as computer viruses and like malicious attacks begin to target PDAs and mobile phones, as such devices gain more processing power and intelligence, and users become ever more reliant on them for voice and data services.
- **Wireless emission and public health**: Concerns persist on the long-term impact on public health from cellular emission, radiation and electromagnetic interference in the face of rapid consumer adoption of mobile phones. While no conclusive evidence exists to suggest significant risks, a more precautionary approach is prudent pending further research.

CONCLUSION

Mobile telecommunications have seen an evolution from a voice focus to data-centricity. For now, 3G networks present a viable channel for distributing practically any digital content. The future along the technology roadmap continues to emphasize quality multimedia delivery. Cellular devices are expected to improve in form and function, benefiting from advances in display, storage, imaging, processing and battery technologies. Historically, new handsets were required for each successive generation of wireless infrastructure and their timely volume availability at mass market prices remains crucial to the success of future networks.

The continued proliferation of mobile-enabled portable consumer electronics and the rising demand for ubiquitous computing will contribute to the volume and value of m-commerce, and begin to unleash the power of the mobile Internet.

KEY TERMS

LBS (Location-Based Services): The provisioning of value-added services to cellular subscribers based on the physical location of their mobile devices within the network.

M-Commerce (Mobile Commerce): The ability to browse, interact with and make payment for goods and services directly from mobile terminals such as cell phones, personal digital assistants (PDAs) and portable computers.

SMS (Short Message Service): A wireless service for bidirectional transfer of alphanumeric messages among mobile terminals in digital cellular networks.

WAP (Wireless Application Protocol): An open, extensible and unified global standard for delivering information and providing interactive services over cellular networks to mobile devices.

INTRODUCTION

The widespread usage of new telecommunication technologies implies the demand on payment via Internet since the '90s. First, these solutions were applied only by pioneer users, while average men still chose traditional payment methods such as payment by cash, cheque, or bank transfer. In the latest decade, the notable improvement of mobile communications allowed the provision of customized services. A new payment method has appeared which is called mobile-payment. Consequently, increasing number of banks provide access to their services via mobile equipment.

Reliable network security is an essential prerequisite for the expansion of the rapidly growing world of electronic payment. Public key infrastructure (PKI) offers the capabilities needed to provide this security. Establishing trust in a wireless public key infrastructure (WPKI) is crucial for the success of applications that will exploit the opportunities created by handheld wireless devices. This trust is based on the reliability of the technology but also on a carefully implemented system of laws, policies, standards, and procedures.

The development of trusted electronic transactions is motivated by legislation. The EU adopted a legislative framework to guarantee the security and acceptance of electronic signatures in 1999. The U.S. adopted legislation for the recognition of electronic signatures in national and global trade in June 2000 (Sievers, 2000).

This article deals with mobile payment and mobile banking services and focuses particularly on the mobile side of the system. First, we introduce the technological background necessary for developing m-services, and we define the m-payment reference model. After that, the differences between chip-card and software based implementations will be presented. Finally, we conclude the article and summarize the main terms used in the article.

BACKGROUND

The Mobile Payment Forum (MPF) (2002) defines mobile-payment (m-payment) as the process of two parties exchanging financial value using a mobile device in return for goods or services. The trusted transactions of a mobile payment system are called mobile payment transactions. The main areas of use are the following:

- m-banking and m-payment, in case of performing banking and payment affairs;
- m-administration, when accomplishing administration tasks; and
- m-government, in case of arranging public administration affairs using the mobile electronic way.

The mobile device and the mobile network have two main roles in m-payment:

- they enable secure client authentication and identification; and
- they support the generation of digital signatures on the client side.

The user authentication means that a service provider determines the identity of a user (Kanniainen, 2001).

The digital signature is an electronic signature that can be used to authenticate the identity of the sender of a message or the signer of a document, and possibly to ensure that the original content of the message or document that has been sent is unchanged. Digital signatures can be used for many purposes, such as authorizing a subsequent transaction or creating a signature of the user with properties fulfilling the requirements of electronic signature laws.

The user authorization means that a service provider ensures that the user has viewed and accepted a transaction contract (Kanniainen, 2001).

The technological background exists for developing services based on trusted mobile transactions. The bandwidth of the mobile channel is only a small fraction of that of the Internet, but user authentication, digital signature transfer, authorization control require low bandwidth from the mobile network. Even low-end mobile devices support WAP functionalities (Wireless Application Protocol Forum [WAP Forum], 2001c) and text message sending. Their SIM card implements SIM Application Toolkit (SAT) and supports the necessary cryptographic algorithms at chip-card level. These are essentials to implement client-side banking applications (Van der Merwe, 2003).

Smart-phones with increased processing speed have already been introduced to the market. They support the development of software-based banking applications without using the functionalities of chip-card and relying only on the security of software-based encryption algorithms (Mobey Forum Mobile Financial Services Ltd. [Mobey], 2003).

In 2004 the Trusted Mobile Platform was introduced by IBM and Intel. It is a software and hardware requirement specification for mobile equipment (Trusted Mobile Platform, 2004) in secure environment.

Trusted mobile services are based on PKI technology. PKI offers strong authentication and encryption mechanisms and facilitates the secure exchange of sensitive messages in public information networks (Torvinen, 2000). PKI functions permit detection of messages that have been tampered with or altered during transmission. PKI summarizes the processes and techniques performing key-certification in public cryptography architecture. Each entity in the PKI system has at least one key-pair which consists of a private key and a public key. The private key is the secret of a given entity never discovered to others. Public keys are certified by a trusted third party called Certification Authority (CA) (WAP Forum, 2001a).

WPKI is a PKI where at least the user-side of the system uses wireless medium. WPKI uses more compact certificates then PKI and its certificate acquisition process is adapted to mobile environment (WAP Forum, 2001b).

Several international technical organizations were founded starting from the late ’90s, elaborating standard solutions or directives for trusted mobile transactions. Such organizations are Radicchio, Liberty Alliance, GSMA, ETSI M-COMM Working Group, OMA, MPSA, Mobey Forum, and Mobile Payment Forum, for example. Members of these organizations are mobile operators, financial institutions, research, developing, and standardization organizations (see Table 1).

Table 1. Organizations specifying trusted mobile transactions

Name	Foundation	Members
Radicchio (T2R)	Mars 2002	GSMA, Liberty Alliance, ETSI
Liberty Alliance	Sept 2001	VeriSign, Nokia, Sun, RSA, Vodafone, American Express, Novell
MPSA (SimPay)	Mars 2003	Vodafone, T-Mobile, Orange, Telefónica Móviles
Mobey Forum	Mai 2000	VISA, ABN-Amro Bank, Nokia, Deutsche Bank
MeT	April 2000	NEC, Nokia, Panasonic, SonyEricsso2n
Mobile Payment Forum (MPF)	Nov. 2001	American Express, JBC Co. Ltd., MasterCard International and Visa International
Open Mobile Alliance (OMA)	June 2002	Vodafone, Ericsson, WAP Forum, IT companies

MOBILE-PAYMENT SERVICES

An m-payment system involves a wireless device that is used and trusted by the customer. M-payment is not a new payment instrument but an access method to activate existing payment transactions processed by banks.

Mobile payment transactions (and systems) can be classified upon location basis or value basis. On location basis, local and remote environments are distinguish (Mobile electronic Transactions [MeT], 2001), on value basis, micro (<10Euros) and macro (>10Euros) payment (Mobey, 2003). In local environments transactions are usually initiated over a short-range wireless technology such as Bluetooth or RFID (Saleem, 2002). A typical application would be retail shopping using an account-based payment made from a mobile device. In remote environment the connection between the content server and mobile device is established via a Public Land Mobile Network, such as the GSM cellular network (Mobey, 2003).

The four main parties involved in a mobile payment transaction (see Figure 1)—the user, the network operator, the financial institution, and the merchant—share many of the same concerns that need to be addressed by a mobile payment standards body (Henkel, 2001; MPF, 2002).

- Consumers are mostly concerned with security, ease of use, and privacy. They also require the payment scheme to work across multiple devices, including mobile phones, PDAs, wireless tablets, and handheld computers.
- Mobile operators’ principal concerns revolve around standardization and interoperability. Operators want payment to be seamless, allowing them to compete on services and applications.

Figure 1. The mobile payment transaction

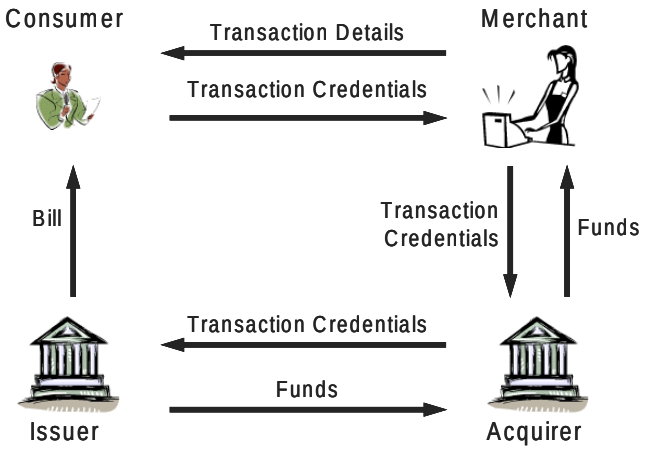

Figure 2. The reference model of the m-payment transaction

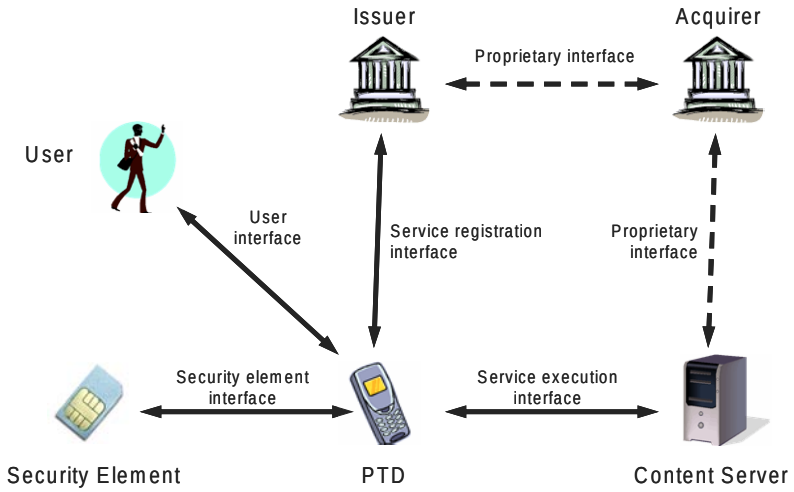

- Financial institutions, meanwhile, are primarily concerned with ensuring the integrity of the payment system and reducing the risk of fraud. M-payment solutions must have synergy with existing payment instruments and infrastructure, systems, processes, and rules.
- Merchants or content providers want the payment process to be transparent to the user, as this encourages greater usage and/or propensity to complete a purchase. They also want any payment scheme to facilitate swift and easy completion to ensure they get paid on time.

Figure 2 shows the reference model of mobile payment systems.

The main elements of the reference model are the following:

- **Mobile Device:** Its main functions are the authentication of the subscriber's identity and granting of the permission for the operation of a secure transaction. It is called Personal Trusted Device (PTD) by MeT (2001).
- **Security Element:** The mobile device includes a security element which provides a tamper-proof

environment to run the necessary cryptographic functions. It contains the user's private-public key pairs and root certificates (used to verify other certificates) (Mobey, 2003).

- **Issuer:** This is the user's bank or a provider via which the mobile electronic transactions are running. One of its main functions is to issue certificates for the subscriber when the user registers himself for the m-banking service. The issuer should produce at least two certificates for the user, which are the following: one is used during the authentication process; the other is used during the digital signing process.
- **Content Provider:** It corresponds to the merchant. The content provider supplies content to the user's mobile device. The application running on a content server may request the user to perform user authorization (sign a transaction).
- **Acquirer:** The acquirer provides a single point of contact between issuers and content providers. In mobile payment transactions, the acquirer's role is to provide the business rules and relationship among multiple content providers and issuers. As a consequence, banks do not need to make agreements with every merchant and vice versa.

A consumer decides to pay in a shop using mobile payment service. When the transaction is initiated, he sends the URL of his bank to the merchant. The merchant redirects the user to the issuer (bank) and sends him the total amount. The bank and the user authenticate each other; the bank sends the transaction data to the user. If the user decides to authorize the transaction, he signs the content with his digital signature by entering his signing PIN. Then the bank connects to the merchant and requests his authorization to finish the transaction. After this, the bank redirects the user's browser to the page of the merchant, and the merchant notifies the user about the successful termination of transaction (Vilmos & Karnouskos, 2003; Karnouskos, Hondroudaki, Vilmos & Csik, 2004).

TECHNOLOGICAL SOLUTIONS FOR M-PAYMENT SERVICES

The security element—defined in the reference model—can be implemented in many ways, depending on the agreement of banks, m-payment service issuers, and mobile operators. Two main categories exist: chip-card based solutions or software-based solutions. In chip-card based (Kanniainen, 2001) solutions, security-related functions and keys are stored on the chip-card. Applications not requiring a tamper-proof environment (e.g., the menu of the service) can be stored both on a chip-card and/or a mobile device. In software-based (Mobey, 2003) solutions all parts are implemented in software on the mobile device, including cryptographic functions, certificate and key storage. In case of chip-card implementations banks, and mobile operators have to decide either to put banking applications and keys on the same chip-card or on a separate one.

Security element implementations can also be classified by distinguishing between SIM-card dependent and SIM-card independent solutions referring to the role of mobile operator. In case of SIM-card dependent solutions, the applets, keys, and a part of the certificates for the banking and payment applications are stored on the chip-card under the control and authority of the mobile operator. In case of SIM-card independent solutions nothing from the banking application, private key and certificate for m-payment is stored on the chip-card for mobile operators.

SIM-Dependent Solutions

Advantages

SIM-dependent solutions are advantageous for the user because all functionalities are integrated into one chip-card and one device. The merchant can strongly authenticate the user through a trust chain starting from his bank and ending at the user's bank. Device manufacturers do not need to develop multi-card devices. The security level of this solution is high. The chip-card is portable from one device to another, can dispose standard interface via the device, and applications on the chip-card are protected against viruses.

Disadvantages

The main disadvantage of SIM-dependent banking applications from the bank's point of view is the dominant role of the mobile operator in the system. The bank and the mobile operator have to agree on their choice of chip-card manufacturer, the set of applications, and keys to upload to the card. The mobile operator can influence the choice of technical solution for the banking application. Besides these, it is the bank who has to handle the financial responsibility and risks. Mobile operators can charge the bank with costs of service. Registration for m-payment and m-banking service can be done in the stores of the mobile operator.

SIM-Independent Solutions

An SIM-independent solution means that the mobile operator does not have to change its SIM cards. There are two major types of SIM-independent solutions. The implementation of security element can be:

- a second chip-card (dual-chip device [Kanniainen, 2001]), which may be either one common chip-card

for all banks or one separate chip-card for each bank; or
- implemented in software as an application that is downloadable to the mobile device.

Dual-Chip Solution

Advantages
Banks become independent from the mobile operator because they provide the user a separate chip-card. The tasks of registration, chip-card distribution, and other services of the bank and of the mobile operator diverge. Later, newer applications can be downloaded over the air (OTA) to the chip-card provided by the bank without affecting the applications of the mobile operator. The mobile operator and the m-payment provider may choose chip-card manufacturer independently. The mobile operator does not have to extend its registration and chip-card distribution system. The device manufacturer gains a dominant role because new, dual-chip card devices are needed, and mobile operators and banks would support this activity. The user can feel himself more secure because his security data are not only on one card, but can also see the separation between mobile operator and banking services. The user does not have to change his SIM-card. The merchant can strongly authenticate the user through the trust chain of banks. High security applications can be implemented using this solution.

Disadvantages
In general, we cannot expect the introduction of these devices from device manufacturers. There are several reasons for this. The size of the device would grow, their hardware structure would change, and the production of new devices would be expensive. Another problem is that banks would have to handle chip-card management. In the case of one common chip-card for all banks, banks would need to agree on the application set installed on the chip-card, or they would have to choose the same m-payment service provider. Banks usually do not want to deal with the distribution of new chip-cards into the phones. This solution is costly for banks.

For the big-sized dual-chip devices, a future solution may be the use of secure RFID chips (Mobey, 2003). These chips do not need real slots; they are contactless. It is enough to put them near the device, on its back, for example. In this case, the bank would give an RFID chip to the user at the registration. Secure communication between the RFID chip and the mobile device is indispensable.

Software-Based Solutions

In the case of a software based security element (Kanniainen, 2001; Mobey, 2003), all the banking application are uploaded on the device without the need of any SIM-based function.

Advantages
This is a cheap and quick solution for banks and mobile operators. Device manufacturers tend to produce smart-phones capable of running these applications. Mobile operators will have traffic increase on their networks due to m-services. Theoretically, banks could upload their own applications separately from mobile operators, and banking services could work easily. In practice, they have to cooperate with mobile operators because operators have the only control over the communication channel. The applications are easy to upgrade but require high caution. The downloading of new applications to a coded device may require some agreement with the mobile operator.

Disadvantages
One of the disadvantages of software-based solutions, from a technical point of view, is the huge and rapidly increasing number of new software environments and operating systems. The client application must be prepared to run in several environments and should pass many audits during development. Besides this, if software-level encryption is used, viruses and malicious code pose a much higher risk than in the case of chip-card based solutions. Chip-cards filter out non-standard messages by default.

FUTURE TRENDS

A key issue concerning mobile payment is interoperability. As interoperability can be achieved by the use of (preferably international) standards, the intensive standardisation work is very important for mobile payment systems to get widely used.

Another important issue is a PKI as global as possible and trusted by all the players of the system. As Lannerström (2000) states, wireless devices offer tremendous flexibility when combined with a PKI. With the use of a PKI for wireless systems, a mobile device turns into an inexpensive but powerful device by which the user can be securely authenticated and digital signatures can be produced. As these features are absolutely necessary for mobile payment systems, PKI will also play an important role in the evolution of these systems.

CONCLUSION

In this article, the main concepts of m-payment were presented. The article gives a general overview of m-payment solutions, without going into too much technical detail but addresses technical issues. First, the mobile payment model was presented; the four participants were introduced. Then, we focused on the difference between chip-card based and

software-based client side banking applications. We analyzed them from the point of view of participants in the m-payment business.

KEY TERMS

Authentication: Proof of identity.

Digital Signature: An electronic signature based upon cryptographic methods of origin authentication. Usually it is appended to a message to assure the recipient of the authenticity and integrity of the message.

Mobile Payment: The process of two parties exchanging financial value using a mobile device in return for goods or services.

Mobile Transaction: Trusted transactions of a Mobile Payment system.

PKI: The abbreviation of Public Key Infrastructure, a set of policies, processes, server platforms, software, and workstations used to administer certificates and public-private key pairs, including the ability to issue, maintain, and revoke public key certificates.

Registration: A procedure where the account of the given services and the subscriber's identity are coupled.

RFID: Abbreviation of Radio Frequency Identification, a transponder technology for the contactless recognition of objects.

SAT (SIM Application Toolkit): A standard operational environment for applications stored on the SIM (and the third generation USIM).

SIM (Subscriber Identity Module): The subscriber dependent part of the mobile equipment.

Smart-Phone: Voice centric mobile phone with information capability.

Mobility-Aware Grid Computing

Konstantinos Katsaros
Athens University of Economics and Business, Greece

George C. Polyzos
Athens University of Economics and Business, Greece

INTRODUCTION

Grid computing has emerged as a paradigm for coordinated resource sharing and problem solving in dynamic, multi-institutional virtual organizations (Foster, 2001). A grid computing system is essentially a large-scale distributed system designed to aggregate resources from multiple sites, giving to users the opportunity to take advantage of enormous computational, storage, or bandwidth resources that would otherwise be impossible to attain. Current applications of grid computing focus on computational-expensive processing of large volumes of scientific data, for example, for earthquake simulation, signal processing, cancer research, and pattern search in DNA sequences.

At the same time, the recent advances in mobile and wireless communications have resulted in the availability of an enormous number of mobile computing devices such as laptop PCs and PDAs (personal digital assistants). Thus, it is natural to extend the idea of resource sharing to mobile and wireless computing environments. Resource-sharing collaboration between mobile users appears as a promising research direction toward the alleviation of the inherent resource constraints present in mobile computing environments. Either in the context of mobile ad hoc networks (MANETs) or in wireless networks based on fixed infrastructure (i.e., cellular networks, wireless local area networks (WLANs), small- or large-scale communities of mobile users can form mobile grid systems and collaborate in order to either achieve a common goal (otherwise impossible to achieve) or simply overcome their individual limitations. In the following, we highlight the fundamental issues toward the realization of a computational mobile grid system.

BACKGROUND

The research area of mobile grid is relatively new compared to the traditional (fixed) grid and mobile and wireless computing research areas. A consensus on the exact character of mobile grid computing has not been reached yet. Hence, a classification of the existing approaches is provided in the following, aiming at the clarification of the mobile grid concept. At the same time, the most significant research directions within each approach are described.

As mentioned earlier, a primary distinction is made between various research efforts in the area based on whether mobile devices act exclusively as resource consumers or as resource providers as well.

Mobile Devices as Resource Consumers

In this case, research is motivated by the fact that mobile devices are considered to have limited computational and/or storage capabilities (Banavar, Beck, Gluzberg, Munson, Sussman, & Zukowski, 2000; Migliardi, Maheswaran, Maniymaran, Card, & Azzedin, 2002; Park, Ko, & Kim, 2003; Srinivasan, 2005). The grid, in this case, can provide the resources missing in mobile devices on demand. The emerging problems here stem from the mobile and wireless character of the devices and include intermittent connectivity, device heterogeneity (in terms of hardware and operating system), and limited battery life. The use of proxies is proposed in Park et al., which act as gateways to the grid. These proxies undertake the role of the mediator between the mobile device and the grid system, and try to hide device heterogeneity and intermittent connectivity by acting on behalf of the mobile device.

Other approaches target the provision of a "smart" environment for pervasive computing (Banavar et al., 2000; Srinivasan, 2005). Here, mobile devices are considered as pure access devices with no need for enhanced processing and/or storage capabilities (Migliardi et al., 2002). The role of the grid is to provide all the functionalities required by users, pushing this way the complexity of the system to the network rather than to the edges.

Mobile Devices as Resource Providers

In this case, mobile devices participate in grid systems as resource providers as well (Kurkovsky & Bhagyavati, 2003; Li, Sun, & Ifeachor, 2005; Litke, Skoutas, & Varvarigou, 2005; Park et al., 2003; Phan, Huang, & Dulan, 2002). Strong emphasis is given to two important factors. First, even though mobile devices have limited resources compared to their

stationary counterparts, they seem to increasingly gain sufficiently powerful CPUs and storage means. In effect, they are considered capable of providing useful resources. Second, since the number of mobile devices continuously increases, their aggregate resources cannot be considered negligible (Phan et al.). Again, mobility and device heterogeneity pose significant challenges, especially due to the mobility of the resource providers. Moreover, an important problem rises here: Since mobile devices are strictly personal and at the same time resource constrained, it is not a given whether their resources will be offered by the device owners for the sake of collaboration or not.

In a second-level classification, two fundamentally different architectures have been proposed in an effort to exploit resources relying on mobile devices. Their difference concerns the underlying networking topology.

Mobile Grids on Site

In mobile grids on site (Katsaros & Polyzos, 2007a; Kurkovsky & Bhagyavati, 2003; Kurkovsky, Bhagyavati, & Ray, 2004; Park et al., 2003; Phan et al., 2002), mobile devices residing in a well-defined area, such as a cell in cellular networks or a WLAN hot spot, are coordinated by a central entity (residing at the access point or base station, BS) in order to perform a task (computational grid). The advantage of this approach is that the BS does not suffer from the constraints imposed by mobility. Therefore, it is considered suitable to act as a mediator capable of hiding the heterogeneity of the participating devices from the requesting node, coordinating the overall execution of the submitted job, and even allowing the grid system to appear to the rest of the network as an ordinary grid node (Phan et al.). What is more, these networking environments are characterized by the concentration of a large number of mobile nodes yielding a potentially large amount of aggregated resources, usually under a single administrative domain (Katsaros & Polyzos).

Mobile Ad Hoc Grids

In the case of mobile ad hoc grids (Gomes, Ziviani, Lima, & Endler, 2007; Li et al., 2005; Marinescu, Marinescu, Ji, & Boloni, 2003), there is no stationary entity responsible for the coordination of the overall job execution. In environments such as MANETs, the absence of fixed nodes imposes difficulties in resource discovery, job scheduling, and monitoring. The instability of the network topology induces further difficulties due to unique ad hoc characteristics such as network partitioning and multihop routing. An approach toward overcoming this limitation is the formation of a virtual backbone consisting of a number of possibly more powerful mobile nodes responsible for coordinating the mobile nodes residing in a certain area of the overall ad hoc network (Li et al.; Marinescu et al.).

TOWARD THE REALIZATION OF A MOBILE GRID

Collaboration and Contribution

As implied earlier, the very essence of a mobile grid system depends on the actual availability of the existing mobile resources. Given that mobile devices are in principle personal devices with limited resources, at least in comparison to stationary ones, a critical issue concerns the willingness of the mobile users to offer their resources, that is, the willingness to collaborate. Therefore, a crucial target for the realization of mobile grids is to ensure this willingness, and this is subject to the incentives given to the owners of the mobile devices.

In the simplest case, the incentives may be inherent in the community of the collaborating mobile users; that is, mobile users may collaborate in order to achieve a common goal. However, mobile nodes may participate in a community where no common goal exists. In this case, mobile nodes would possibly engage in a mobile grid system to overcome their individual limitations, but it is not straightforward why they would also provide their own resources as well. Hence, in environments where users are considered rational (or selfish), proper incentive schemes are required to motivate collaboration. A simple approach, borrowed from the context of peer-to-peer systems, is based on reciprocity; that is, mobile users may consume resources offered by other mobile users as long as they also provide their own resources (Katsaros & Polyzos, 2007a). Apparently, a balance between consumed and offered resources must be struck for each participant in order to eliminate free riding (see also the "Security Issues" section).

This balance is strongly influenced by the fact that the willingness for collaboration is directly affected by the actual amount of the resources that are required to be offered. Special care must be given in order not to drain the already limited resources of mobile nodes as this would inevitably discourage users from participating in the mobile grid. In effect, the power of a mobile grid system must come from the aggregation of small amounts of resources from multiple mobile devices at a time. Additionally, mobile-device owners must be given the flexibility to control the degree of actual contribution to the mobile grid with respect to several criteria, such as available power and current device workload.

Operation in a Mobile Environment

As discussed earlier, the main target of a mobile grid system is to exploit the large number of participating mobile nodes by harvesting relatively small amounts of resources at a time from each of them. In the case of a computational mobile grid, what is desired is to take advantage of the parallel character of task execution in multiple nodes. The scheduler of the system is responsible for the decomposition of a submitted job into smaller tasks, which are then assigned to each available mobile node and executed in parallel. However, in a wireless and mobile networking environment, noise and intermittent connectivity impose delay and other overheads on the communication between the scheduler and the mobile nodes.

In this context, a fundamental design decision is whether a task executed by a mobile node must be aborted upon disconnection in the sense that it will be rescheduled, that is, submitted to another mobile node, or whether it must be carried out by the mobile node until connectivity with the scheduler is reestablished and the results can be returned back. In the architectures presented in Kurkovsky and Bhagyavati (2003) and Kurkovsky et al. (2004), the first approach is followed in view of the latency incurred by a handoff (the process of transferring a connection, established between a mobile node and the core network, to another point of attachment, i.e., another base station or access point). Obviously, even though recent research efforts have shown that, in certain networking environments, this approach yields better results (Katsaros & Polyzos, 2007a), this issue requires further investigation as it is subject to the connectivity characteristics of the participating mobile nodes. The bandwidth, storage, computational, and energy resources spent for the execution of a task are obviously wasted if the assigned task is aborted upon disconnection. From a system designer's point of view, this may lead to the underutilization of the available resources. From a mobile user point of view, this fact will lead to user annoyance unless a proper accounting mechanism ensures that he or she will indeed receive the credits for the already offered resources.

It is stressed at this point that the aforementioned approaches do not constitute the primary means for addressing the problem of intermittent connectivity. Other techniques such as load balancing and task replication (Katsaros & Polyzos, 2007b; Litke, Skoutas, Tserpes, & Varvarigou, 2007) can be employed in order to smooth the effects of the unstable networking environment. Moreover, it is noted that the above approaches are not mutually exclusive in a mobile grid system. For example, building connectivity profiles for each mobile node may assist an intelligent scheduler in dynamically choosing between these approaches.

Security Issues

In the considered context, distributed job execution comes with potential risks both for the integrity of the application and the resource provider.

The integrity of a mobile grid application is heavily affected by potential malicious mobile-node behavior. First, the integrity of the processing results is compromised insomuch as a malicious mobile node attempts to deliberately alter the results, possibly in a goal-oriented way. Second, the free-riding problem may reduce the overall system utility. Furthermore, input and output data confidentiality may also be a requirement. Promising research directions for the confrontation of these risks include the use of code and data encryption techniques (Sander & Tschudin, 1998), the introduction of redundancy in the system, and the employment of proper incentive schemes and reputation mechanisms (Kamvar, Schlosser, & Garcia-Molina, 2003) in order to discourage free riders.

On the other hand, there are serious security considerations regarding possible attacks performed by the mobile code against the mobile node on which the code is executed. To name a few of the risks, malicious mobile code may destroy files and applications, divulge confidential information, perform actions on behalf of the device owner without his or her consent and knowledge, and so forth. Possible countermeasures include the authentication of the mobile code dispatcher, code verification, and access control. The access rights of the mobile code on the hosting mobile node can be limited to a secure set of functions (i.e., the sandbox approach, a tightly controlled environment for the safe execution of untrustworthy code and programs). For example, the Java Virtual Machine (JVM) verifies byte-code properties before execution and additionally performs checks at run time.

FUTURE TRENDS

As already established, mobile grid computing is a new and promising research area. Even though current trends seem somehow vague, a clearer view of the research perspectives is becoming apparent as research continues.

First, the resource constraints of mobile devices impose the need for research on suitable schemes that will foster participation in the mobile grid. Initial approaches on this issue include game theoretic investigations of pricing strategies (Ghosh, Roy, & Das, 2007) as well as incentive schemes that tie the consumption of resources to the contribution of resources (Katsaros & Polyzos, 2007a). The personal character of mobile devices, with respect to ownership and usage, also requires further investigation so as to attain the

unobstructed personal use of a mobile device that participates in a mobile grid as a resource provider.

Furthermore, current research efforts focus on the feasibility of the mobile grid paradigm in mobile ad hoc networks (Gomes et al., 2007; Lima, Gomes, Ziviani, Endler, Soares, & Schulze, 2005; Zottl, Gansterer, & Hlavacs, 2007). The focus is on resource discovery and scheduling issues. Resource discovery has been widely studied in the context of ad hoc networks under the term *service discovery* (the process of finding the provider of a certain type of service or resource in a computer network; Gao, Yang, Zhao, Cui, & Li, 2006); however, under the scheduling requirements introduced by the mobile grid concept, the problem cannot be considered solved. The problem here is to discover a group of mobile nodes, rather than a single service provider, satisfying the resource requirements of the mobile grid. The discovery process may significantly vary, subject to these requirements and the nature of the application. For instance, the target may be to discover the suitable resource providers that will yield an optimal division of a job into independent tasks, with respect, for example, to the achieved response time. In another case, the desired outcome may be a set of resource providers that can efficiently handle the execution of interdependent tasks. Things may get more complex if the heterogeneity in resource provider characteristics and capabilities is taken into account. A further complication is introduced in multihop networks by data-intensive applications since collaboration is implicitly assumed by intermediate nodes that forward the volume of data to the actual computing nodes. In such scenarios, the selection of resource providers involves the intermediate nodes as well. The interconnection between resource discovery and scheduling is becoming apparent. Scheduling has recently drawn the attention of researchers, not only in the context of MANETs but also in networks with fixed infrastructure (Ghosh et al., 2007; Katsaros & Polyzos, 2007a). The main target here is to devise adequate scheduling policies that will try to conceal intermittent connectivity and yield enhanced performance, taking into account significant constraints such as energy limitations and human factors (e.g., personal device usage).

CONCLUSION

The emergence of the mobile grid paradigm has been characterized by the variance of the incipient research approaches. In this article, we have examined the commonalities and the differences among these approaches in an effort to unravel the strands of this research area. From our point of view, the ubiquity of mobile resources urges the investigation of resource sharing schemes in mobile communities of users. Toward this direction, we have highlighted the fundamental issues and problems emerging from the coalescence of the grid and the mobile computing paradigms.

KEY TERMS

Accounting Mechanism: This is the process of recording (a summary of) the details of service consumption that usually follows successful authentication and authorization.

Free Riding: Free riding is a problem in P2P (peer-to-peer) systems, in which peers tend not to contribute resources in order to minimize their own costs while at the same time benefiting from the contributions of other peers.

Incentive Scheme: It is a mechanism used to provide the motive to the actors of a system for a certain behavior.

Load Balancing: Load balancing is the technique used to spread workload or resource consumption between many resource providers in order to improve resource utilization and/or performance.

Mobile Grid Computing: It is the computing paradigm for coordinated resource aggregation and sharing in which mobile computing devices act either as resource consumers or as resource providers or both.

Replication: Replication involves introducing redundant replicas of a resource in a system in order to improve reliability, performance, availability, and/or fault tolerance.

Reputation Mechanism: It is a mechanism used in P2P systems to associate the identities of peers with the opinions of other peers about the contribution of the former, and to acquaint the participating peers with this association. It is mostly used to discourage free riding.

A Model for Characterizing Web Engineering

Pankaj Kamthan
Concordia University, Canada

INTRODUCTION

The Internet, particularly the Web, has opened new vistas for many sectors of society, and over the last decade it has played an increasingly integral role in our daily activities of communication, information, and entertainment. This evidently has had an impact on how Web applications are perceived, developed, and managed.

The need to manage the size, complexity, and growth of Web applications has led to the discipline of Web engineering (Ginige & Murugesan, 2001). It is known (Kruchten, 2004) that conventional engineering practices cannot be simply mapped to software engineering without the engineer first understanding the nature of the software, and we contend the same applies to Web engineering. This article proposes a systematic approach to identify and elaborate the characteristics that make Web engineering a unique discipline, and considers the implications of these characteristics.

The rest of the article is organized as follows. We first outline the background and related work necessary for the discussion that follows, and state our position in that regard. This is followed by a model to uniquely posit the nature of Web applications based on the dimensions of project, people, process, product, and resources. Next, challenges and directions for future research are outlined. Finally, concluding remarks are given.

BACKGROUND

The notion of a Web application has evolved from its origins in the mid 1990s. For the sake of this article, by a Web application we will mean a Web site that behaves more like an interactive software system specific to a domain (such as health, entertainment, commerce, and so on) rather than a catalog. If the recent predictions (Jazayeri, 2007) are correct, then it is likely that the crosspollination of software engineering and Web applications will continue to flourish.

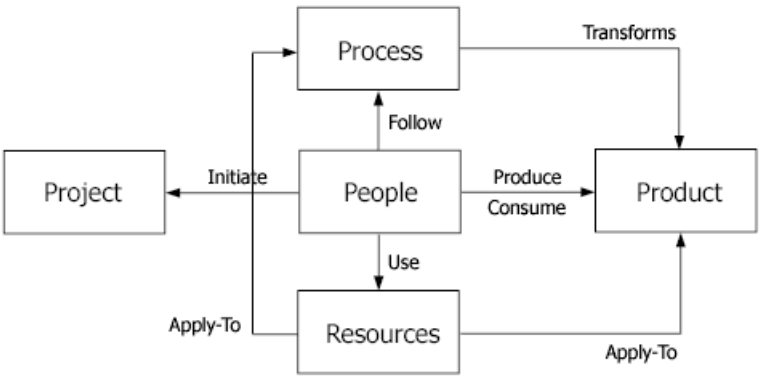
There has been some previous work that presents unique aspects of Web engineering, which we now discuss chronologically. It has been highlighted that Web applications differ from traditional software due to their focus on publishing, strong emphasis on quality attributes such as usability, and shorter initial delivery cycles (Overmyer, 2000). It has also been pointed out that the development of Web applications involves several social and technical disciplines and different sets of skills compared to conventional software development (Ginige & Murugesan, 2001), but stakeholders have not been considered as possessing one of the viewpoints. A model for the characterization of Web applications has been presented (Lowe, 2002), but details of individual characteristics are not given. It has also been noted that Web applications vary in many ways from traditional software including in the uncertainty of the domain, often shorter time to market, and rapid changes in technologies (Lowe, 2003; Ziemer & Stålhane, 2004); however, the arguments are often based on perception than technical reality. It has been pointed out that different types of Web applications vary along the lines of their nature, form, purpose, and development (Selmi, Kraïem, & Ghézala, 2005). An overview of the client-side properties of Web applications related to usability has been presented, and based on it, a more precise usability model has been derived (Bruno, Tam, & Thom, 2005). The variations between software engineering and Web engineering have been pointed out (Mendes & Mosley, 2006); however, the criteria focus on the development and underlying technologies rather than the stakeholders. Finally, the differences between Web applications and traditional software mentioned above have been recently amassed in a survey (Al-Salema & Samahab, 2007).

A MODEL FOR THE CHARACTERIZATION OF THE UNIQUE NATURE OF WEB ENGINEERING

In this section, we propose a model labeled henceforth as 4P+R for a characterization of the unique nature of Web engineering. The model, along with its high-level nonmutually exclusive elements, namely people, project, process, product, and resources, is illustrated in Figure 1.

The 4P+R model for Web engineering could be applied in a few different contexts. First, it could serve as a starting point for a reference model for Web engineering. Second, the existence of a body of knowledge is a sign of maturity of a discipline, and the 4P+R model could contribute to (and, once established, benefit from) the Web engineering body of knowledge (WEBOK), as is the case with the software engineering body of knowledge (SWEBOK) and the project management body of knowledge (PMBOK). Third, the 4P+R model could also be used as a basis for Web engineering pedagogy. In particular, it could be useful for deciding the

Figure 1. A high-level view of the elements of the 4P+R model of Web engineering



prerequisites and the selection of topics for an intensive course on Web engineering.

We do not claim that the 4P+R model is static or complete. Indeed, the model is subject to evolution along with the discipline of Web engineering and, indeed, the Web itself. We next discuss the elements of the 4P+R model in detail.

People Viewpoint

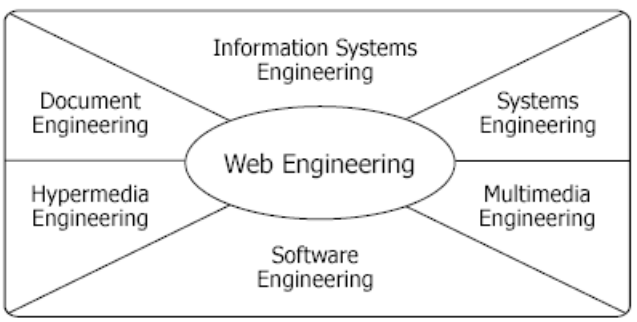
A stakeholder is a person or organization who influences a Web application or who is impacted by that Web application. In this section, we take the people view of a Web application and consider the challenges facing the stakeholders.

There are systematic approaches for the identification and refinement of stakeholder classes (Sharp, Galal, & Finkelstein, 1999). We identify two broad classes of stakeholders with respect to their roles in relation to a Web application, namely, a producer and a consumer. (There are other possible stakeholder classes such as legislators, but their characteristics are not unique to Web applications.) The mapping between stakeholders and roles is many to many. For a successful realization of the contract between producer and a consumer, the technical as well as the social differences between the development of traditional software and of Web applications need to be acknowledged and acted upon.

Producer

A producer (provider, project manager, marketing manager, engineer, media producer, graphic designer, or maintainer) is a person who owns, finances, develops, deploys, operates, or maintains the Web application. As shown in Figure 2, the desirable knowledge and skills (Kamthan, 2007) demanded of a producer go beyond what is part of the conventional training of a typical software engineer. Unfortunately, courses related to the Web offered at universities and training

Figure 2. The universe of engineering disciplines on which Web engineering draws upon



schools often tend to focus primarily on the manipulations of the moving target and popular client- and/or server-side technologies of the day rather than on the value added to the organization producing the Web application, human-oriented aspects of the Web application, or the fundamentals of analysis and design.

The scope in which a producer functions is limited by several factors, which often present unique challenges with respect to controllability and the domain of responsibility. Although the issues related to the network or domain name service are crucial, they are often not within the direct control and purview of an engineer. Furthermore, the use of hypermedia is at the heart of a Web application that strives for connection to the external information universe. However, a producer essentially also does not have any explicit control over the external resources pointed to by any (unidirectional) hyperlinks in the Web application. An engineer may perform timely checks but is not directly responsible for the integrity of external hyperlinks or for the content of the resources they point to (which can change without any notification). Unlike a desktop application, a producer essentially has little or no control over the consumer's environment: no explicit control over the end-user device or the user agent deployed by a user for accessing a Web application, and apart from some rudimentary data on the client side (such as the knowledge of the device, operating system, and user agent), little knowledge of the user preferences, particularly on a first-time use. An engineer is responsible for the information user interface of a Web application (Figure 3) but not for the user agent's user interface even though the rendering of the former (responsibility of the producer) intimately depends on the capabilities of the latter (external to the realm of responsibility of the producer).

Consumer

A consumer (novice or expert user) is a person who interacts with a Web application for some purpose. Aside from certain locale-specific legal restrictions, virtually any person of any age, of any cultural group, of any educational background, and so on could be a consumer of a Web application. This, at least in principle, creates a rather large consumer base for the producer of a Web application to contend with.

A consumer has absolute control over the choice of client-side computing environment, from its procurement to operation. However, a consumer has little or no control over the context in which a Web application operates or the availability of a Web application. For example, a Web application could be installed, upgraded, or even removed without prior notification.

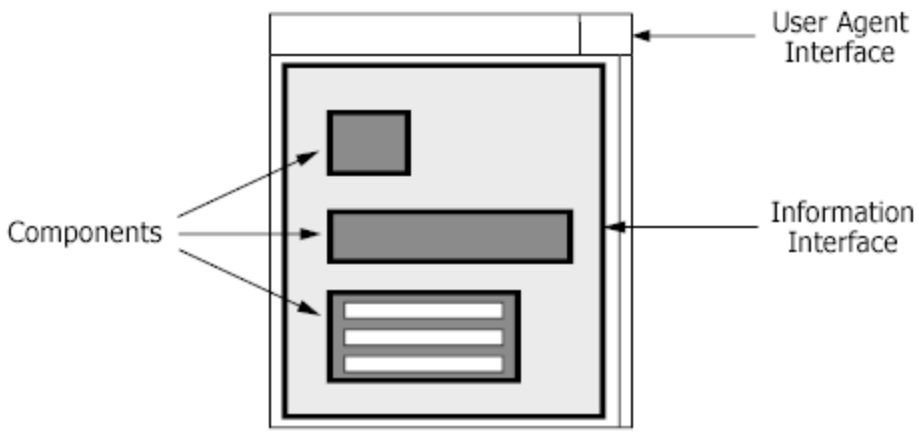
Project Viewpoint

In this section, we take the project view of a Web application. Based on that view, we consider the issues of legality and cost that are central to project management.

Legality

The stakeholders of a Web application and the Web application itself need not be colocated. For instance, they may be geographically located anywhere in the world: in different jurisdictions in the same country or in different countries. So, the laws that govern the producer and the consumer of that Web application may be different. This has direct implications toward the producers and consumers of commercial Web applications.

Figure 3. The user interface of a Web application explicitly depends on the capabilities of the user agent



Cost

The cost of production and delivery may be entailed with any type of software, including Web applications. However, there are differences between how cost and effort of conventional software and Web applications are estimated (Reifer, 2000). The equation has somewhat changed with the ascent of open-source software (OSS) and their widespread deployment in Web applications.

A Web application itself is never really purchased and owned by a consumer. However, there are three dimensions of cost for a consumer of a Web application: (a) connectivity to the Internet, (b), installation and use of client-side software to access the Web application, and (c) access to the Web application itself. Although many of the publicly available Web applications allow free-of-cost access, there are Web portals that charge for initial registration.

Process Viewpoint

In this section, we take the process view of a Web application and consider the issues underlying analysis and synthesis. The selection of a suitable development process for Web applications needs to consider several factors masquerading as potential risks, of which domain understanding and evolvability are critical.

Domain Understanding

A unique aspect of the Web is that it is open to any domain, and for some of these domains, interactive networked applications may never have been built before. The engineers have to deal with domains of which they do not have complete knowledge, and cannot elicit and specify all requirements at the inception of the project.

Evolvability

The frequent changes in the technological environment and their corresponding support in client-side devices and user agents can impact the requirements elicitation process.

Typically, a Web application, particularly if it provides time-sensitive information, requires frequent maintenance. At the same time, unlike most desktop applications, a Web application may have a predetermined, fixed life time known at the outset: Examples include Web applications for events such as a conference, the Olympics, or a music concert. This makes maintenance an integral, high-priority phase in the life cycle of a Web Application.

At the core of above-mentioned risks is unpredictability. Therefore, instead of developing the entire Web application in one cycle, it is preferable to build it iteratively and incrementally based on feedback from the customers and users. In particular, before moving on to implementation, frequent bidirectional exchange between requirements and design may be expected (Lowe, 2003; Zowghi & Gervsasi, 2001).

In recent years, agile methodologies (Highsmith, 2002) have emerged to mitigate risks by being human-centric (accommodating customers and users) and by introducing flexibility in the development processes. According to surveys (Khan & Balbo, 2005), agile methodologies have been successfully applied to Web applications. However, most agile methodologies are weak in their adoption of preventative approaches toward the improvement of the quality of a Web application.

Product Viewpoint

In this section, we take the product view of a Web application. Based on that view, we consider the issues of delivery, heterogeneity, and quality.

Delivery

The delivery context of a Web application is different from the stand-alone (desktop) software environment in many ways. Web applications are only delivered on request, in part, and one resource at a time, identified by a uniform resource locator (URL); they are not acquired and installed in entirety like desktop software.

Heterogeneity

A rich Web application has the ability to present information in a heterogeneous manner that includes text, mathematical symbols, graphics, audio, and video. For example, apart from its native information, a Web application may need to include advertisements from external sources. Indeed, markup languages based on the extensible markup language (XML) provide the capability to Web applications of being both document and data oriented.

The architecture of a Web application, by necessity, will require two or more subsystems to operate in a client-server environment, namely, a Web user agent (browser) and a Web server. Moreover, there may be other (not necessarily colocated or under the same ownership) subsystems such as an application server, multimedia server, or a database server. The quality of these subsystems will naturally impact the overall context in which a Web application operates.

Quality

There are different views of quality (Wong, 2006). From the ISO/IEC 9126-1:2001 standard, we define the quality of a

Web application to be the totality of characteristics that bear on its ability to satisfy stated and implied needs.

Although quality is a classical issue for most computer systems, there are unique quality-related concerns in the decentralized, heterogeneous networked environment of the Web. In particular, concerns related to certain quality attributes, including accessibility, interoperability, privacy, reliability, security, and usability are amplified in the context of a Web application. Indeed, low reliability, poor usability, and laxness in security have been identified as major causes of failures in Web applications (Pertet & Narasimhan, 2005). Also, managing the dichotomy of provision for personalization in the light of respecting privacy remains a major concern to many users (Paine, Reips, Stieger, Joinson, & Buchanan, 2007), where the benefits of respecting one can adversely affect the other. The conventional quality models such as the ISO 8402:1994 standard and the ISO/IEC 9126-1:2001 standard do not take into account all the aforementioned quality attributes and therefore are not sufficient for Web applications in their current form.

Resources Viewpoint

In this section, we take the resource view of a Web application. Based on that view, we consider the unique aspects that entail from it, particularly those related to reuse.

Every application will utilize resources during production and upon delivery. The resources during the production of a Web application could consist of expert entities of knowledge (principles, guidelines, and patterns), tools, and techniques. They are not fundamentally different from that of other applications except that some of them have yet to stabilize and mature.

Reuse

The distributed environment of the Web leads to a plethora of opportunities as well as to legal challenges associated with information reuse. For instance, the same database system could be used by multiple Web applications, and conversely, a single Web application could utilize multiple database systems. Although the request for a resource may have been made to a single specific address, not all or any parts of that resource that are delivered may originate from the same address.

Indeed, some of the parts of the resource may be hosted on external servers whose bandwidth is used without request. For example, this is possible via various forms of transclusion, such as framing (including and presenting information from external sources in a multiwindow document without permission from the original authors and without explicit knowledge of the users) or inlining images (including images from external sources without permission of the original authors).

FUTURE TRENDS

In this section, we consider two directions of evolution of the Web, namely, the Semantic Web and Web 2.0, and briefly outline their implications for the 4P+R model for Web engineering.

The Semantic Web has recently emerged as an extension of the current Web that adds technological infrastructure for better knowledge representation, interpretation, and reasoning (Hendler, Lassila, & Berners-Lee, 2001). Although there have been many advances toward enabling the technical infrastructure of the Semantic Web in recent years, there is much to be done in addressing the social issues (Lassila & Hendler, 2007). In particular, the cost-benefit ratio in the production of large domain-specific ontologies, the performance of these ontologies over the network, and the usability of query formulations on devices with restricted capabilities present but a few unique challenges (Kamthan & Pai, 2006) for a broad acceptance of Semantic Web applications.

The pseudonym Web 2.0 (O'Reilly, 2005) has been used to describe the apparent humanization and even socialization of the Web as it moves toward becoming a means of participation and collaboration. Indeed, applications like del.icio.us, Flickr, MySpace, Wikipedia, and YouTube are but a few examples of this phenomenon where a consumer becomes a coproducer in a social network. This has blurred the lines between the roles and responsibilities of a producer and a consumer with respect to the corrective and perfective maintenance of a Web application. It has also raised issues of legality and security and, in general, of the credibility of Web applications (Kamthan, 2007) not previously encountered. For example, the potential for the distribution of inaccurate medical information from unqualified sources has particularly had an acute impact on the user perception of health-related Web applications.

CONCLUSION

A Web application aims to provide some value to a stakeholder and it is the goal of Web engineering to help realize that. Although there have been many advances toward enabling the technological infrastructure of the Web in the past decade, there is much to be done in addressing the social challenges.

In conclusion, for a coherent evolution of the discipline of Web engineering, its unique nature needs to be approached systematically. To address that, we need to consider Web engineering from different, time-invariant viewpoints. The 4P+R model presents one direction in furthering the understanding of Web engineering. Although the model is subject to evolution, we believe that a suitable management of stakeholder dynamics as it manifests on both the client

and the server side will continue to play a crucial role in the model.

KEY TERMS

Agile Development: It is a philosophy that embraces uncertainty, encourages team communication, values customer satisfaction, vies for early delivery, and promotes sustainable development.

Delivery Context: It is a set of attributes that characterizes the capabilities of the access mechanism, the preferences of the user, and other aspects of the context into which a resource is to be delivered.

Personalization: It is a strategy enabling delivery that is customized to the user and the user's environment.

Quality: It refers to the totality of features and characteristics of a product or a service (such as a Web application) that bear on its ability to satisfy stated or implied needs.

Stakeholder: It is a person or organization who influences a Web application or who is impacted by that Web application.

Web Application: It is an application specific to a domain Web site that behaves more like an interactive software system. In general it will require programmatic ability on the server side and may integrate or deploy additional software (such as application servers, media servers, or database servers) for some purpose (such as dynamic delivery of resources).

Web Engineering: It is a discipline concerned with the establishment and use of sound scientific, engineering, and management principles, and disciplined and systematic approaches to the successful development, deployment, and maintenance of high-quality Web applications.

Modeling ERP Academic Deployment via Adaptive Structuration Theory

Harold W. Webb
The University of Tampa, USA

Cynthia LeRouge
Saint Louis University, USA

INTRODUCTION

Academic/industry collaboration can change learning processes and improve outcomes by integrating resources and creating opportunities not otherwise attainable (Wohlin & Regnell, 1999). However, each institution's culture and organizational objectives influence the collaborative relationships developed as advanced information technologies (e.g., computer aided software engineering tools, enterprise resource planning [ERP] systems, and database tools) are adopted. The challenge is to facilitate mutual understanding and acknowledge distinctions in addressing each organization's goals. The aim of these relationships is the appropriation of ERPs in a manner that enriches educational experiences, while providing industry benefit.

There are many quandaries associated with this phenomenon. How does the deployment of ERPs facilitate educational processes? To what degree should these resources be utilized? What tools and methods should be used? What is the role of the ERP vendor? Can academic independence be maintained?

Without a framework to identify relevant variables, it is daunting to begin to assess the impact of varying degrees of adoption, identify effective processes of deployment, and move toward assessing costs and benefits. Though some frameworks address academic/industry collaboration (Mead et al., 1999), few have considered the implications of ERPs on the evolution of inter-institutional collaborative relationships. This exposition augments a framework for understanding the forces at work when integrating ERPs into educational settings (LeRouge & Webb, 2002, 2005).

We begin our discussion by reviewing adaptive structuration theory (DeSanctis & Poole, 1994) as the foundation for the academic/industry ERP collaboration framework (LeRouge & Webb, 2002). We discuss academic/industry collaboration constructs and their relationships within the context of ERP systems and then integrate examples, findings, and issues from recent research.

USING AST TO MODEL ERP DEPLOYMENT IN THE ACADEMY

Adaptive structuration theory (AST), an extension of structuration theory (Giddens, 1982), has been used as a framework to study organizational change processes during advanced information technology adoption (Poole & DeSanctis, 1992). Adaptive structuration takes a socio-technical perspective. Human actors and organizational context are introduced within this perspective as moderators of technology impact. The adoption of an advanced technology, therefore, is a process of organizational change resulting from the mutual influence of the technology and social processes.

The premise at hand is that in academic settings, human actors and organizational context collectively moderate the processes by which ERPs are appropriated. Such dynamic processes affect not only institutional and industry outcomes resulting from the appropriation, but also the evolution of the relationship between industry and academia. The number of academic institutions adopting ERPs is increasing (Rosemann & Maurizio, 2005). However, use is not a perfect proxy for effectiveness, as ERPs serve some institutions better than others (Antonucci, Corbitt, Stewart, & Harris, 2004).

ERP system adoption within the context of colleges of business is of interest and has considerable impact for a number of reasons: market demand, level of commitment required, interdisciplinary functionality, and level of system sophistication. To provide insight, we reintroduce our AST-based model for organizing constructs and relationships for this phenomenon (see Figure 1). We augment this model and understanding by providing recent research examples, findings, and issues related to construct attributes (provided in Tables 1 through 9).

Advanced Information Technology Structure

Two ways to describe contributing social structures offered by advanced information technologies are "structural features," referring to the types of rules and resources embedded in the system, and "spirit," the intended purpose and utilization of

Table 1. Advanced information technology (ERP) structure and spirit attributes associated with ERP curriculum

Attributes (LeRouge & Webb, 2002)	Examples, Findings, and Issues Related to Construct
♦ *Structural features*—(Restrictiveness and Comprehensiveness) ♦ Capturing Spirit	EXAMPLES • *Capturing spirit*: Create learning modules focused on decision-making using data-rich business processes in an ERP environment—not software features (Strong, Johnson, & Mistry, 2004) • *Working within structure*: Students run a range of ERP functions in complex multi-semester business simulations (Draijer & Schenk, 2004) FINDINGS • *Working within structure*: Ensure students understand the business environment and avoid the "not seeing the forest for the trees" problem (Fedorowicz, Gelinas, Usaff, & Hachey, 2004) • *Capturing spirit*: Student background in understanding underlying business processes is critical to ERP classroom success (Rosemann & Maurizio, 2005) ISSUES • *Structural Features*: Complexity of ERP subject matter is a challenge (Rosemann & Maurizio, 2005) • *Capturing Spirit*: Recognizing there is a curriculum gap in engineering-based information technology programs—a failure to emphasize business processes (Peslak, 2005)

the system (DeSanctis & Poole, 1994). Regarding structural features, an ERP is a comprehensive database structured to support diverse organizational processes through a large number of application modules. Each module is geared toward a functional or industry-specific process. ERP systems challenge colleges with a level of cross-discipline sophistication and flexible feature sets that require substantial training.

The spirit of ERP systems can be described as the intention to process operational level transactions, support multi-level decisions, and aid strategic management of major corporations. The goals of ERP use in colleges of business are primarily educational and exploratory in nature and often focus on discipline-specific subsystems rather than cross-discipline business processes. With respect to technology spirit, the potential exists for a gap in appropriation between business use and academic use of ERP systems. This gap in system goals and values may have implications for academic/industry collaboration unless innovative cross-discipline approaches are taken as shown in Table 1.

External Environmental Structure

The demand for graduates to work with ERP systems is strong and acts as an external structuring force (Rosemann & Maurizio, 2005). Other external sources of influence are detailed curriculum guides for computer science (Lidtke & Stokes, 1999) and information systems (Gorgone & Gray, 2000). Table 2 highlights critical success factors and issues related to external structure.

Technology Infrastructure

Technology infrastructure is a major cost consideration for academic adoption of ERP systems (Becerra-Fernandez, Murphy, & Simon, 2000; Watson & Schneider, 1999). These systems typically cannot be deployed or maintained without considerable support. Industry may facilitate appropriation through donated services; however, colleges face additional costs. Table 3 lists collaborative relationships such as SAP's University Competence Center (UCC) hosting program, which is becoming a critical success factor for academic adoption (Rosemann & Maurizio, 2005).

Educational Organization Structure

The philosophies of appropriating ERP systems among educational entities vary widely. The overall philosophic quandary involves balancing conceptual technology education and the development of technology-specific skills. Table 4 identifies a number of critical success factors affecting educational organization structure.

Education Process

Structuration has at its core motivated and practical actions. Rules and resources embodied in social institutions are appropriated by participants and enter into the production and reproduction of a social system (Poole & DeSantis, 1992). Academic/industry collaborative interaction is embodied in the appropriation of the ERP into the educational process. Educators determine the curriculum strategy and the degree of appropriation for ERP systems. While the degree of appropriation has been addressed by academic institutions in a variety of ways ranging from inclusion of exemplary material within courses to new course creation to establishing new degree programs, issues related to the educational process remain (Table 5).

Table 2. External environmental structure attributes associated with ERP curriculum

Attributes (LeRouge & Webb, 2002)	**Examples, Findings, and Issues Related to Construct**
♦ Accreditation standards & curriculum studies ♦ Technology vendor market position ♦ Industry standards & technology trends ♦ Technology market competition & end user demands ♦ Technology-enabled labor supply ♦ Student interest (added 2006)	FINDINGS • *Technology-enabled labor supply*: Favorable job prospects is a top five learning critical success factor (CSF) (Rosemann & Maurizio, 2005) • *Student interest*: High student interest is a top five teaching CSF (Rosemann & Maurizio, 2005) • *Industry standards and technology trends*: Positive industry reaction to ERP specific knowledge (Rosemann & Maurizio, 2005) • *Accreditation standards and curriculum studies*: Emergence of ERP education centered conferences (Fedorowicz et al., 2004) ISSUES • *Accreditation standards and curriculum studies*: Lack of an established body of academic texts (Fedorowicz et al., 2004) • *Industry standards & technology trends*: Adaptation of vendor provided training material and courses require university resources including faculty time and travel (Fedorowicz et al., 2004)

Table 3. Technology infrastructure attributes associated with ERP curriculum

Attributes (LeRouge & Webb, 2002)	**Examples, Findings, and Issues Related to Construct**
♦ Software & hardware ♦ Internal maintenance & software support ♦ Database creation and maintenance ♦ Computer lab facility & student remote access ♦ Industry monetary donation or grants to support technology infrastructure ♦ Industry donation of ERP technician expert time (added 2006)	EXAMPLES • *Database creation and maintenance*: o SAP UCC hosting center with test and operational ERP instances for simulation development and testing (Draijer & Schenk, 2004). o Hosted solutions are increasing in popularity (Rosemann & Maurizio, 2005) o Hosting recommended to outsource non-competencies (Fedorowicz et al., 2004) FINDINGS • *Internal maintenance and software support*: Faculty support is a top five teaching CSF (Rosemann & Maurizio, 2005) • *Computer lab facility & student remote access*: Resourcing the technical infrastructure is one of the top four critical challenges (Strong et al., 2004) • *Internal maintenance and software support*: Systems support is a top five teaching CSF (Rosemann & Maurizio, 2005) • *Industry donation of ERP expert time*: Maintain technical support relationships with ERP experts (Fedorowicz et al., 2004)

Appropriation and Delivery Structure

The appropriation structure leads to instructional design choices. ERP systems are adaptable to many models of learning. The model of learning chosen may affect the instructor's approach and utilization of these tools. Conceptual presentation and demonstration may adequately support knowledge-level learning objectives, while experiential learning models may better support higher-order learning objectives (Leidner & Jarvenpaa, 1995). The application of appropriate learning models remains a challenge (see Table 6).

Emergent Forms of Educational Method

One emergent educational method is the use of problem-based learning. In one situation, graduate students work with industry partners to design ERP solutions for a business problem. Completed solutions are used as the basis of teaching cases to support undergraduate courses (Stewart & Rosemann, 2001). Table 7 highlights other innovative approaches and outstanding issues.

Joint Outcomes

The purpose of ERP appropriation and academic/industry collaboration is to achieve mutually beneficial joint outcomes (Stewart & Rosemann, 2001). The desired joint outcomes may include facilitating the educational mission, gaining competitive advantage, accessing educational resources, enhancing reputation, increasing revenue, and providing a staffing source (Mead et al., 1999). The academic institution, industry, or both may desire these goals. However, joint

Table 4. Educational organization structure attributes associated with ERP curriculum

Attributes (LeRouge & Webb, 2002)	**Examples, Findings, and Issues Related to Construct**
♦ Departmental structure ♦ Major program requirements ♦ Course objectives ♦ Instructor preferences ♦ Interdisciplinary cooperation (added 2006)	EXAMPLES • *Interdisciplinary cooperation*: Process-oriented ERP business simulations integrating multiple disciplines across academic department lines (Draijer & Schenk, 2004) • *Major program requirements*: Enterprise decision-making modules in integrated curricula (Strong et al., 2004) FINDINGS • *Instructor preferences*: Lecturer training is a top five teaching CSF (Rosemann & Maurizio, 2005) • *Departmental structure*: o Strong academic leadership and support is one of four critical challenges (Strong et al., 2004) o Need to share successful teaching materials among faculty (Fedorowicz et al., 2004) • *Interdisciplinary cooperation*: Faculty motivation and commitment is one of four critical challenges to cross-discipline faculty collaboration (Strong et al., 2004)

Table 5. Education process attributes associated with ERP curriculum

Attributes (LeRouge & Webb, 2002)	**Examples, Findings, and Issues Related to Construct**
♦ Learning models (collaborative learning, hands-on experience, simulations, conceptual presentations, programmed instruction, real-world exposure, case studies) ♦ Supporting technologies and resources (textbooks on technology, presentation tools, asynchronous communication tools, synchronous communication tools, computer-based training modules)	FINDINGS • *Supporting technologies and resources*: o Course material is a top five teaching and learning CSF (Rosemann & Maurizio, 2005) o Provide much support to students working on ERP assignments: face-to-face, e-mail, discussion lists, and online FAQ (Fedorowicz et al., 2004) • *Learning models*: o Learning approach is a top five learning CSF (Rosemann & Maurizio, 2005) o Mix of models: introductory hands-on exercises, routine uses of ERP in business operations via simulation, project development to implement changes in the ERP simulation environment (Draijer & Schenk, 2004) o Configuration matrices are suggested as a mechanism to specify how learning objectives are to be achieved in a specific learning context (LeRouge & Webb, 2004) ISSUES • *Learning models*: Most course modules are not in depth and do not cover specialized ERP capabilities (Rosemann & Maurizio, 2005) • *Supporting technologies and resources*: Vendor training materials are often outdated, too "hands-on," and lacking conceptual foundation (Rosemann & Maurizio, 2005)

Table 6. Appropriation and delivery structure attributes associated with ERP curriculum

Attributes (LeRouge & Webb, 2002)	**Examples, Findings, and Issues Related to Construct**
♦ Appropriation moves (direct use, relate to other structures, interpretation of structures, or judgment of features) ♦ Faithfulness ♦ Instrumental uses ♦ Attitude	FINDINGS • *Faithfulness*: Practical application is a top five learning CSF (Rosemann & Maurizio, 2005) • *Appropriation moves*: o Ability to change organizational structures during simulations to accommodate new technology and emerging theory is a strength (Draijer & Schenk, 2004) o By integrating the concerns-based adoption model from the field of education with AST, patterns of appropriation for a given instance can be measured that may impact outcomes, and be affected by a given profile that describes the state of AST structure constructs (LeRouge & Webb, 2004) ISSUES • *Instrumental uses*: Confounding technical implementation expertise with user expertise is one of the top four critical challenges. ERP should be used to link functional area concepts, and processes (Strong et al., 2004)

Table 7. Emergent forms of educational method attributes associated with ERP curriculum

Attributes (LeRouge & Webb, 2002)	Examples, Findings, and Issues Related to Construct
♦ Educators enrolling in corporate training programs ♦ Project/task specific internships ♦ Industry experts participating in classroom presentation ♦ Students/educators participating in ERP specific list serves ♦ Credit and/or increased access to technology training programs for students ♦ Industry development of targeted educational tools, databases, and exercises ♦ Phased learning (added 2006)	EXAMPLES • *Phased learning*: o Step-wise progression of roles of students introduced into increasingly complex set of interrelated business simulations (Draijer & Schenk, 2004) o Use of SDLC concept with multiple interactive exercises (case analysis, ERP failure presentation, and hands-on) (Grenci & Hull, 2004). • *Industry experts participating in classroom presentation*: o Include industry professionals integrated into curriculum as guest speakers (Fedorowicz et al., 2004) o Industry professionals as system consultants (Rosemann & Maurizio, 2005) FINDINGS • *General issue*: Integrating enterprise systems alters both course content and pedagogy (Fedorowicz et al., 2004) ISSUES • *Educators enrolling in corporate training programs*: Vendor ERP-specific training not directly transferable to university classes—more how to than why (Fedorowicz et al., 2004) • *Industry development of targeting educational tools*: Faculty must be willing to ask for help in adapting ERP materials (Fedorowicz et al., 2004)

Table 8. Joint outcomes attributes associated with ERP

Attributes (LeRouge & Webb, 2002)	Examples, Findings, and Issues Related to Construct
♦ Student learning/education in technology arena ♦ Increased work pool & employable students ♦ ERP market exposure ♦ Contribution to industrial research and development effort & academic research ♦ Continued/enhanced program attractiveness	EXAMPLES • *Increased work pool & employable students*: Favorable industry response—hiring students from a more sophisticated labor pool (Rosemann & Maurizio, 2005) • *Student learning/education in technology arena*: Students report learning system complexity while experiencing latest software (Draijer & Schenk, 2004) FINDINGS • *Student learning/education in technology arena*: Proposed ERP maturity model with metrics for assigning maturity level and maturity focus to a given curriculum (Antonucci et al., 2004) • *Continued/enhanced program attractiveness*: Outcomes generate feedback loops that sustain appropriation patterns or lead to adaptive change in level of use, structural variables, or both (LeRouge & Webb, 2004) ISSUES • *Continued/enhanced program attractiveness*: Recognition that some ERP implementations are foundering while others flourish (Antonucci et al., 2004) • *Student learning/education in technology arena*: Must manage both faculty and student expectations (Fedorowicz et al., 2004) • *Increased work pool & employable students*: Competitive advantage for colleges of business (Draijer & Schenk, 2004) • *Student learning/education in technology arena*: Metrics needed to evaluate effectiveness (Al-Mashari, 2003)

outcomes from academic appropriation are not guaranteed (see Table 8).

Structure of Academic/ Industry Collaboration

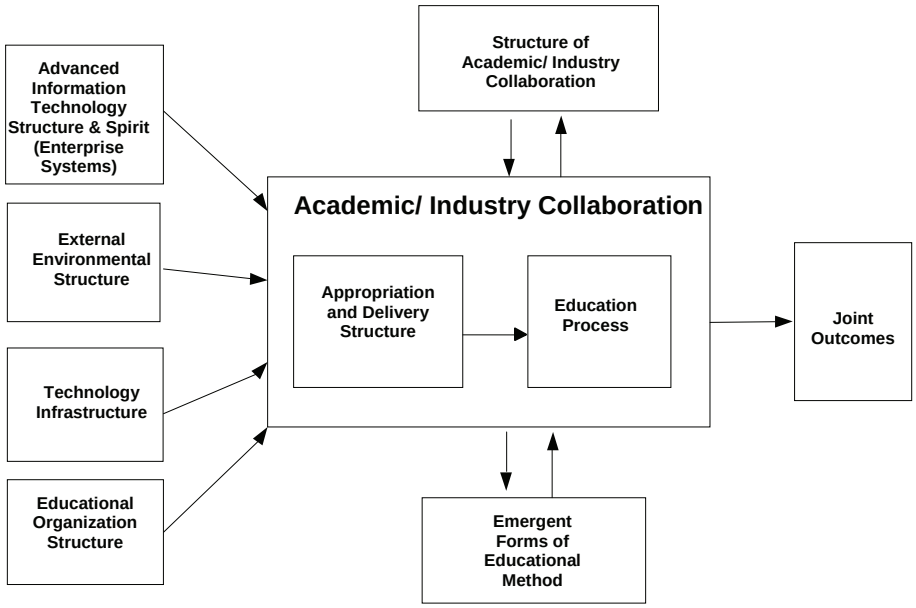
The collaborative system is not a recognized organization, but a structured social practice of interdependence that has broad spatial and temporal extension (Giddens, 1982). The existence of ERP alliance programs may be considered a representation of social practices affecting the relationship created between industry and academia. Representations of the implied social practice may be found in industry alliance program agreements and curriculum guides encouraging industry participation and the study of ERP system concepts (Gorgone & Gray, 2000; Lidtke & Stokes, 1999).

Practices suggested for a successful collaboration (Powell, Diaz-Herrera, & Turner, 1997) include centralized coordination, right mix of knowledge and experience, cooperative planning, curriculum flexibility, communica-

Table 9. Structure of academic/industry collaboration attributes associated with ERP curriculum

Attributes ***(LeRouge & Webb, 2002)***	**Examples, Findings, and Issues Related to Construct**
♦ Rules (*industry participation in curriculum development studies; inclusion of ERP in curriculum development research; academic participation in industry development; educator participation in corporate training programs)* ♦ Resources (*technology alliance programs; opportunities for field research*)	EXAMPLES • *Resources*: o SAP UCC program (Draijer & Schenk, 2004) o Academic alliances: SAP, Oracle, Microsoft • *Rules*: o Collaboration with multiple universities on an international level to develop advanced courses (Draijer & Schenk, 2004) o Collaborative curriculum development teams across institutions (Al-Mashari, 2003; Stewart & Rosemann, 2001) • ISSUES • *Resources*: Academic alliance membership is becoming increasingly difficult (Rosemann & Maurizio, 2005) • *Rules*: Most universities do not collaborate with other institutions (70%) but are interested in doing so (76%) (Rosemann & Maurizio, 2005)

Figure 1. Adaptive Structuration Theory Applied to Industry/Academic Collaborations adapted from DeSanctis and Poole (1994) (LeRouge & Webb, 2002)



tion, and objectivity. Mead et al. (2000) argue for the need to establish metrics to monitor and modify collaborative processes. Table 9 highlights trends in academic-industry collaboration structures.

FUTURE TRENDS

The appropriation of ERPs in colleges of business is a modern phenomenon that aspires to bridge the industry-academic gap while fulfilling educational goals. From a practical perspective, industry and students often desire opportune practical training and education from academic institutions (Stewart & Rosemann, 2001). However, the costs of appropriation may be high and the impact of appropriation on educational processes and collaborative relationships may be either positive or negative (Antonucci et al., 2004). Stakeholders should recognize the potential influence of structure and social context on desired outcomes when embarking on the process of academic/industry collaboration. ERP appropriation and associated collaboration decisions may affect the educational foundation and career prospects of the technological work force (Rosemann & Maurizio, 2005). Research studies cited support the 2002 model constructs (Figure 1). Further research is needed to evaluate relationships among the constructs and attributes identified in the

framework, refine metrics, and determine the effect on both academe and industry.

CONCLUSIONS

Adaptive structuration recognizes that technology appropriation may be a key factor in the evolution of affected social structures. Adaptive structuration theory gains predictive and descriptive power by identifying social complexities and relationships associated with the adoption of advanced information technologies. The major contribution of this exposition is further specification and support of an AST-based model to better understand the dynamics of academic/industry collaboration as they evolve on campus and in the workplace.

KEY TERMS

Advanced Information Technology Structure: Rules and resources offered by systems such as enterprise resource planning systems that support the intended purposes and utilization of those systems.

Appropriation and Delivery Structure: Rules and resources that determine the choices made by educators regarding strategies for integrating learning model(s) and supporting technologies within a selected instructional design.

Educational Organization Structure: Rules and resources offered by the internal educational institution, that are derived from how it is organized as well as program requirements, curriculum, and course objectives.

Education Process: Use of learning models and supporting learning technologies to deliver the learning experience and/or training with students.

Emergent Forms of Educational Method: New methods and techniques employed or used in the education process.

External Environmental Structure: Rules and resources offered by outside interests including academic standards bodies, technology developers, industrial organizations, employers, and end users.

Joint Outcomes: The direct output and by-products of the education process including student learning, employable work force, market exposure, and contributions to research.

Structure of Academic/Industry Collaboration: Representation of social practices among the stakeholders affecting academic/industry collaboration that result in the establishment of rules of practice and the provision of resources.

Technology Infrastructure: Required supporting activities and facilities including network, hardware, software, development, and maintenance.

Modeling for E-Learning Systems

INTRODUCTION

Computer-based instruction is touted as an effective tool to support knowledge dissemination within predefined learning environments. Indeed, many see it as a way to overcome geographical or social barriers to knowledge transmission and educational institutions. However, its domain of application has traditionally been restricted to basic skills and educational contexts. Recently, dynamic and complex business environments shaped by technological changes and the downsizing trend of the '90s placed new constraints on the underlying assumptions (Fuglseth, 2003). Organizations are now pushing for skill flexibility, demanding specialized knowledge and requiring faster learning curves from employees. Many advocate Internet-based education materials as one way to meet those challenges (Bernardes & O'Donoghue, 2003; Karoulis et al., 2004; Storey et al., 2002; Strazzo & Wentling, 2001). However, this raises important questions concerning both effectiveness and efficiency of such tools and materials. Indeed, developing interactive multimedia-based courseware remains pretty much a black art, consuming enormous resources. So far, there is a lack of established models to predict the performance and evaluate how adequately courseware can meet user needs. In fact, developing courseware should take into account the target constituency requirements, organizational context, and the stated educational or training goals. Developing the wrong training materials can lead to costly investments in creating and maintaining content to match the increasing expectations on e-learning. Perhaps this can explain the recent rash of failed e-learning projects—current results do not measure up to business and individual expectations yet.

A better understanding of the many factors affecting e-learning performance would allow individuals and organizations to achieve the expected benefits. In so doing, development teams need methods, techniques, and tools to evaluate in advance which features are needed to achieve higher outcomes, namely, performance and satisfaction. Thus, the need to develop predictive models to improve learning effectiveness is in order.

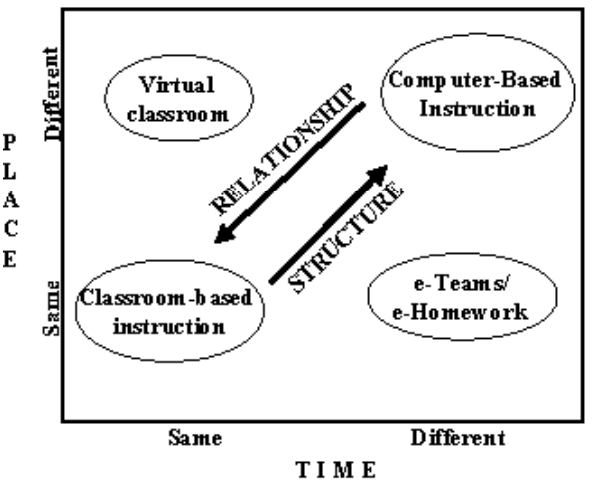
This overview includes four sections. "Background" presents a proposed e-learning theoretical framework to guide our analysis based upon the reviewed literature. "Key Issues" section describes main issues arising from the proposed e-learning conceptual framework. "Future Trends" describes our vision on how to approach e-learning initiatives and future trends. Finally, we present a general conclusion.

BACKGROUND

Organizational investment in e-learning strategies reflects strategic choices regarding skill development through e-learning. According to Wentling, Waight et al. (2000), e-learning involves acquiring and using distributed knowledge facilitated by electronic means in synchronous or asynchronous modes. As shown in Figure 1, knowledge could be distributed geographically within varying time frames.

Thus, the effective use of technology-based instruction would provide to organizations the ability to succeed at operational levels. This justifies the adoption of a holistic approach to courseware evaluation as a diagnostic and managerial tool. We propose a framework, shown in Figure 2, which comprises three basic entities, business processes, people, and information systems, and three main relationships: (a) interaction between people and systems, (b) process-based

Figure 1. Proposed types of e-learning in terms of time and place



roles played by people during this interaction, and (c) having the learning task be executed, as part of the e-learning experience, by people performing their process-based roles. This framework could lead to working techniques and approaches that assist development team members in designing work-related e-learning experiences within organizational contexts. To motivate a workable approach, we will now discuss each of these entities and relationships.

Reviewed literature strongly suggests that the external and internal fit among business strategies, culture, human resource practices, and leadership styles is critical to worker performance. Moreover, work contexts, for example, physical and technological conditions surrounding individual tasks, affect people's perceptions and, in turn, influence their motivation to engage into and perform learning tasks (Astleitner, 2001; Bandura, 2000; Chen, 2002; Dix et al., 1998; Kim, 2000; Liu & Dean, 1999; Reeves & Nass, 1996; Strazzo & Wentling, 2001; Vouk et al., 1999; Welbourne et al., 2000; Wentling et al., 2000).

Within the e-learning experience, business processes provide yardsticks to define educational or training goals and monitor outcomes. However, we need also to consider the roles people perform when interacting with courseware. Such process-based roles could be as diverse as e-learners, e-instructors, e-speakers, systems and courseware designers, supervisors, reviewers, human resource managers, and information technology officers among many others.

Human-computer interaction can model parts of the e-learning experience in accordance with Norman's extended model (Dix et al., 1998). Furthermore, the experience is also shaped by the way people relate to systems. This is supported by Reeves' and Nass' (1996) work, which suggests that people relate to media as they would relate to real people, treating them with affection and courtesy. Building on these findings, we argue that the more e-learning systems themselves are easy to use and learn and are "nicely behaved," the likelier e-learners will engage in the experience and profit from their outcomes.

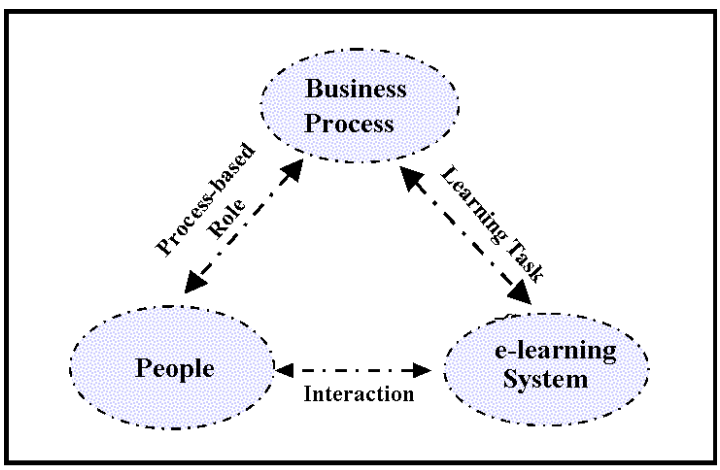
The interplay among these three relationships (process-based role, learning task, and interaction) relates to a just-in-time learning concept. Strategic knowledge acquisition should be enmeshed in current activities to support employees in learning new skills when performing day-to-day business tasks. We believe this concept can foster gradual alignment between learning outcomes, and technology with strategic aspects of business.

KEY ISSUES

We identify structure and relationship as the main issues within our framework as presented in the previous section. Figure 1 shows different modes of e-learning regarding the use of technology in education, both in terms of distance and time. As technology gets more extensively used for delivery, the need for course structure becomes higher and the relationship between instructor and e-learner turns increasingly weaker. Figure 1 also shows this relationship as defining three types of e-learning, which are set apart from conventional classroom instruction.

This shows that using technology to support learning requires higher course structure than traditional classroom-based instruction to be effective (Karoulis et al., 2004; Liu & Dean, 1999). However, current approaches take a one-size-fits-all method to provide courseware delivery regardless of differences in place and time. We cannot argue strongly enough that delivery needs to be tailored to context (space and time) to overcome the barriers imposed by structure and to improve the e-learning experience. This should be done differently for different students with diverse cognitive styles, roles, and tasks within organizational contexts. We will now discuss factors affecting structure and relationship.

Figure 2. Proposed e-learning framework



As for structure, organizations identify training needs taking into account work context, business process dynamics, individual tasks, objectives, and areas for performance improvement. A business-process approach driving the design and the development of interactive course contents should focus on skill gaps to define instructional objectives in order to meet performance standards. In this way, setting up appropriate goals for training evaluation poses the same requirements both for electronic and traditional media. However, as courseware becomes available and distributed through the Internet, quality of service (QoS) becomes an increasingly important factor to e-learner satisfaction. Thus, technology becomes another structural issue.

From the technology standpoint, three aspects are critical to e-learner satisfaction. The first is courseware evaluation (Chen, 2002; Karoulis et al., 2004; Kim, 2000; Liu & Dean, 1999; Storey et al., 2002; Strazzo & Wentling, 2001; Wentling et al., 2000). Indeed, users' perceptions of mismatch between content and structure reduce their motivation to learn and perform (Astleitner, 2001). Usability is a second aspect affecting both engagement and acceptance. It measures the extent to which a computer system can be used to complete well-defined tasks or achieve specified goals productively and satisfactorily for the intended users in a given context (Dix et al., 1998). Last, but not the least, user modeling completes the set of key technological aspects for e-learners' satisfaction. User modeling is the knowledge a system has about the user's level of knowledge and intentions, processed as users interact with systems. Knowledge of both user and task domains should allow intelligent and adaptable systems to properly respond to the competence levels and needs of the tasks within contexts of use (Dix et al., 1998). This holistic understanding would help developers take into consideration users' expectations at the early stages of system design. In this way, expected learner performance would supplement the metrics suggested by the literature (Dix et al., 1998; Wentling et al., 2000) concerning the implementation of strategies and quality-of-service goals.

Regarding relationship issues, two factors are relevant for this overview: cognitive styles and motivation. Cognitive styles are individual characteristics that serve as stable indicators of how learners perceive, think of, remember, and solve problems (Kim, 2000; Liu & Dean, 1999). This characteristic is consistent with major dimensions of individual differences and explains stable individual performance across tasks over time. Thus, it is a key variable in designing effective systems for a particular user group, especially at early stages of the interaction. Indeed, results show that cognitive styles can help in explaining usability problems when browsing hypermedia documents (Chen, 2002; Kim, 2000; Liu & Dean, 1999). However, research results are numerous and mixed and give no consistent evidence about the relationship between cognitive styles and learners' performance in computer-based settings (Shih & Gamon, 2001; Wentling et al., 2000).

Motivation can be defined as the internal set of processes (both cognitive and behavioral) through which human energy becomes focused on the direction of effort (Welbourne et al., 2000). This definition is twofold. First, the internal set of processes by which human energy becomes focused describes the "agentic" nature of individuals in interaction with their environment (Bandura, 2000; Liu et al., 2002). A second relevant aspect of motivation is the direction of effort, which implies individual goal orientation assessed using defined internal success criteria. These two motivation-related aspects require that development teams actively involve different user roles at early stages of system design to get high usability, learnability, acceptance, and usage levels in order to likely match specific individual, task, and contextual characteristics. In this way, organizations could be more effective in creating the conditions to foster knowledge acquisition, transfer, and reutilization across different learner groups.

FUTURE TRENDS

Currently, people perceive learning as a product rather than a process. Adopting the latter view would require a holistic approach to analyze e-learner experience. This may lead to a paradigm shift in dealing with process, especially since learning, as an activity, is deeply enmeshed in interdependent and rapidly evolving organizational processes. Our vision is to pursue useful endeavors to effectively support learning by people within organizational contexts during their performance of work-related tasks. In this sense, e-learning systems would become tools for people to use, as often as needed, to acquire new knowledge related to current or future tasks. For this to happen, we need to develop a close people-process-system fit. To achieve that, cost-effective, integrated tools for courseware and competence-building evaluation within specific knowledge domains are in order. This requires coordination of efforts, information, and competencies among the key players, including universities, companies, government, and research communities. Such coordination is fundamental to achieve skill development at individual, organizational, and societal levels, articulated with defined strategies. Table 1 summarizes the topics identified in our analysis and describes specific research goals toward the fulfillment of this vision.

CONCLUSION

We have discussed a holistic approach covering business processes, e-learners, and information systems fit, while stressing the need for quantitative models, especially in evaluation. The interplay among these entities defines the

Table 1. Identified research topics

Issues	Proposed research topics
Learning task	How do e-learning initiatives relate to organizational knowledge management practices?
E-learner	In what conditions could e-learning be effective for everybody? Are there usability metrics universal across roles, levels of technology experience, cognitive styles, job levels, organizational contexts, and cultures? Does task complexity level mediate users' perception about usability? Would the initial role assigned by people to media hold steadily throughout the learning process, or does it change over time, motivated by learners' habits?
Interaction	To what extent is learners' trust and performance affected by perceived support for privacy, confidentiality, and security at the system level? Could software agents be the new "hidden persuaders" (Packard, 1957/1981) to get learners to go further into the skill-development cycle, overcoming obstacles along the way? Should such concerns be incorporated into a design discipline centered on ethical and deontological roles?

organizational space for the just-in-time learning concept. The expected benefits lie in aligning learning outcomes with business strategies.

KEY TERMS

Business Process: A set of organized work-related tasks and resources to pursue a specific organizational objective influencing learning experiences by defining two specific relationships: process-based roles (between business process and people) and learning tasks (between business process and information systems).

E-Learning Experience: A process by which people identify work-related learning needs, formulate related goals and the associated internal level-of-success criteria, search for feasible online options to achieve defined learning goals, select and acquire choices, and engage into and complete them successfully by achieving the related goals in a productive and satisfactory manner.

E-Learning Framework: A formal construct to diagnose and manage learning outcomes in terms of the operational dynamic of three basic entities: business process, information systems, and people.

Just-In-Time Learning: Strategic knowledge acquisition enmeshed in business activities to support employees in learning new skills when performing day-to-day tasks, while fostering the alignment between learning outcomes, technological and strategic business issues.

Learning Task: A set of steps with a defined learning goal addressing specific training needs identified within business processes driving the definition of proper instructional design and e-learning system requirements.

Motivation to E-Learn: An individual variable denoting an internal set of processes (both cognitive and behavioral) by which human energy becomes focused on learning particular work-related content (whether by actively interacting with courseware, participating in a virtual class, self-studying, doing e-homework alone or in group) to achieve specific learning goals.

Process-Based Role: The combination of a set of expected work-related behaviors, responsibilities, and the associated set of required competencies to perform within business settings in order to achieve organizational goals.

People-Process-System Fit: A degree of consistency among learner groups, business processes, and e-learning systems that (a) reflects the target constituency requirements, organizational context, and the stated educational or training goals, (b) applies the principles and approaches of constructivism, user-centeredness, participatory design, quality management, and organizational development to instructional design of courseware, and (c) translates into expected performance levels.

Modeling Information Systems in UML

Peter Rittgen
University College of Borås, Sweden

INTRODUCTION

The first approaches to object-oriented modeling appeared already in the second half of the 1970s, but not much happened for more than a decade so there were still barely more than a handful of modeling languages at the end of the 1980s. It was the early 1990s that witnessed an ever-growing market in competing object-oriented methods so that potential users found it increasingly difficult to identify any single method that suited their needs. This phenomenon came to be known as the "method wars." Toward the end of 1994, two of the "big" players, Grady Booch and Jim Rumbaugh, decided to join forces by integrating their respective approaches, the Booch method and OMT (object modeling technique). In late 1995, Ivar Jacobson became a member of this team merging in his OOSE method (object-oriented software engineering). The efforts of the "three amigos" aimed at overcoming unnecessary differences between the individual approaches and also improving each of them by creating a common, standardized modeling language that could serve as an industry standard. The result was the release of the Unified Modeling Language (UML), version 0.9, in June 1996. The UML partners, an industry consortium, performed further work on UML. This led to the versions 1.0 and 1.1 being introduced in 1997. The latter was adopted by the OMG (Object Management Group) in the same year. The current version is 2.0 (OMG, 2005, 2006).

BACKGROUND

UML is a language to support the development of software systems. It features a common framework that provides a set of diagram types covering different aspects of an information system. Here we will focus on the ones we deem to be most important: class diagram, use case diagram, and activity diagram. The first is the principal diagram for the static view on a system. The second is often put forward as the central diagram in communication with the user (see, e.g., Dobing & Parsons, 2000). The latter plays a central role in the information-system (or business-oriented) perspective (see following sections). Elementary concepts of the UML are actor, activity (and state), object, and class.

An actor is a human being or a (computer) system who/which is able to perform activities on his/her/its own. The actor typically represents a group of similar human beings/systems and corresponds to the role the actor performs in the given context. *Teacher* is an example for such an actor. In UML, actors are shown as stick figures.

An activity refers to a logically connected set of actions that are carried out as a unit in some order. These actions might be executed sequentially, alternatively, concurrently, or in any combination thereof. *Grade exam* is an example for an activity.

"An object is an abstraction of a set of real-world things such that:

- all of the real-world things in the set—the instances—have the same characteristics,
- all instances are subject to and conform to the same rules" (Shlaer & Mellor, 1988, p. 14).

The structure (attributes) and behavior (operations) of similar objects are gathered in their common class. The values of the attributes at a certain point in time represent the state of the object. Classes are drawn as rectangles with the object identifier printed in bold face. Additional horizontal compartments can be introduced for the attributes and operations of the class. The object is depicted in the same way with the object identifier underlined (optionally followed by a colon and the respective class identifier). *Grade* is an example of a class, *F: Grade* that of an object.

Figure 1 shows how these concepts are related to each other: actors perform activities that involve objects. Each object is an instance of precisely one class. The class diagram shows classes and their relations (called associations). An

Figure 1. Language overview

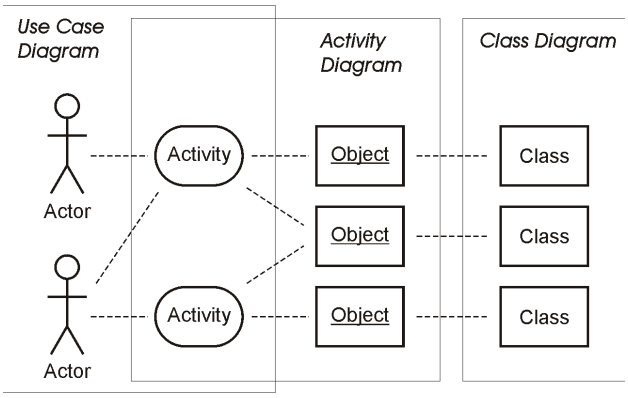

Figure 2. A use case diagram

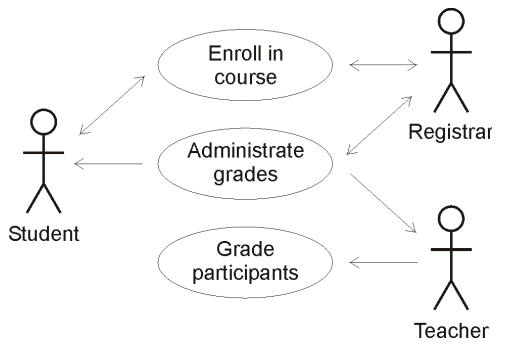


activity diagram gives a detailed account of the order in which activities are executed. It can also show the relevant states of the involved objects. The use case diagram visualizes use cases (complex activities) and their relation to actors.

Use Case Diagram

Use cases have been introduced in 1992 by Jacobson and his colleagues. Their book is now available in the second edition (Jacobson, Christerson, Jonsson, & Övergaard, 2004). A use case describes a way in which an actor can interact with your organization. It forms part of a use case scenario, a business situation that is supposed to be supported by the information system in question. Figure 2 gives an example of a use case diagram involving three use cases and three actors.

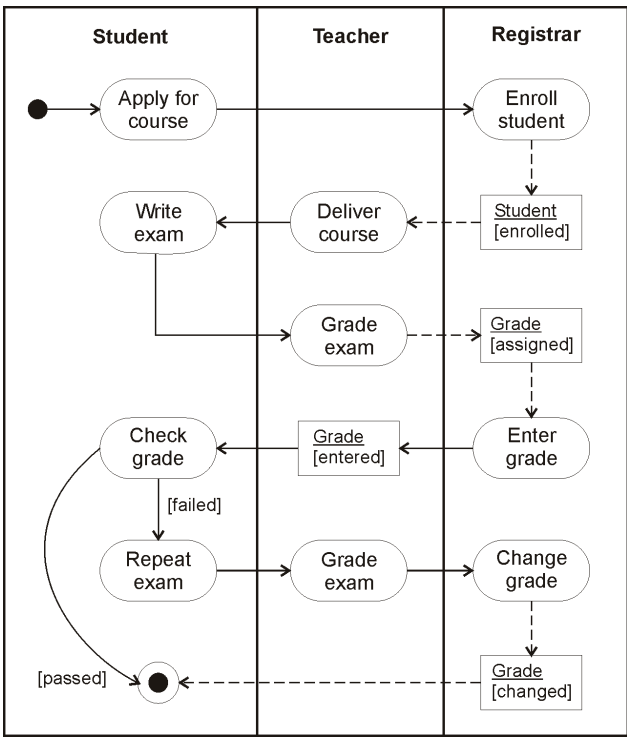
The arrows indicate the direction of the information flow. So the registrar can both read and enter/change grades, whereas teachers and students can only read them. Often the arrowheads are omitted to simplify modeling. Each use case is detailed by a description in structured English of the activities that make up this use case. The use case diagram and the use cases form the basis for the development of class diagrams and activity diagrams. The former specify the static structure of the information that is handled by the use cases, and the latter give a precise, formalized account of the process logic.

Activity Diagram

An activity diagram consists of the detailed activities that make up the use cases. Figure 3 gives an example of such a diagram in relation to the use cases of Figure 2.

The use case *Enroll in course* comprises the activities *Apply for course* (performed by the student) and *Enroll student* (performed by the registrar). *Grade participants* maps to *Grade exam* assuming that the grade for the course is determined by a final exam only. The use case *Administrate grades* involves the activities *Enter grade*, *Check grade*, and *Change grade*. Note that the activity diagram also contains

Figure 3. An activity diagram



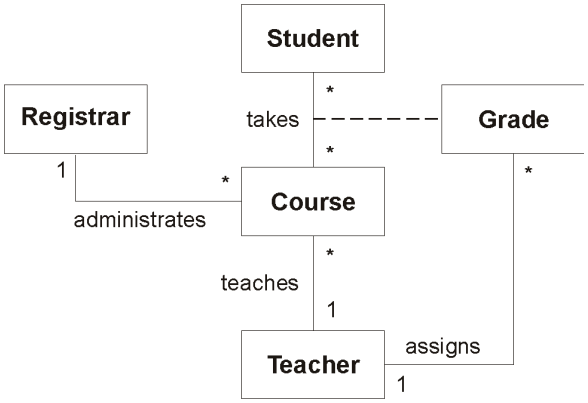
activities that are not present in the use case diagram, such as *Deliver course* and *Write exam*. That is because, in our example, they are not supposed to be supported by the information system and hence do not constitute use cases of such a system. But they are still an important part of the overall business process.

The business process in Figure 3 starts with the initial state (the black dot). The activities are in the boxes with round sides. The rectangles contain objects-in-state where the object identifier is underlined and the object's state is enclosed in square brackets. So after *Enter grade*, for example, the object *Grade* is in state *entered*. Alternative paths leaving an activity must be labeled by so-called guards that determine under which condition each path is taken. These guards are also enclosed in square brackets and should be mutually exclusive. The process terminates when the final state is reached (i.e., the circle containing the black dot). Actors are included in the form of so-called swim lanes. Concurrent execution is achieved by introducing synchronization bars. For more detailed information on activity diagrams we refer the reader to OMG (2005, p. 402 ff).

Class Diagram

A typical approach to identifying classes is that of looking at the nouns contained in a textual specification of the system.

Figure 4. A class diagram



Jacobson et al. (2004) suggest that we should limit our attention to the nouns contained in the use case diagram instead to avoid having to eliminate inappropriate class candidates. If we apply this to the use case diagram of Figure 2, we arrive at the class diagram of Figure 4 where all the nouns of the former map to a class of the latter. Observe that the noun *participants* maps to the class *Student*.

The class diagram also shows associations between the classes that indicate the way in which they are related to each other. A single line is drawn connecting the respective classes. It can be labeled with a verb that determines the nature of the association. In addition, we can also specify the cardinality with the asterisk referring to an unlimited number. In the example a *Teacher teaches* a number of *Course*s, but each *Course* is only taught by one *Teacher*. *Grade* is a so-called association class. It qualifies the relation between *Student* and *Course* and is therefore attached to the association path by a dashed line. For further details on class diagrams refer to OMG (2005, p. 134 ff).

MODELING INFORMATION SYSTEMS IN UML

UML has been designed primarily to support the development of software systems. In such systems the software artifact plays the central role, and the role of human beings is restricted to the specification of requirements and later on the use of the system. An information system, on the other hand, is a human activity system (sometimes also called a socio-technical system) where some part of the system *might* be *supported* by software (Buckingham, Hirschheim, Land, & Tully, 1987).

The focus being on software systems, it is natural that UML does not emphasize the aspects of an information system that aim at the value and support it can provide to the business, such as strategy (e.g., value chains and strategic goals) and organization (e.g., organizational charts and business processes). These issues are dealt with in "business modeling" (also called enterprise modeling), but UML is beginning to advance into that field, too. The OMG, for instance, claims that business processes can be represented in UML (OMG, 2005, p. 306). This claim can, however, be challenged in a number of ways. First of all, there is very little direct support for business processes in the basic UML diagrams (Bruno, Torchiano, & Agarwal, 2002). Instead many of the required concepts are "hidden" in extensions to UML, such as enterprise collaboration architecture (ECA) (OMG, 2004a). Another issue is whether UML models are indeed "understandable" enough to form a solid basis for the communication between "developers" and "users." An empirical study of UML's usability (Agarwal & Sinha, 2003) showed that UML diagrams score between 4.3 and 5.3 on a 7-point Likert scale, that is, the ease-of-use of UML is closer to indifference (4) than to the optimum (7). Understandability of UML is also weakened by construct redundancies, inconsistencies, and ambiguities (Shen & Siau, 2003).

Candidate languages for business processes (in native UML) are use cases and activity diagrams. The former have been criticized for their conceptual flaws (Dobing & Parsons, 2000) such as fragmentation of objects and for construct overload and ambiguity (Shen & Siau, 2003). In addition, they restrict the specification of process logic to a textual form, which is neither rigorous nor expressive enough for typical flows of control. Activity diagrams come closer to fulfilling the requirements of a business-process language and are therefore often used in that way (see the next section).

FUTURE TRENDS

So far, there is still an abundance of languages used for business modeling, for example, architecture of integrated information systems (ARIS) (Scheer, 1999), open system architecture for computer-integrated manufacturing (CIMOSA) (AMICE, 1993), integrated definition (IDEF*) (Ang, Pheng, & Leng, 1999), integrated enterprise modeling (IEM) (Spur, Mertins, & Jochem, 1995), dynamic essential modeling of organization (DEMO) (Reijswoud, Mulder, & Dietz, 1999), and GRAI integrated methodology (GIM) (Doumeingts, 1998). Often modelers also pick out particular model types from integrated methods or use "stand-alone" languages that were developed for specific purposes. In the area of business process modeling these include event-driven process chains (EPC) (from ARIS), Business Process Modeling Language (Arkin, 2002), IDEF3 (Mayer et al., 1997), Tropos (Castro, Kolp, & Mylopoulos, 2002), and petri nets (Aalst, Desel, & Oberweis, 2000).

But how can we bridge the gap between these enterprise-modeling languages and UML? One approach consists of devising mechanisms that "translate" domain models into UML models. Such a translation is by no means straightforward but typically involves the reconstruction of the domain model as a UML diagram by a modeler who is experienced in both the domain language and UML. It usually involves the loss of information that was present in the domain model and the necessity to add information not yet represented. This implies also the risk of introducing errors, or more precisely inconsistencies between the original and the translated model. Examples of such an approach can be found in many of the languages mentioned due to the popularity of UML, for example, EPC to UML (Nüttgens, Feld, & Zimmermann, 1998), IDEF and UML (Noran, 2000), Tropos and UML (Mylopoulos, Kolp, & Castro, 2001), DEMO and UML (Mallens, Dietz, & Hommes, 2001), or Petri Nets and UML (Gou, Huang, & Ren, 2000).

Another—and perhaps even more promising—approach is to equip UML itself with domain support. This can be done in at least two ways: extending existing concepts or introducing new ones (typically in the form of profiles). A major effort toward the latter is being made under the heading "Enterprise Distributed Object Computing (EDOC)" and was adopted by the OMG in February 2004 (OMG, 2004a-g), but work is still ongoing. Its core is the enterprise collaboration architecture ECA (OMG, 2004a). The former approach is followed by several researchers independently. In the area of business processes and workflows, they primarily investigate extensions of use cases and activity diagrams, for example, Rittgen (2003) or Dumas and Hofstede (2001).

CONCLUSION

The UML is a widely used modeling language in the area of software systems modeling, but it still has to gain ground in domain modeling, especially in business (or enterprise) modeling. Promising steps have already been taken that have so far led to results such as EDOC. But there is still a need for research that provides the core concepts and diagrams of the UML with domain-specific semantics to make them more useful for business modeling. On the other hand, add-on concepts such as EDOC processes require a tighter semantical integration with the existing models. Future research and development will show which of the paths toward integration is more promising and will hence be taken. But all approaches mentioned share a common goal: to improve the communication and understanding between the different people involved in shaping an information system and thereby also improving the system itself.

KEY TERMS

Activity: A logically connected set of actions that are carried out as a unit in some order. It is associated with a state (called action state) in which the system remains while the activity is performed.

Actor: A person or (computer) system that can perform an activity. The actor does not refer to a particular individual but rather to a role (e.g., *Teacher*).

Attribute: A property of an object/class. The class *Car*, for example, can have an attribute *Color*, its value for the object *MyCar: Car* might be *blue*.

Class: A template for similar objects defining attributes and operations.

Object: An abstraction of a set of real-world things that has state, behavior, and identity. An instance of its class where the values of the attributes determine the state and the operations the behavior.

Operation: A function or transformation that may be applied to or by objects in a class. The class *Account*, for example, might have the operations *Open*, *Close*, *PayIn* (*Amount*), and *Withdraw* (*Amount*).

State: A certain combination of attribute values of an object.

Modeling Security Requirements for Trustworthy Systems

Kassem Saleh
American University of Sharjah, UAE

Ghanem Elshahry
American University of Sharjah, UAE

BACKGROUND

To increase users' trust in the systems they use, there is a need to develop trustworthy systems. These systems must meet the needs of the system's stakeholders with respect to security, privacy, reliability, and business integrity (Mundy, deVries, Haynes, & Corwine, 2002). The first major step in achieving trustworthiness is to properly and faithfully capture the stakeholders requirements. A requirement is something that the system must satisfy or a quality that the system must possess. A requirement is normally elicited from the system stakeholders, including its users, developers, and owners. Requirements should be specified before attempting to construct the system. If the correct requirements are not captured properly and faithfully, the correct system cannot be built. Consequently, the system will not be usable by its intended users. The success of any system depends on meeting requirements classified under two complementary types. First, the functional requirements are the system's operations from the user's perspective describing the visible and external interactions with the system under consideration. Second, the non-functional requirements (NFRs) are mainly the system's constraints imposing special conditions and qualities on the system to construct. Consequently, system acceptance testing must be based on both functional and non-functional system's requirements. Unfortunately, it is reported that about 60% of errors originate from the requirements and analysis activities (Weinberg, 1997).

Surveys have shown that large numbers of IT-based systems were implemented starting from their elicited functional requirements without a clear and formal consideration of their non-functional counterparts such as security requirements. Furthermore, system requirements engineers and analysts are not well-trained in capturing security requirements early in the system development process. Security assurances are often based on the traditional and ad hoc approach of conducting penetration tests followed by a patching process. This approach is very costly and endangers the fulfillment of the basic goals of system security, namely confidentiality, integrity, availability, and accountability. Recently, many researchers addressed security requirements engineering as an integral and essential element of systems engineering. Devanbu and Stubblebine (2000) propose a roadmap for software engineering for security, and Henning and Garner (1999) consider life cycle models for survivable and secure systems.

Non-functional requirements can be classified under three broad categories (Robertson & Robertson, 1999): system-related, process and project-related and human-related requirements.

The rest of this article is organized as follows. The next section overviews the security goals and requirements. The third section introduces security requirements modeling using the Goal-Oriented Requirements Language (GRL) (ITU, 2002) and UMLsec, a security extension to the Unified Modeling Language (Jurjens, 2005; Elshahry, 2005), and its modifications. The fourth section provides some examples of using GRL and UMLsec models for requirements specifications. We conclude in the final section and provide items for further investigation.

SECURITY GOALS AND REQUIREMENTS

The main system security goals to achieve are confidentiality, integrity, availability, and accountability. Confidentiality ensures that only authorized users or applications are allowed to interact with the system. Integrity ensures that critical data has not been changed in an improper way in the system. Availability ensures that the information and/or services are readily available to an authorized user on demand. Accountability ensures that once authorized users access the system, they are accountable for all of their actions (Whitman & Mattord, 2005). Normally, security requirements should not be specified in terms of the types of security mechanisms or controls that are currently used for implementation. To achieve the security goals, security requirements should be identified. These requirements can be structured around the 12 security requirement types identified in Firesmith (2003).

Table 1 maps and shows the contributions of the security requirements to the security goals. For example, survivability,

Table 1. Mapping security requirements to security goals

Security Requirement	Confidentiality	Integrity	Availability	Accountability
Identification Requirements	•	O		O
Authentication Requirements	•	O		O
Authorization Requirements	•	O		O
Immunity Requirements	O	•	O	
Integrity Requirements		•

physical protection, and system maintenance requirements contribute to the system availability security goal.

MODELING SECURITY REQUIREMENTS

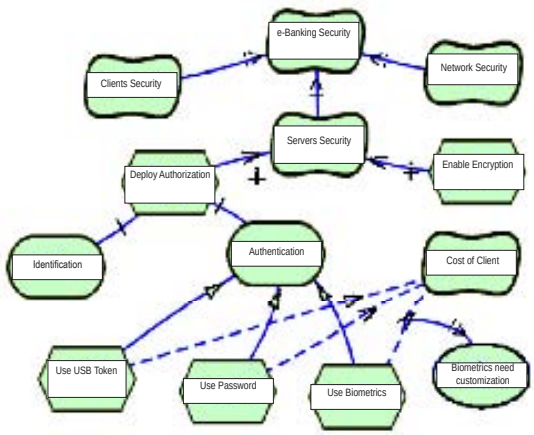
Modeling is an important process that can be used for specifying and analyzing requirements. There are many advantages of developing a model before starting the design process. Desirable modeling formalisms are executable and therefore allows the modeler to verify the model and its dynamic behavior before accepting it. An acceptable model is the basis upon which the design process can build. Moreover, correctness of the implemented system can be checked by verifying the conformity of the system to its specified requirements model. There are many existing modeling languages and formalisms. The most famous is the Unified Modeling Language (UML) (OMG, 2003). UML is a de facto standard in the software industry, and it is being generalized to model systems in general (OMG, 2005). However, we are aware of two modeling formalisms that are capable of expressing security requirements in the model. First, the Goal-Oriented Requirement Language (GRL) (ITU, 2002) is a language for supporting goal-oriented modeling and reasoning of requirements, especially for dealing with non-functional requirements such as security and performance. GRL provides the elements to express several concepts appearing during the requirement elicitation phase. Second, UMLsec, an extension to the UML, has been developed by Jurjens (2005) to express security requirements. It is worth mentioning here that another extension to UML, SecureUML, was introduced in Lodderstedt, Basin, and Doser (2002). However, this extension is only to specify role-based access control to support authorization requirements.

Goal-Oriented Requirement Language (GRL)

GRL is a graphical modeling language for capturing NFRs in general. There are three main categories of elements in GRL: intentional elements, links, and actors. The intentional elements in GRL are goals, tasks, softgoals, resources, and beliefs. These elements are used for models that allow answering questions such as why particular behaviors, informational and structural aspects were chosen to be included in the system requirement; what alternatives were considered; what criteria were used to deliberate among alternative options; and what the reasons were for choosing one alternative over the other. GRL supports the reasoning about scenarios by establishing mappings between intentional GRL elements and non-intentional elements in scenario models of the User Requirements Notation—Functional Requirements (URN-FR). Modeling goals and scenarios are complementary and may help identifying further goals, scenarios, and scenario steps important to stakeholders, thus contributing to the completeness and accuracy of the elicited requirements.

A GRL model consists of several goal model structures. Each structure represents a requirement category. For example, Figure 1 shows an e-banking security system as the root of the security requirements. A requirement can

Figure 1. E-banking requirements in GRL



be represented as a goal, softgoal, or task. A softgoal is a condition that the actor would like to achieve. However, unlike in the concept of goal, there are no clear-cut and subjective criteria for checking whether the condition has been achieved. The figure shows that Use USB Token, Use Password, and Use Biometrics are means for achieving the authentication security goal. Also, Deploy Authorization and Enable Encryption contributes positively to the Servers Security softgoal.

For a complete tutorial on GRL, the reader can refer to Amyot (2003).

Unified Modeling Language for Security (UMLsec)

The UMLsec extension has been developed by Jurjens (2005) based on his security-critical system development experience in industrial projects involving government agencies, banks, insurance companies, and smart cards. Security goals such as confidentiality, integrity, availability, and accountability are offered as specification elements and stereotypes in the UMLsec extension. UMLsec properties are used to evaluate different kinds of security-related diagrams. The UMLsec encapsulates knowledge on security engineering and makes it available to system engineers who may not be experts in security. UMLsec took advantage of three metalanguage mechanisms for extending the UML: stereotypes, constraints, and tagged values. Stereotypes are used with tags for security requirements formulation. The constraints criteria determine whether the requirements are met or not. The extension provides core profile that includes the main security requirements.

Stereotypes, included between <<>>, define new types of modeling elements extending the semantics of existing types in the UML metamodel. The new element can capture some aspect of a new domain, like security, not supported by the standard UML elements and stereotypes. Constraints supply conditions and restrictions for UML model elements. A constraint can be specified in any format as long as it is written inside braces. If, for example, a class has *password* as one of its attributes, constraint can be applied as {password can't be blank}. Tagged values are name-value pairs in curly brackets {} associating data with model elements. A tagged value is designed to explicitly define a property. For example, If nodeName represents the node where the component resides, {location = nodeName} may be attached to a component.

UMLsec Stereotypes

UMLsec stereotypes are used to describe security requirements for access control, confidentiality, integrity, and so forth. In the following, we describe the main security-related stereotypes introduced by Jurjens (Jurjens, 2005), in addition to our own additional stereotypes including the <<audit log>>, <<multiplicity>>, <<no misuse>>, and <<standard>> .

<<audit log>> stereotype can be used by the node elements to completely record any transaction information or activity. The logging fields include: event ID, event date, event time, event user, and event action (allowed or denied). Audit logs records are tamperproof since they include the integrity tag. The authors introduced <<audit log>> stereotype to fulfill several security requirements such as audit log, non-repudiation, and the intrusion detection system security requirements (Elshahry, 2005).

<<encrypted>>, <<internet>>, <<LAN>>, <<multiplicity>>, and <<wire>> link stereotypes are used in deployment diagrams to denote the corresponding types of communication links. It is required that each link carries at most one of these stereotypes except for <<multiplicity>>. The <<multiplicity>> link stereotype is introduced to fulfill the survivability security requirements. <<multiplicity>> stipulates multiple network links per device (Elshahry, 2005). <<Issuer Node>>, <<multiplicity>>, <<LAN>>, <<POS Device>>, and <<Smart Card>> node stereotypes are used in deployment diagrams to denote the respective kinds of system nodes. It is required that each node carries at most one of these stereotypes except for <<multiplicity>>. The <<*multiplicity*>> node stereotype is introduced to fulfill the survivability security requirements. <<*multiplicity*>> stipulates multiple active devices such as servers, routers, switches, or storage.

<<fair exchange>> stereotype stipulates that the interaction is performed in a way that prevents parties from cheating. For example, in the e-commerce context, it is the require-

ment that, after a prepayment, the buyer either receives the purchased good or the money can be reclaimed.

<<guarded access>> stereotype means that each <<guarded>> object in the subsystem can only be accessed through the object specified by the tag {guard} attached to the <<guarded>> object. However, the <<guarded>> stereotype labels objects that are supposed to be guarded in the scope of <<guarded access>> stereotype. It has a tagged value {guard} that defines the name of the corresponding guard object.

<<high>>, <<integrity>>, and <<secrecy>> stereotypes are used as dependency constraint for <<secure links>> stereotype in static structure or component diagrams. Dependencies, stereotypes, denote dependencies that are supposed to provide the respective security requirement for the data that is sent along them as arguments or returned values of operations or signals.

<<no misuse>> stereotype can be used as link or node stereotype to detect, alert, prevent any misuse of the system, such as a repeated request for system component in an irregular manner. The <<*no misuse*>> stereotype was introduced to fulfill the immunity security requirements.

<<standard>> stereotype is a node (system or subsystem) stereotype indicating the security standard the system or subsystem must conform to. <<*iso17799*>> is one instance of <<*standard*>> stereotype. ISO 17799 is an international standard for the code of practice for information security management (ISO/IEC 17799, 2000).

Table 2 lists the four stereotypes that were added to the existing UMLsec stereotypes. A table showing all UMLsec stereotypes and detailed description can be found in Jurjens (2005).

Table 3 shows the mapping of the security requirement types to the modified UMLsec stereotypes. For example, authorization requirements can be role-based (<<rbac>>) or subject-based (<<guarded access>>). Intrusion detection and prevention, non-repudiation, and auditing requirements are related to the <<audit log>> stereotype since audit logs are instrumental in meeting these requirements.

EXAMPLE

A local financial institution, consisting of head office and 20 branches, offers several banking services through branches, call centers, and automatic teller machines (ATM). The bank business unit, sales department, would like to deploy e-banking services to service their customers'; on the other hand they are faced with the risk element in terms of the e-banking transactions security. Along with a wide variety of features in e-banking services, today's customers also want assurance that their e-banking services are completely secure. The aim of this example is not to provide complete requirement specifications, but to give a flavor of using formal modeling languages. The following fitures were generated using the available tools for GRL (GRL, 2005) and UMLsec (Jurjens, 2004).

GRL Representation

The e-banking system security requirements are shown in Figure 2 from the system stakeholders perspective using the GRL. E-banking security softgoal is the root of the required security components. There are several ways for representing each component depending upon the scope of the design. Some requirements can be grouped into one softgoal; for example, identification, authentication and authorization are combined into the access control softgoal. Defense and hardening softgoal combines the intrusion detection system, physical security, intrusion prevention system, immunity (anti malicious software system), and system maintenance security requirements. The other security requirements such as confidentiality (for secrecy and privacy requirements), integrity, availability, and survivability, are represented individually. Non-repudiation and security auditing requirements are deployed as tasks contributing to the execution of the Tracking softgoal.

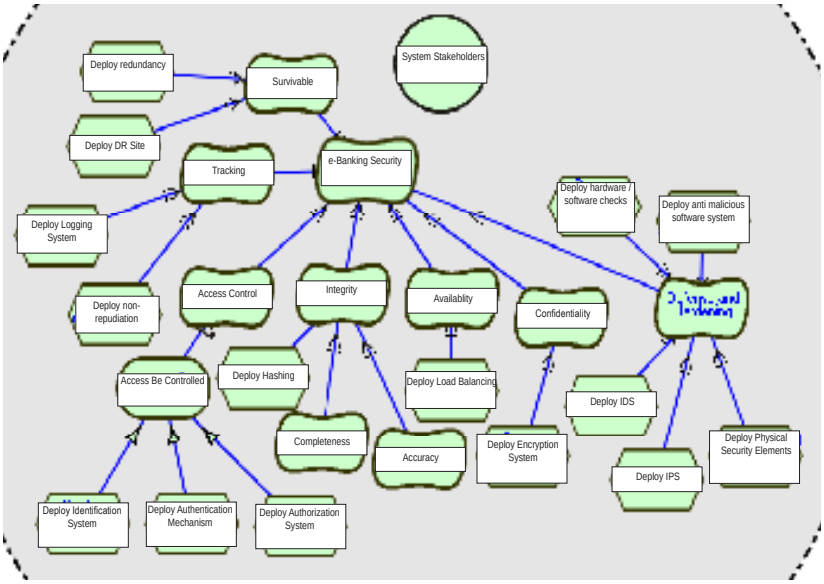
Table 2. Four stereotypes added to UMLsec

Stereotype	Base Class	Tags	Constraints	Description
<<*audit log*>>	Subsystems, node	integrity		Log event activity (audit security requirements)
<<*multiplicity*>>	Link, node			Load balancing and redundancy (survivability requirements)
<<*no misuse*>>	Subsystem		Prevent misuse	Antivirus and network traffic (immunity requirement)
<<*standard*>> *like* <<*iso17799*>>	System, subsystem			Standard to adhere to (standard conformance requirement)

Table 3. Mapping security requirements to UMLsec stereotypes

Security Requirements	Security Stereotypes
Identification Requirements	<<guarded access>>
Authentication Requirements	<<guarded access>>
Authorization Requirements	<<guarded access>>, <<rbac>>
Immunity Requirements	<<no misuse>>
Integrity Requirements	<<integrity>>, <<critical>>
Intrusion Detection Requirements	<<no misuse>>, <<audit log>>
Intrusion Prevention Requirements	<<no misuse>>, <<no down-flow>>, <<no up-flow>>, <<audit log>>
Non-repudiation Requirements	<<provable>>, <<fair-exchange>>, <<audit log>>
Privacy/Secrecy Requirements	<<encrypted>>, <<secure links>>, <<data security>>
Security Auditing Requirements	<<provable>>, <<audit log>>
Survivability Requirements	<<multiplicity>>
Physical Protection Requirements	<<secure links>>, <<LAN>>, <<wire>>, <<multiplicity>>
System Maintenance Requirements	<<no misuse>>, <<multiplicity>>
Security Conformance Requirements	Standard like <<iso17799>>

Figure 2. GRL diagram for the e-banking security requirements

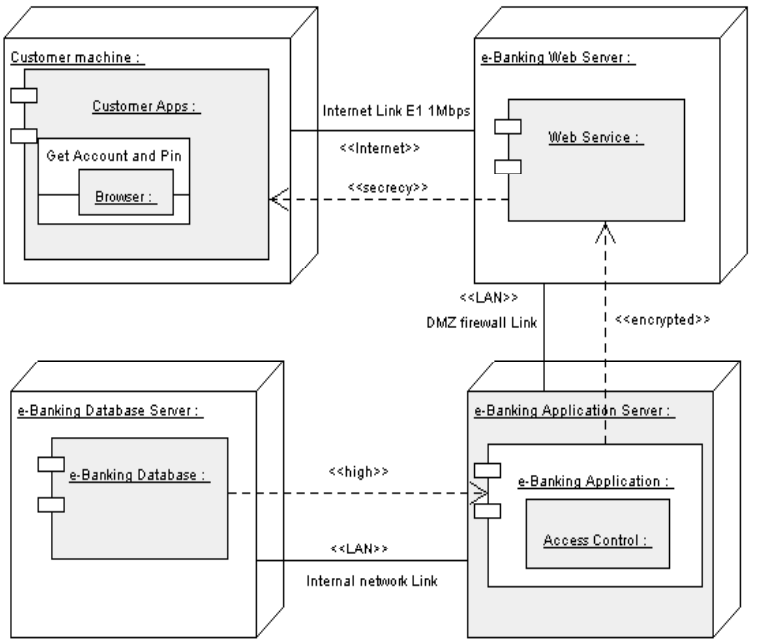


UMLsec Representation

Unlike a GRL diagram that can describe all elicited security requirements, a single UMLsec diagram can only represent related security requirements or a partial view of the modeled system security. Normally, many UMLsec diagrams would be needed to capture all system security requirements. Although GRL model can describe the security requirements and mechanisms in one diagram, it does not enforce or validate the requirements. On the other hand, UMLsec diagrams permit the expression of security-relevant characteristics within the model in the system specification and validate them using the available tools (Jurjens, 2004).

The e-banking Web service connectivity example in Figure 3 shows a deployment diagram with four node instances: customer machine, e-banking Web server, e-banking Application aerver, and e-banking database server.

Figure 3. E-banking Web connectivity deployment diagram



Customer machine and e-banking Web server nodes are connected via a link stereotyped <<Internet>>. There is also a <<secrecy>> stereotype dependency from the e-banking Web server component to "Get Account and Pin", thus the e-banking Web server is able to communicate with the Browser for getting the account and pin code. <<secrecy>> and similar dependency stereotypes, like <<integrity>> and <<high>>, denote dependencies that are supposed to provide the respective security requirement for the data that is sent along them as arguments or returned values of operations or signals. These stereotypes are used in the constraint for <<secure links>> stereotype. <<audit log>> stereotypes specifies the requirement that the application server must keep audit logs of all transactions it processes. Also, the <<multiplicity>> stereotype specifies the high availability and survivability requirement needed for the Web servers. Figure 4 shows an e-banking sequence diagram. In this diagram, a role-based access control (rbac) security mechanism is required, in which a legitimate client requests account balance inquiry. The user should be able to get the account status since account balance service is defined in the general clients' profile.

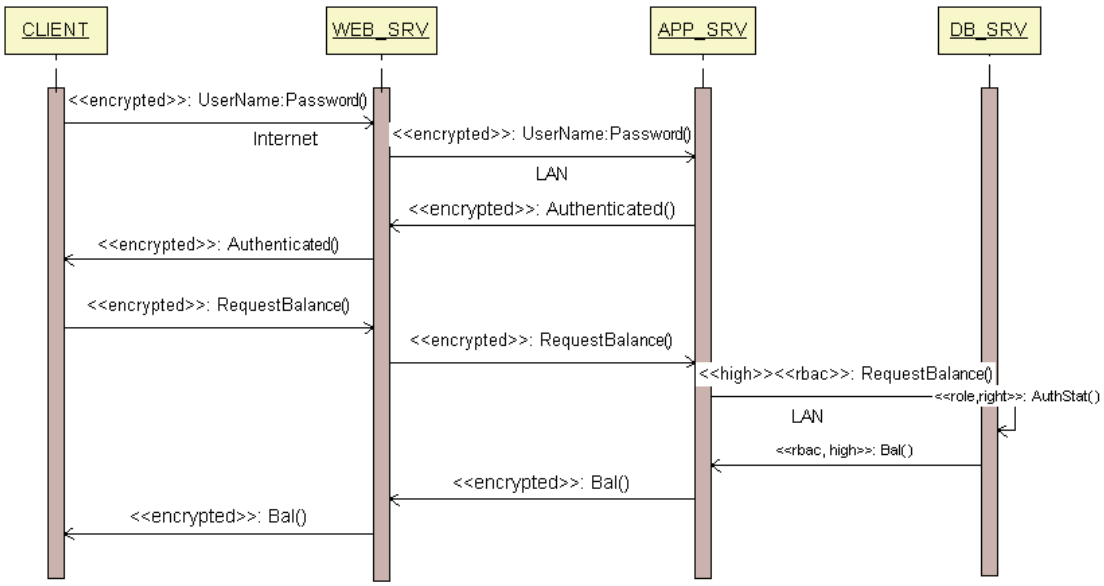
FUTURE TRENDS

A formal link between the two modeling languages needs to be established. In addition, a theoretical foundation to check some desirable properties of security requirements, such as consistency, correctness, conciseness, and completeness of requirements need to be developed. Moreover, the generation of security test cases starting from the formal security requirements specifications to check the conformity of the security implementations requires further investigation. Finally, the effects of security requirements on other non-functional requirements should be formally studied.

CONCLUSION

With the increasing dependency on information technologies for doing business using computers, palms, wireless devices, and the Internet, there is a need to formalize the process of embedding security while developing any information technology-based system. A formal process for the engineering of security in systems under development would lead to the delivery of trustworthy and dependable systems. This formal process for security engineering starts with the security requirements capture and elicitation. The use of formal modeling languages for the specification of security requirements has been addressed. The aim of this

Figure 4. E-banking sequence diagram specifying <<rbac>>



formalization is to increase the trustworthiness of the system under development, and hence, increase users' trust in the system they use to perform their tasks. Meeting security requirements captures many of the features and goals of trustworthy systems. The Goal-Oriented Requirement Language and extensions on the Unified Modeling Language to describe system security requirements have been introduced in a formal way.

KEY TERMS

Functional Requirement: A functional requirement is a system feature or functionality that is directly visible to external system users.

Non-Functional Requirement: A non-functional requirement is a system feature that is not directly visible to the system users. However, it may have an impact of the quality of the visible system features of functional requirements.

Security Engineering Process: The security engineering process is the process of embedding system security starting from security requirements elicitation and ending with security implementation testing.

Security Requirement: A security requirement is a security feature required by system users or a quality the system must possess to increase the users trust in the system they use. In general, a security requirement is considered as a non-functional requirement.

System Model: A model is a high-level abstraction describing behavioral (dynamic) and architectural (static) aspects of a system. A desirable model is an executable and verifiable model.

Trust: Trust is a relative user's perception of the degree of confidence the user has in the system he/she uses.

Trustworthy System: A trustworthy system is a system that gains a high level of trust by its users by satisfying the specified security, privacy, safety, availability and business integrity requirements.

Models and Techniques for Approximate Queries in OLAP

Alfredo Cuzzocrea
University of Calabria, Italy

INTRODUCTION

Since the size of the underlying data warehouse server (DWS) is usually very large, response time needed for computing queries is the main issue in decision support systems (DSS). Business analysis is the main application field in the context of DSS, as well as OLAP queries being the most useful ones; in fact, these queries allow us to support different kinds of analysis based on a multi-resolution and a multi-dimensional view of the data. By performing OLAP queries, business analysts can efficiently extract *summarized knowledge*, by means of SQL aggregation operators, from very large repositories of data like those stored in massive DWSs. Then, the extracted knowledge is exploited to support decisions in strategic fields of the target business, thus efficiently taking advantage from the amenity of exploring and mining massive data via OLAP technologies. The negative aspect of such an approach is just represented by the size of the data, which is enormous, currently being tera-bytes and peta-bytes the typical orders of data magnitude for enterprise DWSs, and, as a consequence, data processing costs are explosive.

Despite the complexity and the resource-intensiveness of processing OLAP queries against massive DWSs, client-side systems performing OLAP and data mining, the most common application interfaces versus DWSs, are often characterized by small amount of memory, small computational capability, and customized tools with interactive, graphical user interface supporting *qualitative*, *trend analysis*. For instance, consider the context of retail systems. Here, managers and analysts are very often more interested in the product-sale plot in a fixed time window rather than to know the sale of a particular product in a particular day of the year. In others words, managers and analysts are more interested in the trend analysis rather than in the *punctual*, *quantitative analysis*, which is, indeed, more proper for OLTP systems. This consideration makes it more convent and efficient to compute approximate answers rather than exact answers. In fact, typical decision-support queries can be very resource intensive in terms of spatial and temporal computational needs. Obviously, the other issue that must be faced is the accuracy of the answers, as providing fast and totally wrong answers is deleterious. All considering, the key is proving fast, exploratory answers with some guarantees on their degree of approximation.

On the other hand, in the last few years, DSS have become very popular: for example, sales transaction databases, call detail repositories, customer services historical data, and so forth. As a consequence, providing fast, even if approximate, answers to aggregate queries has become a tight requirement to make DSS-based applications efficient, and, thus, has been addressed in research in the vest of the so-called approximate query answering (AQA) techniques. Furthermore, in such data warehousing environments, executing multi-steps, query-processing algorithms is particularly hard because the computational cost for accessing multi-dimensional data would be enormous. Therefore, the most important issues for enabling DSS-based applications are: (1) minimizing the time complexity of query processing algorithms by decreasing the number of the needed disk I/Os, and (2) ensuring the quality of the approximate answers with respect to the exact ones by providing some guarantees on the accuracy of the approximation. Nevertheless, proposals existent in literature devote little attention to the point (2), which is indeed critical for the investigated context.

BACKGROUND

Multi-dimensional models represent data as univocally associated to positions in a multi-dimensional space and support query and mining tasks according to a multi-resolution view of data. The growing attention towards such models was stirred up by recent advances of OLAP systems, which allow us to efficiently support data analysis for a wide range of modern application fields ranging from Business Intelligence to sensor network data management and QoS-based (quality of service) systems. Traditionally, OLAP technology was adopted for supporting just-in-time (summarized) knowledge extraction in decision-making processes of very large organizations, but its reliability and effectiveness has made OLAP engines a (very) popular component of a plethora of data-intensive systems. *Data cube* (Gray, Bosworth, Layman, & Pirahesh, 1996) is the fundamental data model of the OLAP technology, and effectively supports the above mentioned analysis goals. According to such a model, multi-dimensional data are organized in cubes that are characterized by a set of dimensions and a set of measures. The first set, which contains the analysis parameters or, more properly,

the *functional attributes*, allows us to univocally locate *data cells storing measures*, which are the values of interest for the target decision process, and on which various kinds of OLAP queries, which retrieve data by means of multi-dimensional aggregations, are executed.

Range queries (Ho, Agrawal, Megiddo, & Srikant, 1997) are an important class of OLAP queries that are very often executed on data cubes. They are defined as the application of a given *SQL aggregation operator* (such as SUM, COUNT, AVG, etc.) over a set of selected contiguous ranges in the domains of the dimensions. For instance, a *n*-dimensional range-SUM query over a *n*-dimensional data cube *A* can be generally formulated as follows:

$$SUM(l_0 : h_0, l_1 : h_1, \ldots, l_{n-1} : h_{n-1}) = \sum_{l_0 \le i_0 \le h_0} \sum_{l_1 \le i_1 \le h_1} \cdots \sum_{l_{n-1} \le i_{n-1} \le h_{n-1}} A[i_0][i_1]\ldots[i_{n-1}]$$

such that $\langle l_k : h_k \rangle$ is the range defined on the dimension d_k.

APPROXIMATE QUERY ANSWERING TECHNIQUES

There is a clear taxonomy of methods proposed for supporting approximate query answering: We distinguish between methods based on *pre-computation* and methods based on *online computation*. Methods belonging to the first class compute *synopses*, which are succinct representations of the original data, in an off-line mode, and we use them instead of the original data for answering queries, thus obtaining approximate answers. Methods belonging to the second class perform sampling at query time, so that answers can be continually improved (by progressively enlarging the data sample) under user control. Many techniques for compressing data cubes and evaluating range queries over their compressed representation have been proposed. Several compression models, which have been originally defined in different contexts, have been used to this end. In the following section, we focus our attention on both the most popular techniques such models are based on, that is, *histograms*, *wavelets*, and *sampling*.

Histograms

Ioannidis and Poosala (1999) introduced the use of histograms for providing approximate answers to set-valued queries. Histograms are data structures obtained by partitioning a given data domain into a number of mutually disjoint blocks, called *buckets*, and then storing for each bucket some aggregate information, such as the sum of their items. Histograms were originally proposed for query size estimation inside query optimizers, and to summarize multi-dimensional data distributions (Poosala & Ioannidis, 1997; Poosala, Ioannidis, Haas, & Shekita, 1996). In the latter case, the data distribution to be compressed consists of the frequencies of values of the attributes in a given relation, and queries are evaluated by performing linear interpolation on the stored aggregate values. Subsequently, histograms have been effectively used to estimate range queries in OLAP (Poosala & Ganti, 1999). Many techniques for building multi-dimensional histograms have been proposed in literature, each of them based on particular properties of the data distributions characterizing the input domains. Typically, statistical and error metrics-based properties are taken into account, and greedy algorithms are considered to mitigate the computational cost of processing very large data cubes. Among all the alternatives, we focus our attention on the following histograms, mainly because they describe approaches that we retain having a similar spirit to ours: Equi-Depth (Muralikrishna & DeWitt, 1998), MHist (Poosala & Ioannidis, 1997), and GenHist (Gunopulos, Kollios, Tsotras, & Domeniconi, 2000) histograms.

Given a *n*-dimensional data domain *D*, the Equi-Depth histogram $H_{E\text{-}D}(D)$ is built as follows: (1) fix an ordering of the *n* dimensions $d_0, d_1, \ldots, d_{n-1}$; (2) set $\alpha \approx n$-th root of desired number of buckets; (3) initialize $H_{E\text{-}D}(D)$ to the input data distribution of *D*; (4) for each *i* in $\{0, 1, \ldots, n\text{-}1\}$ split each bucket in $H_{E\text{-}D}(D)$ in α equi-depth partitions along d_i; and finally (5) return resulting buckets to $H_{E\text{-}D}(D)$. This technique presents some limitations: fixing α and a dimension ordering can result in poor partitions, and, consequently, there could be a limited level of *bucketization*.

The MHist histogram overcomes the Equi-Depth histogram performances, as stated by experimental results shown in (Poosala & Ioannidis, 1997). The MHist build procedure depends on the parameter *p* (specifically, such histograms are denoted by MHist-p histograms): contrarily to the previous technique, at each step, the bucket *b* in $H_{MH}(D)$ (i.e., the output histogram) containing the dimension d_i whose marginal is the most in need of partitioning is chosen, and it is split along d_i into *p* (e.g., $p = 2$) buckets.

GenHist histograms are a new class of multi-dimensional histograms that are different from the previous ones with respect to the build procedure. The key idea is the following: given an histogram *H* with h_b buckets on a *n*-dimensional input data domain *D*, the proposed technique builds the output histogram $H_{GH}(D)$ by finding n_b overlapping buckets on *H*, such that n_b is an input parameter. To this end, the technique individuates the number of distinct regions that is much larger than the original number of buckets h_b, thanks to a greedy algorithm that considers increasingly-coarser grids. At each step, the algorithm selects the set of cells *J* of highest density and moves enough randomly-selected points from *J* into a bucket to make *J* and its neighbor cells "close-to-uniform." Thus, the innovative contribution is to define a truly multi-dimensional split policy, based on the concept of *tuple density*.

Wavelets

Wavelets (Stollnitz, Derose, & Salesin, 1996) are a mathematical transformation which defines a hierarchical decomposition of functions (representing signals or data distributions) into a set of coefficients. They were originally applied in the field of image and signal processing. Recent studies have shown the applicability of wavelets to selectivity estimation (Matias, Vitter, & Wang, 1998), as well as to the approximation of both specific forms of query (like range queries) (Vitter, Wang, & Iyer, 1998), and "general" queries (Chakrabarti, Garofalakis, Rastogi, & Shim, 2000) (using join operators) over data cubes. Specifically, the compressed representation of data cubes via wavelets (Vitter et al., 1998) is obtained in two steps. First, a wavelet transform is applied to the data cube, thus generating a sequence of coefficients. At this step no compression is obtained (the number of wavelet coefficients is the same as the number of data points in the examined distribution), and no approximation is introduced, as the original data distribution can be reconstructed exactly applying the inverse of the wavelet transform to the sequence of coefficients. Next, among the N wavelet coefficients, only the $m << N$ most "significant" ones are retained, whereas the others are "thrown away," and their value is implicitly set to 0. The set of retained coefficients defines the compressed representation, called *wavelet synopses*. In order to execute the wavelet decomposition procedure for a given data domain D, first a wavelet basis function set must be chosen: *Haar Wavelets* (Chakrabarti et al., 2000; Vitter et al., 1998) are conceptually the simplest wavelet basis functions, and therefore, widely used in literature. It has been shown that wavelet-based techniques improve the histogram-based ones in the summarization of multi-dimensional data (Vitter et al., 1998), and, thus, they have been used for approximate query answering (Chakrabarti et al., 2000).

Sampling

Random sampling-based methods propose mapping the original multi-dimensional data domain in a smaller subset by sampling: this allows a more compact representation of the original data to be achieved. Query performances can be significantly improved by pushing sampling to query engines, with very low computational overheads. Traditionally, random sampling-based techniques have not been considered as performing as well as other more resource-intensive techniques such as multi-dimensional histograms and wavelet decomposition. However, they have recently been of renewed interest from the database and data warehousing research communities, due to their computational requirements, which are very low. (Hellerstein, Haas, & Wang, 1997) propose a system for effectively supporting online aggregate query answering, and also providing probabilistic guarantees about the accuracy of the answers in terms of *confidence intervals*. Such a system allows a user to execute an aggregate query and to observe its execution in a graphical interface that shows both the partial answer and the corresponding (partial) confidence interval. The user can also stop the query execution when the answer has achieved the desired degree of approximation. Therefore, the whole process is interactive. No synopses are maintained since the system is based on a random sampling of the tuples involved in the query. Random sampling allows an unbiased estimator for the answer to be built, and the associated confidence interval is computed by means of the Hoeffding's inequality (Hoeffding, 1963). The drawback of this proposal is that response time needed to compute answers can increase since sampling is done at query time. The absence of synopses ensures that there are not additional computational overheads because no maintenance tasks must be performed.

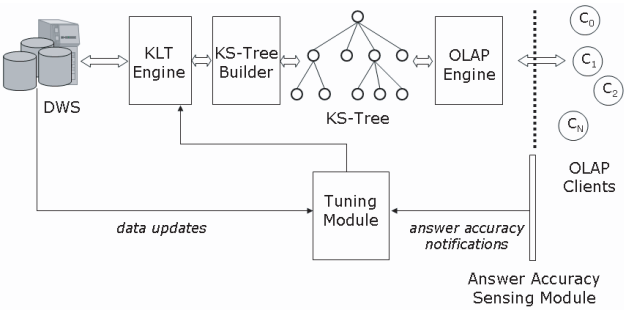
Recently, in Ganti, Lee, and Ramakrishnan (2000), a weighted sampling scheme that exploits workload information to continuously tune a representative sample of data is proposed. In Chaudhuri, Das, Datar, Motwani, and Rastogi, 2001, this novel approach is extended towards a more accurate scheme in which the presence of *data skew* (i.e., asymmetric peak values in the data distributions) and *low selectivity* of queries is considered; experimental results shown in (Chaudhuri et al., 2001) clearly show that the accuracy of the approximate answers is outperformed by taking into account a more "adaptive" scheme rather than a more "static" one. More recently, in Babcock, Chaudhuri, and Das (2003), the previous work is further extended by arguing that (1), for many aggregation queries, appropriately constructed biased samples can provide more accurate approximation than uniform samples, and (2) consequently, proposing an improved technique that dynamically constructs an ad hoc biased sample for each query by combining samples selected from a family of non-uniform samples built during the preprocessing phase.

S-OLAP:COMPRESSING MULTI-DIMENSIONAL DATA CUBES VIA PROBABILISTIC SYNOPSES

s-OLAP (see Figure 1) attempts to solve the aforementioned issues in dealing with querying massive data warehouses, provided by OLAP interfaces, and, on the basis of dimensionality reduction and *probabilistic synopses*, defines a methodology for obtaining fast, approximate answers to range queries, along with *probabilistic guarantees* on their degree of approximation. s-OLAP is a multi-user system that sits between a DWS and the OLAP clients that interact with the former by performing query and report tasks.

A very important issue in the approximate query processing research issue is just dealing with multi-dimensional data

Figure 1. The s-OLAP system



domains and queries. In fact, many interesting, state-of-the-art techniques focused on the approximation of set-valued queries on relational databases, one-dimensional and two-dimensional queries on data cubes have been proposed during the last years; nevertheless, presently, there are very few techniques that allow us to efficiently evaluate with approximation multi-dimensional queries on multi-dimensional data cubes. In order to address this critical challenge, in Cuzzocrea (2005), we propose a dimensionality reduction technique, based on the well known Karhunen-Loeve transform (KLT) (Jain, 1989). KLT allows us to obtain an *m*-dimensional data domain D_m from a given *n*-dimensional data domain D_n, such that $n >> m$, providing D_m a *summarized description* of D_n. The details of this transformation technique for obtaining dimensionality reduction of multi-dimensional data cubes are given in our article (Cuzzocrea, 2005). More specifically, in (Cuzzocrea, 2005), a MOLAP-based representation technique that allows us to significantly reduce the overall error caused by the projection of the input *n*-dimensional data cube over a smaller *m*-dimensional data domain is presented, along with some other effective optimizations for "tailoring" the KLT to efficiently support approximate query answering in OLAP.

In the s-OLAP system, our technique (Cuzzocrea, 2005) is used to obtain a *collection* of two-dimensional data domains (i.e., $m = 2$), said CoD_2, from the input *n*-dimensional data cube *A* (i.e., one transformed domain for each of the (MOLAP) data cubes representing *A*), and, the (KLT-based) *transformation relation* between *A* and the CoD_2 is exploited for building a R^+-tree like data structure, called *KS-Tree*, which is a synopsis data structure for *A*, that is, a persistent object that represents in a summarized fashion the knowledge kept in *A*. In other words, *KS-Tree* allows us to efficiently represent and query the (probabilistic) synopses built on *A*, and some others related information. Therefore, any query *Q* against the original data cube *A* is (1) redirect to the *KS-Tree* built on *A*, denoted by *KS-Tree*(*A*), and (2) evaluated against it, thus providing an approximate answer to *Q*, denoted by $\tilde{A}(Q)$.

The ratio of choosing the two-dimensional ones as output data domains of the KLT is suggested by the amenity of designing a very efficient query strategy, yet introducing low spatio-temporal costs because low-dimensional domains (i.e., 2) are processed. *KS-Tree* is also *self-adjustable*: s-OLAP periodically reconfigures it according to the *current* accuracy of the retrieved (approximate) answers, which is measured on the basis of an empirically-determined threshold τ.

The underlying theoretical framework for providing probabilistic guarantees on the degree of approximation of the retrieved answers is another important feature of s-OLAP. To this end, we adopt the so-called *tail inequalities* (such as Markov's inequality, Chebyshev's inequality, or Hoeffding's inequality (Hoeffding, 1963, etc.), which are important results coming from the theoretical statistics. Such inequalities give probabilistic bounds on the estimation of a parameter of a given statistics (such as mean value, variance, co-variance, etc.) defined on a set of random variables. It is well-recognized that, by using a tail inequality in the estimation of a given observed parameter *p*, the introduced error is at most ε with probability that is at least $1 - \delta$ (i.e., *with high probability*, as commonly intended), being ε and δ positive integers. We highlight that this property plays a critical role in our system: In fact, providing approximate answers without any bounds on their accuracy would be fruitless. To support this feature, *s*-OLAP builds probabilistic synopses starting from the original multi-dimensional data in such a way that these synopses "encode" the Hoeffding's inequality (Hoeffding, 1963) and computes the approximate answers against them, thus providing (theoretically-proofed) probabilistic bounds on the answers.

As shown in Figure 1, the main components of s-OLAP are the following:

- **KLT Engine:** It is the component that codifies our dimensionality reduction technique presented in Cuzzocrea (2005), and, given the target data cube, obtains the collection of two-dimensional data domains CoD_2.
- **KS-Tree Builder:** It is the component that takes the collection CoD_2 as input and builds the KS-Tree.
- **KS-Tree:** It is the synopsis data structure for the target data cube.
- **OLAP Engine:** It is the component that is in charge of (1) intercepting queries posed by OLAP clients; (2) parsing and re-writing them in terms of queries against the KS-Tree; (3) running the evaluation of the queries against the KS-Tree; and finally, (4) forwarding the approximate answers towards the OLAP clients.
- **Tuning Module:** It is the component that collects queries and answers on the s-OLAP interface, and periodically checks the current degree of accuracy of the answers, said *a*; if *a* is smaller than τ, then it activates the KLT Engine in order to compute a more accurate

(compressed) representation of the target data cube, thus improving the quality of the "next" answers.

CONCLUSION

Compressing multi-dimensional data cubes is an important research challenge for the database and data warehousing research communities, which still ask for solutions capable of capturing all the (complex) requirements described in this article—ranging from representation and storage issues to maintenance and query issues. At the same time, this research topic plays a leading role for the efficiency and the effectiveness of a wide range of modern IT applications, which also have a relevant impact on day-to-day real life. Given these considerations, we presented some interesting models and techniques for supporting OLAP-based summarized knowledge extraction from massive data warehouses.

FUTURE TRENDS

AQA techniques can be successfully applied in quality of answer (QoA)-based OLAP tools, which are gaining momentum in the context of next-generation DWS applications. The philosophy of such systems resembles QoS-based systems ones where client applications and service providers can mediate on the quality of available services, thus defining new service-oriented computing paradigms and drawing new scenarios for intelligent service delivering. In a similar spirit, in QoA-based OLAP tools, OLAP users/applications, and DWSs can mediate on the accuracy of the answers. This leading feature can be achieved through realizing that compressing data is a way to handle the accuracy of data (i.e., their degree of compression), and, as a consequence, the accuracy of the retrieved answers (i.e., their degree of approximation).

KEY TERMS

Multi-Dimensional OLAP (MOLAP): An in-memory-storage model that represents a multi-dimensional data cube in form of a multi-dimensional array.

OLAP Engine: A software component positioned on the top of an OLAP server that is in charge of implementing OLAP query functionalities against DW data and providing answers to OLAP users/applications.

Online Analytical Processing (OLAP): A methodology for representing, managing, and querying massive DW data according to multi-dimensional and multi-resolution abstractions of them.

Online Transaction Processing (OLTP): A methodology for representing, managing, and querying DB data generated by user/application transactions according to flat (e.g., relational) schemes.

Query Engine: A software component positioned on the top of a data server (e.g., RDBMS server) that is in charge of implementing query functionalities against DB data and providing answers to users/applications.

Query Optimizer: A software component that extends the functionalities of a target query engine by optimizing the execution plan of a given query statement (e.g., SQL statement founding on joins over multiple relational tables).

Set-Valued Queries on Relational Databases: Queries returning as result a domain (or, equally, a set) of tuples extracted from relational tables.

Models in E-Learning Systems

Alke Martens
University of Rostock, Germany

INTRODUCTION

Models are everywhere. Terms like "modeling" and "model" are part of everyday language. Even in research, no overall valid definition of what a model is exists. Different scientific fields work with different models. Usually, the term "model" is used intuitively to describe something which is sort of "abstract". This is a rather vague concept, but all models have in common that they are abstractions in a broad sense and that they are developed for a certain purpose, for example, for testing and investigating parts of reality, theories or hypotheses, for communication, or for reuse. In e-learning the notion of models is frequently used in a rather naive and uncritical way. The main purpose of developing models seems to be lost in the overwhelming amount of available models. A situation has emerged where the development of a new special purpose model often seems to be much easier than the reuse, validation, or revision of existing ones.

In the following section approaches to define the term "model" will be sketched to provide a (historical) background in relation with computer science. Afterwards, an overview over existing models and different approaches to categorize e-learning models will be given. A future trend suggests a new categorization of e-learning models. The chapter closes with a conclusion.

BACKGROUND

In the 17th century the ancient Italian term *modello* became famous in fine arts. In contrast to its former narrow sense, nowadays the term is part of everyday language. "Models can be developed based on natural artifacts or things, on hypotheses, on theories, or even based on pure fiction. The modern interpretation of model is: the object which is the result of a construction process" (Martens, in press). However, the broad usage of the notion of model makes it difficult to exactly define the term. Mueller summarizes: "Each definition of 'model' is insufficient: It covers only a small range of the reach of use" (Mueller, 2005). Accordingly, the aim of the following sketch is not to give a definition of the term model, but to describe some perspectives on models and characteristics of models. Model is a cross-disciplinary concept – moreover, most models are inherently crossdisciplinary. Generally, models have in common that they are abstractions and interpretations. A model abstracts parts of the real world, or it sketches something new, which did not exist before. The model is always a summary of the main aspects of an original, as it abstracts from special parts and only takes into account what can be perceived as the generalization. Mathematically spoken, a model is a subset of a set of originals. Thus, a model is also a simplification and a reduction on the parts which are the most important for the model developer. As a model is an interpretation, the modeler's viewpoint, intention, and the purpose of the model also influence the model. A simple example might be the model of an ape—the designer of toy apes will use a completely different model of an ape than a scientist investigating ape behavior. Mueller (2005) describes the basic meaning of the term model as: "A model is a simplified part of reality or potentiality. It can be material or idealistic, graphic or abstract and describes a has-been, actual or future state". Stachowiak (1973) has summarized this in the three main characteristics of models, which are representation, reduction, and pragmatics. The *representation characteristic* of a model means that each model represents an original. This does not mean that a model must have its counterpart in reality (or the physical world). The original of a model can also be an assumption, a hypothesis, a theory, or a product of fantasy. The *reduction characteristic* implies that the model's attributes are a real subset of the attributes of the original. A model never comprises all attributes of the original. The *pragmatic characteristic* is that the model's purpose is to replace the original in a certain context, for example, to answer questions, for investigations, experiments, or under certain conditions.

Several different sources, for example, Flechsig (1983), Ludewig (2002), Mueller (2005), Reihlen (1997), and Troitsch (1990), agree about at least two perspectives on models. Models can bee seen alternatively as reproduction or representational interpretation of something (*descriptive model*), or as prescriptive interpretation of something (*prescriptive model*). This distinction focuses on two different perspectives of model development, that is, the model's background and the model's purpose. A *descriptive model* reproduces or represents a part of the real world; it is always based on an original. The model depicts something existing; it is a description and abstraction. The purpose of such a model is to document, to facilitate, to show, to allow for communication, etc. Instead of describing part of reality, *prescriptive models* describe something new, which does not exist before the model. The model itself is used to construct the original and not vice versa. A classical example for such

a model would be Charles Babbage's difference engine.

Ludewig (2002) describes yet another type of model, which he called the *transient model*. This model starts as a descriptive model which is modified and changed, and finally becomes a prescriptive model, as it not necessarily has a counterpart in reality any longer. This situation can be found if a state in the real world should be changed, but the modification might be dangerous or irreversible. Then a process might be to start with a descriptive model of the state, perform the modifications on the model (which changes the descriptive to a prescriptive model) and perform tests and experiments on the model. Later, the modifications might be applied to the state in the real world. Such a situation is a classical modeling and simulation situation.

In modeling and simulation, modeling is necessarily a part of research (see e.g., (Troitsch, 1990; Zeigler, Praehofer & Kim, 2000). Modeling and simulation is – roughly spoken – used to investigate existing or artificial systems (von Bertalanffy, 1969). The investigation takes place based on experiments performed on models of these systems. Thus, if someone wants to investigate an existing or to develop an artificial system, he usually starts with the design of a model of such a system. Some steps are required before the model can be designed, which are system identification, definition of the level of abstraction (e.g., system border, level of detail), definition of the model's purpose (e.g., investigate, experiment, teach), and decision about the model representation or the modeling language. All these steps influence how the model is designed, and how the model can be used, reused, and validated. After executing some experiments, the model is usually validated and probably refined or redesigned.

MODELS IN E-LEARNING SYSTEMS

Looking at e-learning, a large amount of different models can be found. Examples are student models (e.g., Wei, Moritz, Parvez & Blank, 2005), evaluation models (e.g., Daniel & Mohan, 2004), cognitive models (e.g., Schroeder, Moebus & Pitschke, 1995), expert knowledge models (e.g., Seitz et al, 1999), process models (e.g., Martens, 2005), and data models (e.g., LOM, 2002). These models are described in different ways, for example, graphical, formal, or verbal. Some of the models are based on modeling languages, old ones like the language of mathematic and newer ones, like the UML (Unified Modeling Language) (e.g., Booch, Rumbaugh & Jacobson, 1999). In some research papers, even the notion of metamodels occurs (e.g., Grob, Bensberg & Dewanto, 2005).

Baker (2000) has made an approach to describe roles of models in Artificial Intelligence and Education (AIED). He distinguishes between three major roles: models in AIED are used as scientific tools, as components or as basis for design. He observed that currently, these different roles of models are mixed. As Baker's distinction does no help to structure e-learning models, another approach is chosen. To structure the amount of models described earlier, Stachowiak's (1973) three characteristics can be taken into account. Optimally, for each model the model developer should explain in advance what the model represents, where abstraction took place, and what the model's purpose is. In this context, three different categories for e-learning models can be suggested: models for e-learning system development, educational models, and models of the application domain. *Models for e-learning system development* include standards (e.g., LOM, 2002), formal models like the Tutoring Process Model (e.g., Martens, 2005) or patterns (e.g., Harrer & Martens, 2006; Harrer & Martens, 2007), and software engineering models (e.g., Pawlowski, 2000). These models are used to represent (computer based) e-learning system. They abstract from the programming and realization of the e-learning program. The purpose of the models is to provide for content and implementation independent descriptions and to facilitate communication about (technical) parts, structure, and relations in the designed e-learning program. *Educational models* either have a pedagogical background or are related to educational research, for example, investigation of human learning and behavior, like cognitive models (e.g ACT-R, described at Anderson & ACT Research Group, 2001). They can for example represent theories of learning, pedagogy, and didactic. Necessarily they abstract from real human behavior in teaching and training situations. The purpose is again support in system design and communication about realization and evaluation of learning approaches which underlie e-learning systems, but on another level then the system development level. *Models of the application domain* are related to the teaching and training field. The models represent the knowledge structures on which the teaching and training content is based (e.g., Illmann, Martens, Seitzet al., 1999). However, they abstract from details. They are used to provide for content independent descriptions of the teaching and training material, and – again – are used as a basis for system design and communication about content independent knowledge structures, relations, and adaptation possibilities. An additional category might be *design models*, which are related with the HCI development (Human Computer Interfaces) and research in this area.

The distinction between descriptive, prescriptive and transient, as described in the previous section, can be applied on the three categories of models. In e-learning, *descriptive models* can be for example data models like (LOM, 2002), which document and thus help to facilitate the reproduction of learning materials. Usually, descriptive models in e-learning are models of the application domain (as sketched above), which are used for teaching and training. Unfortunately, these models are seldom communicated or made explicit, but they are implicitly represented in the way teaching and training

content is offered. Examples are case-based training (e.g., (Illmann, Martens, Seitz & Weber, 2001), the model of the inner ear (Kinshuk, Oppermann, Rashev & Simm, 1998), or a content model used in military teaching and training, for example (Rickel, Gratch, Hill, Marsella & Swartout, 2001). In educational games, learners can train models of behavior which they can later on apply if they are confronted with an equal real world situation (Prensky, 2001). In e-learning *prescriptive models* are often educational models (as sketched above). For example in (Künzel & Hämmer, 2006) the e-learning system itself is only the environment, in which a model of a learning theory or of a pedagogical strategy is tested. Another example is Krahmer and Martens (2003), where a planner is used to reason about cognitive processes based on the sequence of steps chosen by the learner in an Intelligent Tutoring System (ITS). Teaching and training systems, which are based on *transient models*, might be found in game-oriented education.

FUTURE TRENDS

The usage of a clearly defined and purpose oriented categorization of existing and new developed models, as described earlier, can facilitate communication about models – moreover, if a model category is extended by information about who is the developer and who is the potential user. It is a means to support model reuse and model validation. An approach towards model reuse is sketched by the component based plugin architecture described in (Oertel, Himmelspach & Martens, 2008). The component based design, based on model descriptions of high quality, will be a future trend.

Ongoing work leads in the direction of establishing and extending e-learning patterns as a means for design and development (as described in Harrer & Martens, 2007), and into developing a model matrix which combines the model categories with developers and potential users. Such a model matrix can then be used in e-learning system development, for example, by combining existing models or model ideas for developing a new type of system.

CONCLUSION

The intention of this chapter is to help structuring the broad field of "models", which exist in the context of e-learning. As abstractions, models are a means to facilitate communication. However, the situation is complicated if models for different purposes are compared and mixed – moreover if the application domain has a strong interdisciplinary character, as e-learning research. Thus, it is important to communicate not only the model itself, but also the model's purpose. Potentially, the intended user type of the model can be associated, for example, the computer scientist, the designer, the pedagogy expert, the learning psychologist, and the training domain expert.

A first step in this direction is the purpose oriented category which is described in this article. The category distinguishes between three main branches of model usage, that is, usage for software development, educational research, and describing an application domain. A potential fourth category would be models for design. These categories have been developed based on Stachowiak's (1973) three characteristics of models. The three main characteristics of models summarize main model properties, following the questions: What does the model represent? What does the model exclude? and What is the model's purpose? The distinction between prescriptive, descriptive and transient models, which is another general approach to distinguish models, can be used to sketch the role of existing models, but does not lend itself to be used to develop categories of models for an application domain. Baker's distinction between models as scientific tools, as components or as basis for design could be used to distinguish models, which are part of the categories described earlier. For example, a model of the application domain can be used as scientific tool, but also as basis for design (e.g., the model of the medical domain described by Illmann et al., 2001).

KEY TERMS

E-Learning: Electronically supported learning.

E-Learning System: Is in the context of this chapter focused on computer-based teaching and training systems. Usually, the term covers a broad range of systems and techniques which are used in educational settings, for example, Peer Help Systems, Teleteaching, virtual classrooms, to name but a few. A more detailed definition can be found in Kaplan-Leiserson (2002).

Models for E-Learning System Development: Abstract from programming and realization, provides for content and implementation independent descriptions, and is used for communication about technical aspects of the e-learning system. Included are standards, formal models, patterns, and software engineering models.

Educational Models: Abstract from real human behavior in teaching and training. They are related to pedagogical or educational research, and can represent theories of learning, pedagogic, and didactic. They are used for communication and system design at the educational level.

Models of the Application Domain: Abstract from real content, and provide structures and relations in the teaching and training field of the e-learning system. They are used to communicate about underlying content related knowledge structures in the application domain.

Prescriptive Model: Describe something new, which does not exist before the model.

Descriptive Model: Depicts something existing. It reproduces or represents a part of the real world.

Transient Model: Starts as a descriptive model, which is performed to become prescriptive model.

Model-Supported Alignment of IS Architecture

Andreas L. Opdahl
University of Bergen, Norway

INTRODUCTION

An *information system (IS)* is a system that communicates, transforms, and preserves information for human users. An information system comprises one or more software applications and databases, and their relationships to their human users, operators, and maintainers.

A modern enterprise has many information systems that can be related in various ways. For example, information systems can be *related by exchange* because they exchange data through message passing or shared databases, or because they exchange functions through remote procedure calls or Web services. Information systems can also be *related by overlap* because they maintain the same data or provide the same functions. Information systems can be related in many other ways too, either *directly*, such as when one IS controls another, or *indirectly*, for example, because several ISs depend on the same run-time platforms or because they compete for their users' attention or for computer resources. In addition to being related to one another, information systems can be related to the *surrounding organization* in many ways. For example, organization units such as departments, individuals, or roles may be the *owners*, *users*, *operators,* or *maintainers* of ISs; organizational goals and strategies can be *realized by* ISs; organizational processes can be *supported* or *automated by* ISs; and so on.

The *information systems (IS) architecture* of an enterprise comprises its information systems, the relationships between those information systems, and their relationships to the surrounding organization. In addition to single enterprises, *alliances* of enterprises and *parts* of enterprises, such as divisions and departments, can have IS-architectures too. The above definition implies that *every* enterprise has an IS-architecture, even if that architecture is not explicitly talked about, described, or managed: 'IS-architecture' is a way to look at organizations and their information systems.[1]

IS-architecture alignment is the process of selecting an *IS-architecture vision* towards which the architecture should be incrementally but systematically evolved. This article will present a model-supported framework for aligning an IS-architecture with its surrounding organization (Opdahl, 2003a). The framework shows how an enterprise's *current* IS-architecture can be represented in an enterprise model, from which *candidate architecture visions* can then be generated, before one of them is selected as the enterprise's IS-architecture vision.

BACKGROUND

Zachman (1978) defines 'IS-architecture' as "the sum total of all information-related flows, structures, functions, and so on, both manual and automated, which are in place and/or required to support the relationships between the entities that make up the business." In the last few decades, several IS-architecture methods have been proposed in both industry and academia (Opdahl, 2003a).

A related term is *information architecture (IA)*, used by some authors (e.g., Periasamy & Feeny, 1997) as a synonym to 'IS-architecture', although IA can also be used to emphasize the information sharing and information management aspects of IS-architecture. Another related term is *enterprise architecture (EA)* (McGovern et al., 2004), sometimes called *enterprise information architecture (EIA)* (Cook, 1996), which, according to Chorafas (2002), "is to align the implementation of technology to the company's business strategy" and "to make technology serve innovation economics." 'EA'/'EIA' is sometimes used synonymously with 'IS-architecture', but can also be used to emphasize organizational aspects such as process structure and organizational roles.

IS-architecture alignment can also be understood as an intermediate step (or level) between ICT strategy and detailed IS planning (Brancheau & Wetherbe, 1986).

IS-ARCHITECTURE ALIGNMENT

A *good IS-architecture* should be *strategically* and *operationally fit* to the enterprise, *simple and well structured*, *well managed,* and *clearly and explicitly described*. These characteristics are explained as follows:

- *Strategically fit* means that the IS-architecture should support the enterprise in pursuit of its goals and strategies. This is of course the primary characteristic of a good IS-architecture.
- *Operationally fit* means that the IS-architecture should be integrated with the enterprise's *organizational structures*, such as its *market structure*, *product structure*, *process structure*, *function structure*, *organization structure,* and so on. Although operational fitness may not be a goal in itself, some degree of operational fitness is necessary to achieve strategic fitness.

- *Simple and well structured* means that the IS-architecture should not be unnecessarily complex, because a complex IS-architecture will be difficult to comprehend and understand, and difficult to change without unanticipated consequences. It will therefore be hard to manage.
- *Well managed* means that the principles, activities, roles, and responsibilities for IS-architecture maintenance and evolution should be well-defined and properly taken care of. An IS-architecture that is not explicitly and properly taken care of may start to drift and quickly become unnecessarily complex and/or strategically and operationally unfit.
- *Clearly and explicitly described* means that the enterprise should always document both its *current* IS-architecture and its IS-architecture *vision*. Whereas the current architecture should be represented by a sketch or blueprint,[2] the vision should additionally be documented by a set of higher-level evolution principles.[3]

IS-architecture alignment is the process of selecting such a set of higher-level principles—expressed as an IS-architecture vision—towards which the IS-architecture is to be incrementally but systematically evolved.

Henderson and Venkatraman's (1993) *strategic alignment model* distinguishes between the external and internal domains of businesses on the one hand, and between the business domain and the ICT domain on the other hand. In consequence, their framework distinguishes between *strategic integration*, which is "the link between business strategy and I/T strategy," and *functional integration*, which is "the link between organizational infrastructure and processes and I/S infrastructure and processes" (Henderson & Venkatraman,

Table 1. The core metatypes in the representation framework. For each metatype, a brief description is given, along with examples of possible sub-metatypes (from Opdahl, 2003a).

Metatype (Subtype examples)	***Description***
Goal (mission, vision, business objectives, etc.)	The motives/rationales for the **Activities** carried out by the **Organization Units** and for other **Phenomena**. ***Goals** can be either explicit statements or implicit ideas. They can be either shared or individual and either official or private.*
Strategy (business strategies, principles, plans and standards, etc.)	Guidelines for how **Organization Units** carry out **Activities**. *G**uidelines** can be either formal or informal.*
Organization Unit (divisions, business units, departments, work groups, employees, project groups, boards, committees, etc.)	One or more persons. *An **Organization Unit** can be either an individual or a group. It can be either permanent or temporary. Note that a **Role** is a subtype of **Organization Unit**, i.e., an individual unit at the type level. The **Role** subtype is so important in enterprise modeling that it should often have its own icon.*
Activity (functions, processes, tasks, some projects, etc.)	Actions or events that occur in the enterprise. ***Activities** can either be singular, continuous, or repeated.*
Information	A pattern of information or data that is used and/or produced in the enterprise. ***Information** can be on electronic or other formats, e.g., paper.*
Application	A software system that automates or supports an **Activity** in order to let an **Organization Unit** accomplish an **Goal**.
Database (electronic archives, libraries, etc.)	A collection of data or information in the enterprise. *A D**atabase** can be in electronic or other form.*
Basic Software (operating systems, protocols, etc.)	A group of cooperating programs that are used by Applications and Databases.
Computing Equipment (computers, peripherals, etc.)	A piece of hardware.
Network	A communication network that connects computers with other computers, peripherals, and/or networks.
Phenomenon	Any of the above, i.e., either an objective, a strategy, an organization unit, an activity, information, an application, a database, basic software, computing equipment, a network, or an instance of one of the extensional metatypes.

1993). Relative to Henderson and Venkatraman's model, IS-architecture alignment focuses on 'functional integration' and on the 'internal domain' of enterprises.

MODELING ORGANIZATIONS AND IS-ARCHITECTURES

The framework for model-supported alignment relies on a structured view of an *organization* (Opdahl, 2003a) as a collection of *organizational elements* with *organizational relationships* between them. There are different types of elements, such as *goals*, *organization units,* and *activities*. Table 1 lists the most important ones, with further details given in Opdahl (2003a). The terms used in Table 1 are only suggestions. In real projects, they should be refined into more organization-specific terms. For example, 'organization unit' could be replaced by terms such as 'division', 'department', 'project group', 'role', and 'position', and the term 'activity' could be refined into 'project', 'process group', 'process', 'process step', 'operation', 'business function', and so forth. The framework defines many types of organizational relationships too (not shown in Table 1), such as goals that are *realized-by* activities and organization units that *carry-out* activities and that are *responsible-for* goals.

According to the framework, a part of the organization forms an *IS-architecture*, which is correspondingly viewed as a collection of *IS-architecture elements* and *relationships*. Examples of IS-architectural element types are *applications* and *databases*, and an example of a relationship type between IS-architecture elements is that applications *manipulate* databases. There are also various types of relationships between IS-architecture elements and other organizational elements, such as databases that *store* information, and activities that are *supported-by* applications and that *manipulate* information.

IS-architecture elements form *IS-architecture areas*, which may comprise several different types of elements. A particularly important type of IS-architecture area is the enterprise's *information systems*, which are collections of tightly coupled applications and databases that are related to the rest of the organization. But the framework also allows for other types of IS-architecture areas that group other kinds of IS-architecture elements, for example *responsibility areas* that group information systems into larger clusters. IS-architecture areas are important because they can be used to make the IS-architecture simple and well structured, and thereby more manageable: in a good IS-architecture, the architecture areas support the enterprise's goals and strategies, and the elements in each architecture area are closely related to one another, whereas there are few relationships between elements that belong to distinct areas.

Figure 1 shows the most important organizational and IS-architectural element types in the framework. Goals and strategies are executed by the grey-shaded operational organization, whose three domains are shown as layers in Figure 1. The *organizational domain* comprises organization units, activities, and information; the *information systems domain* comprises IS-architecture areas, applications, and databases, whereas the *ICT-infrastructure domain* comprises basic software, computing equipment, and computer networks.

Importantly, many elements in the framework are *decomposable*. For example, an organization unit can have sub-units, and an information element can have sub-elements. Decomposable elements of the same type form *organizational structures*, similar to organizational *dimensions* (Armour, 2003). Examples of organizational structures are the hierarchy of organization units in an enterprise and its business function hierarchy.

Figure 1 is also a sketch of a more detailed underlying *metamodel* (Opdahl, 2003a). The metamodel can be seen as a model of a modeling language for representing IS-architectures and the organizations that surround them. The metamodel has been implemented in a graphical enterprise-modeling tool, supported by the Computas-Metis modeling and metamodeling tool family. The framework and tool can be used to represent an enterprise's *current* IS-architecture, as well as *candidate* and *selected* IS-architecture *visions*.

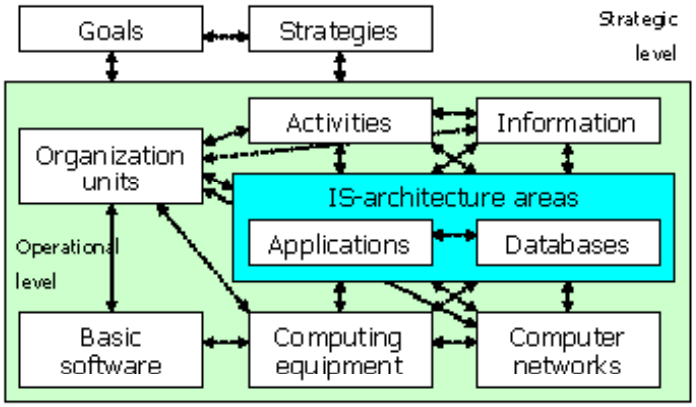
ALIGNING ORGANIZATIONS AND IS-ARCHITECTURES

The framework for model-supported alignment centers on *operational* and *strategic fitness*, the two most important characteristics of a good IS-architecture. Firstly, the framework systematically investigates alternative ways to achieve operational fitness by generating a candidate architecture vision for each of them. Secondly, the generated candidate visions are evaluated and compared according to their strategic fitness, before one of them is selected as the enterprise's IS-architecture vision. In other words, the framework investigates different ways to achieve operational fitness and selects one of them according to strategic fitness.

In the first step, different ways to align the IS-architecture with the surrounding organization are investigated systematically, inspired by an approach outlined by Kiewiet and Stegwee (1991). Each candidate architecture vision is expressed as a set of *IS-architecture principles* used for grouping IS-architecture elements into IS-architecture areas. Each principle prescribes one way to group one type of IS-architecture element and, together, the set of principles prescribes one way to group all the element types in the architecture.

A principle for grouping IS-architecture elements (of a particular type) comprises (a) an organizational structure,

Figure 1. The core of the IS-architecture representation framework. The core metamodel can be extended with metamodels that represent other metatypes, such as products and locations and IS architecture areas other than information systems (Opdahl, 2003a).



(b) possibly a hierarchical level of decomposition of that structure, and (c) a relationship, possibly indirect through several intermediate relationships, between that structure (at that level of decomposition) and an IS-architecture element (of that type). According to the principle, two IS-architecture elements will belong to the same group if they have the same relationship (c) to an element at the appropriate level of decomposition (b) in the organizational structure (a). For example, applications (a type of element) may be grouped into information systems (a type of architecture area) according to the business function (an organizational structure) that they support (a particular relationship). Furthermore, applications can be grouped into a few large information systems according to high-level business functions or into many smaller information systems according to lower-level, more decomposed functions (decomposition levels in the hierarchy of business functions) (Opdahl, 2003a).

This structured view of IS-architecture alignment, along with the equally structured views of organizations and IS-architectures presented in the previous section, makes it possible to systematically investigate all possible sets of principles, either manually or automatically. If the current IS-architecture and its surrounding organization are represented in an IS-architecture model, it is even possible to automatically generate models of each candidate architecture vision.

The first step of the alignment framework ensures that the generated candidate visions will be both *operationally fit, simple and well structured,* and *clearly and explicitly described*. But it does nothing to satisfy the most important criterion of all, *strategic fitness*. In the second step, the candidate architectures are therefore evaluated and compared according to strategic fitness. The framework does *not* currently support automatic selection of optimal or satisficing architectures leaving this task for manual assessment according to, for example, the enterprise's goals and strategies. However, automatic generation of enterprise models for candidate architecture visions should make selection easier by making assessments of and comparisons between candidates more concrete. Developing heuristics for critiquing, shortlisting, prioritizing, and selecting candidate architectures remains a topic for further work.

FUTURE TRENDS

This article has outlined how enterprise models can be used to help enterprises align their IS-architectures with the surrounding organization. But model-supported alignment of IS-architectures is only one among many important ways in which future enterprises can benefit from enterprise models. For example, new ICT systems will gradually become adaptable and manageable through enterprise models, as when a new customer resource management (CRM) system is tailored by modifying associated models of information processes and markets. Later changes to the enterprise model can then be automatically reflected in the running CRM system, so that both initial adaptation and subsequent management can be done at the model level.

When the enterprise's ICT systems thus become controllable through enterprise models, there is a danger that enterprises become more rigid and uncoordinated as a result, because the models are expressed in many different and unrelated modeling languages. This danger can be avoided by *integrating* the modeling languages and technologies

used to control different ICT systems. As a result, the enterprise can become better coordinated because its ICT systems become semantically integrated. The enterprise can also become more flexible because changing ICT systems through enterprise models is easier than changing them at the implementation level. There is therefore a need for theories and tools for tightly integrating a broad variety of enterprise models and modeling languages (Opdahl, 2003b; Opdahl & Sindre, 1997), including information and process models, actor and organization models, and goal and business-rule models. In this light, the alignment framework is only a partial contribution to developing theories and tools for tying together ICT systems in a flexible way through tightly integrated enterprise models.

CONCLUSION

The article has presented a model-supported framework for aligning an IS-architecture with the surrounding organization. One advantage of the framework is that it does not only derive blueprints of future architectures, but also generates *principles* for evolving the current IS-architecture towards the architecture vision. Another advantage is that the framework can in principle be supported by a tool, which can in the long run be developed into an *IS-architecture* (or *enterprise architecture*) *workbench*. The workbench could gradually be extended to supplement the framework with a variety of alternative approaches to ICT strategic alignment.

The framework needs to be developed further. When tool support becomes available, it must be validated by industrial case studies. Further research is also needed on how to compare candidate architectures and how to best represent and visualize IS-architectures. Also, the framework in its present form is *reactive* rather than *proactive*, because it takes the surrounding organization as a given. Although it should not be difficult to modify the framework to better support proactive use, this needs to be investigated.

Behind the alignment framework is a broader view of tomorrow's enterprises, whose ICT systems will be controlled by comprehensive enterprise models. As a result, *enterprise model integration* will become a prerequisite for ICT systems integration and thereby become the key to successful *enterprise integration*. In the enterprises of the future, the cost of establishing and maintaining large models will be shared by many different areas of use. For this to happen, new theories, technologies, and tools are needed to develop, maintain, and operate large models that integrate multiple perspectives on the enterprise and that are used for different purposes (Opdahl, 2003b; Opdahl & Sindre, 1997).

KEY TERMS

Enterprise Model: A diagrammatic representation of an enterprise or part of an enterprise. An enterprise usually focuses on certain aspects of the enterprise, such as its goals and strategies, its business processes, its organization structure, its information and knowledge, etc.

Information System (IS): A system that communicates, transforms, and preserves information for human users. An information system comprises one or more computerized data systems along with their human users, operators, and maintainers.

Information Systems Architecture, IS-Architecture: The set of information systems in an organization, the relationships between those information systems, and the relationships between the information systems and the rest of the organization.

IS-Architecture Alignment: The process of selecting an IS-architecture vision that is strategically and operationally fit for the enterprise, simple and well structured, well managed, and clearly and explicitly described.

IS-Architecture Model: An enterprise model that focuses on the enterprise's IS-architecture and that can be used to represent a current architecture or to illustrate a candidate or selected architecture vision. An IS-architecture sketch is a high-level model, whereas an architecture blueprint is more detailed.

IS-Architecture Principle: A high-level rule that can be used to make decisions about developing and/or evolving individual ICT systems.

IS-Architecture Vision: A coherent set of IS-architecture principles that together guide all the aspects of IS-architecture evolution that are considered important.

ENDNOTES

1 This contrasts authors who define 'IS-architecture' as a 'blueprint' or 'sketch' of how the enterprise's ISs *are* or *should be* organized. In the terminology of this article, although a blueprint or sketch can *represent* or *describe* an IS-architecture, the blueprint or sketch *is not* the architecture.

2 The difference between the two is that a *sketch* is a rough representation that is used to communicate central aspects of an IS-architecture, whereas a *blueprint* is intended as a complete description of the architecture.

3 Principles are preferable to blueprints because a blueprint is only valid for as long as the rest of the organization stays roughly the same, whereas a principle can be useful even after the organization has undergone changes, although the enterprise's principles must of course be re-evaluated from time to time as it evolves.

Moderation in Government-Run Online Fora

Arthur Edwards
Erasmus Universiteit Rotterdam, The Netherlands

Scott Wright
De Montfort University, UK

INTRODUCTION

A Dutch Internet dictionary has defined the moderator as "a person who exercises censorship on a mailing list or newsgroup."[1] Censoring the content of online discussion has often been considered as conflicting with the Internet's libertarian tradition of free speech and unrestrained communication (Tsagarousianou, 1998). However, as the famous PEN-experiment (public electronic network) in Santa Monica (1990-96) showed, the desirability of free speech must be weighed against other legitimate concerns such as the need to facilitate discussion and counteract possible abuses of the medium (Docter & Dutton, 1998).

This article analyses government-run online fora in which citizens and social organizations can discuss amongst themselves—or with government officials and elected representatives—issues of public concern. Effective moderation is considered crucial because the perceived anonymity in online fora weakens the norms of constitutive/self censorship that regulate face-to-face behaviour. It is thought that this can lead to "flame wars," polarized debates and dominant minorities. Thus, while the anonymity of online environments may diminish the psychological thresholds that can limit participation, it may also exacerbate them—inhibiting the social cooperation needed to accomplish complex communicative tasks. Moderators, it is suggested, can mitigate such problems by stimulating and regulating discussions—facilitating purposeful social action (Coleman & Gøtze, 2001; Edwards, 2002, 2004; Wright, 2006a).

Initial empirical analyses of online political discussion tended to focus on usenet newsgroups and found that debates were of poor deliberative quality and reinforced rather than changed pre-existing views (Davis, 1999; Hill & Hughes, 1998; Wilhelm, 2000). We must not extrapolate from this that all online political discussion is of poor quality—or, indeed, that all online discussion must be of high deliberative quality. The Internet provides us with a virtual commons upon which diverse interests can set up camp; the relative "free-for-all" provided by usenet can perform a useful socio-political function alongside regulated, government-led discussions. The two are not mutually exclusive. It is important that government-run online forums have clear aims, and are designed, structured, and moderated (or not) to ensure these are achieved (Wright, 2005; Wright & Street, forthcoming). A minimum level of moderation is normally required for legal reasons. Of course, this is balanced by local laws and rules on the right to free speech.

THE VARIED ROLES OF THE MODERATOR

A moderator can be defined as a person (or group of persons) who facilitates a discussion in view of its goals and agenda. Moderators can perform a wide range of functions from censorship to facilitation, dependent on the aims and context. The Guide for Electronic Citizen Consultation, published by the Dutch Ministry of the Interior (1998), mentions three moderator roles:

- **Host:** Guiding and making participants feel at ease
- **Discussion leader:** Progresses discussions and makes sure that all discussants have a chance to participate
- **Arbiter:** Designates which postings are inappropriate and removes them

Drawing on work by White (2002) and others, Coleman et al. (2001) have fleshed out this approach listing various metaphors to designate potential roles. These include: "social host," "project manager," "community of practice facilitator," "cybrarian," "help desk," "referee," and "janitor." White relates each role to specific types of communities. These designations are useful as they highlight the variety of potential functions.

Broadly speaking, two types of moderation have been adopted by governments: content moderation and interactive moderation (Wright, 2006a). To moderate the content of respondents' posts is to perform an act of censorship. Content can be moderated by electronic or human filters. Electronic filters are crude as they take no account of context and can be easily circumnavigated. Human moderation negates these problems, but raises further issues such as the subjectivity in making decisions. Content moderation is typically conducted silently: moderators do not reply to posts, facilitate discussions, or feed the discussions into the policy process. Furthermore, people whose messages

are considered inappropriate are not given an explanation for their message being deleted. This is, thus, a restricted and narrow approach to moderation. It is primarily suited to government-run discussions in which tens of thousands of messages are expected; where it would be unfeasible to adopt more interactive measures because of resource costs, and where pre-moderation would inhibit the flow of the discussion.

Governments have adopted various forms of interactive moderation by choosing specific roles from the list previously outlined to meet their aims. In this article, we go beyond a "pick and mix" approach by developing a "management" model of Internet discussions. The underlying claim of this model is that it specifies the principle tasks that have to be performed in the design and management of *decision-influencing* online policy fora. The model builds on theories of deliberative democracy, in which, citizens commit to resolve problems of collective choice through free public deliberation. Following Benhabib (1994), three principles can be derived that constitute a deliberative procedure. The first principle builds on Habermas' (1971) ideal speech situation and states that participation in deliberation is governed by norms of equality and symmetry; decisions are made by the force of arguments rather than power manoeuvres. Moderators advance these norms by attempting to promote discursiveness amongst participants and stopping the more active participants from dominating debates and agendas. They also encourage politicians and other institutional actors to participate. Benhabib's second principle states that all participants have the right to question the assigned discussion topic. This can be achieved by moderators being open to new or amended discussion topics both at the start and during the discussion. The third principle argues that everyone has the right to initiate reflexive arguments about the rules of the discourse procedure, and how they are applied. It suggests that the moderation policy should be transparent and negotiable. A users panel can be set up to resolve disputed decisions by moderators. Together with the agenda, the rules can be consolidated in a commonly agreed discussion group charter.

To specify possible moderator roles in interactive moderation, we use a management approach. This suggests that certain general "management functions" have to be performed. We distinguish (1) the strategic function, (2) the conditioning function, and (3) the process function (see Figure 1). The strategic function is to establish the boundaries of the discussion and to embed it in the political and organizational environment. This includes the following tasks:

- Establish the *goals* of the discussion, both for citizens and the institutional decision making system
- Establish and maintain the *substantive domain* of the discussion (i.e., the boundaries of the agenda within which themes and issues may be raised)
- Obtain *political and organizational support* for the discussion
- Establish the *status* of the discussion in terms of their influence on decision making
- Ensure that the *results* of the discussion will actually be carried over into the decision making process and to give feedback on this to the participants

The *conditioning* function involves the provision of all kinds of resources (including the recruitment of participants) to ensure the health of discussions such as:

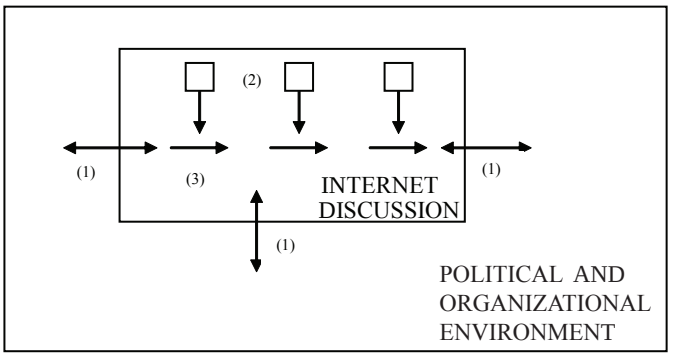
- Solicit people to join the discussion as participants
- Provide information
- Provide supporting technologies, such as moderation software, simulation models, and visualization

The *process* function includes all tasks that establish the discussion process as a cooperative, purposeful activity:

- Set the interactional goal of the discussion (i.e., the kind of results to be reached by the participants within the discussion, for instance, exploration of problem definitions or consensus about a proposal of policy measures)
- Specify the agenda of the discussion, within the substantive domain established in the strategic function: the questions, propositions, or themes
- Set the schedule of the discussion
- Manage the discussion process: its interactional goal, agenda, and schedule. For example, assign messages to discussion lines or open new discussion lines
- Facilitate the progress of the discussion by making summaries during the discussion
- Stimulate interactivity in the discussion by, for example, encouraging participants to take part in the discussion and to give reactions to specific contributions
- Set and maintain the rules of the game

As an analytical tool, this model can be used in two ways. First, in an actor-oriented way, it can be used as an instrument to discover what moderators do (Edwards, 2002). Second, in a process-oriented way, it can be used to ascertain how the different management functions are performed and which actors are involved. Used in this way, the model allows for contributions to the management of online discussions by actors other than the moderator. Especially important is the distinction between what the moderator does and what the initiators of the discussion do (Edwards, 2004—see next).

Figure 1. The management of government-run online fora (Edwards, 2002; reprinted with permission from IOS Press)



Note: 1 = strategic function; 2 = conditioning function; 3 = process function

EMPIRICAL FINDINGS ON MODERATION

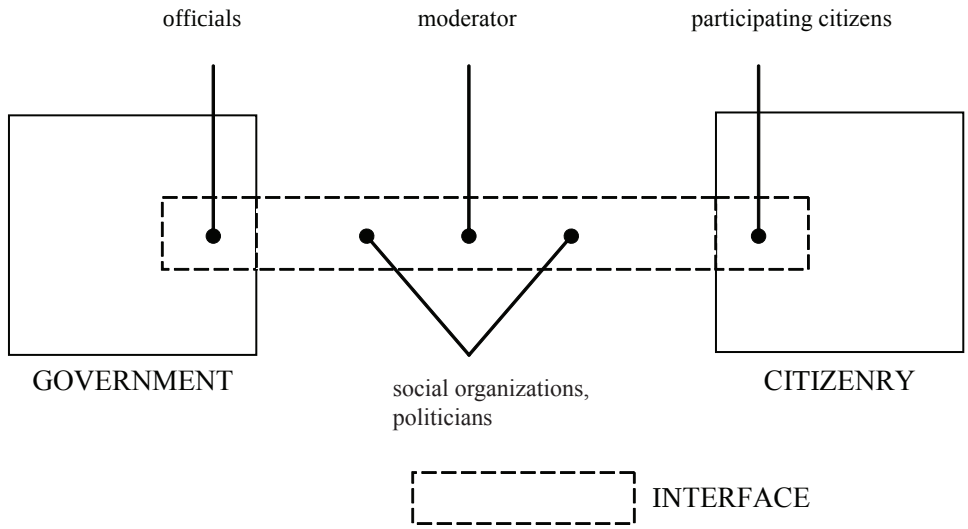
Empirical analyses have shown that governments have adopted a wide range of moderation strategies on their discussion fora—with varying degrees of success. Content moderation has proved the most controversial approach. It has led to conspiratorial atmospheres amongst participants (Coleman, Hall, & Howell, 2002); moderators receiving death threats (see Wright, 2006); and generated bad publicity for governments (Wright 2006a). Most notably, the Downing Street Web site's adoption of content moderation for its discussion fora led to accusations of control-freakery and censorship in *The Times* (Tom Baldwin, 18 March 2000), and technological naïvety in *The Observer* (Ros Coward, 20 February 2000). Empirical analysis (Wright, 2006a) has suggested that the problems were due to various unadvertised moderation policies such as removing all messages that replied to one subsequently deemed unacceptable.

Interactive moderation has proved a much more successful, and popular, method for facilitating discussion. Referring to our management model, case studies indicate that the moderator's primary involvement relates to the process function (Edwards, 2002, 2004; Lührs, Albrecht, Lübcke, & Hohberg, 2003; Jensen, 2003; Trénel, Märker, & Hagedorn, 2001; Wright, 2006a). Moderators have actively sought to enhance interactivity by, for instance, encouraging politicians and civil servants to contribute and reply. Edwards (2002) established that this activity is often conducted "behind the scene" (by the use of e-mail, for instance). In his analysis of the e-democracy forum, Wright (2006a) gives several examples of how the moderator directly intervened, thereby generating further discussion. Moderators also help to formulate discussion themes (often cooperating with the initiating agency and citizens). Furthermore, to keep the discussion on track as a purposeful activity, moderators manage discussion lines and make summaries. Finally, moderators are involved in setting and maintaining rules. The setting of the discussion rules can be a complicated process in which the initiators and the moderator may have different positions.

The extent to which moderators are required to filter offensive messages varies significantly. Edwards concluded from his research that, in practice, moderators had to intervene only infrequently. This finding is supported by analysis of the Nordpol debate in Denmark: only one message was deleted, while another user was forced to post an apology for making insulting comments about a private company. (Jensen, 2003, p. 46) Moreover, in the case of irrelevant postings or spam the debate tended to be quite self-regulatory. These findings contradict Wright's (2006a) analysis of two British central government-run fora. On the Downing Street Web sites content-moderated fora, 53.9% were missing at the end, while on the interactively moderated e-democracy forum some 26.25% of messages were blocked.[2] The differences may be explained by the facilitating activities of the moderator encouraging a more civil debate; less controversial topics; or the nature of the participants. As far as the conditioning function is concerned, in the cases analysed by Edwards moderators and initiators often cooperated in recruiting participants and in providing information—either directly or by inviting others, notably public agencies, interest groups, and political parties to provide their views on the subject.

With regard to the strategic function, there are numerous examples of moderators passing results and summaries of discussions to policy makers, although these are often subsequently ignored. However, it seems plausible that the strategic tasks, such as establishing the goals of the discussion, its status, as well as obtaining organizational and political support, are accomplished by the initiators themselves. Here we can indicate a clear demarcation between

Figure 2. Actors involved in government-run online fora (Edwards, 2004)



the management tasks that are fulfilled by the initiators and the moderators. We conclude that moderators are fulfilling important roles as intermediaries between citizens and public administrations: they enhance the interactivity and openness of online discussions as well as their relevance for public policy making.

The performance of moderators is, however, dependent on several *institutional and organizational factors*. Moderators do not function in isolation; they have to cooperate with other actors. Figure 2 depicts the interface of actors that are involved in the discussions.

Given the importance of their role, deciding who should moderate online fora is crucial. In government-initiated discussions, moderators can be civil servants, independent ("third party") moderators, or selected citizens. As intermediaries, moderators are agents of both the initiating government and participating citizens. This suggests that the relative autonomy of independent moderators places them in a better position to strike a balance. Independent moderators can still be biased though, for example when providing information or making summaries. Moderation by civil servants is acceptable if activities are transparent and negotiable; that is, if citizens have no reason to question their impartiality. Censorship is inherently subjective and open to accusations of bias—even where none exists. This has led Wright (2006a) to argue that it is necessary to separate out the censorial and facilitation roles of the moderator: censorship being conducted by an independent body with facilitation by civil servants. Involving citizens in the moderation process can also be valuable. In Bremen, an online discussion was moderated by a team consisting of four citizens, a civil servant, and an expert. They found that citizen moderators performed an important feedback function and that their local knowledge was important (Westholm, 2003). Citizen moderation and moderation by government staff are less appropriate where the issue is controversial.

Generally, the moderator's position is embedded in *organizational arrangements* in which the initiating government and sometimes also social organizations are represented. In the "project groups," "supervisory teams," or "editorial groups," the moderator, public officials, and representatives of other organizations work together in organizing and managing the discussion. These arrangements are of strategic importance, because they embed the discussion in the organizational and political environments. On the one hand, they impose some limits on the autonomy of the moderator, but on the other hand, they may enhance the relevance of the discussion, and its impact on the regular policy process.

The position of *social organizations* deserves particular attention. Social organizations can figure in various roles, for instance as initiators of a discussion, as information providers, or as participants. The involvement of social organizations in online discussions, their interaction with individual citizens, civil servants, and politicians, is an important subject for further research.

The participation of *politicians* is important, as they are the final decision makers in a representative democracy. Their commitment will be beneficial to the discussion's impact on political decision making. Politicians often show a reluctance to involve themselves in 'interactive policy exercises' with citizens, whether face-to-face or online

(Coleman et al., 2001). Moderators should encourage their participation. Equally, they must not dominate discussions as this may inhibit open citizen participation. According to Jensen (2003, p. 46), the presence of politicians "thus seems to be a two-edged sword." Here lies another example of the "sense of balance" that moderators have to show.

A possibility for strengthening the position of the *participating citizens*, and thereby enhancing the openness of the discussion, is to present the agenda and the moderation policy at the start of the discussion as proposals that are open to amendments. The outline of the discussion would then be consolidated in a commonly agreed upon charter. Also, procedural rules could be established for amendments or additions to the agenda during the discussion. Other provisions can be made to further the openness and negotiability of the moderation.[3] Furthermore, citizens can be invited to make suggestions as to relevant information or to forward information to be placed on the discussion site. Finally, the conclusions of the discussion could be consolidated in a collaboratively drafted summary.[4]

FUTURE TRENDS

A recent trend is the development of specific *discourse support systems* (i.e., systems of information and communication technologies for supporting a discussion) (Luskin, Fishkin, & Iyengar, 2004; Noveck, 2004; Sack, 2005). They provide a Web-based platform as well as a methodology and appropriate tools for enabling a fruitful dialogue. Generally, they also provide a set of features for moderating the discussion (Gordon & Richter, 2002; see also Coleman et al., 2001).[5] The moderator tasks will be more and more embedded in such systems of both social and technical components. More and more, the technical components will enable cooperative work and design by the participants.

CONCLUSION

Moderators are emerging as democratic intermediaries; facilitating government-citizen interactions in virtual environments. In this article, we focused on one such virtual environment: online discussion fora.[6] In so far as these forms will enter in the practice of democratic governance, moderators will establish themselves as elements of the information and communication infrastructure between the citizenry and public administration. Moderators can enhance the quality of online discussions and their relevance for political decision-making. We must add a note of caution though: a poorly designed and explained moderation policy can have negative consequences and thus moderation policies must be carefully considered in the light of the discussion goals.

The moderator's tasks will increasingly be embedded in socio-technical environments. The organizational arrangements, procedures, discussion rules and how the technological components are designed are all important. In developing these arrangements, due attention must be given to ensuring the openness of the discussion, and the transparency and negotiability of the moderation.

KEY TERMS

Content Moderation: A form of electronic or human filtering that blocks (censors) messages against pre-defined criteria. It is typically conducted silently and suitable only for discussions receiving thousands of messages.

Deliberative Procedure: A discussion that is governed by the norms of equality and symmetry in participation and the right of the participants to question the agenda and the discussion rules, as well as the way in which the agenda and rules are applied.

Discourse Support System: A system of information and communication technologies, providing a Web-based platform, a methodology, and appropriate tools for fruitful discussions.

Interactive Moderation: Moderators perform a variable suite of activities to facilitate productive debates such as bringing in external speakers, replying to messages, framing debates, and prompting further debate.

Moderator: A person or group of persons who facilitates a discussion in view of its goals and agenda.

The Conditioning Function of the Management of Online Discussions: Take care of all kinds of conditions and provisions to further the discussion.

The Strategic Function of the Management of Online Discussions: Establish the boundaries of the discussion and embed it in the political and organizational environment.

The Process Function of the Management of Online Discussions: All tasks that have to do with the discussion process as a cooperative, purposeful activity:

Modern Passive Optical Network (PON) Technologies

Ioannis P. Chochliouros
Hellenic Telecommunications Organization, Greece

Anastasia S. Spiliopoulou
Hellenic Telecommunications Organization, Greece

INTRODUCTION

Presently, not only the European Union (EU) but the global community faces a decisive priority to "redesign" its economy and society, in order to meet a variety of challenges imposed by the expansion of innovative technological features, in the scope of the new millennium. The rate of investments performed and the rapid development of electronic communications networks-infrastructures, together with all associated facilities in the scope of broadband evolution, create novel major opportunities for the related market sectors (Chochliouros, & Spiliopoulou, 2005). Modern digital-based technologies make compulsory new requirements for next-generation components and for much wider electronics integration. This critical challenge also raises the issue for considering the "evolution" from current large legacy infrastructures towards new (more convenient) ones, by striking a "balance" between backward compatibility requirements and the need to explore disruptive architectures to appropriately build (and offer) future Internet, broadband, and related service infrastructures. More specifically, for the entire European market a number of evolutionary initiatives, as they currently have been encouraged by the latest EU strategic frameworks, relate first and foremost to the technological expansion and the exploitation of ubiquitous broadband networks, the availability/accessibility of dynamic services platforms, and the offering of "adequate" trust and security, all in the framework of converged and interoperable networked environments (European Commission, 2006).

However the global information society cannot deliver its major benefits without a "suitable" and appropriately deployed infrastructure, able to fulfill all requirements for increased bandwidth. During recent years, optics and photonics have become increasingly pervasive in a broad range of applications. Therefore, photonic components and subsystems are nowadays indispensable in multiple application areas, and consequently they constitute concerns of high-strategic importance for many operators. In this critical extent, fiber is constantly becoming an essential priority for wired access, as it can provide excessive bandwidth and additional advantages, if compared to similar alternative options of underlying infrastructures (Agrawal, 2002). There are several market and investment evidences demonstrating that a significant part of next-generation access networks will be based on optical access (Chochliouros, Spiliopoulou, & Lalopoulos, 2005).

This is due to the fact that we are presently witnessing an extraordinary expansion in bandwidth demand, mainly driven by the development of sophisticated services/applications, including video-on-demand (VoD), interactive high-definition digital television (HDTV), IPTV, multi-party videoconferencing, and many more. These facilities require both the existence and the use of a "fitting" underlying network infrastructure, capable of supporting high-speed data transmission rates that cannot be fulfilled by the "traditional" copper-based access networks. In fact, market actors are currently focusing on developing and deploying new network infrastructures (Leiping, 2005) that will constitute future-proof solutions in terms of the anticipated worldwide growth in bandwidth demand (reaching a rate of 50% to 100% annually), but at the same time be economically viable (Prat, Balaquer, Gene, Diaz, & Fiquerola, 2002). To this aim, fiber-access technologies evolve quite rapidly as they can guarantee "infinite" bandwidth opportunities, for all prescribed market needs, either corporate and/or residential.

BACKGROUND

A great majority of users currently benefit from rather high-speed communication services offered through DSL (digital subscriber line) access technologies. DSL's deployment has been widely supported by incumbent operators, as they were able to exploit their already laid copper infrastructure to offer broadband connectivity services to their customers, without being actually obliged to realize severe investments in access infrastructure. However, such schemes are considered as "short-term" market solutions, since the aging copper-based infrastructure is rapidly approaching its essential speed limits, while simultaneously, modern applications definitely "push" data rates beyond the capabilities of such networks. As a consequence, such networks "generate" a type of "limitation"

(or a "bottleneck") concerning requirements of bandwidth and service provision between the operator and the end user. In contrast to this option, optical access architectures allow communication via optical fibers and can provide significant advantages to the customers' needs mainly by providing a fully practical (and viable) solution to the access network "bottleneck problem," as they can support extremely high and symmetrical bandwidth to the end user (Green, 2006). Furthermore, they future-proof the network operator's CAPEX investment, as they offer simple and low-cost speed upscale, whenever necessary. While the cost of installing optical access networks has been considered as "extremely high" in the past, this has been falling progressively, and such infrastructures currently seem to be the main broadband access technology of the decade (Frigo, Iannone, & Reichmann, 2004). Optical access networks are not a new concept, as they have been considered as a potential solution for the subscriber access network for quite some time. Their deployment costs as well as their corresponding equipment costs have been dramatically reduced in recent years. Current experience has demonstrated that once fiber is installed, no significant additional investments (or reengineering) are likely to be required for the next few decades; in fact, fiber-based networks can offer fast and easy repair, low-cost maintenance, and simple upgrade. The specific category of Passive Optical Networks (PONs)—as explained in detail in the subsequent parts of this article—are now viewed as probably the "best solution" for bringing fiber to the home, since they are composed of only passive elements (fibers, splitters, splicers, etc.) and are therefore very low priced. In addition, a PON can support very high bandwidths and can function at long distances (of up to 20 km) significantly higher than these supported by high-speed DSL variants.

PON ARCHITECTURE AND DEPLOYMENT

The advent of video-on-demand and interactive gaming has prompted the deployment of immense broadband infrastructures. Because of its large bandwidth, passive optical networks are currently seen as a "proper" technology to make this happen. PON technology, nowadays being broadly adopted and deployed in multiple areas all over the world (with remarkable growth rates in North America and Japan where it provides the main solution for fiber-to-the-home (FTTH) exploitation), constitutes a convenient solution for exploiting the "undoubted" and beneficial usage of the broadband perspective (Gumaste, & Anthony, 2004; Cisco Systems, 2007).

PONs allow individual homes, larger residential or office buildings, and wider premises to be connected to public telecommunications networks directly via fiber with a high bit rate. Even across great distances, they provide users with a very high transfer capacity, which is essential for all modern data services such as high-resolution television reception or home entertainment services. PON is a very recent, *and still developing,* access technology based on the specification originally developed by the Full Service Access Network (FSAN) vendor consortium (http://www.fsanweb.org/) for the APON (ATM (asynchronous transfer mode)- based passive optical network) case. However, as discussed in a subsequent part of this article, several variants have been deployed, with distinct characteristics (Ramaswami, & Sivarajan, 2002).

A PON is a point-to-multipoint, fiber-to-the-premises network architecture where unpowered optical splitters are used to enable a single optical fiber to serve multiple premises (typically 32 different lines). A relevant configuration reduces the amount of fiber and central office (CO) equipment required, if compared with "traditional" point-to-point architectures. The "deletion" of active components implicates that the access network consists of one bi-directional light source and a number of passive splitters that divide the data stream into the individual links to each customer (Kramer & Mukherjee, 2000; Green, 2006). A PON system typically consists of optical line terminals (OLTs), optical network terminals (ONTs), optical network units (ONUs), and passive splitters, as shown in Figure 1.

The OLT is located in the network operator's CO in a telecommunications application, or in the CATV (cable TV) provider's head-end. The OLT can either generate optical signals on its own, or pass optical signals (e.g., synchronous optical network–SONET) from a collocated optical cross-connect or other device, broadcasting them downstream through one or more ports. The OLT provides the interface between the PON and the backbone network. These typically include: standard time division multiplexed (TDM) interfaces such as SONET/SDH (synchronous digital hierarchy) or PDH (plesiochronous digital hierarchy) at various rates, Internet protocol (IP) traffic over gigabit or 100 Mbit/s Ethernet, and ATM UNI (user-network interface) at 155-622 Mbit/s.

The ONU or the ONT terminate the circuit at the far end. An ONT is a single integrated electronics unit, and it is used to terminate the circuit inside the premises in an FTTP (fiber-to-the-premises) scenario, where it serves to interface the optical fiber to the copper-based inside wire. In fact, it presents the native service interfaces to the user.

An ONU is the PON-side half of the ONT, terminating the PON; it may present many converged interfaces (such as xDSL or Ethernet) towards the user. It typically requires a separate subscriber unit to provide native user services such as telephony, Ethernet data, or video. In practice, the difference between an ONT and ONU is frequently ignored, and either term is used generically to refer to both classes of equipment (Mukherjee, 1997). The ONU is used in an FTTC (fiber-to-the-curb) scenario, where the fiber stops at the curb, with the balance of the local loop being provisioned over

embedded copper (unshielded twisted pair-UTP) in conventional telecommunications networks and coaxial (coax) in CATV networks. An ONU also is used in an FTTN (fiber-to-the-neighborhood) scenario, in which it is positioned at a centralized position in the neighborhood, with the balance of the local loop being provisioned over embedded coax or UTP. While this scenario maximizes the use of embedded cable plant, *and therefore minimizes the costs associated with cable plant replacement,* it compromises performance to some extent.

The passive optical splitter "sits" in the local loop between the OLT and the ONUs (or ONTs). The splitter divides the downstream signal from the OLT at the network edge into multiple, identical signals that are broadcast to the subtending ONUs. Each OLT/ONU is responsible for determining which data are intended for it, and for ignoring all others (Keiser, 2006). Upstream signals are supported by a time-division multiple access scheme, with the transmitters in the ONUs operating in burst mode. FSAN supports both symmetric and asymmetric modes.

A PON uses small, inexpensive, low-power optical splitters, rather than the relatively large, expensive, "power-hungry" optical repeaters employed in more traditional optical networks. In particular, the neighborhood switches are replaced by cheap (or reasonably priced) passive (i.e., requiring no electric power) splitters, whose only core function is to split an incoming signal into many identical outputs (Gorshe, 2006).

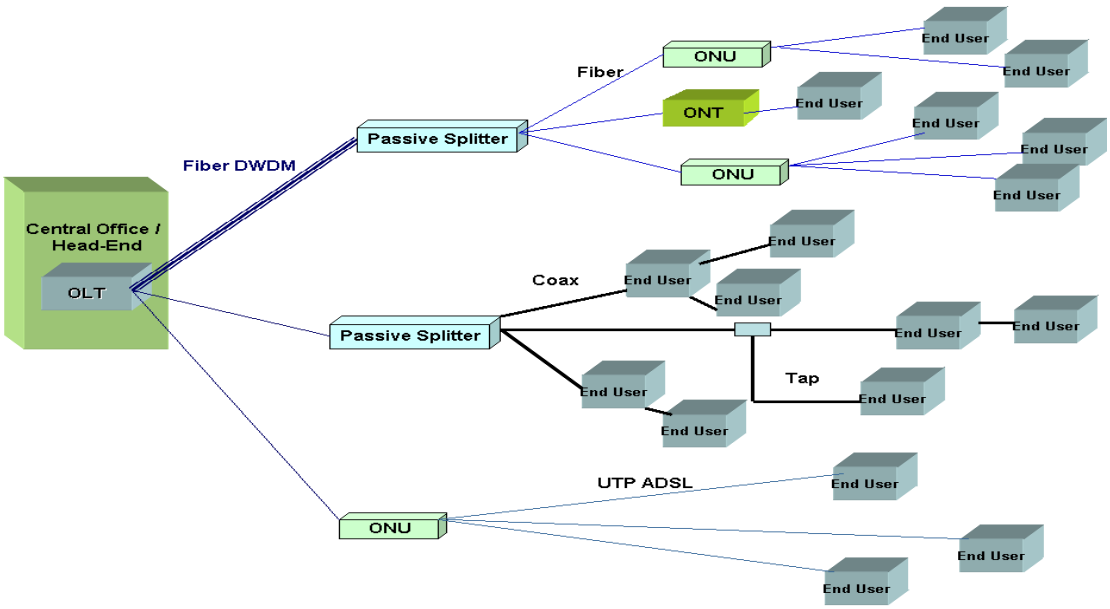
Downstream signals are broadcast to each premise by sharing a fiber. The OLT sends a single stream of downstream traffic that is "seen" by all ONTs. Each ONT only reads the content of those packets that are addressed to it, while encryption is used to prevent eavesdropping on downstream traffic. Upstream signals are combined using a multiple access protocol, invariably time division multiple access (TDMA). The OLTs "range" the ONUs in order to provide time slot assignments for upstream communication.

PON APPLICATIONS

A PON is a "pure" media network, which circumvents from any impacts caused by electromagnetic interference or lightning. As a consequence, a key reason to deploy it is to decrease the spectral interference created by copper-fed applications like asymmetric DSL (ADSL). Moreover, the fault rate is considerably decreased, bandwidth limitations are removed, reliability is strongly improved, and maintenance cost is significantly cut (as service is less expensive to maintain because there are no active loop devices and because fiber is less expensive to maintain in the long run than copper). In fact, a fiber-based PON solution using passive elements can deliver cost savings, which can add up to a 40-60% lower cash expense for labor. Savings mainly result from lower customer contacts associated with service orders and trouble reporting, outside plant operations, central office operations, and network operations (Rashid, 2004).

Simultaneously, a PON has a fine transparency and wide bandwidth, thus being applicable to a variety of signals of any format and of any bit rate. Moreover, it provides a very

Figure 1. Basic passive optical network (PON) architecture



good solution for technically and economically supporting "triple-play" services.

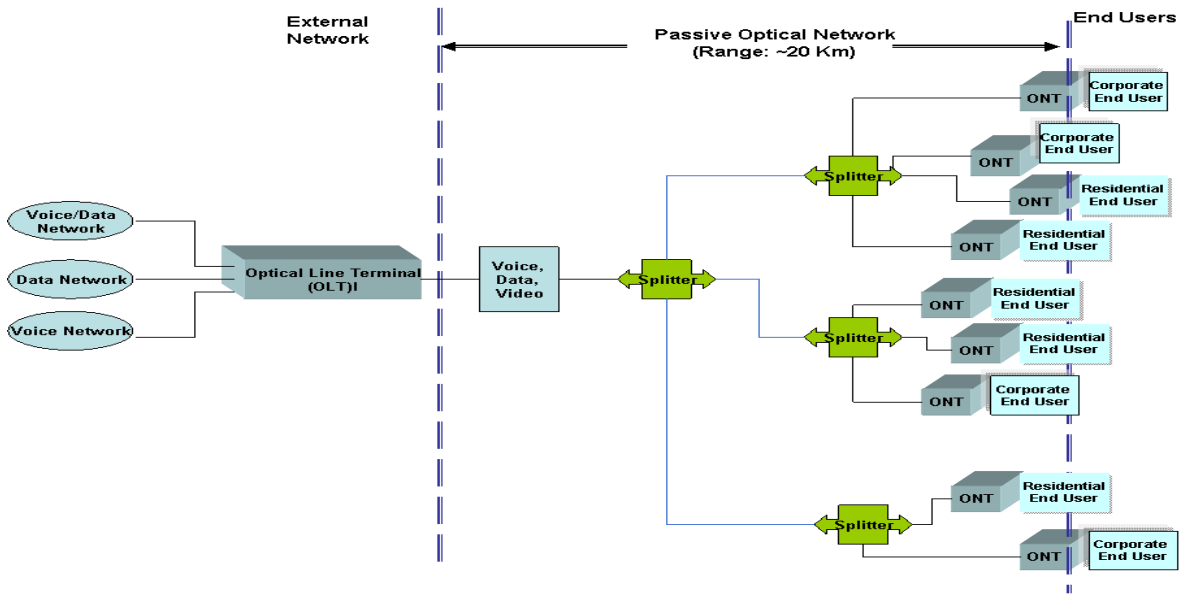
In a PON the entire downstream bandwidth is transmitted to the power splitter, and a portion of the optical power is delivered to each subscriber. Since bandwidth in a passive system is not dedicated to each subscriber, each user shares the total capacity of the system. Thus, potential customers/users have the opportunity to share end-office equipment and optical fibers, thus resulting in lower usage costs with shorter distance of the fiber, and less transmitting/receiving equipment (Nakano, 2006). However, PONs must physically restrict the number of subscribers on a power splitter to achieve higher throughputs. If the total network capacity is exhausted, then the electronics at each end (CO and CPE–customer premises equipment) must be upgraded to a newer technology.

PONs can also be used to backhaul traffic from remote DSLAMs (digital subscriber line access multiplexers) to CO-based DSLAMs, or for wireless backhaul between base station controllers and mobile switching centers. Furthermore, in a short-term, PON networks can be used in conjunction with other gear in the network. One possible configuration can suggest PON equipment to provide the backbone for an expanded DSL network, where PON extends the reach of DSL and brings it closer to the customer, allowing IPTV and VoD services to be deployed over existing copper connections to the home. Services offered can cover a broad range of network requirements like bit rate, symmetry/asymmetry or delay, and range from video distribution, *with varying degrees of interactivity,* to electronic data transfer, LAN interconnection, transparent virtual paths, and so forth.

PONs are especially attractive to today's carriers (or network providers) that have to reduce (or minimize) capital and operational costs, while maximizing the overall revenue per customer. These criteria must be achieved without sacrificing performance or network reliability, and a PON has all the ingredients to deliver these goods (Chanclou, Gosselin, Palacios, Álvarez, & Zouganeli, 2006). PONs are therefore considered as a "conformant solution" currently offered in the marketplace for bringing FTTH, since they comprise only passive elements and so they implicate low cost (Green, 2006). Moreover, when providing opportunities of high bandwidths, a PON can quite satisfactorily function at distances of up to 18-20 km in some cases, considerably higher than the distances supported by existing high-speed DSL variants (as shown in Figure 2). Besides, PONs do not engage the existence of any complex equipment (such as multiplexers/demultiplexers) in the local loop, in the proximity of the subscribers; this attribute drastically decreases the rates of installation and maintenance cost, and allows for uncomplicated upgrades to higher speeds, as such kinds of upgrades need only be performed centrally (i.e., at the network operator's central office) where the appropriate active equipment is established (ITU, 2005a).

Standardization of PONs is of fundamental meaning if they are indeed to be widely deployed and so to constitute a conformant future's broadband access infrastructure. From a network operator's perspective, standardization "translates" into cost reduction and adequate interoperability, while for a manufacturer it offers assurance that the products will successfully meet any probable market requirements, in order to be (widely) acceptable in international markets.

Figure 2. A passive optical network



Consequently, well-defined standardization effort provides certainty-guarantee for performing investments in the relevant field.

There are three fundamental PON standards in the marketplace: broadband PON (BPON), gigabit PON (GPON), and Ethernet PON (EPON). The first two generations of standards have been endorsed by the ITU (International Telecommunication Union), while the third is from the IEEE (Institute of Electrical and Electronic Engineers). The most significant differences between each type of PON technology are the supported line rates and the type of packet processing used, as discussed (among other features) in the subsequent sections.

Following the first release of the ATM-based passive optical network (APON) a few years ago, there were several releases of technical standards, all following the tracks of TDMA-based bandwidth sharing. APON was supposed to be a good solution and was intended primarily for business applications; however its use finally faded out, due to its high cost, limited service capacity, low bit rate, low efficiency, and most importantly, the decline of ATM technology in the global arena.

Broadband PON was based on APON (ITU, 2005a, 2005b). It added support for WDM (wavelength division multiplexing), dynamic and higher upstream bandwidth allocation, and survivability. It also created a standard management interface, called "OMCI," between the OLT and ONU/ONT, enabling mixed-vendor networks. A typical APON/BPON provides 622 Mbit/s of downstream bandwidth and 155 Mbit/s of upstream traffic, although the standard accommodates higher rates. BPON suffers from the very aggressive optical timing of ATM and the high complexity of the ATM transport layer.

The GPON standard (ITU, 2003) represented an improvement in both the total bandwidth and bandwidth efficiency through the use of larger, variable-length packets (PMC-Sierra, 2006). Again, the standard permits several choices of bit rate, but the industry has converged on asymmetrical operation of 2.488 Mbit/s of downstream bandwidth, and 1.244 Mbit/s of upstream bandwidth. The standard, instead of ATM encapsulation, uses GPON encapsulation method (GEM), which allows very efficient packaging of user traffic, with frame segmentation to allow for higher quality of service (QoS) for delay-sensitive traffic (such as voice and video communications). Moreover, GPON uses generic framing procedure (GFP) protocol to provide support for both voice- and data-oriented services. A big advantage over other schemes is that it interfaces to all provided main services while GFP-enabled networks packets belonging to different protocols can be transmitted in their native formats (Sims, 2007). GPON supports ATM, Ethernet, and WDM using a superset "multi-protocol" layer. The standard offers an abundant number of network management functions.

The emergence and deployment of IP technology has forwarded the concept of EPON, where APON's physical layer has been preserved, while replacing data link layer protocol (ATM) with Ethernet (Kramer, 2005). Thus, EPON was capable of providing a wider range of services with extended bandwidth, lower cost, lower complexity, and simplified timing (Hajduczenia, da Silva, & Monteiro, 2006). By sending and receiving signals within an Ethernet frame, less expensive and more versatile Ethernet parts can be used, thus helping to keep components simple and reduce costs. The basic features of this variant implicate that ATM and SDH layers have been removed. The IEEE 802.3 Ethernet PON standard (EPON or "GEPON" in order to emphasize the "gigabit" aspect of the service) was completed in 2004 (http://www.ieee802.org/3/) as part of the Ethernet First Mile Project (Beck, 2005). It uses standard 802.3 Ethernet frames with symmetric 1 Gbit/s upstream and downstream rates; however, recently (i.e., starting in early 2006), work began on a very high-speed 10 Gigabit/second EPON (XEPON or 10-GEPON) standard (http://www.ieee802.org/3/av/). EPON is applicable for data-centric networks, as well as full-service voice, data, and video networks.

However, with various emergent branches of PON technology, it is not yet possible to identify which one will be the most appropriate for next-generation optical access networks. Time to market, technology maturity, system availability, operational considerations, video compression performance, service requirements, engineering rules, and business impacts all need to be taken into account in making decisions regarding how to deploy PON (Nortel Networks, 2004).

The industry is looking at ways to deliver even more bandwidth over longer distances than ever before. Two ways of doing this are by increasing the number of optical wavelengths being used on the PON fiber, and by increasing the bandwidth and bandwidth efficiency of each wavelength. There are currently the following relative options deployed in the international environment: (i) the "traditional" TDMA-PON (Davey et al., 2006), and (ii) the "novel" WDM-PON (Banerjee et al., 2005; Lee, Sorin, & Kim, 2006) and OCDMA-PON.

FUTURE TRENDS

The main disadvantage of PONs is the requirement for complex mechanisms to allow shared media access to the subscribers so that data traffic collisions are avoided. This is due to the fact that although a PON is a point-to-multipoint topology from the OLT to the ONU (i.e., downstream direction), it is multipoint-to-point in the reverse (upstream) direction. This implies that data from two ONUs transmitted simultaneously will go into the main fiber link at the

same time, and thus will collide as the OLT is not able to discriminate them. Therefore, it is obvious that there needs to be an appropriate mechanism implemented in the upstream direction, so that data from each ONU can reach the OLT without colliding and getting distorted. An effective way to realize this can be via the usage of a wavelength division multiplexing (WDM) scheme, in which each ONU is allocated a dedicated wavelength to communicate with the appropriate OLT, so that all ONUs can use the main fiber link simultaneously (Park et al., 2004). In a similar way, the time division multiplexing (TDM) scheme can also be used, in which each ONU is allowed to transmit data only at a specific time window dictated by the OLT. The essential PON architecture permits simple service upscale whenever there is a need for more bandwidth, and this can be achieved through a combination of WDM and TDM schemes in the access fiber—that is, where different wavelengths carry different TDM PON streams or even better by using a WDM access scheme, where each subscriber is allocated a different wavelength (ITU, 2005b). In fact, WDM-PONs offer a very exciting perspective: they represent the next generation in PON development and promise to bring extended bandwidth to end users by fully utilizing the fiber's spectral windows. Although WDM-PONs truly have the potential of supporting enormous bandwidth rates (together with scalable functionality and ease of customization), their actual major drawback is associated with the high costs of the required equipment. Hence, there is currently a significant effort of research interest on finding appropriate ways to lower the high costs of such schemes, mostly by addressing the need for expensive broadband light sources. It should be expected that further progress in the area will entirely "transform" their adoption in the marketplace.

CONCLUSION

Growing demand for high-speed Internet is the primary driver for new access technologies that enable experiencing broadband. Fiber can sustain very high capacity, resulting in a high revenue potential (Hasegawa, Kuritani, Makino, Shimada, & Gorshe, 1990). A PON, utilizing passive splitters and shared-media configuration, can carry a veritable pipe of high bandwidth for users to share downstream, presenting a high-speed and inexpensive access scheme for multimedia service (Davey et al., 2006). The fundamental benefits of PON technology are flexibility, reliability, and simplicity.

The compelling advantages of PON for network operators and their customers are more than simply clear. These include a long-term life expectancy of the fiber infrastructure, lower operating costs through the reduction of "active" components, support for greater distances between equipment nodes, and most importantly, much greater bandwidth. PONs can also enable the use of new applications and services, such as high-resolution television, video telephony, e-learning, or even business applications. Furthermore, the passive splitting of the fibers means that expensive and high-maintenance active network elements are not necessary, while simultaneously the number of optical components is kept to a minimum.

Extended demand for bandwidth and progress in electro-optics have made passive optical networking into an attractive and quite convenient solution for bringing fiber to the customer. Since PONs eliminate active components on the loop, they can provide cost savings up to 10 times that of SONET, and they are now reaching cost equivalence with DSL and hybrid fiber coaxial (HFC). In addition, the combination of PON and WDM increases bandwidth availability and cost advantages even further.

Among the key reasons to deploy PONs is to decrease the spectral interference created by copper-fed applications (like ADSL). This results in a service that is less expensive to maintain, while PONs let operators go into new markets and share fibers among residential and small business customers. Other applications include buildings that are just out of reach of fiber in a metropolitan network, or even in-building networks to bring fiber to additional floors. Either way, once PON is deployed, it offers flexible bandwidth, which is important since business tenants commonly move within or out of buildings. PONs can also be used to backhaul traffic from remote DSLAMs, or for wireless backhaul between base station controllers and mobile switching centers of marketing at vendor Terawave.

During the deployment of the optical access network, market players are seriously taking into account OPEX (operational expenditure), which constitutes an integral part the lifecycle of the network. As a type of pure-medium network, the PON is nowadays considered by most operators as the "best technology that is currently available" and better oriented to synchronize with future optical access technology, although the CAPEX (capital expenditures) may be somewhat higher than that for peer-to-peer and copper wire access. In order to fulfill requirements imposed by both operators and users, PON technology may further develop according to the following alternatives:

1. Although hard in implementation due to the excessive requirements imposed on international industry, it is possible to expand the bandwidth of each single wavelength, to reach up to 10 Gbps.
2. The other option is to increase the number of wavelengths, that is from 16-wavelengths (CWDM) and 32-wavelengths (DWDM), to 64-wavelengths and 128-wavelengths, or more.

Nevertheless, crosstalk between channels brings several problems, especially when the number of wavelengths reaches a certain threshold, which results in an exponential cost increase. Consequently, WDM-PON technology alone will

not be able to fully satisfy the requirements of carriers/users in terms of the price performance ratio.

While PON has been discussed for decades, only today are network operators seriously deploying this exciting technology and increasing its penetration (Pesavento & Kelsey, 1999). Until very recently, PON deployment has been constrained by the pace of protocol standardization, equipment availability and cost, conservatism in moving to new technology, regulatory uncertainty, but most importantly by the cost of installing new fiber all the way to customer sites. However, a PON driver is the sharp decline of cost of fiber deployment in the access space over the last 10 years. In the mid-1990s, the capital cost for fiber access was around $7,500 per subscriber. This has fallen to less than $2,000 today and is expected to drop to less than $1,000 per subscriber in the near future. With this spectacular decrease in capital cost for fiber access, an enormous barrier for fiber-to-the-user (FTTU) has been virtually abolished.

Market researchers view PON as a rapidly growing market segment (Ernhofer, 2006). According to recent estimates (Rashid, 2004), the 2004 market volume amounted to approximately US$525 million, and this figure was expected to rise to 2.15 billion by 2008, corresponding to an average annual growth rate of 42%. Especially high growth is predicted for two regions: in particular North America, where high volumes of data must cross great distances; and Asia, where the next few years will see the emergence of modern urban areas with completely new infrastructures. Deployment is being driven primarily by established operators, offering a wider range of enhanced services to retain and increase their revenues. With the capability to support both today's and tomorrow's services, PON technology is an ideal solution for market players and consumers as well.

KEY TERMS

Asymmetric Digital Subscriber Line (ADSL): Transmission technology that consists of modems attached to twisted-pair copper wiring that transmit from 1.5 Mb/s to 8 Mb/s downstream (to the subscriber) and up to 1.5 Mb/s upstream, depending on line distance.

Broadband PON: A term used to refer to the entire system described by the G.983.x family of ITU-T Recommendations. This includes a wide range of broadband services and goes beyond ATM access.

Ethernet: A large, diverse family of frame-based computer networking technologies that operates at many speeds (typically at 10, 100, or 1000 Mb/s) for local area networks (LANs). The name comes from the physical concept of the ether. It defines a number of wiring and signaling standards for the physical layers, through means of network access at the media access control (MAC)/data link layer, and a common addressing format. (Ethernet has been standardized as IEEE802.3.)

Ethernet Passive Optical Network (EPON): A type of PON technology that runs on the Ethernet protocol. EPON is applicable for data-centric networks, as well as full-service voice, data, and video networks.

FTTH (Fiber To The Home): A form of fiber optic communication delivery in which the optical signal reaches the end user's living or office space.

Optical Line Termination (OLT): The service provider endpoint of a passive optical network; placed at the central office or head end of a fiber-based system. Also called *optical line terminal.*

Passive Optical Network (PON): Network in which fiber optic cabling (instead of copper) brings signals all or most of the way to the end user. It is described as passive because no active equipment (electrically powered) is required between the central office (or hub) and the customer premises. Depending on where the PON terminates, the sys-

tem can be described as an FTTx network, which typically allows a point-to-point or point-to-multipoint connection from the central office to the subscriber's premises; in a point-to-multipoint architecture, a number of subscribers (for example, up to 32) can be connected to just one of the various feeder fibers located in a fiber distribution hub, dramatically reducing network installation, management, and maintenance costs.

Point-to-Multipoint (P2MP, PTMP, or PMP) Communication: Refers to communication that is accomplished via a specific and distinct type of multipoint connection, providing multiple paths from a single location to multiple locations.

SONET (Synchronous Optical NETwork): A protocol for backbone networks capable of transmitting at extremely high speeds and accommodating gigabit-level bandwidth. It has been standardized by the American National Standards Institute (ANSI).

Triple-Play Services: The ability of a telecommunications operator to supply voice, data, and video applications all at once. A typical example of a triple-play proposal would include one or multiple phone lines, a high-speed Internet connection, and television/video services (such as HDTV), all offered by the same provider. Also known as *bundled services.*

Monitoring Strategies for Internet Technologies

Andrew Urbaczewski
University of Michigan-Dearborn, USA

INTRODUCTION

Most large organizations that provide Internet access to employees also employ some means to monitor and/or control that usage (Reuters, 2002). A 2005 AMA report indicates that 76% of companies monitor worker's Web surfing, while 26% have fired workers for improper Internet usage (AMA, 2005). This chapter provides a classification and description of various control mechanisms that an organization can use to curb or control personal Internet usage. Some of these solutions are technical, while others rely instead on interpersonal skills to curb cyberslacking.

After a review of goals for a monitoring program, a list of different activities to monitor and/or control will also be provided. Then a discussion of different techniques for monitoring and associated products will be explored, followed by a discussion of fit between corporate culture and monitoring.

BACKGROUND

The Worker's Perspective

In this age of cell phones, pagers, wireless PDAs, e-mail, and home network links, many employees may feel like the employer owns them not just during the workday, but perhaps constantly. Though tiresome, the worker may accept this as an unfortunate circumstance of 21st century knowledge work. However, in the tit-for-tat that this availability demands, the employee may feel that he or she should be allowed to use the Internet at work to take care of quick business tasks such as paying bills, sending an e-mail, or checking that evening's movie listings. So long as it isn't excessive, the employee may wonder why the employer even cares. Employers can and do care for many reasons, some more profound than others.

Goals for Monitoring

Why do companies monitor their employees? Organizations monitor for many reasons including simply "because they can." An electronic monitoring effort is often difficult to establish and maintain, so before an organization begins such an effort, there should be clear monitoring goals.

The popular press is filled with stories of employees frittering away time on the Internet (Swanson, 2002). In the beginning, employees were likely to spend unauthorized time on the Internet at pornography and gambling sites, but now news and online shopping are more likely outlets for cyberslacking (Reuters, 2002). This is quite the opposite of employers' expectations when they implemented Internet connections.

Responding to these challenges, employers created acceptable use policies (AUPs). Some organizations already had AUPs implemented to keep out electronic games, and they simply modified those policies. Other organizations created new AUPs, which directly addressed the Internet's productivity threat. AUPs are useless without enforcement, but in today's litigious society it behooves accusers to be certain of transgressions before enforcing the policy. Monitoring tools create an irrefutable log of usage which can stand as legal evidence. Some employers hope the mere threat of punishment will keep employees from cyberslacking, often with some success (Urbaczewski & Jessup 2002). Listed next are some possible goals of a monitoring effort.

Increase Employee Productivity

The Internet was introduced into many organizations as a tool to increase employees' efficiency. While traditional IT packages provided few opportunities for employees seeking to slouch on employer time, the Internet posed an entirely different situation. Computers now had the capability to be an electronic equivalent of a water cooler, break room, or smokers' perch. To curb the potential problem of employees wasting time while appearing to be busy, an organization could implement a monitoring program which completely blocks and/or records the amount of time spent at non-work-related Internet sites. An alternative could be limiting access to frivilous sites to non-production hours only, such as during lunchtime.

Bandwidth Preservation

In some organizations, concerns are not productivity-based but rather that network bandwidth is being dominated by applications and instances not directly work related. An example might be listening to streaming audio or watching streaming video, both constant drains on bandwidth. People

can also engage in excessive file transfers across networks which results in reduced network performance. Two possible solutions to this problem are to purchase more bandwidth or limit the usage of existing bandwidth, with monitoring programs aiding in the latter solution.

Legal Liability Reduction

Along with productivity and bandwidth usage, organizations are also concerned about Internet usage from the potential exposure it brings to legal liability (Langin, 2005). Consider the following fictitious scenarios:

- "Organization X today was sued for negligence, as an employee was running a child pornography server inside the corporate network."
- "ABC corporation today was sued by a former employee who is now in treatment with Gambler's Anonymous. He is charging that ABC, by placing an unrestricted Internet terminal on his desktop, essentially gave him unfettered access to the virtual casinos thriving on the Internet."
- "Company B is defending itself today against a privacy lawsuit. It is charged that when an employee downloaded a file-sharing program, that program was equipped with a backdoor, which allowed malicious hackers entrance into Company B's networks. These hackers then took thousands of credit card numbers and personal data from the databases..." (a similar real-world incident happened with employees of the state of Oregon in May 2006, where about 2,200 taxpayers had their personal information compromised due to spyware picked up on a laptop computer by a worker surfing pornographic sites during downtime (Keizer, 2006).

Organizational Secret Protection

As blogging has become a popular way of communicaitng in the 21st century, many companies have realized that it is easy for employees to write their ideas and opinions about circumstances at their corporations, often with embarrassing results for the employee and/or the employer. Google and Microsoft are two well-known examples of companies that have dealt harshly with non-approved blogging by their employees, and a scandalous sex-for-money-and-favors blog detailing the life of a staffer in a U.S. Senator's office caused much embarrassment for those involved. Organizations may not want their internatl business practices or daily routines exposed to the outside world, so they use control of blog postings to keep this control. While their control over employee postings when not in the office may be murky, the organization may exert its right to keep this control during business hours.

Other possibilities like sexual harassment suits and industrial espionage make the legal risks mount. Organizations indeed may wish to monitor Internet connections to prevent any potential legal liabilities from allowing illegal activities to be conducted on their networks.

STRATEGIES AND TECHNIQUES FOR MONITORING

Different Monitoring Strategies

Once an organization decides it will monitor, it needs to know what to monitor. While Web pornography is probably the most reported off-topic use of the Internet in an organization, it is certainly not the only transgression that might come from an Ethernet card. Excessive personal e-mail, filesharing, instant messaging, multimedia streaming, and usenet browsing and posting are among other ways that employees use the corporate Internet connection for personal enjoyment.

There are several different control mechanisms that an organization might use, generally grouped into one of two categories: managerial and technical. The managerial techniques for monitoring are similar to ways that monitoring of employees has been done for decades: walking around and keeping one's eyes open. When a manager starts to wonder about an employee's performance or collegiality, then the manager starts to pay more attention to that employee's work habits.

Overall, however, the most popular means of monitoring employees is through technology. In many ways, this makes sense—a technical solution to a technological problem. Electronic monitoring operates like "big brother" (Zuboff, 1988), keeping a constant watchful eye on the network and its connected systems (or whatever subset of those systems/hours that a manager may choose to watch). Records can then be kept and offered as later "proof" of an offender's cyberslacking or lack thereof.

Electronic Monitoring Techniques

Logging at the Gateway

Many logging technologies are designed to capture and record packets as they enter and leave the organization, or at least the header information that indicates the sender, recipient, and content of the message. Gateway logging is useful in that it provides a central point of network control. However, it is difficult to accurately gauge how long an employee stares at a particular page, and if all that time he or she is actually staring at that page or if he or she has actually gone to lunch and returned later. Moreover, gateway logging can be

defeated by the use of encryption tools like PGP (www.pgp.com, see McCullagh (2001) for a more detailed description of an FBI case with the Phildelphia organized crime ring), or even tools like Anonymizer.com that allows a person to surf the Web anonymously using their gateways and encryption tools. In cases where these technologies are used, a separate technology might also be needed.

Blocking: Keeping Productive Employees Productive

Sixty-five percent of companies (AMA, 2005) utilize blocking software to keep employees from visiting certain Web sites. Organizations may not even look at the logs to see who was trying to view these sites--rather it serves simply as a friendly reminder that these sites are not to be viewed on company time. While the software is never foolproof, and relays can be used to get around the blocking software, it reminds the employees of the policies and makes a policy violator's defense of "I didn't know I wasn't supposed to do this" less believable. Akin to locking the doors on one's car that will not stop a determined thief, it does make the owner's intentions known and makes the target less appealing.

Spying at the Client

When gateway logging is insufficient, one can monitor and record connections directly at the source. A keystroke logging program can record everything that a person types on a computer, and many even include technologies to take screenshots or use the Web camera on the desk to prove that it was the person actually sitting at the computer and not someone who just walked up to the terminal.

Client sniffing programs are excellent at recording exactly what the user is doing with the computer at any given time. Many will record all the user's keystrokes, mouse movements, and active windows, allowing the reconstruction of the entire computing session. Moreover, they can capture other undesirable activity, such as playing games and typing job application letters. However, these programs are not without their own faults. First of all, the manager must install the program on the user's computer, which may not be as easy as it sounds, especially with laptop and other mobile computers. Second, the program must not be detectable (and thus deletable) by the monitored employees. Managers then must sift through mountains of captured data to determine if there is any untoward activity, or enough to warrant further investigation. However, products are available which meet the above concerns to varying degrees, and the next section will discuss some of those products.

Software Products for Controlling Internet Usage

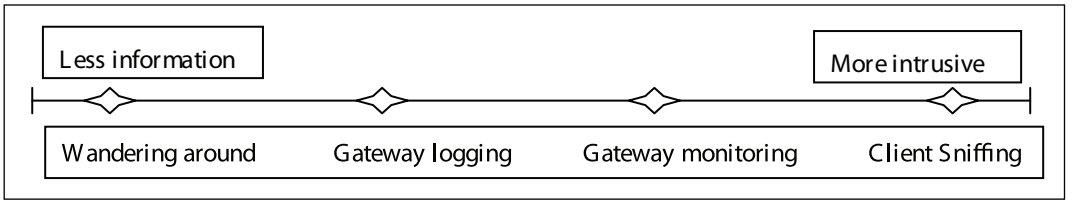
As previously mentioned, there are various products available to serve as control mechanisms. They are grouped below into five categories. Note that software products come and go, and the availability of certain products and companies are subject to market forces. The categories themselves should remain stable for the time being, although who knows what the future may hold. For example, if this chapter was being written in 1999, there would likely be no section on file-sharing.

Web Monitoring Products

As the popular press articles have largely focused on employee cyberslacking as a problem with personal Web usage, a number of products have been created to help employers manage these problems. The software products are all customizable to some degree, but there are two main classifications of these products: those that *monitor* and record Web usage, and those that actively *block* access to certain Web sites deemed inappropriate. The listing below, which is not intended to be exhaustive, details several of these products.

Cybersitter (www.cybersitter.com), *NetNanny* (www.netnanny.com), and Bsafe Online (www.bsafehome.com) are three programs that are geared largely at individuals, as they are installed on the client and maintain logs of Web pages seen by the users. *Websense* (www.Websense.com) however, is designed to monitor the Web usage of an entire network. It runs near the firewall and logs all Web requests leaving the network. All of these programs can be configured to block and/or record access to certain Web sites. Some

Figure 1. Monitoring strategies present a tradeoff between information and intrusiveness



of these programs can be tailored to allow different access rules at different times of day. For example, an organization may wish to allow its employees to use the Internet for shopping and other personal entertainment before and after normal business hours and on the lunch hour but not during the work day.

E-Mail Monitoring Products

E-mail can easily be monitored by simply examining accounts for incoming mail or logging the actions of the simple mail transport protocol (SMTP) server for outgoing mail. These logs are often difficult to read, especially with large volumes of mail and users. A series of products can assist in parsing the logs or searching for users or keywords, like *MIMESweeper* (www.mimesweeper.com) and *message inspector* (www.cyberguard.com). Encrypted e-mail can present its own challenges, and additional policies may be necessary regarding the use of strong encryption in an organization.

Monitoring e-mail sent through popular Web-based providers like Yahoo! or Hotmail can be difficult as well, because the message never passes through the SMTP servers for the organization, nor does the organization have direct control over users' mailboxes. Monitoring these types of mail services is usually done through a general monitoring tool, as listed in another section below.

File-Sharing Monitoring Products

File-sharing has a history of waxing and waning between one of the easiest applications to monitor to one of the toughest. Users of file-sharing services often try to devise ways to run their services around and through corporate attempts to halt them. Other problems were created by users demanding that they be allowed to use these programs, especially at high-profile universities like Yale and Indiana. In those cases, something had to be done to limit the amount of bandwidth these services could use, because other legitimate traffic was being delayed. A number of hardware and software solutions cropped up to aid network managers in their quest to reduce or eliminate file-sharing traffic.

On the software side, it was previously mentioned that already existing firewalls can be configured to block traffic on certain TCP (OSI layer 4) ports. Other programs, like *DynaCommI:scan* (http://www.futuresoft.com/products/antispyware/overview), are designed to examine the packets at the application layer (OSI layer 7) to determine the type of packet and whether or not to block it. Hardware solutions like *Packeteer* (www.packeteer.com) plug into the network to control the amount of bandwidth available to certain applications. Packeteer has been most popular at colleges and universities, which in general do not want to be accused of censorship or limiting access to resources, but still have to deal with bandwidth concerns amongst thousands of users.

Instant Messaging (IM) Monitoring Products

IM's "fire-and forget" nature made it one of the toughest applications to monitor for a long time. The problem was exacerbated because the employers generally did not control the IM servers or the clients. In 2002 applications were created which successfully monitor IM applications and content, implemented largely to comply with certain US Securities and Exchange Commission (SEC) requirements on keeping logs of all transactions between brokerage houses and their customers. Enterprise IM applications continue today with the likes of AIM Pro, an AOL and WebEx IM program designed for deployment within the organization and subject to its controls. IM is usually not monitored to conserve bandwidth, but it can become a productivity drain similar to e-mail.

Facetime (www.facetime.com) is probably the leader in monitoring organizational IM. The Facetime product can record all IM activity, important in SEC-regulated businesses and government agencies with freedom of information requirements. *Vericept* (www.vericept.com) also has all-purpose monitoring capabilities, but focuses largely on monitoring, blocking and recording IM activity. Organizations looking to block and monitor IM and communicate securely using encryption might turn to *Compliancer Hub* (www.communicatorinc.com).

General Monitoring (Spying at the Client) Tools

There are a series of more powerful, less-specific tools available for almost total user monitoring, classified as general monitoring tools. These tools are installed at the client and can create a record of almost everything a user does with the computer. Records can be written to a network database or even e-mailed to another account.

Spector CNE (www.spectorsoft.com) and Track4Win (www.track4win.com) are sniffing programs designed for enterprise monitoring. There are also many programs targeted at individuals, including *Pearl Echo* (www.pearlsw.com) and *eBlaster* (http://www.spectorsoft.com). Managers are often surprised at the sheer amount of data these programs provide, quite often more than a manager really wants to know. One should carefully consider the implications before implementing a general monitoring tool. Employees may react strongly to such total monitoring.

FUTURE TRENDS

Seeking the Recommended Fit between Goals and Monitoring Solutions

If productivity is a major concern, one might begin with a passive but comprehensive logging tool. Cyberslacking can be easily seen and measured, but it is done unobtrusively. When an employee's productivity falls, as observed traditionally, the technical data showing cyberslacking are available. This can be used for implementing positive disciplinary measures, or for supporting a termination. Periodically and when a situation occurs, employees should be reminded of the organization's policy about personal Internet usage and resulting enforcement actions. This is not to embarrass potential offending parties, but rather to keep the policy salient.

If legal liability is the major concern, minimally intrusive means can also be used for the monitoring and recording of transmitted data. In December 2002, five major Wall Street brokerage houses were fined $1.65 million for not keeping e-mails the required two years. An organization can avoid these types of penalties by simply logging and maintaining records of Internet traffic without any review, except on an as required basis. The RIAA and other entertainment industry groups in early 2003 began warning organizations to actively ensure that their employees were not using company networks to access copyrighted music and video files, lest the companies themselves be held liable. The RIAA has been supplying offenders' IP addresses and access times to companies and universities, idenitfying individuals who may have traded in music and video files. In the end, a company pursuing this strategy would be more concerned with record-keeping than record-reviewing.

An organization pursuing the third goal, bandwidth preservation can likely use the least passive of all monitoring tools--simply observing bandwidth usage spikes where they occur, and witnessing their relationship to organizational goals. A firm that sees bandwidth constantly full with apparently work-related material may want to investigate adding additional bandwidth resources. At the same time, organizations that suddenly block or "throttle" access to popular Internet destinations known for non-work related information will likely solve many problems. Employees are more likely to realize that they need to get to work or identify another means of entertainment than they are to complain and cause a ruckus over no longer being able to access these sites at all or at high speeds.

CONCLUSION

This chapter has detailed several types of control mechnisms. It has listed goals for monitoring, applications to monitor, and means of accomplishing the monitoring. Furthermore, it lists names of actual tools that can be used to accomplish the monitoring. What this chapter so far has not discussed is the viability and consequences of the monitoring.

In a series of studies, it was found (not surprisingly) that Internet monitoring indeed has a significant positive effect on keeping employees on task (Urbaczewski et al., 2002). However, it was also found that monitored employees were more likely to turnover and less likely to participate in other organizational activities. Could this happen in all organizations? Possibly, but the key to remember when establishing monitoring is:

Make the monitoring strategy fit the corporate culture.

Some organizations have a culture where monitoring of most (if not all) activities is simply expected. These industries generally include those handling cash or financially-related transactions (e.g., banks, casinos) or deal with physical and/or national security (CIA, FBI, R&D labs, etc.). In these cases, monitoring fits the culture, and if the organization is already monitoring employees in other ways, it also makes sense to monitor computer systems.

Other organizations have cultures which generally detest monitoring. Some industries, like publishing, academia, and other "civil liberties" organizations do not generally monitor their employees, as their foundations are centered on freedom of speech and the unfettered search for the truth. The introduction of monitoring in these industries will likely result in a culture clash between employees and management (Simmers, 2002).

The question then becomes "how does one then reap the benefits of monitoring without angering employees and creating unwanted stress in the organization?" Valli (2004) argues for provisions that enforce policies while at the same time not destroying the atmosphere of trust and fairness. Communication of the control mechanisms to the employees, with a clear understanding of how it supports corporate goals and principles, is key. Explicit statements of who will be monitored, what will be monitored, and when monitoring will occur should also be communicated to the employees, largely through AUPs.

KEY TERMS

Acceptable Use Policy (AUP): A policy created in an organization to outline the permitted and restricted uses of the company's networks and computer systems.

Bandwidth: Colloquially, the amount of network capacity available for a connection.

Blocking: A means of disallowing access to Internet content and services by restricting access at the corporate gateway.

Cyberslacking: The process of using the Internet to waste time during a workday, similar to how an employee might spend time in a colleague's office or on the telephone.

Logging: Creating a record of all employee Internet usage.

OSI Layer 4: The transport layer of a network connection, which provides service differentiation and connection management. From the open systems interconnect model.

OSI Layer 7: The application layer of a network connection. It describes how applications work with the network operating system. From the open systems interconnect model.

Motivation for Using Microcomputers

Donaldo de Souza Dias
Federal University of Rio de Janeiro, Brazil

INTRODUCTION

Information technology implementation is an intervention we make in order to improve the effectiveness and efficiency of a sociotechnical system. Using microcomputers to help individuals perform their jobs and tasks is one of the most important actions we take when implementing this technology effectively. Information systems effectiveness has been extensively studied using, mainly, user satisfaction and quality of information constructs to evaluate users' acceptability (Iivari & Ervasti, 1994; Ives et al., 1983; Neumann & Segev, 1979). However, sometimes, the result of this intervention is not successful and may even generate difficulties related to people participation in the process. This leaves us with a question: What motivates individuals to use microcomputer technology in their daily activities?

Theorists and empirical researchers have been trying to understand the relevant motivators for the implementation and use of computer technology based on the idea that people make an effort if an activity is enjoyable or offers external rewards (Igbaria et al., 1996; Schwartz, 1983). They have been aiming to find out how individuals feel motivated to work with computers, and what motivates them to use computers in their daily activities.

BACKGROUND

Computer and information technology usage is determined by intrinsic as well as extrinsic motivation (Deci, 1975; Igbaria et al., 1996). The main driving forces considered in the literature as motivators for computer and information technology adoption are perceived usefulness, perceived ease of use, and perceived enjoyment (Davis, 1986, 1989; Igbaria et al., 1996). However, it is known that some individuals create personal obstructions to using technology (Pirsig, 1981), particularly, microcomputer technology (Igbaria & Parasuraman, 1989; Martocchio, 1994). They resist microcomputers usage and experience anxiety when they have to deal with them. We present results found in previous studies for relations and comparisons among the motivational forces above (Dias, 1998a, 1998b, 2002; Dias et al., 2002). The results presented here, all statistically significant at $p < 0.05$, were based on constructs measured using the instrument developed in Dias (1998a) and presented in the Appendix.

MAIN MOTIVATIONAL FORCES

Figure 1 shows the results for the relationships among perceived enjoyment, perceived ease of use, and perceived usefulness found in Dias (1998a). The author focused on the motivators perceived usefulness, perceived ease of use, and perceived enjoyment. The aim was to find out how Brazilian operations managers felt about using computer technology in their workplaces, how the perceived usefulness of computers is affected by ease of use and users' enjoyment in working with them, and how to find opportunities to act according to this acquired knowledge, in order to increase the quality of microcomputer technology usage in organizations. In his study, the author emphasized the relationships among these perceived motivators for using microcomputer technology. The impact of the motivators on systems usage or microcomputer adoption was considered to be beyond the scope of his research.

The path analysis model used was based on the natural precedence of intrinsic motivational factors over extrinsic motivational factors, as proposed by the Freudian theory of psychoanalysis (Freud, 1976).

The data for that study were gathered using a questionnaire administered personally to 79 Executive MBA students at a Brazilian university. Respondents held managerial positions in 55 companies, ranging from small firms to large corporations, located in Rio de Janeiro. The average age of respondents was 36, and they had an average of 11 years working experience. All of the participants were college graduates. Managers said they used microcomputer technology mainly because they perceived it as a useful tool to increase the quality of their work, to accomplish tasks more quickly, and to increase the productivity of their jobs.

Figure 2 shows results of a model in which computer anxiety and enjoyment were considered as antecedent variables to ease of use and usefulness (Dias, 1998b). We found that managers who were more anxious about computer technology tended to find it more difficult to use. On the other hand, enjoyment had a positive direct effect on ease of use and usefulness, as stated before.

In a study made at a private university located in Rio de Janeiro, with data gathered from 336 undergraduate computer information systems students, Dias et al. (2002) tested the influence of some antecedent variables on enjoyment, ease of use, and usefulness. They found that (a) the fact that a student worked part-time in an area related to information

Figure 1. Relationships among enjoyment, ease of use, and usefulness

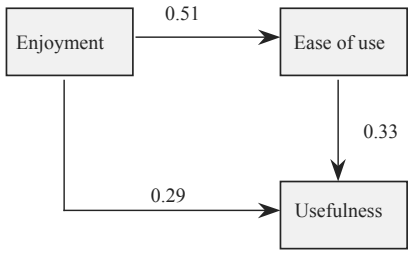

Figure 2. Anxiety and enjoyment as antecedent variables

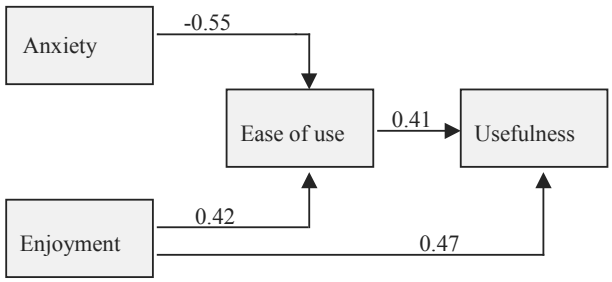

Figure 3. Motivation level for graduate, undergraduate, and elementary school students

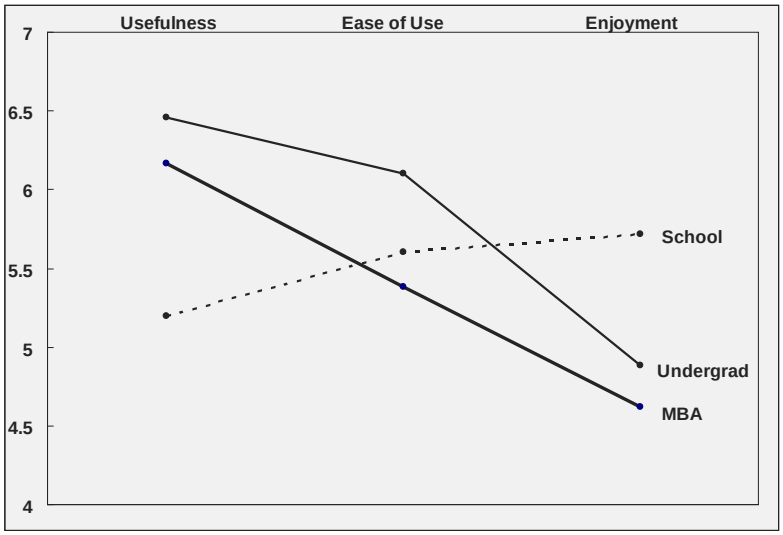

technology positively influenced his or her perception of how easy it was to use microcomputers; (b) enjoyment with microcomputers seemed to decrease as students attained seniority in the university; and (c) older students perceived greater usefulness for microcomputers.

Level of education and age have shown influence on microcomputer attitudes (Igbaria & Parasuraman, 1989). Dias (2002) did a study on the motivation for using microcomputers among different classes of users. He aimed at finding out how graduate, undergraduate, and elementary school students, which represent very specific strata of educational level and age, would differ on the motivational factors examined here. The data for his study were gathered as follows:

- Fifty-three Executive MBA students of a leading Brazilian public university: The average age of respondents was 36, and they had an average of 11 years working experience, all participants were managers and had a college degree.
- Forty-six students aiming for degrees in Business Administration at a private university located in Rio de Janeiro: The average age of respondents was 22.
- Thirty-nine elementary schools students enrolled in the fourth to eighth grades of private (82%) and public schools located in the city of Rio de Janeiro: The students used microcomputers regularly at school, at home, or at relatives' homes.

Factor analysis confirmed that the statements for usefulness, ease of use, and enjoyment constituted three distinct perception constructs for the three classes of users. It confirmed the existence of three factors that accounted for 63.5% of the total variance in the 138 interviewees.

Figure 3 shows the motivational profile for graduate, undergraduate, and elementary school students on the usage of microcomputers.

Table 1. Actions for successful implementation of microcomputers

Action	Motivational Forces
Develop friendly systems	Ease of use/enjoyment
Encourage user participation in systems development	Usefulness/ease of use
Implement intensive user training	Ease of use
Sell the system to users	Usefulness
Facilitate access to microcomputers	Ease of use
Respond to user needs	Usefulness
Use up-to-date technology	Usefulness/enjoyment
Align business and information technology	Usefulness

Dias (2002) found that there was a statistically significant difference in the perceived enjoyment, perceived ease of use, and perceived usefulness of using microcomputers among MBA, undergraduate, and elementary school students. MBA and undergraduate students were most motivated by microcomputer technology usefulness. Elementary schools students mostly enjoyed the play aspect of microcomputers.

We did a study with managers in order to better understand these motivational forces and to generate recommendations for increasing the motivation for using microcomputers. Thirty-six managers were split into six working groups and asked to (1) discuss their experience in using microcomputers in their organizations (taking into account personal resistances for using computers in the workplace), situations in which this technology is used compulsively, motivators they thought were important for using computers for task execution, and organizational culture; and (2) propose actions they thought should be taken in the implementation of microcomputers in their workplaces that would lead to a more effective usage of this technology.

The main actions suggested and the corresponding motivational forces are presented in Table 1. We found that in order to attract adult users, information systems should be friendlier, use up-to-date interfaces, and be developed with user participation. In addition, it is important to offer intensive user training, to market the new systems to users heavily, and to fully meet the users' needs in the specification of the systems.

Although managers showed less unanimity on the motivating power of enjoying themselves while using microcomputers, this motivation factor clearly showed its significance. Enjoyment seems to serve more as self-motivation, while usefulness seems to be linked to a feeling of duty—something that the organization expects managers to do or to attain.

FUTURE TRENDS

According to the World Summit on the Information Society (WSIS, 2003):

The global Information Society is evolving at breakneck speed. The accelerating convergence between telecommunications, broadcasting multimedia and information and communication technologies is driving new products and services, as well as ways of conducting business and commerce. At the same time, commercial, social and professional opportunities are exploding as new markets open to competition and foreign investment and participation.
The modern world is undergoing a fundamental transformation as the Industrial Society that marked the 20th century rapidly gives way to the Information Society of the 21st century. This dynamic process promises a fundamental change in all aspects of our lives, including knowledge dissemination, social interaction, economic and business practices, political engagement, media, education, health, leisure and entertainment. We are indeed in the midst of a revolution, perhaps the greatest that humanity has ever experienced.

Several new concepts lay the foundation for prospering in the next form of information and communication technology. The future microcomputer usage will be based upon ubiquity, universality, uniqueness, and unison (Watson et al., 2002). The keys to managing network-driven firms will be based on this notion of ubiquitous networks. In addition, we have to consider the new generation of students entering business schools around the world. These students are quite different from the students of the last decades, and we have to consider the technological, social, and cultural changes that are developing. The implications for the next-

generation organization and information systems based on the Internet and mobile microcomputer technology have to be considered, and the motivational forces discussed here will probably have to be readdressed.

CONCLUSION

The research described here on motivation for using microcomputers offers several contributions for theory and practice. It confirmed that there are three positively interrelated motivators for computer technology usage: perceived usefulness, perceived ease of use, and perceived enjoyment. It also found that perceiving microcomputers as easy to use is negatively related to people's anxiety toward using them.

The research also compared the perceived reasons for using microcomputers among different classes of users and showed that there are significant differences in the motivation for using them among graduate, undergraduate, and elementary school students. Elementary school students have greater enjoyment in using microcomputers than MBA and undergraduate students in Business Administration. MBA and undergraduate students in Business Administration perceive greater usefulness in the usage of microcomputers than elementary school students, and they said that they used microcomputers mainly because this increased the quality of their work and allowed them to accomplish tasks more easily and quickly. Undergraduate students in Business Administration think it is easier to use microcomputers than do MBA and elementary school students. MBA students think it is most difficult to use microcomputers in their daily tasks.

We should emphasize that the motivational forces studied here could not apply equally to different countries, cultures, or organizational environments. A study made by Straub et al. (1997) compared the technology acceptance model (TAM) (Davis, 1986) across three different countries: Japan, Switzerland, and the United States. The study was conducted by administering the same instrument to employees of three different airlines, all of whom had access to the same computer technology innovation—e-mail. They used perceived ease of use and perceived usefulness as independent variables. The results indicated that the model holds both for the United States and Switzerland, but not for Japan, suggesting that the model may not predict motivation for technology use across all cultures. Harris and Davidson (1999) examined microcomputer anxiety and involvement of groups of microcomputer-using students in six developing countries: China, Hong Kong, Malaysia, New Zealand, Tanzania, and Thailand. Differences in computer anxiety were found to exist between some of the groups, which were probably attributable to demographic factors. Differences were found to exist between the microcomputer involvements of some of the groups, which could be attributed to cultural factors.

APPENDIX

Please indicate your agreement or disagreement with the following statements, related to the usage of computers in the workplace, using a 7-point scale ranging from *fully disagree* (1) to *fully agree* (7). Please refer to Appendix 1 on the previous page.

KEY TERMS

Computer Anxiety: Degree to which an individual is nervous in his or her interaction with computers; the uneasiness some people feel when they have to use a microcomputer. Anxiety results from a danger or a danger threat. As a feeling, it has a clearly unpleasant character.

Computer Self-efficacy: A judgment of one's capability to use a computer. It incorporates judgments of an individual on his or her skills to perform tasks using a microcomputer.

Extrinsic Motivation: Motivation that derives from what you obtain from engaging in an activity. An example of extrinsic motivation for using microcomputers is using it because you think it is useful for your job.

Intrinsic Motivation: Motivation that derives from the activity itself. An example of intrinsic motivation for using microcomputers is using it because you enjoy it.

Microcomputers Ease of Use: User perception on how simple and easy it is to understand and use microcomputers; degree to which an individual believes that using a particular computer system would be free of physical or mental effort.

Microcomputers Enjoyment: The extent to which the activity of using microcomputers is perceived as being enjoyable in its own right, apart from any performance consequences. It encompasses the feelings of joy, elation, or pleasure associated by an individual to a particular act.

Microcomputers Usefulness: The degree to which an individual believes that using a particular computer system would enhance his or her job performance.

Sociotechnical System: One that focuses on the interaction between the technical and social subsystems that exists

in any work situation. As there is always a social system operating along with any technological system, we need to jointly design these two interrelated systems to get the best results from any work system.

Motivational Matrix for Educational Games

Athanasis Karoulis
Aristotle University of Thessaloniki, Greece

INTRODUCTION

The study of the motivational factor in educational games (aka EduGames) has been limited up to now. A former study (Karoulis, 2004) discussed some aspects and proposed the adherence to the ARCS model of motivation proposed by Keller (Keller, 1983; Keller, 1998), which describes the motivation of any educational piece according to four factors: attention, relevance, confidence, and satisfaction.

Present study attempts to summarize the attributes of any EduGame, as they are encountered in the relative literature (including representations) and to match every one of those attributes to one (or more) of the ARCS-factors of motivation.

The benefit of this approach is a better understanding of the motivational nature of every attribute of every EduGame and an obvious extension is the evolvement of a set of design guidelines for designers of EduGames and educational software in general.

BACKGROUND

Keller's ARCS Model for Motivation

Motivation is the most overlooked aspect of instructional strategy, and perhaps the most critical element needed for employee-learners. Even the most elegantly designed training program will fail if the students are not motivated to learn. Without a desire to learn on the part of the student, retention is unlikely. Many students in a corporate setting who are forced to complete training programs are motivated only to "pass the test." Designers must strive to create a deeper motivation in learners for them to learn new skills and transfer those skills back into the work environment.

As a first step, instructional designers should not assume they understand the target audience's motivation. To analyze needs, the designer should ask prospective learners questions such as:

- What would the value be to you from this type of program?
- What do you hope to get out of this program?
- What are your interests in this topic?
- What are you most pressing problems?

The answers to these types of questions are likely to provide insight into learner motivation, as well as desirable behavioral outcomes.

Keller synthesized existing research on psychological motivation and created the ARCS model (Keller & Kopp, 1987). ARCS stands for attention, relevance, confidence, and satisfaction. This model is not intended to stand apart as a separate system for instructional design, but can be incorporated within Gagne's events of instruction (Gagne, 1985, 1987; Gagne, Briggs, & Wager, 1992).

- **Attention:** The first and single most important aspect of the ARCS model is gaining and keeping the learner's attention, which coincides with the first step in Gagne's model. Keller's strategies for attention include sensory stimuli (as discussed previously), inquiry arousal (thought provoking questions), and variability (variance in exercises and use of media).
- **Relevance:** Attention and motivation will not be maintained, however, unless the learner believes the training is relevant. Put simply, the training program should answer the critical question, "What's in it for me?" Benefits should be clearly stated. For a sales training program, the benefit might be to help representatives increase their sales and personal commissions. For a safety-training program, the benefit might be to reduce the number of workers getting hurt. For a software-training program, the benefit to users could be to make them more productive or reduce their frustration with an application. A healthcare program might have the benefit that it can teach doctors how to treat certain patients.
- **Confidence:** The confidence aspect of the ARCS model is required so that students feel that they should put a good faith effort into the program. If they think they are incapable of achieving the objectives or that it will take too much time or effort, their motivation will decrease. In technology-based training programs, students should be given estimates of the time required to complete lessons or a measure of their progress through the program.
- **Satisfaction:** Finally, learners must obtain some type of satisfaction or reward from the learning experience. This can be in the form of entertainment or a sense of achievement. A self-assessment game, for example, might end with an animation sequence acknowledging

the player's high score. A passing grade on a post-test might be rewarded with a completion certificate. Other forms of external rewards would include praise from a supervisor, a raise, or a promotion. Ultimately, though, the best way for learners to achieve satisfaction is for them to find their new skills immediately useful and beneficial on their job.

A Classification of Multimedia Representations

The locus of this work is to promote an understanding of the correlation between the four factors of the ARCS model and the characteristics of the employed representations. A well accepted taxonomy is the one by de Jong et al. (2004). However, in order to promote understanding of their employment in EduGames, one has to bear in mind a "virtual" game and rely to one's situated experience. To describe the employment of representations, examples of possible applications are used subsequently. Under this point of view, following categories are of interest in EduGames.

- **Multiple representations:** Text, animation, static image representations, sound, and video constitute the majority of the representations employed in EduGames. Usually, one cognitive aspect is presented by means of more than one representation (e.g., video with sound).
- **Code and modality:** The navigational elements are often icons, still or animated. They (the representing world) depict a navigational structure (the represented world), which is usual in educational environments: next, previous, home, exit, repeat, and help. The rest of the representations occur where interaction with the user is possible. A narration prompts the pupil to act and provides help on it. In such a case, we are talking in both cases of *depictive* and *non-equivalent* representations, which are however *multimodal*, as they employ aural, visual, and tactile modes to interact with the user (the user is often asked to type something). Although, from a usability perspective it could be debatable in how far the used navigation icons are intuitive to a novice user of younger age, the application of such a software often shows that children can easily overcome such burdens with little or not at all help. The exploratory nature of children permits them to explore the interface and discover their capabilities. The "prevent errors" usability factor is important here, in order to hinder fatal errors an exploring user could cause.
- Animation seems to provide potency for *dynamic* and *kinesthetic* (manipulable) types of representations. Often, only *concrete*, *pattern imagery,* and *symbolic elements* are represented. Animation for feedback is considered here to belong to the pattern category, as it only informs the user on the correctness or not of their action. It is obvious that we are dealing here with *depictive feedback* (if it is correct or not) and not with *constructive feedback* (in what direction one should seek for the correct solution).
- Affordances: Rarely do the visual representations provide concrete affordances, in helping to visualize the information. In this sense, they help to structure the cognitive activity and provide patterns for experimentation. However, in most cases animations and sound cues are used as feedback or as a helping facility (explaining narration).
- Concerning the underlying theoretical support, the theories of *dual coding* (Paivio, 1990) and *cognitive load* (Chandler & Sweller, 1991; Yeung, Jin, & Sweller, 1998) seem to be implicitly employed in the design of the majority of the systems. Dual coding theory is de facto implemented in any multimedia environment, and its ultimate purpose is to reduce cognitive load (Mayer, 2003), so it can be argued that the use of multimedia animations intends to benefit from these theories. In contrast, *multimedia design theories* seem to be explicitly employed in the design and construction of many interfaces.
- In regards to the *cognitive modeling* support, it is usually not apparent in the designers' intentions, although most interfaces do not provide any problems on it. Children usually can easily work in the interface, without any hindering. One remark must be stated here, concerning the *redundancy* principle and the claim "avoid presenting verbal information in both textual and narrative form especially when graphics are presented at the same time" (de Jong et al., 2004), and a claim stated by Juul (2000) that "it (the game) must not contain narration; everything must happen in the *now* of the playing."
- At this point, the provided *degrees of freedom* must be discussed. Many gaming environments, which simulate "the school" can not be characterized as a constructivist ones, as most of the exercises employed are already known to the pupils from school and must be performed in a pre-defined way. So, it can be argued that the used representations in such environments significantly reduce the degrees of freedom, while they provide only limited affordances.

These characteristics of the multimedia representations usually employed in EduGames are only a subset of the set of attributes to be considered while designing and constructing an EduGame.

MATCHING OF MOTIVATIONAL AND REPRESENTATIONAL CHARACTERISTICS

Accordingly, a combination of most encountered attributes in EduGames is attempted with the factors of the ARCS model. To facilitate this matching, this study proposes the employment of a matrix as follows.

Table 1 presents the four factors of the ARCS model on the top, analyzed in their dominant parameters. On the left-hand column are presented the main attributes of the EduGames, as described in the relative literature (the representations are included).

RESEARCH QUESTIONS

The initial and central question, according to which every cell of the table has to be filled, is: "Are the factors of the ARCS model supported by every attribute and how exactly?"

So, to fill out the table one must consider every attribute on the left-hand column and try to investigate its correlation (if any) to every factor of the ARCS modes, represented by their most dominant parameters. For every matching, a separate investigation must be set up, may it be a case study, a literature review or any other acknowledged approach.

These attributes are collected through an extensive literature overview on the characteristics of EduGames (e.g., Azar, 1998; Malone, 1980a, 1980b)

Representations in EduGames have also been considered as attributes and are listed on the table. A valuable source here are the works (among others) of Ainsworth and Van-Labeke (2004), van der Meij, J., and de Jong, T. (2004), and de Jong et al. (1998).

Another criterion to choose these attributes is their applicability. This is particularly difficult because of the given variety of EduGames. Games encompass many styles and subjects. For example, games may be competitive or cooperative, be played by individuals or groups, and touch on numerous themes, such as adventure, education, social interactions, science fiction, violence, and sexual circumstances. Simulations sometimes are considered games as well. Leemkuil, de Jong, and Ootes (2000) argue that games as learning environments are closely related to simulations, microworlds, adventures, and case studies. The definitions of these environments partially overlap. For instance, the distinction between simulation and games is often blurred, and many recent articles in this area refer to a single "simulation game" entity.

On the other hand, EduGames must underly some guidelines to be characterized as such. Harlow (2004) classifies them in two categories, process and reward. Process comprises the actual playing of the game such as the interface, levels, immersion, content, and interaction of game mechanics, while reward is either the internal game benefit or external feeling of satisfaction or success the player gains from the process. So, some attributes, such as "challenges," "choices," and "rewards" emerge from this approach.

Further on, a great deal of research focuses on computer literacy and basic programming skills. Playing computer games is a popular recreational activity for young people. Not surprisingly, many of these enthusiasts dream that one day they will develop computer games themselves. So why not use game design as a vehicle to teach youngsters computer science? Developing computer games involves many aspects of computing, including computer graphics, artificial intelligence, human-computer interaction, security, distributed programming, simulation, and software engineering. Game development also brings into play aspects of the liberal arts, the social sciences, and psychology. Creating a state-of-the-art commercial computer game is an incredibly difficult task that typically requires a multimillion-dollar budget and a development team that includes 40 or more people. But simpler alternatives—ones within the reach of students and hobbyists—exist. Budding game developers can have fun creating variations on Pac-Man, Space Invaders, or simple platform games (Overmars, 2004).

Under this point of view, attributes such as "assignments in layers" or "present abstract material in real world context" become also critical and are included in the list.

Another aspect is the social dimension of gaming. Kiefaber (2004) argues that gaming is inherently social and playing games has been closely linked with building relationships and social hierarchies throughout history. Not only games are social activities, but also many times the game itself is secondary to the social experience. Video games are now a permanent fixture to our culture, redefining the process by which children mature and develop. Over the past few years however, a great shift towards Internet-based games has been observed and recorded. The lure of multi-player gaming has been interacting with real people, not artificial intelligence. Live opponents or allies make gaming much more unpredictable and much more enjoyable. Nowadays, not only are potential game players connected to the Internet in large and rapidly growing numbers, but their composition is much more diverse and many new gaming possibilities have been created that were not available with non-Internet games. To conclude, attributes such as "cooperation," "competition," "fantasy," as well as almost all representational characteristics listed in the previous table, become also socially important, thus shifting their correct matching to the motivational parameters to an important task.

Table 1. Motivational matrix of educational representations

	Attention		Relevance		Confidence		Satisfaction	
	Curiosity (stimuli variability)	Interest (Inquiry arousal)	Perception of personal needs ac-complish-ment	Relation to a highly desired goal	Expectancy of final sucess	Sucess under control	Extrinsic rewards	Intrinsic com-patibility to anti-citations
Easy to understand								
Options for creativity								
A challenge (goal)								
Assignments (challenges) in layers								
Fantasy (extrinsic & intrinsic)								
Curiosity (sensory & cognitive)								
Multiple representations								
Code & modality								
Feedback (instant & summative)								
Affordances

FUTURE TRENDS

It is obvious that further research has to elucidate the correct matching (if possible at all) and the matching strategy for every EduGame attribute to every (or more) ARCS factors. The cell will hence describe the details of every particular approach.

Research for every case can be in the form of literature review, case studies, experiments, or any other acknowledged approach.

However, this implies a huge amount of research, which is not feasible at this time. On the other hand, some research has already been done and some answers are already given. For example, in regards to the "graphics" attribute, literature gives an extensive focus on it, as it is stated that "they can capture the students' interest" almost in consensus (e.g., Walker, 2003)

So, a more realistic approach here would be to focus on some of the attributes, which are not yet studied by other researchers and set up some case studies or experiments to clarify their correlation to the ARCS parameters.

In more detail, some EduGames attributes must be chosen and implemented in an EduGame environment. Accordingly, a study, which has clear hypotheses, must investigate whether these attributes have any influence on the augmentation of any of the ARCS parameters, which in its turn would lead to the augmentation of any of the four factors of the ARCS model.

This could be a clear indication that the correct manipulation of the particular attribute can lead to an augmentation of one (or more) motivational factor, leading thus to an enhanced motivation of the EduGame, which is the Holy Grail for every educational designer.

Who could benefit from this approach? Educational designers, teachers, and any person involved in educational software could benefit from this research. Results are obviously of a broader applicability than only in EduGames, since the motivational factor is usually hardly understood and implemented in educational pieces. So, a reference to some "motivational guidelines" would be of great interest for designers as well as for evaluators of any instructional approach.

CONCLUSION

The matching of the encountered in the literature attributes as regards educational games with the four factors of the ARCS model proposed by Keller is a daunting task, which however could enlighten many hidden up to now relations between correct instructional design and motivation. Since it is commonly agreed that motivation is the *sine qua non* of successful learning (Prensky, 2003), it would be a valuable result to explicitly know relations of educational attributes that could enhance any motivational factor.

KEY TERMS

ARCS Model: A model describing motivation by means of the four factors of attention, relevance confidence, and satisfaction.

Attributes: Characteristics of an entity, clearly contributing to its utility.

Classification: A taxonomy according to dominant characteristics of some entities.

Educational Games: Computer-based electronic games with high educational value. They usually adhere to the constructivist theory of learning.

Motivational Matrix: A table combining the motivational characteristics with the attributes of other entities.

Multimedia Representations: Chunk of educational information depicting selected aspects of the depicted world by means of multimedia modalities.

Motivations for Internet Use

Thomas F. Stafford
University of Memphis, USA

INTRODUCTION

In light of the importance the Internet has as a channel of commerce, it is important to understand consumer motivations for Internet use (Eighmey & McCord, 1998; Lohse & Spiller, 1998; Schonberg, Cofino, Hoch, Podlaseck, & Spraragen, 2000). In the absence of motivations for Internet use, there can be no motivations for e-commerce use, so Internet use motivations are an important antecedent to e-commerce activities (Stafford, 2003b). The Internet is a telecommunications medium, but it is also far more than a computer-mediated communication channel. In its evolution, the Internet evolved from a basic telecommunications network, to a consumer communications and entertainment medium, to a converged channel of commercial and telecommunications media that combine the utilities of familiar entertainment and communications media such as telephones, radio, and television, along with emerging computer network functionalities.

While remaining at its core a network for the distribution of information and telecommunications services, it has evolved into a combined channel for the delivery of other, richer media—become a medium of conveyance for many separate media delivered simultaneously, or a *meta-medium* (Stafford, Stafford, & Shaw, 2002). In the past, understanding Internet motivations strictly related to computer use was sufficient to characterize Internet user motivations, but in the converged meta-medium of the modern day, we should consider a wider range of potential uses and motivating gratifications arising from use of this complex and converged medium.

Media uses and gratifications (U&G) has been a useful theoretical platform for understanding Internet use in this emerging age of media convergence. This perspective focuses on the process of using the Internet medium, and the gratifications related to the content provided by the network. More recently, Internet U&G research has demonstrated additional motivations for Internet use that expand beyond the traditional usage process and media content motivations found in U&G studies of conventional media. These motivations span usage process and content to include considerations of social motivations for network usage, which is a gratification that traditional media have not generally been able to supply to users (Stafford et al., 2002). These new and emerging media usage gratifications for the Internet are important for site and service operators to understand, if they wish to successfully motivate customer use of and loyalty to their resource. These new motivations are potential differentiators between operators *within* the Internet medium as well as *between* the Internet and conventional promotional media.

BACKGROUND: MEDIA USAGE AND GRATIFICATIONS PERSPECTIVES

It has long been known that media usage is not a random or undirected activity; like all rational human behavior, there are discernable motivations for media use (Katz, 1959). Early U&G research in the radio and television era determined that audiences are not passive consumers of media (Katz, Blumler, & Gurevitch, 1974; Rubin, 1981), and this "active use" tenet of U&G research means that media researchers can find theoretically compelling approaches to simulate more involved media use, which is surely a beneficial outcome to the media and their commercial sponsors.

Media choice is motivated by individual uses and the individual goals related to those individual uses, which has come to be characterized as media usage "gratifications" (Lin, 1977). In this sense, media are like any other product or service that might be marketed to customers. In markets, even media markets, consumers make choices about what to use in an active and selective manner (Levy & Windahl, 1984). This means that media operators cannot presume a captive audience and must strive to understand their audience usage motivations in order to provide a compelling and attractive media experience. This perspective has come to be called the "niche theory" of media use, wherein consumer time for media use is a finite and limited resource that must be actively competed for by available media in product-market fashion, on the presumption that time spent by consumers with one media reduces available time to be spent with other competing media (e.g., Dimmick, Chen, & Li, 2004).

In the competitive scenario of media niche theory, understanding user motivations becomes all the more critical, as media must compete with each other for the available audience, and good understanding of user motivations provides more able competition for scarce audience resources. U&G theory has been quite useful in providing clear and effective profiles of media user motivations in traditional media in the past, as well as in the emerging Internet meta-medium (Eighmey, 1997; McDonald, 1997; Newhagen & Rafaeli, 1996). In view of the multimedia aspect of the modern

Internet, it is considered that opportunities for user gratifications are greatly increased over traditional media (Dimmick et al., 2004); hence a clear understanding of Internet U&G will be useful for effective "niche-theory" marketing of the Internet medium to users.

Classic applications of U&G theory in the traditional media have consistently identified only two key areas of motivation for media use: media content uses and motivations (*gratifications*, in U&G parlance), and media usage process gratifications. Content gratifications concern the *messages* carried by the medium (which could be informative or entertaining), and process gratifications concern *actual use* of the medium, itself (Cutler & Danowski, 1980). The modern analogies would be the Web surfer, who is clearly motivated by the process of using the Internet, versus the highly focused online researcher, who is engaged in searches for very specific message content to support information needs (Stafford & Stafford, 2000).

U&G UP-TO-DATE

In research that has spanned the course of the past decade, an emerging stream of literature documenting Internet-specific media uses and gratifications is now reaching publication. Early research on U&G and the Internet was limited by the practice of adapting measurement scales for usage gratifications from television U&G studies (cf., Eighmey, 1997; Eighmey & McCord, 1998; Rafaeli, 1988). This was a useful transition stage approach for developing an initial understanding of the motivations of early Internet users, but the medium and its users have become far more sophisticated and complex in the intervening years.

Emerging Internet U&G research, which abandons traditional television-based measures and develops scales specifically tailored to the Internet experience, is based on the premise that Internet usage gratifications are different from the motivations that drive the use of other media (e.g., Stafford & Stafford, 1998). This article documents some of the more prominent findings in the process of developing these new Internet-specific U&G dimensions, as well as emerging "second-wave" Internet user motivation and behavioral studies.

The Initial Factors of Internet-Specific U&G

The initial approach to developing Internet-specific U&G profiles began with online qualitative research that sought to investigate the dimensionality of uses and gratifications; in classic measure development manner, Stafford and Stafford (2001a) leveraged their qualitative investigation of Web site users into an online user survey for purposes of identifying new Internet-specific gratifications through multivariate analysis. Exploratory factor analysis identified five Internet-specific U&G factors: searching, cognitive, new and unique, social, and entertainment.

The searching factor was not unexpected and is certainly intuitive to experienced users of the Internet. The cognitive factor was characterized by gratifications related to learning: education, information, learning, and research. The factor "new and unique" was representative of the still-new feeling of the medium at the turn of the century, characterized by user perceptions of the medium that included qualities such as "ideas," "interesting," "new," "progressive," and "relaxing." The entertainment factor (entertainment, fun, and games) was a media content gratification related to having fun with Internet site content. The social factor (chatting, friends, interaction, newsgroups, and people) was distinct in comparison to both traditional U&G dimensions of process and content gratifications, as well as early Internet applications of traditional U&G dimensions in exploratory research, since previous U&G research had never identified a social motivation for Internet use.

Applications of New Internet U&G Factors

With a newly identified social motivation for Internet use, important implications arise. Unlike any of the traditional media, the Internet can be considered as both an interpersonal and a mass exposure medium, with simultaneous gratifications along several mediated channels (Stafford & Stafford, 2001a).

Stafford's (2001) confirmatory analysis of Internet U&G dimensions was applied to investigate Internet diffusion in the consumer market (Stafford, 2003b). Significant differences between innovation adoption categories were found for specific Internet U&G factors. Internet laggards, for example, exhibited the lowest social gratification for online services, while Internet "innovators" (or, early adopters) exhibited the highest social gratifications. Innovators also appeared to be significantly more motivated by content gratifications for Internet use. In a study of AOL users and their uses and gratifications for Internet use (Stafford, 2003a), heavy users also scored higher than light users for both process and social Internet usage gratifications. AOL users were strongly motivated by Web browsing and the guided search for information, in addition to their appreciation for social gratifications related to Internet communications functionality. Interestingly, among all the potential indicators related to U&G factors examined in analysis, online shopping did not appear to be highly gratifying to AOL users (Stafford & Gonier, 2004).

The impact of social gratifications for the Internet appears to be a function of user experience, and a rising generalization is that heavy Internet users are more motivated by

social gratifications than light users (Stafford et al., 2002), which tends to fit with emerging views of Internet user demographics (e.g., Emmannouildes & Hammond, 2000). As an aspect of consumer media marketing strategy, heavy users are desirable consumer targets for ISPs, and this trend could have valuable implications for practice.

Internet U&G factors have also been applied to understand motivations for Internet use in distance education classrooms (Stafford, 2005; Stafford & Stafford, 2003). In the student use of distance course Internet resources, social gratifications were dominant; the conclusion was that students on the remote end of a distance education teleconference feel socially removed and isolated from colleagues in the live sections of classes (cf., Berger & Topol, 2001; Hamer, 2001). Internet technology, including chat and e-mail, as well as IP teleconferencing, acts to reduce the social isolation of distance education courses (Stafford, 2005).

Relationships between Internet-Specific U&G Dimensions

In a study seeking to establish trait validity for Interent U&G factors (Stafford, 2001), process and content gratifications for the Internet were found to be highly related ($\Phi = .72$), but there were much weaker relationships between the social factor and the more traditional process and content gratifications, which tends to reinforce the multi-modal conceptualization of the Internet as providing both personal entertainment and interpersonal communications channels in one meta-channel. The usage process gratification was only moderately related to social gratifications ($\Phi = .38$), and the content gratification was also only moderately related to social gratifications ($\Phi = .34$), so social gratifications for the Internet are distinct from (and not closely related to) standard process and content gratifications for Internet use. The social gratification construct did display excellent measurement qualities, indicated by measurement model fit indices (GFI = .97, AGFI = .95, RMSR = .11, SRMR = .043, NFI = .96, CFI = .97), so social gratifications appear to be a distinct and trait valid area of motivation for Internet use, if not directly related to the better-understood process and content gratifications.

THE SECOND WAVE OF INTERNET MOTIVATION RESEARCH

Now that the Internet is an accepted, even mundane, aspect of modern life, media gratifications studies of the medium are beginning to expand beyond basic identification of Internet-specific gratification dimensions, and to begin to deal with more applied behavioral perspectives of daily Internet use. More applied perspectives of Internet media user motivations now include themes of Internet uses and gratifications related to online advertising (cf., Ko, Cho, & Roberts, 2005; Yang, 2004), the motivations for Internet use among business channel supply chain members (Zank & Vokurka, 2003), and even maladaptive motivations related to over-use and Internet addiction (Song, LaRose, Eastin, & Lin, 2004).

U&G is a mature theoretical paradigm, dating from the advent of the radio era, and it has quickly been adapted to understanding aspects of Internet use. Researchers are also applying other mature theoretical models in similar fashion. For instance, the venerable technology acceptance model sees plenty of application in Internet use research, including explorations of recent evolutions of the model toward more affective components of judgment; playfulness and Internet acceptance have been investigated (Chung & Tan, 2004), and recent advances relayed in the recent unified model (Venkatesh, Morris, Davis, & Davis, 2003) related to extrinsic and intrinsic motivations have been expanded upon (Lee, Cheung, & Chen, 2005; Shang, Chen, & Shen, 2005). These Internet motivational schemes begin to take the study of Internet use away from the media-use motivations approach exemplified by the reference discipline perspectives of communications theory found in U&G and toward the more established technology use perspective favored by the community of IT scholars.

Future adaptations of reference discipline theories to the understanding of Internet use (and, indeed, both U&G and TAM approaches are adaptations of popular theories brought to the IT field from influential reference disciplines) will likely apply behavioral aspects of atmospherics, cultural artifacts, and social network theories, as we begin to understand the Internet as an established and influential multi-modal medium deeply integrated into the emerging modern lifestyle.

CONCLUSIONS

Media use theories have been useful in the intermediate days of Internet development, as scholars have undertaken to understand the multiple channel medium as a converged instance of communication and entertainment unlike others known in society previously. As Internet use becomes more mundane and widespread in modern society, scholars can begin to utilize theories of human and consumer behavior that anchor Internet use in lifestyle and workplace contexts at a more applied level. Yet, to this day, the importance of understanding the motivations for Internet use that arise from its characteristic as a multimodal mediated channel of information and entertainment will remain important as new and more spectacular uses are devised for this robust and rich channel.

Internet social gratifications will be particularly important in emerging perspectives of the network as a manifestation

of culture, lifestyle, and work, since the social gratifications afforded by the Internet are unlike those of any other mediated channel in previous experience, notwithstanding the numerous informational and entertainment gratifications the network provides. Unlike other media studied in the past, where sought content and enjoyment of media usage processes were the defining factors of motivation, the Internet provides standard media gratifications along with interpersonal connectivity, giving it a multi-modal appeal and influence in human life.

Interpersonal communication and interaction with other people over the Internet—the extension and maintenance of social networks via technologically mediated telecommunications networks—seems to characterize the social Internet gratification. Emerging perspectives of Internet user motivations in the recent second wave of Internet use research rely more on motivational bases than could be characterized in line with functional utility (content-based information resources, for example, and usefulness perspectives), or on the affective gratifications that derive from the enjoyable usage processes of the medium (playfulness, atmospherics, and various affective approaches to Internet use motivations relate strongly the Internet process gratifications).

Regardless of the use or gratification that a business may wish to impact in its provision of Internet service and utility, the important point is to realize that users actively interact with the medium, and that uses and gratifications is one of the best ways that exists in which to study active audience motivations for media use. Determining what audience members seek to do, and the benefit they expect to accrue from activity, is the important step in marketing and supporting Internet offerings.

Emerging product utility-based conceptualizations of Internet user motivations notwithstanding, U&G's "active-use" tenet continues to remind us to be customer-centric in our design and provision of products and services, in the realization that users want specific things and they want them because these things bring them enjoyment. Goal oriented activity is the lynchpin of motivation, and understanding the goals sought by our Internet customers will allow us to design and provide more compelling and satisfying offerings. Inevitably, business objectives will be more fully attained in a customer-centric media-based approach to the Internet industry.

KEY TERMS

Active Audience: Uses and Gratifications theory presumes media users are actively involved in selection and use of media and are not passive recipients. This implies the need to specifically target media offerings to perceived user needs.

Content Gratification: Enjoyment of message specifics. Content can mean information, and often does, though it also includes entertainment in the form of medium-carried programming.

Gratifications: What people derive from use—the "why" of media use motivations.

Meta-Medium: A channel of channels, such as the Internet. This term conveys the sense of rich and complex media transmission across a multiplexed channel of conveyance. Numerous motivations for use could arise related to such a complex media venue.

Process Gratification: Enjoyment of media use, as distinguished from enjoyment of specific message content. This is much the same as channel surfing or Web browsing with no goal other than entertainment through engaging in the activity.

Uses: Things people do *with* media—the "how" of media use motivations.

Uses and Gratifications: Customer activities and the enjoyment that derives from such activities, particularly in a mass media context.

Multi-Agent Mobile Tourism System

Soe Yu Maw
University of Computer Studies, Myanmar

Ni Lar Thein
University of Computer Studies, Myanmar

INTRODUCTION

Nowadays, with the emergence of high-speed wireless networks, various portable devices such as personal digital assistant (PDAs), mobile phones, and other wearable equipment are widely used by people in their daily lives. Context-awareness plays a vital role in enabling smart environments, wearable computing, and wireless computing. This article presents the multi-agent system, which uses mobile technology to offer services in the tourism domain.

Agent-based systems are widely used for mobile and distributed information systems. Agents can also help in preventing the user from being overwhelmed by irrelevant information using personalization methods. This technology provides the integration of information from diverse sources, while personalization provides the filtering technique to deliver the relevant information to the users.

The system gives up-to-date information based on the user's preferences and other contextual information such as sight location, weather condition, and special functions that are arranged during the visit. The system consists of two types: Web-based and mobile-based. We design the system as client-server architecture, supporting desktop clients as well as mobile clients on a handheld device with appropriate interfaces. However, in this article, we now focus on the mobile-based tourism system. The handheld device or PDA is used for receiving information from a Web server.

In past years a broad spectrum of different Web-based tourism has been established. The acceptance and consequently the competitiveness of a tourism system are mainly determined by the quantity and quality of data it provides. Therefore, most existing tourism systems try to fulfill the tourist's request (interest) for an extensive data collection (Rumetshofer & Wob, 2005).

Tourism information (e.g., travel schedules, etc.) are distributed, dynamic, and heterogeneous. The users (tourists) may face difficulty using them when planning their trips.

Nowadays, the improvements in wireless communication technologies such as handheld devices to the Internet open up new prospects for e-commerce and e-tourism. Today, new technologies allow more flexible access to information booking services and other tourist support (Belz, Nick, Poslad, & Zipf, 2002). Tourism has been a popular area for mobile information systems. There are a number of obstacles to introducing new technology in tourism. Electronic guidebooks and maps have been a popular application area for mobile technology.

In the near future, a broader range of services will become available to users anywhere, at any time. People can receive their required information by interacting with their PDA from wherever they are. Kanellopoulos and Kotsiantis (2006) stated that the tourism industry makes efforts to implement techniques that can reduce travel cost and improve performance.

A major issue in offering mobile services to nomadic users is the limited display and networking capacity of mobile devices such as wireless application protocol (WAP) phones or PDAs. A possible solution for this is the adaptation of services and contents to the users' personal interests and their current location. The adaptation of services and contents to personal interests mainly filter the available information. Poslad et al. (2001) described the filtering process as based on a user profile describing the interests, abilities, and characteristics of the user.

Ding, Malaka, and Pfisterer (2002) described multi-agent systems as particularly well suited for mobile information systems, and some systems even allow for resource-aware computations in mobile and distributed environments.

Maw and Naing (2006) described the architecture and design of a multi-agent tourism system (MATS). MATS evaluated the similarity value and mean absolute error (MAE) to give the best recommendation to the user.

The central motivation of this article is to extend MATS suitable for the mobile user in the tourism domain. The objective is to give the user the most relevant and updated information according to the user's interest.

The next section provides the definitions and a discussion of the system, and reviews literature of some related works. The main focus of the multi-agent mobile tourism system architecture is then described, and the design considerations and future trends are also discussed, before we conclude the article.

BACKGROUND

In this section, we provide definitions and review some related works. There are a number of research projects related to the tourism system. The multi-agent system, personalization methods, and mobile technology are discussed in the literature.

Wooldridge (2000) defined multi-agent system as a collection of agents that work in conjunction with each other. In multi-agent system architecture, each agent is autonomous, cooperative, coordinated, intelligent, and able to communicate with other agents to fulfill the user's requirements.

The characteristic of agent proactiveness can provide the user with information related to his or her profile. Agents are autonomous, so they act on behalf of a user to reach a goal or solve a problem for the user. Agents filter information that is suitable for the user on the basis of a user profile that stores the user's interests. Agents need an agent platform, which provides communication for the agents, other services, and security features.

There are many advantages in the mobile devices of agent technology, such as providing services to the user in a personalized way.

Personalization means knowing who the user is, what the user's interests are, and recognizing a specific user based on a user profile. Willy (2001) and Rumetshofer and Wob (2005) defined personalization as a process of gathering and storing information about users, analyzing the information, and based on the analysis, delivering the information to each user at the right time.

Personalization is also an important feature of mobile services. Personalization adapts the services to the user location, user preferences, and user profile.

Poslad et al. (2001) described that "Creation of User-friendly Mobile services Personalized for Tourism" (CRUMPET) is a mobile application that uses multi-agent technology to construct a context-aware system. The system combines personalized services, multi-agent technology, location-aware services, and transparent mobile data communication, altogether in order to facilitate the users. The services provided by CRUMPET take advantage of integrating four key emerging technology domains and applying them to the tourist domain: location-aware services, personalized user interaction, seamlessly accessible multimedia mobile communication, and smart component-based middleware that uses multi-agent technology. Its use is mainly limited to providing query and recommendation services.

The GUIDE project (Simcock, Hillenbrand, & Thomas, 2003, Cheverst, Mitchell, Friday, & Davies, 2000) studies the electronic tourist guide system of Lancaster City. It obtains the user position by receiving location messages transmitted from non-overlapping WaveLAND cell base stations dispersed throughout the city. Wireless communication was used via a pen-based tablet computer. While this approach does not need additional hardware on the client side, it results in a lower resolution of positioning information.

The Cyberguide project (Abowd et al., 1997) is a handheld electronic tourist guide system that supplies the user with context-sensitive information. It was built in the mid-1990s, and its goal was to provide the information to a user based on the user's position and orientation. The application is hosted entirely on an Apple MessagePad and used infrared beacons for positioning using a Trimble GPS unit.

Hinze and Buchanan (2006) described the tourist information provider (TIP) as a mobile tourist information system that presents information to the user that is sensitive to the user's context, interest, and the related context of neighboring sights of interest. TIP provides map-based and browser-based information navigation, and uses contextual hierarchy to support outliner-style browsing that is efficient on small-screen, mobile displays (Hinze & Buchanan, 2005). The user dynamically interacts with the system by providing his or her current location while asking for information from the system. TIP also gives recommendation to users based on their current position and the information in their user profiles. They get a list of nearby sights which they might like to visit if they request the system's recommendation.

The IMAGE system proposed e-services for mobile users and introduced the personalized service feature, using agent technology in the context of the IST project IMAGE. In the IMAGE system all roles are implemented as agent types with the exception of the social role, which is realized by all agents that need to be acquainted with their collaborative partners. Their system integrated a set of intelligent agents having different functionalities (e.g., personalized assistance, travel information, and cultural events information), which are necessary in order to cover the needs presented by this specific application field called mobile personalized location-based services.

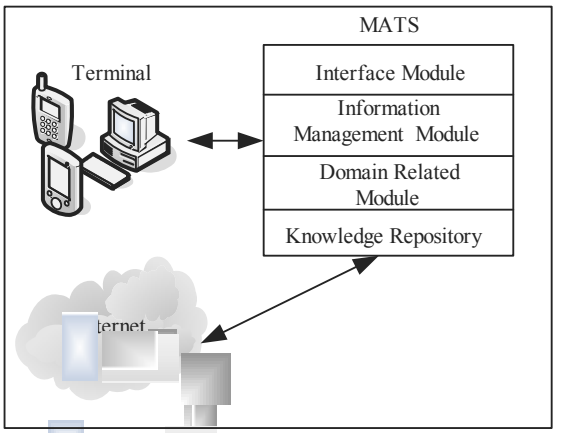
We also provide the services for mobile users by using personalized services with agent technology. The system uses GPS data to recognize the user location. The system gives the recommendation to the user according to the location of the user and user preferences.

MULTI-AGENT MOBILE SYSTEM ARCHITECTURE

A mobile system can be deployed in a wide range of physical environments to support users in diverse tasks. Advanced mobile systems need to exploit information about the environment in which they are working.

In this article, we extend our previous MATS to a mobile system. Figure 1 shows the general architecture of a multi-agent mobile system. A more detailed description is provided in Maw and Naing (2006).

Figure 1. General architecture of proposed system

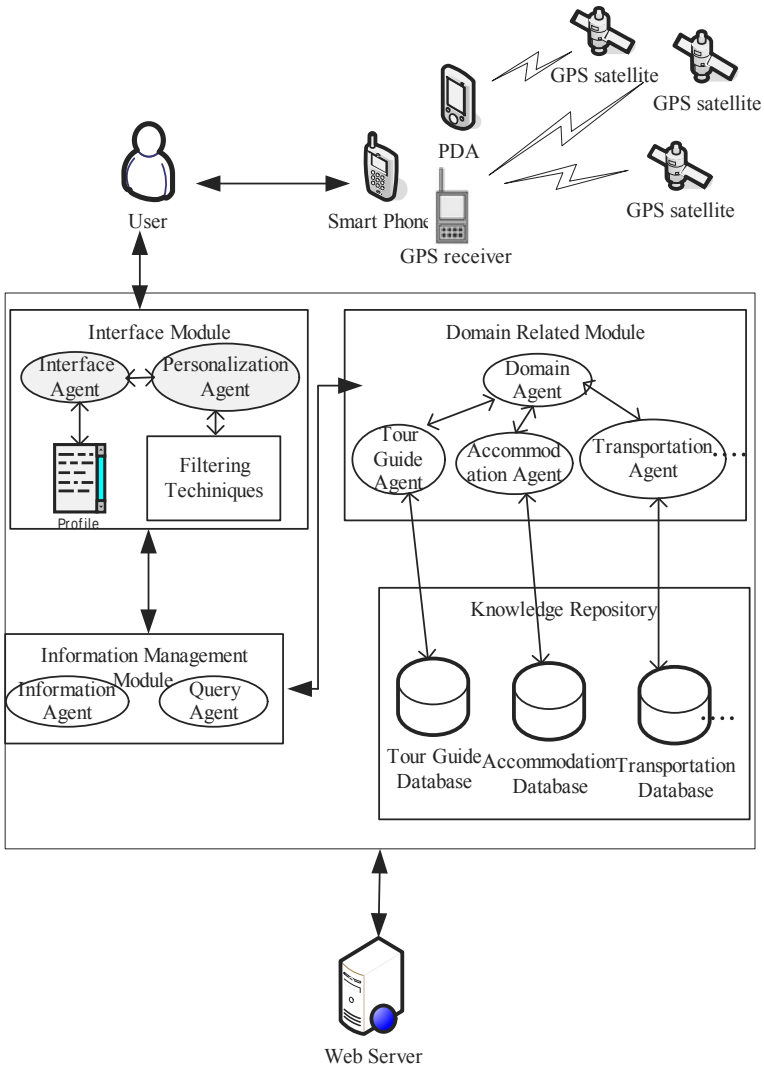


As shown in Figure 2 we provide the actual deployment of agents in smart or mobile devices (such as a PDA or smart phone). In this system, the client device is a handheld device or PDA used as a terminal for receiving information from a Web server and receiving signal from the GPS satellite.

The users are required to define their preferences (interests) as user profiles. Users' information can be changed whenever they want to revise their interests. We use the combination of rule-based personalization with collaborative filtering technique, which can give the user information effectively and efficiently according to the user's interests.

The architecture of multi-agent system is composed of four main modules:

Figure 2. Design architecture of multi-agent mobile system



- interface module,
- information management module,
- domain related module, and
- knowledge repository.

Each part is detailed in Maw and Naing (2006). A brief explanation of each module follows.

In the interface module, the interface agent gets users' information and creates user profiles. The personalization agent performs rule-based personalization with collaborative filtering technique. This technique computes the similarity measure between the users and gives recommendations to the users according to their profiles (Maw & Naing, 2006).

The information management module has two sub modules, namely information agent and query agent. The information agent manages the data to be stored in a corresponding database whenever changes or updates of information occur. The query agent retrieves the information from the knowledge repository through a domain-related module and returns the results to the personalization agent.

The domain-related module is composed of domain agent and many other agents such as tour guide agent, accommodation agent and transportation agent, and so forth. The domain agent performs database queries from the corresponding databases and delivers specific domain solutions.

The knowledge repository consists of tourism information for each domain in a standard structure. It maintains information and makes that information available on demand.

PERSONALIZATION SERVICES

Short (2000) stated that personalization is a key feature that facilitates the use of complex services on mobile devices.

The personalization agent performs the task of gathering the user information, interests, or preferences, and stores the context of information as the user profiles. The next step is to analyze the information and use rule-based personalization with collaborative filtering technique.

Rule-Based Personalization

Rule-based personalization is an important part to exposing relevant content to the user. This yields a very efficient reduction of the number of items that must be processed at a very early stage of the filtering process. It defines a set of rules to tailor the content based on the facts specified in the user profile. The advantage of rule-based personalization is that rules can be adopted for use in any platform and thus are not limited to the Web.

Collaborative Filtering

The collaborative filtering technique is used to obtain one or more numerical ratings for every item. The task is to predict the interest of an active user to a targeted item based on the user profiles. A collaborative filtering system looks for the users who share the same rating pattern with the active user and use the ratings from users to calculate a prediction for the active user. It is the process of computing personalized recommendation by finding users with similar taste. The Pearson correlation coefficient is used to compute the similarity measure (see details in Maw & Naing, 2006).

AGENT PLATFORMS FOR MOBILE DEVICES

An agent needs an agent platform to provide services such as communications of agents. The Foundation for Intelligent Physical Agent (FIPA) is a de facto standard for agent communication languages. To facilitate the development of a multi-agent system, we use the Java Agent Development Framework (JADE). The agents running on the mobile devices use a Light Extensible Agent Platform (LEAP) add-on. JADE-LEAP is used for enabling FIPA agents to execute on lightweight devices running Java. The graphic user interface (GUI) is developed using the Java 2 Micro Edition (J2ME) specification.

LOCATION-BASED SERVICES

Mobile users are moving from one place to another and passing through different locales. Location-based services can provide the location of the user. There are a variety of methods and devices for collecting and sensing the location of the user. Global positioning systems (GPSs), infrared sensors, Bluetooth, the Global System for Mobile Communications (GSM), and the universal mobile telecommunication system (UMTS) are positioning techniques that can be used for sensing location. The most well-known location-sensing system today is GPS.

One of the most powerful ways to personalize mobile services is based on location. We use GPS sensor data to determine the user's location. Far (2005) described that GPS-enabled devices can obtain latitude and longitude with accuracy of about 1.5 M. GPS devices use triangulation techniques by triangularity data points from the satellite constellation that covers the entire surface of the earth.

PDAs have definitely evolved over the years. Not only can they manage the personal information, such as contacts,

appointments, and to-do lists, but today's devices can also connect to the Internet, act as GPS devices, and run multimedia software.

For anyone with a GPS receiver, the system will provide location and time. A GPS provides accurate location and time information for an unlimited number of people in all weather, day and night, anywhere in the world.

The mobile device transmits the subscriber information to the network, and the GPS generates the location of the user. The system can give the information to the user relevant to the user's interest and the location of the user. By knowing the user's location, the system can give recommendations to the user of nearby places of interest.

FUTURE TRENDS

The field of context-aware mobile systems is an emerging research topic. There are many techniques to acquire user location, but mobile devices still have security and privacy issues. For our future work we will focus on the localization system that involves context-awareness of more dynamic information of user location, security, and privacy issues.

Although GPSs have many advantages, there have some limitations in that the issues of such systems are not solved efficiently, such as out-of-signal, inside building, and cost issues. Today's mobile phone comes with a built-in GPS receiver that can be used inside a building and can perform route planning and navigation. We will focus on solving the limitations of conventional the GPS system.

CONCLUSION

In this article, we have presented the architecture of a multi-agent system for mobile devices such as PDAs or handheld devices in the tourism domain. Multi-agent systems efficiently retrieve and filter information from sources that are spatially distributed. Personalization is also a prevailing means to facilitate the use of mobile systems. By using personalization methods, the system can give the best recommendation according to the user's interest. Contextual information such as a user's interests (preferences) is stored in user profiles. By performing the rule-based personalization with collaborative filtering technique, the system gives the relevant information to the user. We described enhancing MATS on mobile devices with GPS.

The main purpose of this article is to discuss the personalization method used in the tourism system and the benefits of the use of a personalized mobile tourism system.

To sum up, this article provides a multi-agent system architecture to offer services in the tourism industry, allowing different users the possibility to obtain up-to-date information about the places they will visit and to plan a specific day.

KEY TERMS

Collaborative Filtering (CF): The process of filtering for information using techniques involving collaboration among multiple agents, viewpoints, data sources, and so forth. It is the method of making automatic predictions about the interests of a user by collecting taste information from many users.

Location-Based Service (LBS): Used to locate a user and provide services specific to the location the users are in at the time by using the power of mobile networks.

Mobile Device: A handheld device such as a smart phone, Bluetooth headset, personal digital assistant (PDA), pager, notebook PC, and so on. PDAs and smart phones are popular mobile devices.

Mobile Technology: The part of technology that involves mobility. Mobile technology includes general packet radio service (GPRS), multimedia messaging service (MMS), Bluetooth, 3G, wireless fidelity (WiFi), global positioning system (GPS), CLI, wireless application protocol (WAP), and short message service (SMS).

Multi-Agent System: A collection of agents that acts on behalf of user in an autonomous way, and in which each agent communicates with the network of agents and then makes decisions to match demand.

Personal Digital Assistant (PDA): A handheld computer that can access the Internet, intranet, or extranets via wireless wide area networks (WWANs) and global positioning systems (GPSs).

Personalization: A process of knowing who the user is, what the user wants, and recognizing a specific user based on a user profile. Delivers the information to each user at the right time.

Rule-Based Filtering: Refers to the personalization resulting from a match of a user profile with content profile based on rules. This form of personalization implements rules based on a user's profile.

Multi-Agent Simulation in Organizations: An Overview

Nikola Vlahovic
University of Zagreb, Croatia

Vlatko Ceric
University of Zagreb, Croatia

INTRODUCTION

Most economic and business systems are complex, dynamic, and nondeterministic systems. Different modeling techniques have been used for representing real life economic and business organizations either on a macro level (such as national economics) or micro level (such as business processes within a firm or strategies within an industry). Even though general computer simulation was used for modeling various systems (Zeigler, 1976) since the 1970s the limitation of computer resources did not allow for in-depth simulation of dynamic social phenomena. The dynamics of social systems and impact of the behavior of individual entities in social constructs were modeled using mathematical modeling or system dynamics.

With the growing interest in multi agent systems that led to its standardization in the 1990s, multi agent systems were proposed for the use of modeling social systems (Gilbert & Conte, 1995). Multi agent simulation was able to provide a high level disintegration of the models and proper treatment of inhomogeneity and individualism of the agents, thus allowing for simulation of cooperation and competition. A number of simulation models were developed in the research of biological and ecological systems, such as models for testing the behavior and communication between social insects (bees and ants). Artificial systems for testing hypothesis about social order and norms, as well as ancient societies (Kohler, Gumerman, & Reynolds, 2005) were also simulated.

Since then, agent-based modeling and simulation (ABMS) established itself as an attractive modeling technique (Klugl, 2001; Moss & Davidsson, 2001). Numerous software toolkits were released, such as Swarm, Repast, MASON and SeSAm. These toolkits make agent-based modeling easy enough to be attractive to practitioners from a variety of subject areas dealing with social interactions. They make agent-based modeling accessible to a large number of analysts with less programming experience.

BACKGROUND

Computer simulation modeling is an established method in scientific and industrial applications, appropriate for obtaining insight into the dynamics of organizations. Modeling is used to represent a part of reality in sufficient detail, and resulting model is an artificial system used for experimentation. There are several situations when replacement of the real system by an artificial one is helpful or even necessary.

- **Inaccessibility of the real world system:** Sometimes a part of the real world system that should be studied, is not accessible either because the system does not exist any more or is not yet put into operation.
- **Real world system is inappropriate for experimentation:** Some real world systems may be affected in undesired way by experimentation. Examining effects of drastic changes in taxing and pricing policies may for example, disturb the fiscal system, or discourage production and consumption.
- **Time scale or behavior of the system is inappropriate for observation:** A number of systems such as investments in some industries generate results over long periods of time, making it hard to collect enough data from the real system for a meaningful analysis. Simulation is using virtual time that can be accelerated or slowed down as needed in order to observe a particular phenomenon.
- **Intensive dynamics of the system:** All elements of simulation model can be taken under full control. This is especially important in economics for the purpose of studying the impact of changes in one factor on behavior of the whole system, while holding all other factors at the same level. This presumption cannot be achieved in a real life economic system (e.g., system of supply and demand).

The model should be able to answer questions directed to the real system. However, it can produce valid output only for the set of experiments defined by the *experimental frame* (Zeigler, 1976) determined in the early stages of

model development. After the model is successfully built, simulation experiments can be performed. In order to gain full control over the experiment, a simulation model is used in a predefined *artificial environment* and a predefined *virtual time* of simulation.

Treatment of virtual time is crucial for selection of the simulation method applied to the model. (1) If virtual time is continuous, then ***system dynamics*** is used. System dynamics focuses on feedback loops of the model whose behavior is represented by differential equations. Model is restricted to macro level, and its properties are described by attributes which represent the state of the system and its changes. System dynamics is used for analysis of the behavior of complex real systems on a macro level, in management, politics, economics, environmental change and so forth. Important advantage of system dynamics is its efficiency due to its high degree of abstraction.

(2) If virtual time is divided into a series of discrete periods, then **event-based simulation** is used (Seila, Ceric, & Tadikamalla, 2003). *Discrete event simulation* advances "time" to the moment (denoted by time stamp) in which at least one model entity needs to execute certain action or change its state. *Simulation clock* defines the beginning and the ending moments of time required for simulation execution. Discrete-event simulation models are primarily used for functional verification and performance evaluation of real world systems.

Standard methods for concurrent processes modeling are queuing networks, Petri nets and cellular automata. (3) **Queuing networks** and **Petri nets** do not include mechanisms for representing inhomogeneous space where the number of entities, their interactions and behavior change over time in dependence on their surroundings. If a conflicting situation occurs in the environment, then probabilistic factors or predefined fixed amounts of system resources and length of activities are used. (4) **Cellular automata** are purely space-based representations where each cell value is calculated on the basis of values of neighboring cells. However, modeling of individual behavior of an entity or modeling of deduction rules using cellular automata requires complex models and overwhelming computing resources (Klügl, Oechslien, Puppe, & Dornhaus, 2004).

Some of the shortcomings of system dynamics and discrete event simulation as well as other methods for modeling concurrent processes can be overcome by the **multi agent simulation** paradigm. The essential idea of agent-based modeling and simulation (ABMS) is that complex phenomena (such as economic systems and business organizations) can best be represented as systems of relatively simple autonomous agents that follow comparatively simple rules of interaction. These agents are capable of making independent decisions and interactions with the rest of the system. Therefore, multi agent simulation uses multi agent systems to represent the structure of simulation models. A multi agent system is composed of multiple interacting agents capable of achieving their goals, which are beyond their individual abilities, through mutual cooperation.

Multi agent simulation consists of simulated agents that "live" in a simulated—*artificial environment*, and in simulated—*virtual time*. Environment can play an important role as it frames the agents' behaviors and interactions. The difference between multi agent simulation and multi agent systems is that agent environment within multi agent systems is "sensed" by the agent as it is, while agent environment in multi agent simulation is artificially created as a part of the simulation model, thus allowing for much more control over the developed system.

There are several advantages of multi-agent simulation in comparison to system dynamics. System dynamics is restricted only to the macro level, making it incapable of answering questions concerning the relationships between different granulites of the observed system (such as relationships between the microeconomic activities and the macroeconomic aggregates) in a simplified way. ABMS, on the other hand, allows introduction of different layers of observations: individual level, population level and a number of customized intermediate levels. Another drawback of system dynamics is the assumption of homogeneity of entities and space, so that individualism and heterogeneity cannot be represented. However, agents may be capable of adoptive behavior and flexible interaction with other entities. They may change their environment and perceive those changes afterward. This kind of flexible feedback loops is not possible using system dynamics or any other simulation approach.

Multi agent simulation deals with systems with similar characteristics as discrete-event simulation does. Discrete-event simulation can be represented as directed graphs called queuing networks. These graphs can have two types of nodes: servers with or without a queue. Servers are used for processing jobs that pass through the graph. If a server is busy, other jobs must wait in line for the server to complete its task. Even though all queues have their own queuing discipline, no job entity may leave the queue due to its own decision. If the job has branching routes, probability-based decisions are made, because all job entities are the same, without internal structure that could allow them to make their own routing decisions. Besides, discrete-event simulation models do not allow for variable system structure (number of servers, paths and interactions are fixed) while in a multi agent simulation model variable system, structure can be achieved via intelligent job agent processing. Agents provide heterogeneity, where classical modeling approaches were based on homogeneity of behavior.

APPLICATIONS OF MULTI AGENT SIMULATION IN ORGANIZATIONS

Multi agent simulation has provided a number of results in exploration of relationships between different microeconomic factors and macroeconomic aggregates. These results were obtained through exploration of influence of individual behavior patterns on overall dynamics of systems, but also through exploration of influence of an agent's perception of overall system on changes in the agent's own behavior. Applications range from modeling agent behavior in stock markets and supply chains to modeling overall transportation of a country; from modeling overall hospital management tasks to predicting spread of epidemics; from modeling bacterial cell behavior to modeling social insect colony behaviors; from consumer behavior to understanding the fall of ancient civilizations. Recent publications offer a number of multi agent simulation applications in economics, business and related fields. These applications can be categorized into three groups depending on their purpose.

1. **Models for theoretic insight:** This category contains applications used to explain economic phenomena and provide better scientific insight and technical understanding of the interactions and interdependencies of system elements. A simulation model of supply chain management can measure deformation of demand information when this information is transmitted as orders move down the supply chain (Moyaux, Chaib-draa, & D'Amours, 2004). This phenomenon causes amplification of the order variability in a supply chain, which results in higher financial costs due to higher inventory levels and agility reduction. The simulation model, consisting of several companies linked in a supply chain, showed that a high level of collaboration between companies is required to achieve low supply chain costs. Other multi agent simulation models were developed with the purpose to provide insight in collaborative strategies of firms within a specific economic environment. A multi agent simulation model of economic systems and industries was used to simulate different populations of firms (such as reactive and adaptive firms) and study their interactions and the final impact on firm dynamics and industry demography (Guessoum, Reheb, & Durand, 2004).
   Some of the models concentrate on particular strategies and their limitations rather then on firm behavior, in order to explore the prevalence and severity of specific economic phenomena (like oligopolies, externalities, inflation, price wares, etc.). Simulation models of this type were developed for the purpose of determining the limitations of an economic environment during a price war with aggressive competitors (Wu & Durfee, 2004). This model suggested that thoughtfully constraining communication in an information economy can improve system performance in the segment of the market affected by a price war. A multi agent model AGEDASI TOF was employed to study price dynamics in a foreign exchange market. In the model a community of agent dealers derives their price quotes out of qualifying information from various news sources through a system of weights assigned to each information source. Dealer-agent's success was rated using transaction volume for each simulation experiment. The results exhibited interesting patterns in the formation of dealers' opinion trends that were used to establish a set of typical agents' strategies (Streltchenko, Yesha, & Finin, 2003).
   A number of models are aimed to provide insight in microeconomic elements of an economy. Even though most microeconomic models fall in the second category of multi agent models, some of them can be used to enhance stakeholders' perception of the processes they are involved in. These models are developed in close cooperation with the management, investors, workers or other professionals that can benefit from better understanding of the business processes at hand. A number of applications are available in health care (see Heine, Herrler, & Kirn, 2005, for further details), production lines and other segments of business.
2. **Prediction models:** This category of multi agent simulation applications contain more realistic models used for prediction purposes and planning. A number of models deal with scheduling tasks. For example, the multi agent simulation model of scheduling in a supply chain management is intended to help in planning the supply chains, ordering and capacities for a company that participates in several supply chains at the same time. This helps a company to improve its performance, especially if its activities and resources are costly and sensitive to scheduling errors. Developed models consist of agents that represent companies within supply chains. Each agent simulates production orders of its company by sending and receiving messages about purchase and sales orders. Scheduling of distributed supply chain does not require the company to uncover all information to its partner, but only information related to external orders between the company and its partner (Nurmilaakso, 2004). This is why the possibility that a competitor may impair a company's performance through suppliers and customers is minimized. Even though schedules generated during experimentation are not optimal, all of them are feasible.
   A number of models were developed with the purpose of reducing operating costs. A good example is the improvement of cargo routing of Southwest Airlines,

where an additional $10 million of revenues were gained from reduced costs of the personnel and multiple freight handling. Probably the most comprehensible multi agent simulation model developed is the model of 24 hour traffic simulation of the entire country of Switzerland, with about 7.5 million simulated traveling agents (Balmer, Raney, & Nagel, 2004). The goal of the model is to make traffic jam predictions.

3. **Environment models and self-organizing models:** This category of models is primarily focused on the simulated environment in which agents operate. Simulated environments can be used as test beds for implementation and testing of ideas about alternative solutions for more or less treatable problems. These electronic laboratories can be used to test assumptions about individual agents, their behaviors and interactions in great detail. If agents change not only their behavior, but also their properties as a response to the simulated environment, then the model represents a self-organizing system. Self-organizing capabilities of agents rely heavily on other agents and the simulated environment.

   A good example of benefits from this type of multi agent simulation model is simulation of the behavior of different work teams engaged in the development of a complex project. Due to a large number of factors such as individual characteristics, social characteristic and temporal and economic costs, finding an appropriate team that can successfully tackle all of the project tasks is a complex problem. The developed simulation model (Moreno, Valls, & Marin, 2003) consists of different classes of agents, some of which represent workers and managers, while others take care of assessments of teams and presentation of statistical data. The type of generated teams depends on the properties of tasks required by the project at hand. The system is able to generate information about expected cost of the project, expected number of days for project completion and expected rate of failure for each proposed team.

   Although numerous multi agent simulations in the field of financial markets were carried out for the purpose of theoretical analysis of dealer strategies, they are mostly used as test beds. These models can be used to test and predict outcomes of specific situations on the markets, or to test the actual multi agent systems designed for business applications, like e-commerce applications. An example of the first type of multi agent simulation model is MAFiMSi (Streltchenko et al., 2003), designed to be used for observation of the consequences of a range of investor behaviors. It can also be used to test different solutions for financial market automation, especially decision making tasks, as these are not fully automated yet. An example of the second case is a specially developed scenario that resulted in a simulated environment for testing multi agent systems intended for supply chain management. TAC SCM (Sadeh et al., 2003) is a simulated computer manufacturing scenario in which software agents tackle complex problems in supply chain management. In this model, agents represent personal computer manufacturers that compete in markets for components (supplies) as buyers and in markets for finished goods as sellers, with the purpose of maximizing profits over a simulated year. Agents have to solve a very complex combinatorial optimization problem, deciding which supplies to purchase and how to allocate the existing resources optimally. Moreover, they have to act in the face of tremendous uncertainty regarding the behavior of suppliers, clients, and competitor agents.

FUTURE TRENDS

Multi agent simulation proves to be the appropriate modeling paradigm for complex business systems as well as for various microeconomic and macroeconomic models. A number of macroeconomic problems and phenomena previously studied using mainly mathematical models are being studied using computer models that support a high number of elements and their interactions. Multi agent simulation models exhibit new advantages as they are computationally efficient and capable of providing significant answers about the behavior of these complex systems.

With the new software toolkits that replace coding with an intuitive visual interface and onscreen menus, this approach to simulation of large scale systems is rapidly becoming accessible to an ever wider range of professionals and scientists. Multi agent simulation models may provide insight in the emergent phenomena, for example, in unforeseen patterns or global behaviors (Holland, 1998) which are not derivable from properties of its constituents. Multi agent simulation will also provide required test beds for emerging technologies and services in the field of microeconomics, as well as enhancing further developments in electronic commerce and overall electronic business.

Some authors also suggest the need for modeling the "internal environment" of the agents in order to mimic the processing capacity and the cognitive structures of the social subjects in the model (Cioffi-Revilla et al., 2004). In this way different patterns of social factors' behavior that may not necessarily be economically efficient and optimum can be simulated. Emotions, for instance, have a great impact on the customer behavior, making it inefficient and theoretically unpredictable. Other applications in economics include simulation of fiscal systems and exchange rate policies,

introduction of government programs, and others. Applications in related fields (like health care, traffic, military, cargo routing, etc.) have important economic aspects.

CONCLUSION

Multi agent simulation paradigms for modeling economic systems combine traditional modeling approaches and agent-based systems, thus providing the capabilities that have not been previously possible. This novel approach offers a number of advantages that distinguish it from discrete-event simulation, system dynamics, queuing networks and Petri nets. The potential provided by multi agent simulation is used by a growing number of professionals from a number of different application areas. Applications include modeling for the purpose of theoretic insight, for predicting behavior of highly complex systems, as well as for creating self-organizing models and environment models for the purpose of testing new technologies and ideas. Problem specification is being less tied to user's knowledge of simulation tools or constraints of traditional modeling approaches, which represents a great promise for many interesting developments and opportunities in the future.

KEY TERMS

ABMS: Abbreviation for agent-based modeling and simulation; a synonym for multi agent simulation.

Artificial Environment: A model of the environment where the simulation model is operating. Environment model

is completely controllable by the modeler. Particular environment models are highly relevant when modeling adaptive elements of the system or when using adaptive capabilities of the agents contained within the model.

Discrete-Event Simulation: A type of simulation where the simulation mechanism advances the simulation clock to discrete points in time. Time advancement can be round-based (simulation clock is advanced for a constant number of time units for each round of the simulation) or step-based (simulation clock is advanced to the time stamp of the next event in the event queue).

Experimental Frame: Establishes the set of experiments for which the model is valid. It has to be determined in early stages of model development.

Intelligent Software Agent: A system situated within a part of the environment that senses this environment and acts on it over time in pursuit of its own agenda.

Multi Agent Simulation: A simulation modeling paradigm that uses software agents to represent the entities of the modeled system that interact with each other and with the virtual environment. These interactions are used to model dynamics in functioning and structure of the real system.

Multi Agent System: A system consisting of a number of agents that interact with each other through communication, thus allowing them to achieve goals that are beyond their individual capabilities.

Simulation Modeling: An established method in science and industry used to map a part of reality in sufficient detail using a model. Developed model should be able to answer questions directed to the real system without disturbing functioning of the real system.

System Dynamics: A continuous simulation of systems exhibiting feedback loops. The feedbacks can either intensify activities of the system (positive feedback) or slow them down and stabilize the system (negative feedback).

Virtual Time: Denotes a time advancement paradigm used to handle the course of events within the simulation model. Event-based simulations use event queues that allow the simulation time to advance to the time stamp of the next event. In this way, the time scale can be stretched or compressed, depending on the needs of the model.

Multiagent Systems in the Web

INTRODUCTION

The rapid evolution of Internet has opened a new era in the distributed systems scenery: the bigger part of the information systems currently developed is focused in Web applications. Typically, the information resources in Web systems are dynamic, distributed, and heterogeneous. Since these computing environments are opened, information resources can be connected or disconnected at any time. This ubiquity of Web and its distributed and interconnected characteristics represent a natural field for multiagent systems (MAS), spreading this kind of application. Software agents can dynamically discover, orchestrate, and compose services, check activities, run business processes, and integrate heterogeneous applications.

Most of the large organizations adopt heterogeneous and complex information systems. These systems must coordinate their applications in order to provide efficient support to business processes and consistent information management. Unfortunately, the operational software underlying these systems usually does not handle multitask distributed heterogeneous applications. Currently, enterprises are strongly interested in the strategic advantages of adopting distributed infrastructures that are designed to be dynamic, flexible, adaptable, and interoperable. In this context, the demand for agent-based applications has increased, opening new types of applications that include e-commerce, Web services, knowledge management, semantic Web, and information systems in general. Interesting solutions to B2B (business to business), e-business, and also applications that require interoperability based on knowledge about applications and business processes, will definitely benefit from the MAS technology. Also, intelligent information agents are regarded as one of the most promising areas for applying agents' technology. Intelligent information agents act in fields like collaborative systems on Internet, knowledge discovery from heterogeneous sources, systems for intelligent management of information, and so on. The Web can also be seen as a big distributed database having XML (extensible markup language) and its extensions or modifications as an underlying data model.

In this context, the MAS development has received support from new tools in order to make it easier for the developer to cope with specific requirements for Web architectures. It is accepted that these improvements in the technology, mainly by the new tools that are becoming available, will lead MAS technology to be explored in its full potential. So, we can state that the application domain of MAS is going to be strongly enlarged, defining a turning point in the systems development activity.

In this chapter, we provide an overview on MAS technology, discuss how this technology is impacting the Web context, and provide a sound description of the concepts that are relevant to the application developers and target users.

BACKGROUND

The adoption of agents' technology in distributed and concurrent systems derives from the idea that cooperation, flexibility, and intelligence of agents can contribute significantly to improve the overall performance and quality of information systems. An agent-based system is composed of autonomous computational entities that possess individual capabilities and goals, and can be grouped to work cooperatively, aiming to reach the system objective. There is not a universally accepted definition to the term "software agent." Wooldridge *et al*. (Wooldridge, Jennings, & Kinny, 1999) explains that this difficulty is partially due to the fact that, for each different application domain, the properties assigned to the agent concept take several important levels, therefore, it is possible to find many types of software agents with different

characteristics, such as mobility, autonomy, collaboration, persistence, and intelligence. The agents' behavior depends on, and is affected by, their properties. Based on previous studies carried by Kendall *et al.* (Kendall, Krishna, Pathak, & Suresh, 1999), the OMG (object management group) (2000), and Garcia *et al*. (Garcia, Silva, & Lucena, 2001) describe the following properties for software agents:

1. Interaction: an agent communicates to the environment and to other agents by means of *sensors* and *actuators*.
2. Adaptation: an agent must self adapt its state and behavior according to the environmental conditions.
3. Autonomy: an agent possesses its own control thread and can accept or refuse a request. Autonomy is understood as the agent capabability to perform its activities independently from the human intervention.
4. Capacity to learn: an agent can learn based on previous experiences when interacting with its environment.
5. Mobility: an agent must be able to transfer itself from one environment to another in order to achieve its goals.
6. Collaboration: an agent can cooperate with other agents in order to achieve its objectives and the system objectives.

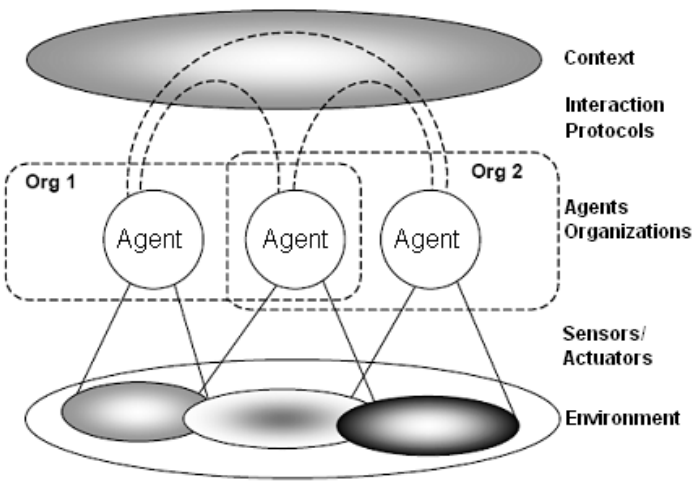
According to OMG (2000), autonomy, interaction, and adaptation can be considered fundamental properties of software agents, while capacity to learn, mobility, and collaboration are not strictly required properties to characterize agents. There is a consensus in the literature that autonomy is the key property for an agent. Agents must present, at least in some extension, independence. They are not completely preprogrammed, but can take decisions based on information from other agents or from the environment.

Ferber (2000) argues that an agent can be defined from the agency characteristics as a physical or a virtual entity, with the following properties or abilities:

- is capable to act in an environment;
- can communicate to other agents;
- is driven by a set of tendencies as individual goals;
- possesses its own resources;
- is capable to perceive its environment (in a certain extension);
- possesses only a partial representation of the environment;
- possesses abilities and can offer services;
- can be able to replicate itself;
- its behavior is driven by its goals, considering the amount of resources and abilities available, and depends on its environmental perception and the messages it receives.

By this definition, an agent can *act,* not only *reason*, and the effect of its actions in the environment can affect future decisions. There are a number of different criteria to classify agents in the literature. For example, Jennings *et al*. (Jennings, Atighetchi, Vincent, & Lesser, 1996) state that to act autonomously, agents must present the following abilities: perception, capacity to belief-based reasoning, to decision taking, and to plan, and ability to execute these plans, including message carrying. Jennings *et al.* (1996) categorize agents according to their levels to solve problems in the following types:

Figure 1. Multiagent system structure



1. *Reactive*: react to modifications in the environment or to messages from other agents. Do not exhibit capacity to reason on their intentions, only reacting to rules and stereotyped plans. Their actions comprise to update the fact base and to send messages to the environment or to other agents.
2. *Intentional*: they are able to reason on their intentions and beliefs, to create and execute action plans. They can reason on the plans, schedule actions, detect conflicts among plans, and also revise plans.
3. *Social*: intentional agents are considered social agents if they keep models from other agents over whom they reason to decide. This kind of agent refers to the idea that multiagent systems can be organized to simulate the behavior of social and organizational structures present in the real world.

Jennings *et al*. (1996) define a *multiagent system* (see Figure 1) as "a low-coupled network of problem solvers that work together to solve problems that are beyond the individual ability or knowledge of each problem solver." Usually, agents grouped in organizations compose multiagent systems.

Designing and developing MAS are not trivial tasks, due to the high level of complexity involved. For this reason, MAS usually are designed and developed using tools or platforms, such as JADE (Bellifemine, Poggi, & Rimassa, 2001) and SOMA (Corradi, Cremonini, & Stefanelli, 1998), among others. These tools provide support for the design, simplifying the development into two abstraction levels. First, in the generic architectural level, such tools abstract the application complexity by providing infrastructure services, as message transport (send/receive, pack/unpack, requests translate), the control over the platform and agents' life cycle, and tasks for services handling (services registry, publication and discovery). Second, in the agents' design level, those tools provide abstract classes that define the hot spots from which specific features of the concrete agents can be implemented. The MAS development has evolved to an increasing reuse of architectures, enabling the developer to focus in implementing the application particularities. The agents life cycle, its internal behavior, and interaction can be modeled by using the conventional UML (unified modeling language) (Booch, Rumbaugh, & Jacobsen, 2000) tools. The life cycle phases of the agents and applications can be designed using the activity diagram, the agent internal behavior can be represented using the state machine diagram, and the interactions of the agents with the architecture and other agents can be modeled by using the sequence diagram. An ACL (agent communication language) or the Blackboard (Ferber, 2000) pattern can be used to design the communication model of the agents. The Blackboard is one of the most widely used patterns in symbolic cognitive multiagent systems. It allows the indirect data communication among independent modules.

MAIN FOCUS OF THE ARTICLE

Due to the recent rising of Web-based technologies, their applications are spreading to domains like e-commerce (electronic commerce) (Rimmel, Clement, & Runte, 1999), B2B (business to business) (Boughaci & Drias, 2005), knowledge management (Jensen *et al.*, 1999), distributed information and database integration, intelligent information systems, and enterprise information systems in general (Adam & Mandau, 2004). E-commerce is the buying and selling of goods and services on the Internet, especially the World Wide Web. Software agents have been used for the individualization and automation of the marketing instruments applied. The use of methods from artificial intelligence enables agents to learn, making possible the automatic optimization of the marketing instruments to satisfy massive individualized needs of the demander. The B2B technology has been used in many business applications, for example, in the logistic support to the buying process (Lim, Park, & Kim, 2005), issuing information about suppliers, existing products in the market, distribution, the buying orders follow-up, payment management, and planning. There exists, nowadays, a considerable research effort to integrate knowledge representation technologies, semantic Web, and agents (McGuinness, & Silva, 2004; Sycara, Paolucci, Ankolekar, & Srinivasan, 2003). The Web semantic community effort to provide a semantic description of services represents a fundamental initiative to enable the larger-scale agents. One of its objectives is to build high-level procedures that can be reusable, and use agents' technologies to facilitate the coordination and dynamic composition of Web services. Decker *et al.* (Decker, Melnik, Harmelen, Fensel, Klein, & Broekstra, 2000) discusses the role of XML in the creation of the semantic Web. The use of agents in Web has also led to significant improvements in fields like information integration, and also those that require knowledge-based interoperability among heterogeneous applications and business processes. XML offers a path to the integration of distributed knowledge in the Internet, and to simplify this integration, collaborative agents have been used (Nodine, Perry, & Unruh, 1998). Integration information using XML has inspired efforts like MIX (mediaton of information using XML) (Baru, Gupta, Ludaescher, Marciano, Papakonstantinou, & Velikhov, 1999), which uses agents to integrate information distributed in multiple sources. The Web is regarded as a distributed database, and XML (and its modifications or extensions) is used as the underlying data model. Klusch (1999) identifies intelligent information agents as one of the most promising agent categories to apply agent's technology. Intelligent information agents act in areas like collaborative systems in the Internet, knowledge discovery

systems from heterogeneous sources, systems for intelligent management of information in corporate *intranets,* or even in the Internet. Enterprise information systems are another promising area to the application of agents technology in the Internet (Fox, Barbucenu, Teigen, 2001). The advances in IT (information technology) are opening opportunities to redesign information systems and processes management. Software agents have been used in conjunction with all the mentioned technologies. They can be designed to carry gathered data and to analyze schedules in different levels, promoting easy task coordination and interoperability in business applications.

The use of agents and MAS in the Internet represents a new generation of applications, based in emerging technologies and in a set of open standards to Web. The combination between agents and Web emerging technologies requires a specific software engineering (Griss & Kessler, 2003) and the evolution of related concepts and standards. The Web standards, established and governed by W3C (Berners-Lee, 1994) affect strongly the development of a wide set of applications and, consequently, the MAS development. The current agent platforms need to be adapted to handle specific Web services requirements and emerging Web technologies (Greenwood, 2005; Odell, 2005). The increasing adoption of Web services and the consequent necessity to establish standards led the W3C to propose the WSA (Web services architecture reference model). This model had its first version published in 2003 (W3C Working Draft 8 August 2003) (Booth, Champion, Ferris, McCabe, Newcomer, & Orchard, 2003), having its last version published in the W3C Working Draft manifesto of November 2004. WSA follows the SOA (services oriented architecture) architectural style, and introduces a set of concepts and abstractions to architectures that uses Web services. Its characteristics demand new concepts to the MAS development, when emerging technologies and open standards for Web are required. Standards used in MAS, like FIPA, conceived in the last decade, are not sufficient to promote the integration of the emerging technologies (FIPA, 2002) with the last established standards for Web.

FUTURE TRENDS

The technologies and systems, running in the Web, described in the previous section, are becoming more and more complex, requiring entities of widely divergent natures, numerous functionalities, and interaction among several devices. The dynamics of requirements changing in the Web are demanding new concepts and a transition from the monolithic architectures, based in passive software components, to more flexible and opened architectures (Garcia, 2005), composed by dynamic and proactive agents. The need for a painless adoption of these technologies induces a demand for new concepts and the internalization of open, flexible, and adaptive architectures. However, the agents technology did not reach its potential, and will not be largely used in business applications until adequate environments to the application development become available (Cowan & Griss, 2002; Curry, Chambers, & Lyons, 2003). A particular point is to understand those issues in the agent technology that make it difficult and/or improve the production of large open systems. Considering this context, we emphasize the following aspects to be approached in the near future in order to improve the agents' adoption:

1. In opposition to the strongly coupled structures used in the current MAS platforms, low-coupled structures should be promoted in a new generation of tools that complies with the new Web standards (Curry *et al*., 2003; Nagappan, Skoczylas, & Sriganesh, 2003).
2. A stronger support to integrate agent technology and the Web technologies using Web services and its open standards are required (FIPA, 2002; Griss *& Kessler,* 2003; Richards, Sabou, Splunter, & Brazier, 2003), in order to facilitate the interoperability among agents and heterogeneous applications; simplify the composition, orchestration, and reuse of distributed services.

SOA is one of the most recent evolutions in distributed computing, and defines an architectural style to build software applications that make use of services in a network like the Web. SOA requires a coordination level much simpler than the traditional architectures, enabling the developer to abstract local and remote distributed services requests. SOA also enables software components, including application functions, objects, and systems processes that are exhibited as services. All functions in SOA are grouped like reusable services: SOA is the contract to services identification, maintaining the rules to access them. All information on requests and answers, exception conditions, and functionalities are defined as part of this interface. The interface contains the necessary information to access the service without knowing its internal design, language, or implementation platform. It receives the requests that arrive in "envelops," that encapsulate the information about the services. In the context of SOA, agents do not communicate directly, there are no explicit messages among them. When an agent needs to request a service, the request is sent to a single server that locates the agent provider to forward the request. This makes the design and implementation simpler, since it is not necessary to know the name and the implementation details of the entity provider of the service. Only the name of the service, and its parameters must be known. In the SOA context, the explicitly message exchanging among agents can be achieved using the Blackboard pattern (Ferber, 2000).

CONCLUSION

New tools for the support of MAS development in the Web context can be considered the most important current trend. The most popular tools available are based in message exchange among agents, requiring a deep knowledge of the internal agents structure by the developers. They are demanded to build an intricate network of messages exchanging to accomplish the development objectives. There are few approaches using SOA in the context of MAS, such as AgentScape (Overeinder & Brazier, 2004) and Cougaar (Helsinger, Lazarus, Wright, & Zinky, 2003). However, none of these are based on a well-known and standardized architecture. The visionary promise of SOA paradigm (MW-4SOC, 2006) is a world of cooperating services, loosely coupled, to enable flexibility in creating dynamic business processes and agile applications that may span organizations and computing platforms and can, nevertheless, adapt quickly and autonomously to changes of requirements or context. Most of the current frameworks and platforms for MAS development adopt communication models associated to the message concept, and are based in an infrastructure characterized by synchronous communication and a strong coupling of components. These characteristics can affect, strongly and negatively, the architecture flexibility and adaptability, increasing the development complexity. New approaches and tools for MAS development are required to take advantage of SOA features, enabling large-scale multiagent systems and its integration with industrial and business applications.

KEY TERMS

Agent Organizations: Can be understood as complex entities where a multitude of agents interact, within a structured environment aiming at some global purpose.

B2B (Business to Business): Exchange of products, services, or information between businesses instead of between businesses and consumers.

FIPA (Foundation for Intelligent Physical Agents): A collection of standards that are intended to promote the interoperation of heterogeneous agents and the services that they can represent.

MAS (Multiagent System): A computational system where agents cooperate or compete with others to achieve some individual or collective task.

SOA (Service-Oriented Architecture): A set of components that can be invoked, and whose interface descriptions can be published and discovered.

Software Agent: In a broad sense, and to have a working definition in a context in where the concept definition is not yet established, we assume that a software agent is an artificial agent that operates in a software environment.

UML (Unified Modeling Language): An object-oriented standard modeling language with a rich graphical notation, and comprehensive set of diagrams and elements.

W3C: An industry consortium that seeks to promote standards for the evolution of the Web and interoperability between WWW products by producing specifications and reference software.

Web Services: Services that are made available by developers (OR industry?) for Web users or other Web-connected programs.

WSA (Web Services Architecture): A set of requirements for Web services standard reference architecture.

XML (Extensible Markup Language): A flexible way to create common information formats and share both the format and the data on the World Wide Web, and intranets.

A Multidisciplinary View of Data Quality

Andrew Borchers
Kettering University, USA

INTRODUCTION

This article introduces the concepts of data quality as described in the literature of several disciplines and discusses research results on how individual perceptions of data quality are influenced by different media (in particular World Wide Web vs. print). A search of literature on "data quality" and "media creditability" reveals that researchers in many disciplines are separately studying the subject. These disciplines include accounting, advertising and public relations, information systems, scientific data collection, education, journalism fields, and others. While these threads have developed separately, these streams of research approach similar issues of how people view the quality of information they receive from different sources.

BACKGROUND

Data quality is an emerging area of research fundamental to the field of information systems. Indeed, the efficacy of systems is in large part driven by the quality of the data that they contain. With the Internet revolution, however, there have been fundamental changes in how information is collected and shared that have a potentially great influence on data quality. This challenge is accentuated with the recent move to "user-generated content" as a part of the broader evolution to Web 2.0 (Schwartz, 2007). In addition, younger generations immerse themselves in media more than their parents do. This has led to the label of the "M-generation." A study by the Kaiser Family Foundation and Stanford University finds young people spending on average 6.5 hours per day in media exposure. Increasingly, this exposure comes in multiple media at one time (Azzam, 2006).

However, with such access and participation comes a challenge as stated by Gilster (as cited in Flanigan & Metzger, 2000):

When is a globe spanning information network dangerous? When people make too many assumptions about what they find on it. For while the Internet offers myriad opportunities for learning, an unconsidered view of its contents can be misleading and deceptive.

Further, organizational responses to data quality have been largely ad hoc (Swartz, 2006) with the majority of firms relying on localized, ad hoc approaches to ensuring data quality.

Recent research and seminars underscore the importance of the topic of data quality. Interest in the discipline has spawned the creation of the International Association for Information and Data Quality, several annual conferences (e.g., *www.iqconference.org*), and the *ACM Journal of Data and Information Quality.* Indeed, Total Data Quality Management (TDQM) has evolved as a field of study extending the concepts of Total Quality Management (Radziwill, 2006). Data quality has emerged as a significant research area.

Information systems and journalism practitioners have echoed the importance of data quality for many years. Research by Redman (1998) summarizes the practical implications of poor data quality. He points out the consequences of poor data quality in areas such as decision making, organizational trust, strategic planning and implementation, and customer satisfaction. Redman conducted (1998) detailed studies and found increased costs of 8-12% due to poor data quality. Service organizations can find increased expenses of 40-60% (Redman, 1998). Strong, Lee, and Wang (1997) support the seriousness of this issue in their study of 42 data quality projects in three organizations. Early research by other authors note data quality issues in a number of settings including accounting (Xu, 2000; Kaplan, Krishnan, Padman, & Peters, 1998), airlines, healthcare (Strong et al., 1997), criminal justice (Laudon, 1986), and data warehousing (Ballou, 1999).

As for a formal definition of data quality, Umar, Karabatis, Ness, Horowitz, and Elmagardmid (1999) quote Redman (1992):

A product, service, or datum X is of higher quality than product, service, or datum Y if X meets customer needs better than Y.

Umar et al. (1999) go on to point out that this definition has been generally accepted and is consistent with the author's work. The definition is somewhat incomplete, however, as it does not delve into the various dimensions of data quality.

A number of authors in the information systems field have gone further than Redman and written conceptual articles on "data quality" (Wand & Wang, 1996; Wang, Reddy, & Kon, 1995; Wang & Strong, 1996; Strong et al., 1997). This work suggests that data quality is a multidimensional

concept (Wand & Wang, 1996) that researchers can view from a number of different perspectives. A panel discussion in 2000 (Lee, Bowen, Funk, Jarke, Madnick and Wand) found five different perspectives to discuss data quality. These included an ontological perspective (specification of a conceptualization) that included different views of reality based on actual observation vs. computer-influenced observations; an architectural perspective, a view that focuses on system infrastructure and its influence on data quality; a context mediation perspective, focusing on communication across space and time; a time-based e-commerce perspective, focusing on the real-time nature of e-commerce; and an information product perspective, focused on data as a product of an organization.

In talking about "data quality," a key beginning is to determine from the literature just what one means by the term. In a definitive work on the topic, Wang and Strong (1996) provide a conceptual framework for data quality. In a way consistent with Redman's (1992) customer perspective, they start by defining "high-quality data as data that is fit for use by data consumers." Using a two-stage survey and sorting process, Wang and Strong (1996) develop a hierarchical framework for data quality that includes four major areas: intrinsic, contextual, representational, and accessibility.

Intrinsic data quality refers to the concept that "data have quality in their own right" (Wang & Strong, 1996). Intrinsic dimensions include accuracy, objectivity, believability, and reputation. Contextual data quality is based on the idea that data does not exist in a vacuum—it is driven by context. Contextual dimensions include relevancy, timeliness, and appropriate amount of data. Representational data quality relates to the "format of the data (concise and consistent representation) and meaning of data (interpretability and ease of understanding)." Accessibility data quality refers to the ease with which one can get to data (Wang & Strong, 1996).

More recent research reinforces many of the concepts presented above. In information systems research, data quality is of particular interest to work on data warehouses and business intelligence. In a recent article noting "BI at age 17" (Martens, 2006), Howard Dresner, author of the term "business intelligence," notes the importance of data quality due to its impact on business process management and operational planning. In studying the maturity of data warehouse projects, Sen, Sinha, and Ramarmuthy (2006) note that data quality is a key determinant. Crie and Micheaus (2006) note that data quality management is a key step in the customer data to value information chain.

Beyond the information systems literature, journalism provides a second relevant body of literature. One of the focus points is on perceptions of Internet credibility (Flanigan & Metzger, 2000; Johnson & Kaye, 1998; Bucy, 2003). The major thrust of this literature is in comparing the Internet to traditional sources with respect to credibility. Note that when referring to "credibility," these authors say "the most consistent dimension of media credibility is believability, but accuracy, trustworthiness, bias and completeness of information are other dimensions commonly used by researchers" (Flanigan & Metzger, 2000, p. 521). Hence, there is a rough correspondence of thinking about "credibility" in the journalism literature to the concept of "intrinsic" and "contextual" data quality in the information systems literature. One author in this field (Bucy, 2003) goes on to differentiate "media" credibility from "source" credibility and suggests that researchers have viewed these two forms of credibility as being separate areas of research.

A third field has contributed to the same discussion, namely, advertising and public relations research. Working on a variety of topics, researchers have asked the question: "What impact does media credibility have in [an] organization's advertising and public relations efforts?" Huh, DeLorme, and Reid (2004) studied media credibility in the context of direct-to-consumer prescription drug advertising. They examined consumer perceptions of credibility based on age and media. Greary (2005) studied the impact on the public relations field of declining media credibility, reported in 2004 to be at a 30-year low. Finally, Cable and Yu (2006) studied job seekers and their organizational image beliefs of potential employers. In their work, they considered three different recruitment media and found media richness to be associated with job seekers' image beliefs.

The concept of data quality also appears in disciplines such as accounting and finance. With the passing of Sarbanes-Oxley legislation and an increased focus on the accuracy financial reporting, new standards focused on data quality are emerging. Clark (2006) reports on the adoption of corporate action standards and points out that data quality is a significant concern. Schwarzkopf (2007) examines source credibility and investors' attitudes toward financial and non-financial performance measures. Interestingly, he noted no difference between more and less experienced investors. He did note, however, that source credibility was most important to investors when viewing financial estimates compared to non-financial performance measures.

In yet another discipline, that of scientific data collection, similar dimensions appear. Radziwill (2006) quotes Loshin (2001) in dividing data quality into four areas: data models, data values, information domains, and data presentation. Within each of these four areas, Loshin gives further dimensions that are quite similar to Wang and Strong's (1996) work. In a similar fashion, Radziwill (2006) also quotes Graefe (2003) in describing data quality criteria in the context of decision process.

It is interesting to note how authors working in multiple disciplines have chosen many of the same dimensions in speaking about data quality. Table 1 summarizes the dimensions these authors have identified using Wang and Strong's (1996) framework.

Table 1. Dimensions of data quality in multiple disciplines

Discipline\ Dimension	Intrinsic Data Quality	Accessibility Data Quality	Contextual Data Quality	Representational Data Quality
Information Systems (Wang, 1997)	Accuracy, objectivity, believability, reputation	Accessibility, access security	Relevancy, value added, timeliness, completeness, amount	Interoperability, ease of understanding, concise representation, consistent representation
Scientific Data Products (Graefe, 2003, quoted in Radziwill, 2006)	Credibility, validity	Availability,	Novelty, relevance, pre-decision availability, validity, information value	Interpretability
Scientific Data Products (Loshin, 2001, quoted in Radziwill, 2006)	Precision, granularity, identifiability, accuracy,	Obtainability, stewardship, ubiquity	Comprehensiveness, robustness, relevance, completeness, currency/timeliness, appropriateness	Clarity, flexibility, essentiality, homogeneity, naturalness, simplicity, semantic consistency, structural consistency, consistency, correct interpretation, agreement of usage
Journalism (Flannigan, 2000)	Believability, accuracy, bias, trustworthy		Completeness	

COMPARISON OF RESEARCH FINDINGS

As noted, many researchers have undertaken work on data quality and media differences over the years. In this section the author will focus on work by Klein (1999, 2001), Flanigan and Metzger (2000), Bucy (2003), and Borchers (2003). All four authors have examined data quality in a similar way, focusing on perceived differences based on media (such as print vs. Internet). In addition, Flanigan and Metzger (2000) examine whether Internet users verify what they find. Borchers (2003) extends the discussion by examining the effect of personal involvement in the topic. Bucy (2003) looks at another aspect in studying the synergy effects of multiple media (TV and Web).

Klein (1999, 2001) has studied perceptions of data quality by surveying a sample of approximately 70 graduate business students conducting class projects. In one early study, Klein (1999) found Web-based material to be more timely, but less believable and of lower reputation, accuracy, and objectivity than printed material. In a more formal result, Klein (2001) found that her subjects perceived traditional text sources to be more accurate, objective, and to have higher reputation and representational consistency. She found Internet sources to be stronger in timeliness and appropriate amount. It would be interesting to repeat her work given the transition from Web 1.0's publication focus to Web 2.0's user collaboration focus (Schwartz, 2007).

Flanigan and Metzger's work (2000) focuses on three areas. First, he looks at the perceived credibility of television, newspapers, radio, and magazines compared to the Internet. The major finding, unlike Klein, is that there is little difference in credibility between media. Second, Flanigan and Metzger (2000) look at the extent to which Internet users verify what they receive. Here he finds that few Web users verify the information they receive. Those with limited Internet experience verify less than those with more experience. Third, and most important to this discussion, Flanigan and Metzger (2000) look at whether perceived credibility varies depending on the type of information viewers are seeking. They cite Gunther in suggesting that "greater involvement with the message results in, first, a wider latitude of rejection."

Bucy (2003) studied the credibility of online and broadcast news sources among younger and older viewers. The study sought to determine if cross-platform media use (that is online and broadcast) had a greater impact on audience perception than exposure to either source alone. Working with 167 subjects from young adults (ages 18-25) and older adults (ages 26-80), Bucy (2003) found significant synergy effects for older adults who viewed both TV and the Web. Between both age groups, credibility between TV and the Web were similar. Notably, older adults had significantly lower credibility scores in general compared to younger adults.

Borchers (2003) considered the literature cited above and examined a number of interesting questions. In keeping with Klein (2001) and Flanigan and Metzger (2000), he examined how people perceive Web-based material compared to printed material, considering dimensions such as "timely," "believable," "reputation," "accuracy," or "objectivity." Second, Borchers (2003) studied whether individuals with personal

involvement in a topic (e.g., cancer) are better discriminators of data quality than those who are not involved with a topic. Finally, Borchers (2003) explores whether women—given their role as healthcare acquirers (Bates & Gawande, 2000; Looker & Stichler, 2001)—are better discriminators of data quality than men on health-related topics such as cancer. This work provides an interesting point to compare with work by Huh et al. (2004) on direct to consumer advertising of drugs.

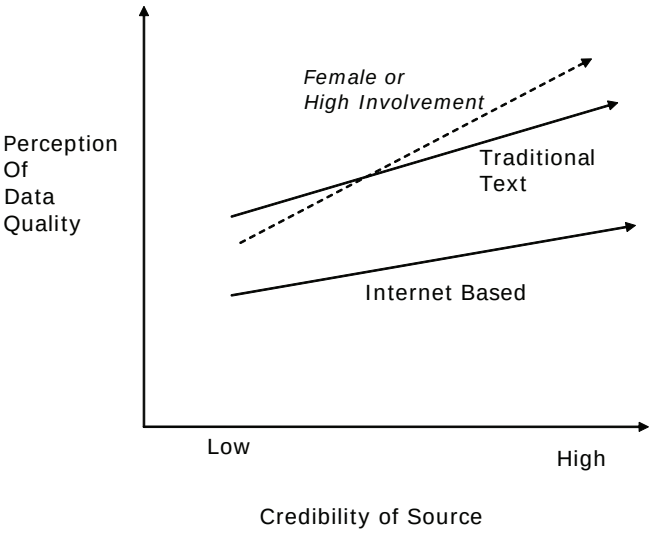
Figure 1 demonstrates what Borchers (2003) hoped to find. H0, his initial hypothesis, is that the perception of low creditable sources is significantly less than high creditable sources. Hence, the two lines for Internet-based and print-based text should have a positive slope. H1 suggests a significant gap between the lines for Internet-based sources and text-based sources on the timeliness, believability, reputation, accuracy, and objectivity dimensions. Borchers (2003) based this assertion on prior literature by Klein (1999). H2 suggests that the slope of the lines should vary based on one's personal involvement in cancer. This is to say, persons with high personal involvement in cancer should be better discriminators of data quality. Finally, H3 suggests that women are better able to differentiate credible from non-credible sources. Hence, the slope of the lines should vary based on gender.

Borchers (2003) studied 127 subjects on their perception of information on cancer based on exposure to Internet and print media. He drew subjects from mid-career students in MBA and MSIS classes at a Midwestern University. His sample was strongly multicultural, with significant U.S., Indian, and Chinese representation. Borchers (2003) randomly assigned subjects to one of four groups. These four groups were shown cancer information based on two sources of information presented in two different formats. One source was a Web site of a highly credible national cancer organization. The second source of cancer information was a Web site of low creditability, a site that touted alternative medical treatments. The third and fourth sources were identical to the first two, with the exception that the researcher presented information in printed form by way of a color document. Borchers (2003) then asked subjects about their perceptions of the data they viewed using Wang's intrinsic data quality dimensions (accuracy, objectivity, believability, and reputation), as well as contextual dimensions (timeliness, relevancy, and appropriate amount of information) and ease of use. Further, subjects were asked about their personal and family experience with cancer, as well as demographic questions (gender, age, and country of birth).

After Borchers (2003) collected data, he tested the dimensions using Cronbach's alpha to be sure they were reliable. Each dimension had a value of .8 or higher. He then generated a second set of statistics using a univariate ANOVA procedure to test each of the research hypotheses. H0 was tested for all eight measured data quality dimensions using the source reputation (high or low) and media (print or WWW) as fixed factors. In testing H2 and H3, he added cancer involvement or gender as random factors. The hypotheses were tested by looking at the product term for source reputation and cancer involvement (H2) or gender (H3). Table 2 summarizes Borchers' findings.

With respect to H0, Borchers (2003) found that his experimental design worked reasonably well. Subjects could easily discriminate between the low and high credible sources. In comparing Internet to print sources (H1), he observed no difference. In examining personal involvement (H2), he found that believability and reputation influenced personal involvement, but only for a subset of respondents. The work did not support the gender hypothesis (H3).

Figure 1. Research design (Borchers, 2003)



FUTURE TRENDS

Researchers should perform future work to extend the work of Klein (1999, 2001), Flannigan and Metzger (2000), Bucy (2003), and Borchers (2003), and to integrate newer literature in the field of data quality. First, researchers can address methodological issues. Readers should note that there are differences in research approach between these authors' work and that each work has methodological weaknesses that can be addressed in future research. Instrumentation in particular is a major concern. How can researchers more accurately measure people's perception of data quality and personal involvement in a topic? Researchers can also conduct studies on participants other than college students, as Bucy (2003) has done. Experimental designs such as Borchers' (2003) can be extended to more precisely test hypotheses. Other weaknesses include research designs. In Flanigan and Metzger's (2000) and Klein's (1999, 2001) work, subjects

Table 2. Hypothesis testing results (Borchers, 2003)

Hypothesis	Dimension	F-Ratio	Significance
H0—Initial Difference due to Reputation	Believable, accuracy, reputation, objectivity, and appropriate amount	10.526 to 24.489	.000 to .002
H0—Initial Difference due to Reputation	Timeliness, relevance, ease of use	< 1.4	> .35
H1—WWW Compared to Print	Timeliness Believable Reputation Accuracy Objectivity Appropriate Amount Relevance Ease Of Use	2.587 1.036 .340 .483 1.132 .617 .030 .620	.110 .311 .561 .489 .290 .484 .865 .484
H2—Personal Involvement with Cancer	Timeliness, Believable reputation, accuracy, objectivity, appropriate amount, relevance, ease of use	With all respondents, F-ratio < 4; U.S.-only respondents had significant interaction on believability and reputation	With all respondents, F-ratio > .05; U.S.-only respondents were significant on believability and reputation
H3—Gender	Believable, accuracy, reputation, objectivity, appropriate amount, relevance, ease of use	All < 4	All > .05

were asked to complete a one-time survey that asked about their perceptions in general of credibility of Internet and print sources. Bucy's (2003) work employed a control group, but did not control the material viewed. In Borchers' (2003) work, subjects were randomly placed in groups that saw exactly the same material in both Internet and text formats. In his study, however, cultural differences among subjects confounded the analysis. Each of these authors also uses surveys as a data collection technique, a potential weakness.

Second, early work focused on print and Internet (especially the WWW) as media. Further research could follow Flanigan and Metzger's (2000) and Bucy's (2003) work in other media, such as TV and radio, or emerging media. Third, researchers can extend tests of personal involvement to topics other than cancer. Huh et al.'s work (2004) on consumer perceptions of direct-to-consumer advertising is one promising topic. The concept of "personal involvement" needs to be developed, perhaps turning to the marketing literature for a base. Finally, as the general population becomes more computer literate and Internet savvy, researchers may find that perceptions of data quality between different media converge (or perhaps diverge). As the "M-generation" (Azzam, 2006) matures and computer technology permits users to multitask between different sources, media credibility may take on new importance.

Having noted these limitations and future areas of work, this line of research is important for several reasons. First, the Internet has become a de facto standard source of information for younger generations. Their perceptions of data quality, particularly compared to print, are a key factor in understanding how people will interpret what they see. Second, the question of personal involvement raises important concerns: Do people become more discriminating in evaluating data quality on topics that have significant influence to their lives? Finally, verification (as described by Flanigan & Metzger, 2000) is yet another interesting topic. To what extent do people verify what they read on the Internet or in print? Verification takes on extra importance with the rise of user-generated content (Schwartz, 2007). Future research should address these and other areas.

CONCLUSION

The work of these four researches (Klein, 1999, 2001; Flanigan & Metzger, 2000; Bucy, 2003; Borchers, 2003) seeks to understand how perceived data quality varies by different media. Flanigan and Metzger's (2000) work extends the discussion to verification of information. Bucy (2003) considers age of participants the synergy effects of multiple media. Borchers (2003) extends the case to include personal involvement.

Do people perceive data quality differently depending on the media that the data comes in? Flanigan and Metzger

(2000), Bucy (2003), and Borchers (2003) suggest that media is not a significant factor. This comes in contrast to Klein's work (1999, 2001), which suggested a difference in perceived data quality on five dimensions: accuracy, objectivity, reputation, timeliness, and appropriate amount.

Do Internet users verify what they see on the Internet? Flanigan and Metzger's (2000) work suggests that relatively few do so, and among inexperienced users even fewer verify what they find. This finding should be particularly distressing to academics and practitioners concerned with delivering high-quality data. As Schwartz (2007) notes, the move to user-generated data is a major trend, but one with questionable value: Will students be able to discern data quality in the myriad of Web resources available to them?

Do people become more discriminating of data quality for topics that they are personally involved in? Borchers' (2003) study provides a first look, at least for cancer information, and finds only limited support for this notion. Finally, does gender play a role in one's ability to discriminate between reputable and non-reputable sources of cancer information? Borchers' (2003) work would suggest that this is not so.

Data quality is an important topic that deserves continued research focus. The Internet revolution has fundamentally changed how people share information. How people perceive the quality of the information they view is an essential research topic for the information systems field.

KEY TERMS

Accessibility Data Quality: An aspect of data quality that refers to the ease with which one can get to data.

Contextual Data Quality: A concept that data does not exist in a vacuum, it is driven by the circumstance in which data is used. Contextual dimensions include relevancy, timeliness, and appropriate amount of data.

Data Quality: A multifaceted concept in information systems research that focuses on the fitness for use of data by consumers. Data quality can be viewed in four categories: intrinsic (accuracy, objectivity, believability, and reputation), contextual (relevancy, timeliness, and appropriate amount of data), representational (format of the data), and accessibility (ease of access).

Internet Credibility: A multi-faceted concept in journalism research that consists of believability, accuracy, trustworthiness, and bias.

Intrinsic Data Quality: A concept that "data have quality in their own right" (Wang & Strong, 1996) including accuracy, objectivity, believability, and reputation dimensions.

Representational Data Quality: A concept that data quality is related to the "format of the data (concise and consistent representation) and meaning of data (interpretability and ease of understanding)" (Wang & Strong 1996).

User-Generated Content: A feature of Web applications that allows participants to add and modify information as contrasted to traditional sources such as publishers or broadcasters.

Multimedia Content Adaptation

David Knight

INTRODUCTION

The previous decade has witnessed a wealth of advancements and trends in the field of communications and subsequently, multimedia access. Four main developments from the last few years have opened up the prospect for ubiquitous multimedia consumption: wireless communications and mobility, standardised multimedia content, interactive versus passive consumption and the Internet and the World Wide Web. While individual and isolated developments have produced modest boosts to this existing state of affairs, their combination and cross-fertilisation have resulted in today's complex but exciting landscape. In particular, we are beginning to see delivery of all types of data for all types of users in all types of conditions (Pereira & Burnett, 2003).

Compression, transport, and multimedia description are examples of individual technologies that are improving all the time. However, the lack of interoperable solutions across these spaces is holding back the deployment of advanced multimedia packaging and distribution applications. To enable transparent access to multimedia content, it is essential to have available not only the description of the content but also a description of its format and of the usage environment in order that content adaptation may be performed to provide the end-user with the best content experience for the content requested with the conditions available (Vetro, 2003).

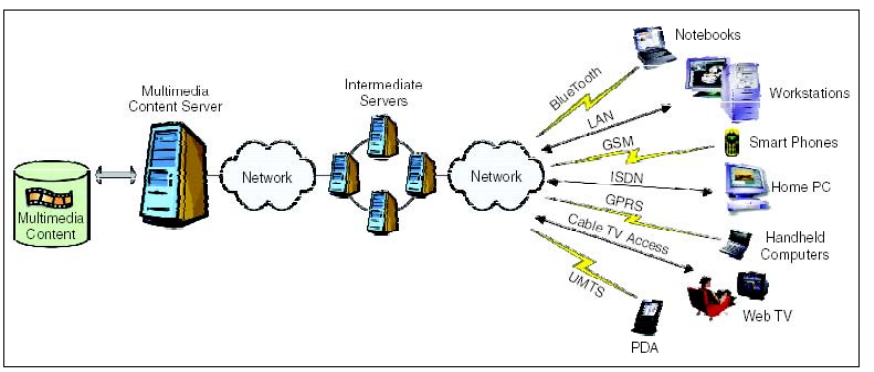
In the following sections, we will look at the background of multimedia content adaptation, why do we require it and why are present solutions not adequate. We then go onto the main focus of the article, which describes the main themes of modern multimedia content adaptation, such as present day work that defines the area and overviews and descriptions of techniques used. We then look at what this research will lead to in the future and what we can expect in years to come. Finally, we conclude this article by reviewing what has been discussed.

BACKGROUND

More and more digital audio-visual content is now available online. Also more access networks are available for the same network different devices (with different resources) that are being introduced in the marketplace. Structured multimedia content (even if that structure is still limited) increasingly needs to be accessed from a diverse set of networks and terminals. The latter range (with increasing diversity) from gigabit Ethernet-connected workstations and Internet-enabled TV sets to mobile video-enabled terminals (Figure 1) (Pereira & Burnett, 2003).

Adaptation is becoming an increasingly important tool for resource and media management in distributed multimedia

Figure 1. Different terminals access multimedia content through different networks



systems. Best-effort scheduling and worst-case reservation of resources are two extreme cases, neither of them well-suited to cope with large-scale, dynamic multimedia systems. The middle course can be met by a system that dynamically adapts its data, resource requirements, and processing components to achieve user satisfaction. Nevertheless, there is no agreement about questions concerning where, when, what and who should adapt (Bormans et al., 2003).

On deploying an adaptation technique, a lot of considerations have to be done with respect to how to realise the mechanism. Principally, it is always useful to make the technique as simple as possible, i.e., not to change too many layers in the application hierarchy. Changes of the system layer or the network layer are usually always quite problematic because deployment is rather difficult. Generally, one cannot say that adaptation technique *X* is the best and *Y* is the worst, as it highly depends on the application area.

The variety of delivery mechanisms to those terminals is also growing and currently these include satellite, radio broadcasting, cable, mobile, and copper using xDSL. At the end of the distribution path are the users, with different devices, preferences, locations, environments, needs, and possibly disabilities.

In addition the processing of the content to provide the best user experience may be performed at one location or distributed over various locations. The candidate locations are: the content server(s), any processing server(s) in the network, and the consumption terminal(s). The choice of the processing location(s) may be determined by several factors: transmission bandwidth, storage and computational capacity, acceptable latency, acceptable costs, and privacy and rights issues (see Figure 2).

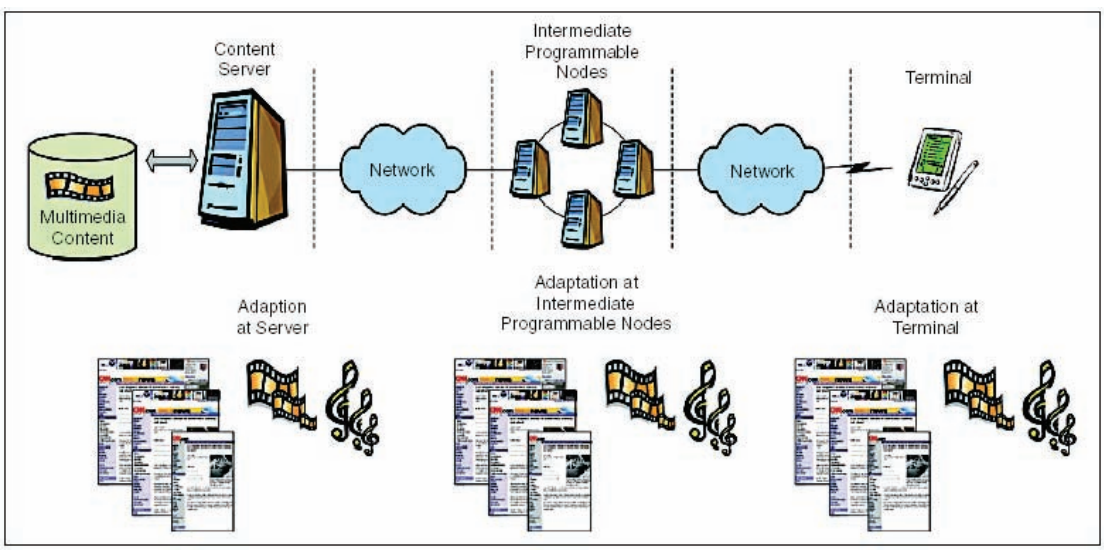
Present adaptation technologies concerning content adaptation mainly focus on the adaptation of text documents. Therefore, one text document will be adapted on demand to the capabilities of different devices or applications. To fulfill this functionality the structure of the content must be separated from its presentation, i.e., the source document is structured using XML (Extensible Markup Language) and then dynamically processed to generate a presentation tailored to the available resources. One possible use case scenario will be to present the same information either on a standard Web browser or a WAP browser.

Efficient adaptation requires that the participating components know from each other and take advantage of adaptation steps done by other components, which needs standardised media, metadata, and communication. Several standardisation bodies (W3C, MPEG, and WAP) have already been established or are currently under development, which have recognised the need to create a framework that facilitates the efficient adaptation of content to the constraints and preferences of the receiving end.

MPEG-7 (ISO/IEC 15938-5:2002) provides tools for content description, whilst capability description and negotiation is provided for with CC/PP (Composite Capabilities/ Preference Profiles, 2003) and UAProf (WAG User Agent Profile, 2001). MPEG-21 (ISO/IEC JTC 1/SC 29/WG 11), the "multimedia framework" includes Digital Item Adaptation (DIA), which enables standard communication of dynamic adaptation of both media resources and meta-data, enabling negotiation of device characteristics and QoS parameters. (Böszörményi et al., 2002)

In this section, the reasons for the need for interoperable and efficient multimedia content adaptation have

Figure 2. Adaptation may be performed at different places



been introduced. A number of standards groups (such as W3C, MPEG and WAP) that facilitate multimedia content adaptation by concentrating on the adaptation of associated XML-type documents have also been mentioned. The next section delves into the different technologies that help make up this exciting field.

MAIN THRUST OF THE CHAPTER

In this section we will look at the main themes found in multimedia content adaptation. We start with a look at a multimedia content adaptation architecture, a discussion on the present state of affairs regarding scalable coding and transcoding, an analysis of the effect the actual location point the adaptation takes place and a brief summary of the relevance of user profiling.

Multimedia Content Adaptation Architecture

The networking access paradigm known as Universal Multimedia Access (UMA) refers to the way in which multimedia data can be accessed by a large number of users/clients to view any desired video stream anytime and from anywhere. In the UMA framework, multimedia information is accessed from the network depending on the following three parameters: channel characteristics, device capabilities, and user preference.

Figure 3 gives an example of different presentations (to suit different capabilities such as formats, devices, networks, and user interests) of the same information.

One option for UMA is to provide different variations of the content with different quality, bit rate, media modality (e.g., audio to text), etc. The problem with this option is that it is not too efficient from the viewpoint of variation generations and storage space. On the other hand, real-time transformation of any content implies some delay for the processing and a lot of computing resources at the server (or proxy server) side. Pursuing either of these two options assumes the use of an adaptation engine. Figure 4 gives a bird's eye-view of such an adaptation engine architecture that is applicable to the adaptation of any type of content.

The architecture consists of an adaptation engine that can be located on the server, an intermediate network device such as a gateway, router, or proxy, or even on the client. This engine comprises of two logical engine modules, the adaptation decision engine and the resource adaptation engine. The adaptation decision engine receives the metadata information about the available content (context, format, and adaptation options) from the resource repository and the constraints (terminal and network capabilities, user characteristics, and preferences) from the receiving side. If there are multiple versions of the content pre-stored in the repository and one of these versions matches the constraints, then this version is selected, retrieved, and sent to the end user. However, if the available resource does not match the constraints, but can be adapted, then the adaptation decision engine determines the optimal adaptation for the given constraints and passes this decision to the resource adaptation engine. The resource adaptation engine retrieves the resource from the repository, applies the selected adaptation, and sends the adapted resource to the end user.

Constraints can be grouped into four broad categories: user and natural environment characteristics, terminal capa-

Figure 3. Different presentations of the same information

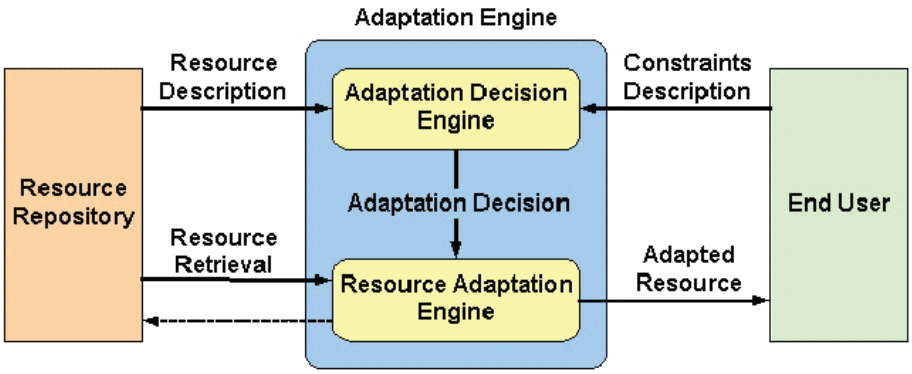
Figure 4. Bird's-eye view of an adaptation engine architecture



bilities, and network characteristics. The terminal and network constraints will set an upper bound on the resources that can be transmitted over the network and rendered by the terminal. Information like the network's maximum bandwidth, delay and jitter, or the terminal's resolution, buffer size, and processing power, will help the adaptation engine determine the optimal version of the resource for the given network and terminal device. As the user is the actual consumer (and judge) of the resource, user-related information, including user preferences, user demographics, usage history and natural environment, is equally important in deciding which resource should be delivered to the terminal.

The adaptation engine needs to have sufficient information about the context and the format of the multimedia resources in order to make a decision whether the resource is suitable for the user or how it should be adapted in order to offer the user the optimal context and quality. The description should therefore include information on the resource type, semantics, available adaptation options, and characteristics of the adapted versions of the resource (Panis et al., 2003).

Scalable Coding

If content is scalable, then adapting content may be done using scalable coding. This removes or alters parts of resources in such a way as to reduce their quality in order to satisfy the receiver's capabilities and needs. Currently available scaling options depend on the coding format to be used. The Holy Grail of scalable video coding is to encode the video once, and then by simply truncating certain layers or bits from the original stream, lower qualities, spatial resolutions, and/or temporal resolutions could be obtained (Vetro, 2003).

Current scalable coding schemes fall short of this goal. MPEG-4 is currently the content representation standard where the widest range of scalability mechanisms is available, notably in terms of data types, granularities, and scalability domains (Pereira & Ebrahimi, 2002).

Transcoding

This is another more complex option that typically refers to transforming the resource from one coding format into another one, i.e., decoding the resource and encoding the resource using another codec (e.g., transcode an MPEG-2 video to an MPEG-1 video). According to Sun et al. (2003), the key design goals of transcoding are to maintain the video quality during the transcoding process and to keep complexity as low as possible. Cavallaro et al. (2003) identify three main approaches to video transcoding: content-blind transcoding, semantic transcoding, and description-based transcoding:

- **Content-blind transcoding** does not perform any semantic analysis of the content prior to conversion. The choice of the output format is determined by network and appliance constraints, independent of the video content (i.e., independent of the way humans perceive visual information). The three main content-blind transcoding categories are spatial conversion, temporal conversion, and colour-depth reduction.
- **Semantic (or intramedia) transcoding** analyses the video content prior to conversion. An example of such analysis is the separation of the video content into two classes of interest, namely foreground and background. Once this separation has been accomplished, the two classes can be coded differently to better accommodate the way humans perceive visual information, given the available network and device capabilities.
- **Description-based (or intermedia) transcoding** transforms the foreground objects extracted through semantic segmentation into quantitative descriptors. These quantitative descriptors are transmitted instead of the video content itself. In this specific case, video is transformed into descriptors so as to produce a textual output from the input video. Such textual output can be

used not only for transcoding, but also for annotating the video content and for translating the visual content into speech for visually impaired users. This transformation is also referred to as cross-media adaptation.

Location of Adaptation

As well as the technologies used, the location used for multimedia content adaptation needs to be addressed. Resource delivery and adaptation can be sender-driven, receiver-driven, or network-driven.

Sender-driven proceeds to adapt resources at the sender/server node depending on the terminal and/or network capabilities received beforehand. After successful adaptation the sender transmits the adapted version of the resource to the receiver. This action requires a serious amount of computational power at the server node and goes at the expense of latency between the receiver's request and the server's delivery.

In contrast, the receiver-driven approach decides what and how to adapt at the terminal side although the real adaptation could take place somewhere else, e.g., on a proxy node. Adaptation directly at the end node could fail due to insufficient capabilities. Additionally network bandwidth will be wasted, too. Nevertheless, adaptation on terminal devices should not be strictly excluded.

The pure network-driven approach is transparent where the network, i.e., the transport system, is responsible for adaptation only. Typical use case scenarios will cover all kind of adaptation approaches described so far, i.e., resource adaptability along the delivery chain, from resource provider to resource consumer. A high-performance server node will provide some kind of pre-processing in order to facilitate easy adaptation along the delivery chain across a wide range of network and terminal devices. Network nodes such as routers or gateways will then perform so-called light-weight adaptations using segment dropping or minor editing techniques whereas proxy nodes could utilise more complex adaptation techniques. Such complex adaptation techniques include not only scaling but also transcoding and cross-media. An adaptive terminal device could perform adjustments due to user and/or usage preferences. The complexity of these adaptations to be done in terminal devices depends on its capabilities, e.g., display resolution, computational power, local storage capacity, and buffer size.

User Profiling

In order for the personalisation and adaptation of multimedia content to take place, the users' preferences, interests, usage, and environment need to be described and modelled. This is a fundamental realisation for the design of any system that aims to aid the users while navigating through large volumes of audio-visual data. The expectation is that by making use of certain aspects of the user model, one can improve the efficacy of the system and further help the user (Kobsa et al., 2001).

This section described the components needed to make up a multimedia content adaptation architecture: transcoding, scalable coding, location of adaptation, and user profiling. The next section discusses the future of multimedia content adaptation by looking at UMA, transcoding, and scalability, specifically.

FUTURE TRENDS

The major problem for multimedia content adaptation is to fix the mismatch between the content formats, the conditions of transmission networks, and the capability of receiving terminals. A mechanism for adaptation needs to be created for this purpose.

Scalable coding and transcoding are both assisting in this. It can be seen that scalable coding and transcoding should not be viewed as opposing or competing technologies. Instead, they are technologies that meet different needs regarding multimedia content adaptation and it is likely that they will coexist.

Looking to the future of video transcoding, there are still quite a number of topics that require further study. One problem is finding an optimal transcoding strategy. Given several transcoding operations that would satisfy given constraints, a means for deciding the best one in a dynamic way has yet to be determined. Another topic is the transcoding of encrypted bit streams. The problems associated with the transcoding of encrypted bit streams include breaches in security by decrypting and re-encrypting within the network, as well as computational issues (Vetro, 2003).

The inherent problem with cross-media (description-based) adaptation is in preserving the intended semantics. What are required are not the blindfolded exchange of media elements and fragments, but their substitution by semantically equivalent alternatives. Unfortunately, current multimedia authoring tools provide little support for producing annotated multimedia presentations. Richly annotated multimedia content, created using document-oriented standards, such as MPEG-7 and MPEG-21 DIA, will help facilitate sophisticated cross-modal adaptation in the future.

For the implementation of UMA, "universal," scalable, video-coding techniques are essential components. Enhancements to existing video-coding schemes, such as MPEG-4 FGS (Fine-Granular-Scalability) and entirely new schemes will help drive the UMA ideal. More efficient FGS-encoders, tests on the visual impact of variability and more improved error resilient techniques are improvements that can be made to scalable coding schemes.

While some technologies such as content scalability and transcoding are fairly well established, there are still vital technologies missing for a complete multimedia content adaptation system vision. Many of these technologies are directly related to particular usage environments. While multimedia adaptation for improved experiences is typically thought of in the context of more constrained environments (e.g., mobile terminals and networks), it is also possible that the content has to be adapted to more sophisticated environments, e.g., with three-dimensional (3-D) capabilities. Whether the adaptation processing is to be performed at the server, at the terminal, or partially at both, is something that may have to be determined case–by-case, depending on such criteria as computational power, bandwidth, interfacing conditions, and privacy issues.

CONCLUSION

The development and use of distributed multimedia applications is growing rapidly. The subsequent desire for multimedia content adaptation is leading to new demands on transcoding, scaling, and, more generally, adaptation technologies. Metadata-based standards, such as MPEG-7 and MPEG-21, which describe the semantics, structure, and the playback environment for multimedia content are breakthroughs in this area because they can assist more intelligent adaptation than has previously been possible.

A prerequisite for efficient adaptation of multimedia information is a careful analysis of the properties of different media types. Video, voice, images, and text require different adaptation algorithms. The complex nature of multimedia makes the adaptation difficult to design and implement. By mixing intelligence that combines the requirements and semantic (content) information with low-level processing, the dream of UMA could be closer than we envision.

KEY TERMS

Bit Stream: The actual data stream, which is the transmission of characters at a fixed rate of speed. No stop and start elements are used, and there are no pauses between bits of data in the stream.

Content Scalability: The removal or alteration of certain subsets of the total coded bit stream to satisfy the usage environment, whilst providing a useful representation of the original content.

Cross-Media Adaptation: Conversion of one multimedia format into another one, e.g., video to image or image to text.

Multimedia Content Adaptation: The process of adapting a multimedia resource to the usage environment. The following factors make up this usage environment: users preferences, device, network, natural environment, session mobility, adaptation QoS, and resource adaptability.

Transcoding: The process of changing one multimedia object format into another.

UMA: How users can access the same media resources with different terminal equipment and preferences.

User Modelling: In the context of adaptation, the describing/modelling of the users preferences, interests, usage, and environment.

This work was previously published in Encyclopedia of Information Science and Technology, edited by M. Khosrow-Pour, pp. 2051-2057, copyright 2005 by Information Science Reference, formerly known as Idea Group Reference (an imprint of IGI Global).

Multimedia Information Filtering

Minaz J. Parmar
Brunel University, UK

Marios C Angelides
Brunel University, UK

INTRODUCTION

In the film *Minority Report* (20th Century Fox, 2002), which is set in the near future, there is a scene where a man walks into a department store and is confronted by a holographic shop assistant. The holographic shop assistant recognises the potential customer by iris-recognition technology. The holographic assistant then welcomes the man by his name and starts to inform him of offers and items that he would be interested in based on his past purchases and what other shoppers who have similar tastes have purchased. This example of future personalised shopping assistants that can help a customer find shopping goods is not too far away from becoming reality in some form or another.

Malone, Grant, Turbak, Brobst, and Cohen (1987) introduced three paradigms for information selection, *cognitive*, *economic*, and *social*, based on their work with a system they called the Information Lens. Their definition of cognitive filtering, the approach actually implemented by the Information Lens, is equivalent to the "content filter" defined earlier by Denning, and this approach is now commonly referred to as "content-based" filtering. Their most important contribution was to introduce an alternative approach that they called social (now also more commonly called collaborative) filtering. In social filtering, the representation of a document is based on annotations to that document made by prior readers of the document.

In the 1990s much work was done on collaborative filtering (CF). There were three systems that were considered to be the quintessential recommender systems. The Grouplens project (Miller, Albert, Lam, Konstan, & Riedl, 2003) initially was used for filtering items from the Usenet news domain. This later became the basis of Movielens. The Bellcore Video recommender system (Hill, Stead, Rosenstein, & Furnas, 1995), which recommended video films to users based on what they had rented before, and Ringo (Shardanand & Maes, 1995), which later was published on the Web and marketed as Firefly, used social filtering to recommend movies and music.

BACKGROUND

Filtering multimedia content is an extensive process that involves extracting and modeling semantic and structural information about the content as well as metadata (Angelides, 2003). The problem with multimedia content is that the information presented in any document is multimodal by definition. Attributes of different types of media vary considerably in the way the format of the content is stored and perceived. There is no direct way of correlating the semantic content of a video stream with that of an audio stream unless it is done manually. A content model of the spatial and temporal characteristics of the objects can be used to define the actions the objects take part in. This content model can then be filtered against a user profile to allow granular filtering of the content, allowing for effective ranking and relevancy of the documents.

Filtering has mainly been investigated in the domain of text documents. The user's preferences are used as keywords, which are used by the filters as criteria for separating the textual documents into relevant and irrelevant content. The more positive keywords contained in a document, the more relevant the document becomes. Techniques such as latent semantic indexing have found ways of interpreting the meaning of a word in different contexts to allow accurate filtering of documents using different syntax, but allow the same semantics to be recognised and understood.

Text documents adhere to the standards of the language they are written in. Trying to do the same for AV data streams, you are faced with the problem of identifying the terms in the content itself. The terms are represented as a series of objects that appear in the content, for example, a face in an image file. These terms cannot be directly related to the objects as there is no method of comparison, or if there is, it is complex to unlock. The title of the document and some information might be provided in the file description, but the actions and spatial and temporal characteristics of the objects will not be described to a sufficient level for effective analysis of relevancy.

MAIN THRUST OF ARTICLE

Information-filtering techniques have been applied to several areas including American football (Babaguchi, Kawai, & Kitahashi, 2001), digital television (Marusic & Leban, 2002), Web applications (Kohrs & Merialdo, 2000), and ubiquitous and pervasive device applications (Tseng, Lin, & Smith, 2002).

Filtering multimedia information requires different approaches depending on the domain and use of the information. There are two main types of multimedia information filtering: collaborative and content based. If the user wants a subjective analysis of content in order to find a recommendation based on their individual preference, then they use collaborative filtering, also known as social or community-based filtering. If, on the other hand, they require an objective decision to filter information from a data stream based on their information needs, then they use content-based filtering.

All of the above systems use either collaborative or content-based filtering or a combination of both (hybrid) as the techniques for recommending predictions on candidate objects. There are existing information-filtering models outside these classic techniques such as temperament-based filtering (Lin & McLeod, 2002), which looks at predicting items of interest based on temperament theory. It works on the same principle as social filtering. Unlike social filtering, the users are grouped on temperaments of the users and not on similar item selection.

Content-Based Filtering

Content-based filtering is suited to environments where the user requires items that have certain content features that they prefer. Collaborative filtering is unsuitable in this environment because it offers opinions on items that reflect preferences for that user instead of providing filtering criteria that tries to disseminate preferred content from a data stream based on a user's preference. Personalised video summaries are the perfect domain to use content-based filtering. The reason for this is that a user will be interested in certain content only within any video data stream. For example, when watching a football game, the user may only be interested in goals and free kicks. Therefore, users can state what content features and other viewing requirements they prefer and then filter the footage against those requirements.

The content-based approach to information filtering has its roots in the information retrieval (IR) community and employs many of its techniques. The most prominent example of content-based filtering is the filtering of text objects (e.g., mail messages, newsgroup postings, or Web pages) based on the words contained in their textual representations. Each object, here, text documents, is assigned one or more index terms selected to represent the best meaning of the document. These index terms are searched to locate documents related to queries expressed in words taken from the index language. The assumption underlying this form of filtering is that the "meaning" of objects and queries can be captured in specific words or phrases. A content-based filtering system selects items based on the correlation between the content of the items and the user's preferences as opposed to a collaborative filtering system that chooses items based on the correlation between people with similar preferences (van Meteren & Someren, 2000).

The main problem with content-based filtering is that it does not perform well in domains were the content of items is minimal and the content cannot be analysed easily by automatic methods of content-based retrieval (e.g., ideas and opinions). Users with eclectic tastes or who make ad hoc choices are given bad recommendations based on previous choices. For example, Dad, who usually buys classic rock CDs for himself, purchases a So Solid Crew album for his 12-year-old son. He may start getting recommendations for hardcore garage dance anthems every time he logs in. CF does not suffer this problem as it will rank on other users' recommendations of similar choices. Comparative studies have shown that collaborative-filtering recommender systems on the whole outperform content-based filtering.

Collaborative Filtering

A purely content-based approach to information filtering is limited by the process of content analysis. In some domains, until recently, the items were not amenable to any useful feature extraction with content-based filtering (such as movies, music, restaurants). Even for text documents, the representations capture only certain aspects of the content, and there are many others that would influence a user's experience, for example, in how far it matches the user's taste (Balabanovic, 2000).

Collaborative filtering is an approach to overcome this limitation. The basic concept of CF is to automate social processes such as "word of mouth." In everyday life, people rely on the recommendations from other people either by word of mouth, recommendation letters, and movie and book reviews printed in newspapers. Collaborative filtering systems assist and augment this process and help people in making decisions.

There are two main drawbacks to using collaborative filtering: the sparsity of large user-item databases and the first-rater problem (Rashid et al., 2002). Sparsity is a condition when not enough ratings are available due to an insufficient amount of users or too few ratings per user. An example of sparsity is a travel agent Web site, which has tens of thousands of locations. Any user on the system will not have traveled to even 1% of the locations (possibly thousands of locations). If a nearest-neighbour algorithm is used, the accuracy of any recommendation will be poor as a sufficient amount of peers will not be available in the user-item database. The

first-rater problem is exhibited when a new user is introduced that has not enough ratings. If no ratings have been given for an item or a new user has not expressed enough opinions, choices, or ratings, no predictions can be made due to the insufficient data available or bad recommendations will be made. In contrast, content-based schemes are less sensible to sparsity of ratings and the first-rater problem since the performance for one user relies exclusively on his or user profile and not on the number of users in the system.

Hybrid Filtering

Both content-based and collaborative filtering have disadvantages that decrease the performance and accuracy of the systems that implement them. If these methods are combined, then the drawbacks of one technique can be counteracted by the techniques of the other, and vice versa. There have been various implementations such as the following.

- By making collaborative recommendations, we can use others' experiences as a basis rather than the incomplete and imprecise content-analysis methods.
- By making content recommendations, we can deal with items unseen by others.
- By using the content profile, we make good recommendations to users even if there are no other users similar to them. We can also filter out items.
- We can make collaborative recommendations between users who have not rated any of the same items (as long as they have rated similar items).
- By utilizing group feedback, we potentially require fewer cycles to achieve the same level of personalisation.

User Profiles

In information filtering, a user's needs are translated into preference data files called user profiles. These profiles represent the users' long-term information needs (Kuflik & Shoval, 2000). The main drawbacks of using user profiles are creating a user profile for multiple domains and updating a user profile incrementally. The user profile can be populated by one or more of the following.

- *Explicit profiling*: This type of profiling allows users to let the Web site know directly what they want. Each user entering the site will fill out some kind of online form that asks questions related to a user's preferences (Eirinaki & Vazirgiannis, 2003). The problem with this method is the static nature of the user profile once it has been created. The stored preferences in the user profile cannot take into account the changing user's preferences.
- *Implicit user profiles*: This type of user profiles is created dynamically by tracking the user's behaviour pattern through automatic extraction of user preferences using some sort of software agent, for example, intelligent agents, Web crawlers, and so forth (Eirinaki & Vazirgiannis, 2003). All these usage statistics are correlated into a usage history that is an accurate interaction between the user and the system. This usage history is then analysed to produce a user profile that portrays the user's interests. The user profile can be updated every time the user starts a new session, making implicitly made profiles dynamic. The downside of this method is that the user initially will have to navigate and explore the site before enough data can be generated to produce an accurate profile.
- *Hybrid of implicit and explicit profiling*: The drawbacks of explicit and implicit profiling can be overcome by combining both methods into a hybrid. This allows the strong points of one technique to counteract the shortcomings of the other and vice versa. The hybrid method works by collecting the initial data explicitly using an online form. This explicitly created data is then updated by the implicit tracking method as the user navigates around the site. This is a more efficient method over both pure methods. In some instances, this hybrid method is reversed and the implicit tracking methods are used initially to produce a profile.
- *Stereotype profiling*: This can be achieved by data mining and analysis of usage histories over a period of visits. This provides accurate profiling for existing users with legacy data that is accurate. The disadvantage of this method is that it suffers from the same static nature as explicit profiling as the profile is created from archive data that might be obsolete, and therefore some updating might be necessary. The predefined user stereotype is a content-based user profile that has been created for a virtual user or group of users who have common usage and filtering requirements for consumption of certain material. The stereotyped profile will contain additional information about the stereotyped user such as demographic and social attributes. This additional information is then used to place new users to stereotyped profiles that match similar demographic and social traits. The new user without the need of any implicit or explicit tracking automatically inherits preference information.

FUTURE TRENDS

Content-based filtering in multimedia information filtering has one innate problem that researchers are trying to solve: How can we extract semantics automatically from structural content of the model? In collaborative filtering, the age-old

Table 1. Multimedia information filtering

	Description	Techniques Used	Advantages	Disadvantages	Future R&D
Information Filtering	filtering a dynamic information space using relatively stable user requirements	SDI systems recommender systems	allows user to constantly receive content they are interested in with minimal user effort	does not support ad hoc queries that are dynamic compared to the information space they are searching (information retrieval)	all of the below
Content-Based Filtering	filtering content from a data stream based on extracting content features that have been expressed in a content-based user profile	vector space model probabilistic/inference models latent semantic indexing	objective analysis of large and/or complicated (e.g., multimedia) sources of digital material without much user involvement	1. content dependent 2. hard to introduce serendipitous recommendations as approach suffers from "tunnel vision" effect	extracting semantics from the structure of the content automatically without human intervention
Collaborative Filtering	filtering items based on similarities between target user's collaborative profile and peer users/group	same as above	1. content independent 2. proves more accurate than content-based filtering for most domains of use enables introduction of serendipitous choices	1. sparsity: poor prediction capabilities when new item is introduced to database due to lack of ratings 2. new user: poor recommendations made to new users until they have enough ratings in their profiles for accurate comparison to other users	solving the sparsity and new-user problem finding other types of ratings schemes that do not use comparisons between users tastes (e.g., filtering using users temperament)
Hybrid Filtering	combines two or more filtering techniques	simple or rule based stereotype collaborative content based	to reduce weak points and promote strong points of each of the techniques used	weak points can outweigh strong points if the hybrid is created naively	using hybrid systems in domains where using one technique presents a large disadvantage/problem
User Profiles	log file containing user's preferences for consumption of content	content-based profiles collaborative profiles	1. user does not need to state preferences each and every time they use the system 2. user can maintain and update preferences with minimal effort compared to ad hoc methods	needs frequent updating or user preferences become stagnant	user profiles that are as ubiquitous and pervasive as the devices/systems that use them standardisation
Explicit User Profiles	user manually creates user profile by means of a questionnaire	questionnaires ratings	preference information gathered is usually of high quality	requires a lot of effort from user to update	collecting new user preferences that reduces user effort
Implicit User Profiles	system generates user profile from usage history of interactions between user and content	machine learning algorithms	minimal user effort required easily updateable by automatic methods	initially requires a large amount of interaction between user and content before an accurate profile is created	new machine learning algorithms for better accuracy when creating implicit user profiles
Hybrid User Profiles	combination of user profile techniques used to create a profile	explicit/implicit user profiles	to reduce weak points and promote strong points of each of the techniques used	N/A	finding effective strategies for deployment and use of hybrid profiles

problem of sparsity and the new-user problem are still the biggest hindrances to using this method of filtering. Sparsity is being solved presently by hybrid systems, and it appears that this will be favoured way of dealing with sparsity (Lin & McLeod, 2002). The most promising solutions appear to be collaboratively filtering, standardised content-based profiles, which allow flexibility for systems to use either pure content-based or collaborative filtering, or a hybrid of both interchangeably.

Current work on user profiles focuses on improving creation techniques such as improved machine learning algorithms that create implicit user profiles more rapidly so that they can be more reliable and accurate in a shorter amount of time. For explicit user profiling, there is the work on selecting items that increase the usefulness of initial ratings that we have already discussed. The main way forward here, though, appears to be hybrid user profiles that are initially explicitly created and then implicitly updated.

With the advent of digital television and broadband, consumers will be faced with a deluge of multimedia content available to them at home and at work. What they will require are autonomous, intelligent filtering agents and automated recommender systems that actively filter information from multiple content sources. These personalisation systems can then collaborate to produce ranked lists of recommendations for all purposes of information the user might require. The key to this kind of service is not in the implementation of these systems or the way they are designed, but rather on a standard metadata language that will allow systems to communicate without proprietary restrictions and aid in end-user transparency in the recommendation process.

CONCLUSION

In the coming years, as nearly all communication and information devices become digital, we will see the development of systems that will be able not only to recommend items of interest to us, but will be able to make minor decisions for us based on our everyday needs such as ordering basic shopping groceries or subscribing to entertainment services on an ad hoc basis. What is required is a model of the user that describes the user's preferences for a multitude of characteristics that define the user's information needs. This model can then be used to filter data and recommend information based on this complete view of the user's needs. This has been done for many years with text files using techniques such as content-based and collaborative filtering, but has always been a problem with multimedia as the content is diverse in terms of storage, analysis techniques, and presentation. In recent years, classical techniques used for text filtering have been transferred and used in the area of multimedia information filtering. New developments such as hybrid filtering and improved metadata languages have made filtering multimedia documents more reliable and closer to becoming a real-world application.

KEY TERMS

Collaborative Filtering: Aims at exploiting preference behaviour and qualities of other persons in speculating about the preferences of a particular individual

Content-Based Filtering: Organizes information based on properties of the object of preference and/or the carrier of information

Hybrid Filtering: A combination of filtering techniques in which the disadvantages of one type of filtering is counteracted by the advantages of another

Information Filtering: Filtering information from a dynamic information space based on a user's long-term information needs

Recommendation: A filtered list of alternatives (items of interest) that support a decision-making process

Recommender Systems: Assist and augment the transfer of recommendations between members of a community

User Profile : A data log representing a model of a user that can be used to ascertain behaviour and taste preferences

Multimedia Software Interface Design for Special-Needs Users

Cecilia Sik Lányi
University of Pannonia, Hungary

INTRODUCTION

Most software engineering companies do not develop for special users, because they do not see the potential in this limited market. But 10% of the population worldwide are handicapped. In the United States, 14% of the population are estimated to suffer from a disability. In the population aged over 65, this figure becomes 50%. Disabilities are strongly linked with age, and our societies are facing a growing number of people aged 75 and more, who are more likely to have impairments or disabilities. This group will comprise 14.4% of the population in 2040, compared with 7.5% in 2003—almost a twofold increase (EU Commission, 2003). It is not a simple task to assess the effectiveness of multimedia for all users with disabilities. The question is more complicated if the users have special needs.

This article provides a minimal requirements list that every software engineer, computer scientist, and Web designer should take into account if they develop a new multimodal software or a new Web site with multimedia elements.

BACKGROUND

Universal usability is sometimes tried to meeting the needs of users who are disabled or work in disabling conditions. This important direction is likely to benefit all users. The adaptability needed for users with diverse physical, visual, auditory, or cognitive disabilities is likely to benefit users with differing preferences, tasks, skills, hardware, and so on (Schneiderman, 2003, p. 41).

The present middle-aged user group, now using the computer for work or entertainment, will soon move into old age. It is the time to realize the problem and prepare for the solution. We should keep in mind today what we will experience when we grow old. We should design such a world now that will help us in the future!

A critical component in designing multimedia software is the production of educational programs. Obviously, it is not a simple task to assess the effectiveness of a multimedia teaching system. There are some organizations that published techniques for the evaluation of multimedia teaching software (Sik Lányi, Bacsa, Mátrai, & Kosztyán 2005a; Sik Lányi, Mátrai, Molnár, & Lányi, 2005b; Sik Lányi, 2006). The question is more complicated if the users have special needs. The literature is increasingly attentive to "Design for All" principles (NCSU, 2007). Several conferences run on the topic of how can computers and assistive technology help handicapped people. The most important ones are the following:

- International Conference on Computers Helping People with Special Needs (ICCHP), recent and upcoming meetings in Linz in 2006 and 2008.
- International Conference Series on Disability, Virtual Reality, and Associated Technologies (ICDVRAT), staged in Veszprém, Hungary in 2002; Oxford, UK in 2004; and Esbjerg, Denmark and Maia, Portugal in 2008.
- The **Association for the Advancement of Assistive Technology in Europe (AAATE)**, in Dublin, Ireland in 2003; Lille, France in 2005; and San Sebastian, Spain in 2007; will be staged in Florence, Italy in 2009.

What is Multimedia?

Multimedia refers to the use of computers to present text, graphics, animation, and sound in an integrated way. Long heralded as the future revolution in computing, multimedia applications were, until the mid-1990s, uncommon due to the expensive hardware required. With increases in computer performance and decreases in price, however, multimedia is now commonplace.

The term *multimedia* describes a number of diverse technologies that allow visual and audio media to be combined in new ways for the purpose of communicating. Applications include entertainment, education, and advertising. In recent years, the term multimedia has taken on many diverse meanings for an ever-increasing audience. Some of us have a form of multimedia "narrowcast" through digital cable. Home DVD editing software can be categorized as multimedia, along with the latest generation of mobile phones, which are capable of taking and sending voice annotated photos. The term multimedia will continue to evolve and take on as many new meanings as the technologies and applications it is being used to describe. From our viewpoint, multimedia is a means of communication that combines text with graphics, sound, animation, full-motion video, and so forth—usually

in a highly interactive way, and it also includes the use of the Internet (Sik Lányi, 2006).

What Does the Attributive Noun "Multimodal" Mean?

A software or hardware instrument is multimodal if it uses at least two media elements, and one or both must be time dependent—for example video, sound, and animation files; we also call this mixed media.

The so-called multimodal interaction provides the user with multiple modes of interfacing with a system beyond the traditional keyboard and mouse input/output. The most common such interface combines a visual modality (e.g., a display, keyboard, and mouse) with a voice modality (speech recognition for input, speech synthesis and recorded audio for output). Multimodal user interfaces are part of a research area in human-computer interaction.

Why Is Human Computer Interaction So Important?

Human computer interaction (HCI) is the study of how humans interact with computers and programs (this also used to be called 'man machine interface'). HCI is a discipline concerned with the design, evaluation, and implementation of interactive computing systems for human use, with the study of major phenomena surrounding them. From a computer science perspective, the focus is on interaction and specifically on interaction between human(s) and computer(s).

HCI is also a growing academic discipline. More than a dozen research journals in HCI are compiling practical results and theoretical frameworks to guide designers. These success stories in HCI and user interface design are paralleled and emulated in university courses, but change often comes slowly. The resistance comes from technology-centered researchers who value mathematical formalism more than psychological experimentation (Schneiderman, 2003, p. 71.).

Special-Needs Users

Disability is such a qualitatively difference of a human capability from its normal feature, which might be in-born or if acquired, can develop backwards only very slowly, or can be permanent and irreversible. The kinds of disabilities are: physical impairment, sensory impairment, cognitive impairment, intellectual impairment, and cumulative impairment.

In 1980, the World Health Organization (WHO) published its classification of impairments, disabilities, and handicaps in a document called, "ICIDH (International Classification of Impairments, Disabilities and Handicaps)." In this document, three levels of the impairments were distinguished. During recent years the ICIDH has been considerably revised. One of the main differences between the previous version and ICIDH-2, now called "International Classification of Functioning (ICF)", is that instead of *disability* and *handicapped,* new descriptions have been introduced. The ICF speaks about *activities* and *participation.* This means on one side that some more broad terms have to be used, and on the other that our attention must be focused on the still-available abilities instead of the disabilities (ICIDH, 1999). However different countries may use different terminology, we use 'special-needs user' in this article.

These people have special needs in daily requirements during all their life. Without assistive technology or special devices, they are not able to satisfy all their needs. The basic needs are eating, moving, communicating, and so on. This article deals only with using multimedia software for the above purposes, because most of the information and communication technology is based on it. If the handicapped users are not able to use these software (including the Internet) in average ways and means, their needs are special, so we call them 'special-needs users'.

Design for All, or Universal Design?

The concept of universal design is clear. Wikipedia (2007) gives the following definition of universal design:

"A relatively new paradigm that emerged from 'barrier-free' or 'accessible design' and 'assistive technology.' Barrier free design and assistive technology provide a level of accessibility for people with disabilities but they also often result in separate and stigmatizing solutions, for example, a ramp that leads to a different entry to a building than a main stairway. Universal design strives to be a broad-spectrum solution that helps everyone, not just people with disabilities. Moreover, it recognizes the importance of how things look. For example, while built up handles are a way to make utensils more usable for people with gripping limitations, some companies introduced larger, easy to grip and attractive handles as [a] feature of mass produced utensils. They appeal to a wide range of consumers. Universal design is a part of everyday living and is all around us. The 'undo' command in most software products is a good example."

But the author's opinion is a bit different; sometimes the everyday software products are not good enough and not easy to use by special-needs users.

Is the concept of Design for All (DfA) similar to universal design? Many specialists discuss the proper definition of DfA, but at the time of this writing, there was no consensus about a proper definition, therefore we give one for the sake of this article. DfA means design of products, services, systems (including information technology) to be accessible—that is,

they should be usable by the widest range of users as possible. Moreover these products, services, and systems should be usable by everybody, including future generations, regardless of age, gender, capabilities, or cultural background.

Laws and Guidelines

Numerous countries have passed legislation encouraging or even requiring accessibility in different settings, ranging from the general to the very specific. Different countries have different laws. One of the most critical laws is Section 508 of the Federal Rehabilitation Act in the United States (U.S. Section 508, 2001), which specifies that starting June 21, 2001, the U.S. government shall stop purchasing any information technology that is inaccessible to people with disabilities, nor will it make available for public use any information technology that is inaccessible (Hung, 2001).

There are "Web Content Accessibility Guidelines" (WCAG 1.0, 2007; WCAG 2.0, 2007), but they are not well known by designers. Moreover, neither addresses multimodal software; although multimedia surrounds us, we are not able to avoid it.

EXPERIENCES AND RECOMMENDATIONS

At the Virtual Environments and Imaging Technologies Laboratory of the University of Pannonia, we have been conducting research work on multimedia use for people with special needs, and developed several such programs (Sik Lányi et al., 2005a, 2005b; Sik Lányi, 2006). Some conclusions from this research follow.

What Are the Advantages of Multimedia Software?

- It is an audiovisual medium.
- It can be interactive.
- The treatment or situation can be reproduced, the same condition can be repeated several times.
- It can be adjusted to individual needs.
- Multimedia systems have an effect on more than one sense and can be more effective.
- It can help creativity, it can be varied.
- One can include the motivating qualities of games in multimedia programs.
- It can be designed to ensure the user experiences success.
- One can use motivating audio feedback.
- It can be used both in individual and small-group therapy.

Recommendations

According to the Census 2000 definition, types of disability are: visually impaired, partially sighted, deaf, hard of hearing, mentally retarded, and physically disabled users. In addition it distinguishes color-blind and elderly people as special-needs users. The following multimedia interface design issues for special-needs users will be summarized in this article.

Visual Impairment and Partially Sighted People

It is very important to keep on the developer's mind that the visual impaired and partially sighted people have no perfect vision. The visus of perfect vision is 1. A partially sighted person's visus is between 0.1 and 0.3.

For Blind Persons

- Ensure that all information can be accessed via text or sound, such that blind users can use screen readers or Braille display to access the information.
- GIVE pre-recorded audio as an alternative mean.
- Allow users to navigate the site by using a keyboard (the mouse is hardly used by blind users).
- Minimize the users' memory load because blind users can only hear one word at a time and need memory to integrate parts of the heard information (Hung, 2001).

For Partially Sighted Persons

- Ensure the text size is large enough, otherwise low-vision users usually need a screen magnifier to enlarge the text.
- Give an audio option to notify low-vision users about new information.
- Minimize the users' memory load because the effective screen size is very small while using a screen magnifier.
- For users with low vision, pictures must be drawn with thick contour lines. The user can be given the option to modify the contour line thickness of the objects. The user must be able to vary the color of the objects and background, and the speed of motion, and to stop the animation (Sik Lányi et al., 2005b).

Color-Deficient (Color-Blind) People

Color blindness is mostly neglected; even those impaired do not consider this a serious problem. Yet, it is quite common

to see combinations of background and foreground colors that make pages virtually unreadable for color-blind users. Background, text, and graphics colors should be carefully chosen to allow for people with color blindness. Designing for color-blind people is complicated. It is not a matter of green/red or yellow/blue combinations.

The most important issue in designing for color-blind users is not to rely on color alone to convey information and not to use color as a primary means to impart information (Karagol-Ayan, 2001).

If we have no possibility to test our software by the help of color-blind people, we have to see it in a grayscale setting, at least to check whether all the information is visible or not.

Deaf and Hard-of-Hearing People

People with impaired hearing may have a limited vocabulary. This is one of the problems with hearing-impaired people. Therefore new information and instructions must use simple language alongside cartoon-like presentation. They still require sounds to accompany the graphics. This also applies to anyone with any cognitive impairment.

Also:

- Give visual information (text and/or picture) that is redundant with audible information.
- Allow the users to configure frequency and volume of audible cues.
- Do not design interactions to depend upon the assumption that a user will hear audio information.
- For deaf and hard-of-hearing people to have access to multimedia applications, ways need to be developed to support the presentation of complex sounds and closed captioning for speech (Sik Lányi, 2006).

Physically Disabled Persons

The biggest problem for people with impaired fine motor ability is using the input devices. Remember:

- Do not design the navigation and input for use only by mouse, because the users might have bad motor ability.
- Do not design the navigation, input, and commands for use by voice input devices because of the control problem of facial muscles.
- Do not develop the navigation using multiple keys simultaneously.

Additionally, the multimedia software must be accessible via the keyboard, therefore it must be easy to use and have a good keyboard navigation system. Thus the task is to find the optimal navigation method for the mobility-impaired user. If the user does not has a special input device, navigation can be facilitated with a moving rectangle, the speed of which is adjustable, or through a voice-controlled navigation or command system (Sik Lányi, 2006).

Mentally Retarded

There is a wide variation of cognitive impairments that could be categorized as memory, perception, problem-solving, and conceptualizing disabilities. Memory disabilities include difficulty obtaining, recognizing, and retrieving information from short-term storage, as well as long-term and remote memory.

It is necessary to design multimedia software or Web pages in ways that minimize the skills and abilities required to navigate them. Auditory output might seem confusing to these users or be difficult for them to understand. The designers need to define terms that may not be known to cognitive disabled persons. Some suggestions include:

- Minimize the cognitive load while navigating in the software.
- Use graphics for navigation whenever possible.
- Avoid animated graphics and the use of overlaid large file sizes. Use animations and dynamic display with care.

Elderly Persons

As the years go by, everybody's ability, talent, and skills slowly but surely are wearing out; all is not lost that is delayed. An elderly person is lucky if he or she has only one health problem; in most cases, he or she has more. Therefore if designers develop multimedia software for the elderly, the designers must consider all the above-mentioned recommendations, as well as:

- For all special-needs users, software may have to include a higher degree of help than usual.
- To ensure software meets users' needs, the elderly must be involved in all stages of its development.

Schneiderman (2005, p. 15) states that designs should be based on careful observation of current users, refined by thoughtful analysis of task frequencies and sequences, and validated through early usability and thorough acceptance tests. Designers seek direct interaction with users during the design phase, development process, and throughout the system lifecycle. Iterative design methods that allow early testing of low-fidelity prototypes, revision based on feedback from users, and incremental refinements suggested by usability-test administrators are catalysts for high-quality systems. This system lifecycle is more proper if we develop for special-needs users. Finally, do not forget to consult

end users, teachers, and caretakers, and test the multimedia software with special-needs users too!

FUTURE TRENDS

The recent revolution in telemedicine, using the capabilities of telecommunication, multimedia, and information technologies to provide and support health care when distance separates participants and doctors, offers an opportunity to address the problem of the unequal geographical distribution of physicians and the lack of health care services in rural and urban districts. These communication systems are multimodal; the designer must develop barrier-free user interfaces that most of the users are able to use, or install them by individual needs. Ongoing advances in telemedicine (i.e., telecommunication, multimedia, and information technologies) are likely to change dramatically.

Current speech recognition systems have evolved technologically to begin having an impact in human computer interface designs that can be used by persons with motor disabilities. A real-time user-friendly programming HCI is able to convert voice commands into computer actions. These voice-controlled HCI systems would be the optimal support solutions for people with motor disabilities.

The future will be such multimedia systems, in which not only 2D information is available, but 3D as well. For example, a 3D virtual person (avatar) with the ability of artificial intelligence will help the user to control the interface, or to fill in an input window and so on.

Avatars—also called "embodied conversational agents" (Cassell, Sullivan, Prevost, & Churchill, 2000)—are the actors in a virtual reality world. They have the following attributes:

- They are similar to humans in their appearance—that is, on the exterior.
- Their movements are like real human movements and their gestures are also similar (hand gesture and face mimicry).
- They have a speech recognition module to understand human voices.
- They have artificial intelligence (Russel & Norvig, 2002) to give the user the correct answer, if there is one.
- They are able to utter an answer by means of a text-to-speech engine.
- They can simulate emotions in behavior and also in their facial expression. Their gestures change according to the way they feel.
- They have machine vision to recognize the user and the user's emotions, if this is necessary.
- The future multimedia systems are able to work together with assistive technology devices as well.

CONCLUSION

This article tried to answer some questions and made minimal guidelines to take into account when one wants to develop multimodal software. These guidelines are useful if one wants to develop multimodal software based on the nowadays-expected so-called "Design for All" or "universal design" theory. This chapter dealt with multimedia to be used by special-needs users and gave a minimal requirements' list for designers, software engineers, and computer scientists. Although research in the area of multimedia, HCI, disability, and AT has grown, and some important findings and guidelines have been proposed, our knowledge is still limited in some areas. There are a lot of unanswered questions.

KEY TERMS

Assistive Technology: A set of products, devices, or technical or software systems that are used by disabled, special-needs users. These could be serial or unique special products that help the disabled people's everyday life, and control or decrease the degree of the disability.

Design for All (DfA or D4All): Design of products, services, and systems (including information technology) to be accessible so that they are usable by the widest range of users as possible. Moreover these products, services, and systems should be usable by everybody including future generations, regardless of age, gender, capabilities, or cultural background.

Disability: A qualitative difference of a human capability from its normal feature, which might be in-born; if acquired, can develop backwards only very slowly; or can be permanent and irreversible. Types of disabilities include: physical impairment, sensory impairment, cognitive impairment, intellectual impairment, and/or cumulative impairment.

Health Condition: An alteration or attribute of the health of an individual that may lead to distress, interference with daily activities, or contact with health services; it may be a disease (acute or chronic), disorder, injury, or trauma, or may reflect other health-related states such as pregnancy, aging, stress, congenital anomaly, or genetic predisposition.

Human Computer Interaction (HCI): The study of how humans interact with computers and programs. HCI is a discipline concerned with the design, evaluation, and implementation of interactive computing systems for human use and with the study of major phenomena surrounding them.

Impairment: Indicates a loss or abnormality of a body part (i.e., structure) or body function (i.e., physiological function). The physiological functions include mental functions.

Multimedia: Manage in one unit text, graphics, animation, sound, and numeric data in an integrated way. This unit includes the production, storing, processing, transmission, representation, and reproduction of such information.

Multimodal: A software or hardware instrument is multimodal if it uses minimally two media elements, and one of them must be dependent on time—for example, video, sound, or animation files; the term mixed media is also used.

Special-Needs Users: Users who are not able to use the average devices or software in an average way. Handicapped people have special needs in daily requirements throughout their whole lives.

Music Score Watermarking

P. Nesi
University of Florence, Italy

M. Spinu
EXITECH S.r.L., Certaldo, Italy

INTRODUCTION

Music publishers, authors and/or distributors have high quantity of music scores in their archives. In classical music, the original music piece is normally kept in paper format, since its production goes back to many years ago. At present, only new light and popular music pieces are in symbolic notation formats. Light and popular music have a limited lifetime when compared with classical music pieces. The duration of the copyrights for that kind of music is about 60-80 years. Content owners are very cautious to transform their classical music pieces in digital format for e-commerce purposes, because they consider it as a highly risky process which could ultimately lose their copyright ownership. The situation is different when it comes to light and popular music, being market life shorter. According to content owners' opinion, e-commerce for music distribution cannot be accepted, unless adequate protection mechanisms are provided, as highlighted in WEDELMUSIC (www.wedelmusic.org) and MUSICNETWORK (www.interactivemusicnetwork.org). They accept to have their music protected only if it is possible to control while at the same time the users exploit content functionalities according to the established permissions and prices. To cope with these problems, mechanisms for protecting digital musical objects are used (see Table 1).

In this article, only problems and solutions for protecting and watermarking music scores are discussed.

Most music scores are still kept in paper format at publisher's archives. A first step to transform them into digital documents can be transforming them into images with a scanner. Another possible solution can be found in transforming them manually into symbolic music with a music editor. Obviously, this latter solution is very expensive, since the music has to be totally retyped. The use of very efficient Optical Music Recognition (OMR) software, similar to the Optical Character Recognition (OCR), seems to be quite unlikely in the next future. Currently, their recognition rate is close only to 90%, which makes this approach not too much reasonable when compared with retyping (www.interactivemusicnetwork.org, see assessment on the Working Group of Music Imaging).

Music images or symbolic music are obtained after music sheet digitalization. In the event of images, no further music manipulation is possible at the level of symbols. On the other hand, images can be easily viewed in any operating systems and with plenty of applications. The symbolic music gives several advantages in the score maintenance and manipulation; it allows the user to perform changes on the music, such as to justify it, change the page settings, add ornaments, accents, expressions, view single parts or the whole score, and so forth. The drawback consists in all these possible operations being performed only if the music editor is available: professional music sheets are produced by expensive and professional music editors.

It is well known that music sheets are distributed in paper format among musicians. Therefore, it seems that such digitizing process is useless. Practically speaking, Internet music sheet distribution, meaning from publishers to consumers, can only be achieved using digital formats. Distribution among users, as it occurs now with photocopies, could be made even via digital music sheets, as Napster did with audio files. Please note that on P2P (peer to peer) application there is also a quite significant distribution of music scores (www.interactive musicnetwork.org, read report on Music Distribution Models of the Working Group on Music distribution).

Table 1. Mechanisms for protecting digital musical objects

• encryption techniques to support any transferring of music objects;
• watermarking audio files in different formats;
• watermarking images of music score sheets;
• watermarking music sheets while they are printed from symbolic notation files.
• definition of digital rights management policies.

Whenever using digital formats, music could be converted again into paper (today musicians play music only from paper sheets).

BACKGROUND

The most relevant features for algorithms of score watermarking can be summed up into three categories (Monsignori, Nesi, & Spinu, 2003):

- *Content Requirements:*
  The embedded data may contain a simple identification code, which allows to recover the publisher and the distribution IDs simply by consulting a Web service. To this end, hiding about 100 bits is typically enough. The code can be encrypted, compressed and may include control and redundant bits to increase robustness.
- *Visual Requirements:*
  The watermark inserted in the printed music sheet has to be invisible for musicians or at least it should not bother musicians during their execution.
  The watermark has to be included in the music printed by the final user in any format if the music is available in symbolic format. Therefore, the watermark reading has not to depend on the availability of the original reference image of the music sheet.
- *Resistance Requirements:*
  The cost to remove watermark must be extremely expensive when compared to any regular purchase of the same music sheet.
  The watermark must resist against music sheet manipulation until the music printed becomes unreadable. Typically, five levels of photocopy are enough to make music unreadable or of a very bad quality.
  The watermark has to be readable when processing each single page or smaller part.

In addition, there are other parameters to be taken into account in order to analyze the technique capability.

- The amount of embedded information has a direct influence on watermark robustness. Typically, the hidden code is repeated several times in the same page; therefore, the bigger is the code, the lower is the number of times such code can be repeated, which means a decrease in the general robustness.
- Embedding strength " There is a trade-off between watermark embedding robustness and quality. Increased robustness requires a massive embedding of hidden bits. This increases music score degradation and watermark visibility.

Please note that watermarking images of scores or watermarking symbolic music lead to the same result: a watermarked music sheet. The watermarked music (symbolic or image) should be kept in some unchangeable digital file formats (like PDF) or in some formats difficult to change (PostScript), image format. The implementations of the algorithms for music watermarking in such two events are completely different (Busch, Nesi, Schmucker, & Spinu, 2002). In the first event, the watermarking is performed while the music score is printed by manipulating graphic primitives such as lines, music fonts, and so forth, and the process may generate a PostScript file or may send the information directly to the printer. In the latter case, the watermarking is performed by manipulating the B/W images.

In order to read the watermarked hidden code, the music sheet has to be scanned and the resulted image has to be elaborated with the watermark reader, to reconstruct the embedded code. The main advantages of distributing symbolic music sheets, instead of images are:

- Lower number of bytes for coding music, easier distribution, lower costs of download, and so forth;
- Higher quality of the printed music sheets, depending on the printer of the final user;
- Possibility of manipulating music notation for transposing, adding annotation, rearranging, and so forth; and
- Possibility of performing a direct music execution from symbolic format to produce MIDI or extended MIDI formats.

All of these features make the use of symbolic music more interesting for music distribution, and therefore its watermarking is very important for music protection.

APPROACHES

According to the user requirements, the printed music sheets must be produced at high resolution and quality. In appreciated music sheets, there is no noise, meaning that the information is in black and white, and therefore no space is left to hide information inside noise or in any kind of noise added-image. This means that the hidden code can be included only under the shape or in the position of music notation symbols. According to such purpose, some common elements of music sheets can be considered: staff lines, stems, note head, bar lines, and so forth. While stepping into such a direction, it is necessary to find a compromise between quality and watermark readability. Quality is very important for musicians and some minor changes could produce readability problems to musicians. They pay attention to the design of musical symbols, and any detectable variation may disturb the musician when playing. In general, the information to

Figure 1. Stem rotation approach

be hidden can be included in the changes considering both their presence and absence, for instance, coding 1 and 0 respectively. In some cases, the magnitude of the change can be used to hide more bits, for example in the orientation, the angle can be variable in order to add more bits.

Stem Rotation

The greatest problems of hiding information in the stem rotation (Busch, Rademer, Schmucker, & Wothusen, 2000) cope with the music score degradation and the low capacity in terms of hidden bits. As depicted in Figure 1, an untrained musician can identify that kind of changes in the music score. This method bothers many musicians when the music is read. In addition, the original music page is needed for watermark reading.

Beam Thickness Modification

By modifying the orientation or thickness of beam lines, it is possible to hide only a few bits. Another important problem has to deal with the presence of beams which is not guaranteed in the music page. Musicians may easily detect the thickness variation when the beam is placed near a staff line. Furthermore, this method requires the original music page in order to perform the watermark reading.

Noteheads Shifting

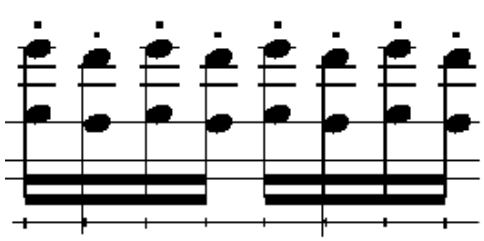
The approach chosen by Schmucker, Busch, and Pant (2001) consists in shifting note heads (see Figure 2). The distance among notes has a musical significance. Therefore, in several cases, the approach may disturb the music reading. In Figure 2, the second chord from the left was moved to left, and musicians may detect the missed alignment of the chords. The displacement has been highlighted with the line below the staff and the gray lines. The movement of notes may generate problems when notes are marked with ornaments, accents, expressions, and so forth. In such cases, the movement becomes evident, thus creating a misalignment of notes with the markers. The idea can work things out and hide a significant code length, if there are enough noteheads in the score page.

If considering the main score, the shifted notes are quite easy to be detected by musicians reading them (according to the needs of simultaneity among parts/layers/voices), while it turns out to be quite invisible in single parts. Such a watermark is easy to be detected by musicians in regular groups of notes, provided that the distance among successive notes of the same beam is non-regular/periodic.

Different Fonts for the Same Music Symbol

According to this technique, different fonts for the selected music symbols are used to hide either 1 or 0, depending on the font used. This implies that the font has to be easily recognized during watermark reading. The approach was proposed for text watermarking by Maxemchuk and Low (1997).

Figure 2. Shifting beamed notes approach



Watermarking Images of Music Sheets

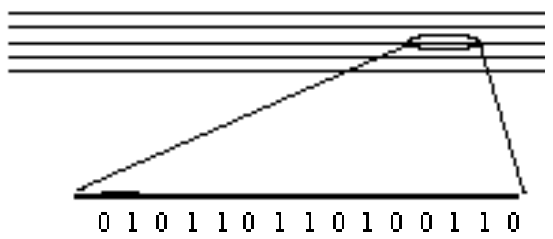
The proposed methods are based on the possibility of storing information by exploiting the relationship of black and white pixels in image segments (i.e., a block) as information carrier (Funk & Schmucker, 2001). The method was elaborated upon Zhao and Koch method (1995) which is based on blocks of distinct size. The ratio of white and black pixels in certain block/area is used to embed a watermark. These areas are treated differently in the process of flipping pixels. The final idea is to embed the watermark only on the black pixels belonging to the staff lines. The fact that the pixel is on a line does not guarantee that it is on the staff line. For this purpose, only horizontal segment having a length greater than a fixed threshold was considered.

Line Thickness Modulation Approach

Figure 3 shows an example of the line modulation. It consists in modifying the lines' thickness in order to insert a binary code made up of several bits. Modulated lines can be easily noted if their presence is known, whereas they are not perceived if their presence is unknown (Monsignori, Nesi, & Spinu, 2001a, 2001b). This approach allows to hide a considerable number of bits in several instances per page, thus making the solution particularly suitable and robust to permit the watermark reading, even out of small parts of the music sheet. This approach has been used in the WEDELMUSIC Editor.

The approach is robust with respect to staff bending, since the watermark is repeated on a large number of staff lines, and it can be read on bended lines. Moreover, a total of 108 bits can be hidden, and a certain number of CRC codes to increase the robustness has been added. This approach can be implemented only starting from the symbolic representation of music notation since the direct manipulation of staff lines on the image may introduce too much noise and produce line deformation.

Figure 3. Staff lines thickness modification



Line Mask Approach

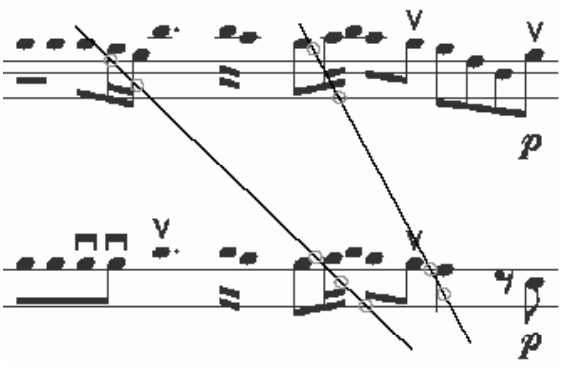
This watermarking approach can be applied to images of music sheet or during the print out of a music score from a symbolic music notation file. The approach consists in marking some points in the music score for virtually hiding a number of lines connecting them (Monsignori et al., 2001a, 2001b). The position and the orientation of the hidden lines are used as the vehicle to hide the watermark code. In particular, the angle between the hidden line and the vertical axis has been used for hiding the information. The idea is not based on writing black lines on the music score (this may only lead up to destroy the music sheet). The points identifying the hidden line may be placed in the intersection among the hidden line and the staff lines, like it occurred with the points in Figure 4, highlighted with circles (in reality, they are interruption on the staff line). In the solution taken, groups of the lines contributing to encoding the same code start from common points. The method allows to hide a large number of bits for each page, and the code can be repeated several time increasing the robustness.

APPROACH VALIDATION

For the validation of these solutions two different phases have to be followed (Monsignori et al., 2003). First, the validation has to be technically performed to assess the robustness against the attacks mentioned at the beginning of this article and to verify the effective coding of a large number of bits, repeated several times per page. As a second phase, the validation has to be focused on verifying the real applicability and acceptability of the solution from experts.

The experts' group has to cover the different needs: publishers, engravers, copyists, and many musicians which are the final users. Therefore, they are a very important category for the watermark validation. A specific watermark approach can be unacceptable for the musicians if the

Figure 4. Points chosen to be marked in the music score



music sheet is not readable or annoying for the presence of evident changes. Typically, copyists are the most exigent. The validation has to request the assessment of a sequence of several different music score pages. Some of them are watermarked; others are not. Different levels of photocopy of the same watermarked or not watermarked music sheets have to be included. Different resolutions (dpi of the printer) of the same music sheets have also been used to assess the minimum acceptance level people involved in the validation. All music sheets were printed at the same magnitude, thus the dimension of the staff line was constant. Its value has been chosen according to that most commonly used in printed sheets.

Experts were informed about the main concepts of watermarking and not about these specific changes made in the music score. They have to perform the assessment individually, without being left with the possibility of a comparison with different pages of music and an exchange of opinions among one another.

FUTURE TRENDS AND CONCLUSIONS

As discussed in this article, the technology of music sheet watermarking is quite mature. Several algorithms have been tested and validated on real applications. The effective value of these solutions is similar to the watermark of Audio file. The presence of a specific watermark in the music sheet may be used to demonstrate the ownership of a music piece over the simple presence of textual fingerprints. In addition, the presence of the watermark can discourage people from any possible and intentional copying action of the music sheet for business purposes. The simple copying of the music sheet among friends is not prevented. The future trends of this technology are mainly in its application for monitoring the distribution of music sheets. In fact, the score watermark can be used for hiding code that can be detected during the simple distribution. This permits the content owners to set up specific services to control the data flow and thus to control and detect the passage of their digital items on the network.

KEY TERMS

Fingerprinting: Used for calling the hidden serial numbers or anything else that should allow to the copyright owner to identify which reseller broke the license agreement. It is used for the multilevel document distribution.

Fragile Watermarking: Techniques that do not guarantee the watermark presence after few document manipulations.

Image Score: An image obtained from a page of music sheet, it can include a main score or a part.

Optical Music Recognition (OMR): Optical recognition of music, transcoding of an image score to a symbolic score format by using a specific algorithm, called OMR.

Robust Copyright Marking: A term used for the techniques that assure a watermark persistence also after the original document was changed in different ways (in the case of the images: cropping, resizing, brightness modification, etc.).

Staff Line: Each single line of the music score staff. The pentagram is made of five staff lines.

Steganography: Techniques that allow secret communication, usually by embedding or hiding the secret information (called embedded data) in other, unsuspected data. Steganographic methods are based on the assumption that the existence of the covert communication is unknown and they are mainly used in secret point-to-point communication between trusting parties. As a result, steganographic methods are usually not robust, that is the hidden information cannot be recovered after data manipulation.

Symbolic Score: A representation of the music notation in symbolic, including a description of music symbols and their relationships. This can be done in some formal specific format such as Finale, Sibelius, WEDELMUSIC, HIFF, SMDL, and so forth.

Watermark: The code hidden into a digital or analog object containing an ID (identification) code or other pieces of information. The watermark is used for identifying the fields of embedded data (serial numbers, logos, etc.) that tell us who is the owner of the object or supply an ID in order to identify data connected with the digital object.

Watermarking: Process of inserting a hidden code or message into a digital or analog object. As opposed to steganography, it has the additional notion of robustness against attacks. As the name suggests, the additional data (the watermark) is added in order to protect the digital document from copyright infringements. Even if the existence of the hidden information is known, it has to be hard for an attacker to destroy the embedded watermark without destroying the data itself.

Watermark Reading: Process of extracting the watermarked code into the watermarked object.

This work was previously published in Encyclopedia of Information Science and Technology, edited by M. Khosrow-Pour, pp. 2074-2079, copyright 2005 by Information Science Reference, formerly known as Idea Group Reference (an imprint of IGI Global).

Neo-Symbiosis

Douglas Griffith
General Dynamics AIS, USA

Frank L. Greitzer
Pacific Northwest Laboratory, USA

INTRODUCTION

The purpose of this article is to re-address the vision of human-computer symbiosis expressed by J. C. R. Licklider nearly a half century ago, when he wrote: "The hope is that in not too many years, human brains and computing machines will be coupled together very tightly, and that the resulting partnership will think as no human brain has ever thought and process data in a way not approached by the information-handling machines we know today" (Licklider, 1960). Unfortunately, little progress was made toward this vision over 4 decades following Licklider's challenge, despite significant advancements in the fields of human factors and computer science. Licklider's vision was largely forgotten. However, recent advances in information science and technology, psychology, and neuroscience have rekindled the potential of making the Licklider's vision a reality. This article provides a historical context for and updates the vision, and it argues that such a vision is needed as a unifying framework for advancing IS&T.

BACKGROUND

Licklider's statement is breathtaking for its vision, especially considering the state of computer technology at that time, that is, large mainframes, punch cards, and batch processing. It is curious to note that Licklider did not use the term symbiosis again, but he did introduce more visionary ideas in a symbiotic vein. An article he co-authored with Robert Taylor titled *The Computer As a Communication Device* made the bold assertion, "In a few years, men will be able to communicate more effectively through a machine than face to face" (Licklider & Taylor, 1968). Clearly, the time estimate was optimistic, but the vision was noteworthy. Licklider and Taylor described the role of the computer in effective communication by introducing the concept of "On-Line Interactive Vicarious Expediter and Responder" (OLIVER), an acronym that by no coincidence was chosen to honor artificial intelligence researcher and the father of machine perception, Oliver Selfridge. OLIVER would be able to take notes when so directed, would know what you do, what you read, what you buy and where to buy it. It would know your friends and acquaintances and would know who and what is important to you. This article made heavy use of the concept of "mental models," which was relatively new to the psychology of that day. The computer was conceived of as an active participant rather than as a passive communication device. Remember that when this article was written, computers were large devices used by specialists. The age of personal computing was off in the future.

Born during World War II, the field of human factors engineering gained prominence for its research on the placement of controls, widely known as knobology, which was an unjust characterization. Many important contributions were made to the design of aircraft, including controls and displays. With strong roots in research on human performance and human errors, the field gained prominence through the work of many leaders in the field who came out of the military: Alphonse Chapanis, a psychologist and a Lieutenant in the U.S. Air Force; Alexander Williams, a psychologist and naval aviator; Air Force Colonel Paul Fitts; and J.C.R. Licklider. Beginning with Chapanis, who realized that "pilot errors" were most often cockpit design errors that could be corrected by the application of human factors to display and controls, these early educators were instrumental in launching the discipline of aviation psychology and human factors engineering that led to worldwide standards in the aviation industry. These men were influential in demonstrating that the military and aviation industry could benefit from research and expertise of the human factors academic community; their works (Fitts, 1951) were inspirational in guiding research and design in engineering psychology for decades. Among the most influential early articles in the field that came out of this academic discipline was George Miller's (1956) "The Magical Number Seven, Plus or Minus Two: Some Limits on Our Capacity to Process Information," which helped to usher in the field of cognitive science and application of more quantitative approaches to the study of cognitive activity and performance.

An early focus of human factors engineering was to design systems informed by known human information processing limitations and capabilities, systems that exploit our cognitive strengths and accommodate our weaknesses (inspired by the early ideas represented in the Fitts' List that compared human and machine capabilities (1951). While the early HFE practice emphasized improvements in the design of equipment to make up for human limitations (reflecting a tradition of *machine centered computing*), a new way

of thinking about human factors was characterized by the design of the human-machine system, or more generally, *human-* or *user-centered computing* (Norman & Draper, 1986). The new subdiscipline of interaction design emerged in the 1970s and 1980s that emphasizes the need to organize information in ways to help reduce clutter and "information overload" and to help cope with design challenges for next-generation systems that will be increasingly complex while being staffed with fewer people.

There have also been theoretical developments in cognitive psychology that provide a foundation for Licklider's vision. Central here is the work by Kahneman (2002, 2003). In his effort to reconcile seemingly contradictory results in studies of judgment under uncertainty, he has advanced the notion of two cognitive systems introduced by Sloman (1996) and others (Stanovich & West, 2002). System 1, termed Intuition, is fast, parallel, automatic, effortless, associative, slow-learning, and emotional. System 2, termed Reasoning, is slow, serial, controlled, effortful, rule-governed, flexible, and neutral. Cognitive illusions, which were part of the work for which he won the Nobel Prize, as well as perceptual illusions, are the results of System 1 processing. Expertise is primarily a resident of System 1 as is most of our skilled performance such as recognition, speaking, and driving. System 2, on the other hand, consists of conscious operations and is commonly thought of as thinking.

System 1 is effective presumably due to evolutionary forces, massive experience, and by constraining context. Most of the time it works quite effectively. System 1 uses nonconscious heuristics to achieve these efficiencies, so occasionally it errs and misfires. Such misfires are responsible for perceptual and cognitive errors. One of the roles of System 2 is to monitor the outputs of System 1 processes.

NEO-SYMBIOSIS: A VISION AND FRAMEWORK FOR CONDUCTING RESEARCH

Licklider's notion of symbiosis does require updating. The term "man/computer symbiosis" is both politically incorrect and factually inaccurate. "Human/machine symbiosis" is preferable. There is also a problem with the term symbiosis itself. Symbiosis implies a co-equality between mutually supportive organisms. However, humans must be in the superordinate position. Dreyfus (1972, 1979, 1992) has made compelling arguments that there are fundamental limitations to what computers can accomplish, limitations that will never be overcome. In this case it is important that the human remain in the superordinate position so that these computer limitations can be circumvented. At the other extreme, Kurzweil (1999) has argued for the unlimited potential of computers. Should it be proven that computers, too, have this unlimited potential, then some attention needs to be paid to Bill Joy and his nightmarish vision of the future should technology go awry (Joy, 2000). In this case, we humans would need to be in the superordinate position for our own survival. Griffith (2005) has introduced the term neo-symbiosis for this updated version of symbiosis.

Kahneman's two system theory plays a central role in neo-symbiosis. It is the System 2 processes that require computer support, not only with respect to the pure drudgery and slowness of System 2 processes, but also with respect to the monitoring of System 1 processes. In most cases, it is a mistake to assign System 1 processes to the computer. This was the fundamental error in many automatic target recognition and image interpretation algorithms that attempted to automate the human out of the loop. The perceptual recognition processes of most humans are quite good. System design should capitalize upon these superb processes and provide support to other areas of human information processing such as search (to overcome a tendency to overlook targets), interpretation keys to provide support for the recognition processes. Other types of System 2 support could include the augmentation (not replacement) of human reasoning processes, support to facilitate adjusting to changes in context to maintain situational awareness and computational support.

A related approach is Joint Cognitive Systems (JCS's) (Hollnagel & Woods, 2005; Woods & Hollnagel, 2006), which represents a specific implementation of cognitive systems engineering. As the term JCS implies, this approach views the human-computer system as a combination of human and machine cognition. Another way of looking at this is that the human is a component of the computer architecture (consistent with our view of neo-symbiosis). In their two volumes, Hollnagel and Woods have developed a sophisticated approach to system design, but it does not draw much from either cognitive psychology or cognitive neuroscience. Neo-symbiosis draws liberally from both cognitive psychology and cognitive neuroscience. In our view, neo-symbiosis is a subset of cognitive systems engineering that may be applied to enrich the field through its focus on human cognition and the supervisory role of humans in joint cognitive systems.

Another related approach is hedonomics. Hedonomics (Hancock, Pepe, & Murphy, 2005) can most easily be thought of as designing technology to climb Maslow's (1970) Hierarchy of Needs. According to Maslow, human needs can be arranged in a hierarchy or pyramid beginning with physiological needs at the base, then proceeding up to safety, love and belonging, self-esteem, and ending with self-actualization at the top. An interesting exercise is to consider how technology can, and sometimes does, facilitate meeting these needs. Hedonomics is certainly in the spirit of neo-symbiosis. Both hedonomics and neo-symbiosis have the same destination. But in its present state, hedonomics presents what is effectively a *brochure* of the destination,

whereas neo-symbiosis provides some *direction* as to how to get to that destination.

Augmented cognition (Schmorrow & Kruse, 2004; Schmorrow, Stanney, & Reeves, 2006; see also Greitzer, 2005) holds much relevance and potential for neo-symbiosis. The program was initiated within the Defense Advanced Research Projects Agency (DARPA) Information Processing Technology Office (IPTO) with the aim to monitor and assess the user's cognitive state through behaviorally- and physiologically-derived measures acquired from the user while interacting with the system, and then to adapt or augment the computational interface to improve performance of the human-computer system. Clearly, the effort here is to address human information processing shortcomings, that is, to augment cognition. A theoretical framework is needed to identify what aspects of human cognition to augment. Greitzer and Griffith (2006) proposed neo-symbiosis, through Kahneman's two system model of cognition, for that theoretical framework. Thought also needs to be given to how human cognition can augment machine cognition in other than a trivial sense. Such human-computer collaboration is needed to realize Licklider's vision of an interaction between humans and computers so that produced levels of performance are achieved that have never been achieved before.

Although it is important to augment human cognition, it is equally important to consider how to leverage human cognition. Consider chess expertise, for example. Rather than trying to build chess playing systems that can defeat grandmasters, why not try to build systems with the grand master in the architecture to achieve unseen levels of chess playing performance. Tournaments could be run in which joint human/computer chess playing systems would compete. This calls to mind the Amazon Mechanical Turk Program (http://www.mturk.com/mturk/welcome) in which humans are invited to be used in programmatic ways by computers to solve problems that the computer can't solve.

FUTURE TRENDS

We shall consider alternative future trends from two different perspectives, a pessimistic perspective in which Licklider's vision is not fully realized, and an optimistic perspective in which desired outcomes and trends do occur. Let us first consider the trends we hope to see in the future.

A most significant facet of this trend will be the occurrence of a revolution in thinking. In a neo-symbiotic system, the human is superordinate. Because system design is theory driven, the system addresses human cognitive shortcomings and leverages human cognitive strengths. To do so requires a model of the human user. There are two levels of user models. One is a generic or nomothetic user model. Essentially, Kahneman's two system model of cognition provides the basis for a nomothetic user model, and there are many human factors handbooks that can assist in building nomothetic models. A second type of user model is an idiosyncratic user model, one that is specific to a particular human user. For example, the chess grand master system envisioned above requires an idiosyncratic model of a specific grand master. In the future, we hope to see systems that develop and refine models of specific human supervisor/partners (users) as a result of interaction with the computers. This is done to a limited extent today, but we envision that this will be taken to new levels of detail and sophistication. It is hoped that research in augmented cognition will become theory driven and will achieve advances to this end. That is, specific cognitive shortcomings would be remedied and specific cognitive strengths would be leveraged.

An article by Griffith and Greitzer (2007) develops a research agenda for neo-symbiosis. This is derived from Kahneman's two system model. Note that the identification of neurological correlates, although potentially helpful and holding vast potential, is not a requirement, nor is it the only enabler for neo-symbiosis. The article shows how requirements can be written to facilitate neo-symbiotic design. The authors also discuss the need for more attention on metrics to assess the extent to which neo-symbiosis has been achieved

Griffith (2006) has argued that neo-symbiosis can be achieved over a wide range of technological sophistication and describes some of its social and political ramifications. In business and industry, for example, the goal of replacing workers with technology would be superseded by using technology to enhance the potential and productivity of workers though their interaction with the technology.

So the bright future for neo-symbiosis is one of increased productivity and fulfillment: That is, people will not only be more productive, but also more fulfilled. They will proceed further up Maslow's hierarchy of needs. People will be happier. Life will be good.

But what if we ignore Licklider's vision? One could argue that the destination will remain the same, but that the journey will take longer. It seems that one could make an argument to this effect along evolutionary lines. A less happy possibility is that we never arrive. We continue to use technology in a non-optimal manner, failing even to address rudimentary usability issues. We fail to achieve the potential and happiness offered by technology as a result of deficient concepts regarding how to think about technology. Yet another scenario is that technology advances, but humanity declines. That is, humans become mentally lazy and potentialities decline as computers are assigned the challenging work. Of course, the most nightmarish vision is that of Bill Joy (2000). Here machines become intelligent and decide that we are no longer needed. The future continues without us.

CONCLUSION

Symbiosis was a metaphor for a vision advanced by Licklider early in the new era of IS&T. Neo-symbiosis is an updating of that vision. We have argued that advances in cognitive theory and computer technology have provided the basis for the realization of that vision. Related approaches have been reviewed. The JCS approach combines human and machine cognition into the architecture. Neo-symbiosis agrees that they need to be combined into the architecture. Hedonomics argues that technology should be viewed as a means for human fulfillment, as does neo-symbiosis. Augmented cognition places heavy emphasis of physiological indices to enhance cognition. Neo-symbiosis is interested in more than enhancing cognition, however. It is also interested in leveraging human cognition so that, in Licklider's words "… the resulting partnership will think as no human brain has ever thought and process data in a way not approached by the information processing machines…". Neo-symbiosis not only provides a goal, but also provides a theoretical basis for achieving that goal.

We have also described several alternative futures. If one takes an evolutionary perspective, we might eventually achieve Licklider's vision, but perhaps not as quickly compared to a more deliberate approach. We also speculated about some darker alternative futures in which humanity cedes the field to technology.

KEY TERMS

Augmented Cognition: This area of research seeks methods for addressing cognitive bottlenecks (e.g., limitations in attention, memory, learning, comprehension, visualization abilities, and decision making) to extend human information management capacity via technologies that assess the user's cognitive status in real time.

Cognitive Systems Engineering: This is a design philosophy that advances a broad system design perspective employing modeling concepts from engineering, psychology, cognitive science, information science, and computer science, emphasizing human cognitive processes in system design.

Hedonomics: This is a design philosophy that considers a hierarchy of human needs in system design.

Human Centered Design: This is a design philosophy that emphasizes the needs and abilities of the user in the design of a system.

Human Factors: This is the field devoted to understanding and applying the properties of human capabilities to the design and development of systems with the aim of improving operational performance and safety.

Joint Cognitive Systems (JCS's): This design philosophy regards a system as a whole comprising people and technology acting together.

Neo-Symbiosis: This is an updating of Licklider's vision in which technology is placed in a subordinate role to the human.

Symbiosis: This is Licklider's vision that in not too many years, human brains and computing machines will be coupled together very tightly, and that the resulting partnership will think as no human brain has ever thought and process data in a way not approached by the information-handling machines we know today.

Two System Theory of Cognition: Although there are a number of two system theories, this refers to Kahneman's concept of Intuitive and Reasoning systems.

Network Effects of Knowledge Diffusion in Network Economy

INTRODUCTION

Network industries are the central nervous system of the 21st century economy. During this time the newly developing "network economy" will act as the engine that will drive world development (Bao, 2001). The most valuable commodity in this economy has become information, and the economics of networks applies to almost all information products and services. Information can be consumed by more than one person. Most importantly, the total social value of information increases as it is shared with more consumers. Consumers of computers and software programs, cellular phones, faxes, and Internet services all have more valuable products as the use of these products by others increases. Whether we call this an "information economy" or a "network economy," the implication is the same—network economics accounts for an increasingly larger share of the economy. It is also the driving force behind many of the innovations and technological changes that occur (Balto, 2001).

At the same time, knowledge is nowadays considered to be a fundamental asset of the organizations. Although this concept is not new, in the few last years increasing attention has been devoted to knowledge and knowledge management (KM) issues within organizations. In fact, due to environmental factors such as the market globalization, the increased product complexity, and the turbulence of competitive scenarios, the powerful role of knowledge as a source of sustainable advantage has been considerably emphasized (Zack, 1999). The knowledge economy represents a strategic new era that human beings are entering. In this new environment of social and economic development, knowledge and information are recognized as being at least as important as physical capital, financial capital, and natural resources as a source of economic growth.

Network economy has provided an equal platform for the participation of all of society. It creates unique values and establishes an operational system in the globalization context, depending on the knowledge as core resource, utilizing the network as the fundamental mode, and taking the information industry as leadership. However, in the knowledge economy, networks are adapted better to knowledge-rich environments because of their superior information-processing capabilities. They minimize idiosyncratic investments in fixed assets and technology, and thus are more flexible and responsive to change. "In an economy where the only certainty is uncertainty, the only sure source of lasting competitive advantage is knowledge" (Nonaka, 1994). And one of the most important aspects is that network economy needs to utilize the knowledge diffusion to create more value. Because knowledge diffusion is the core process of knowledge management to explore more network effects and knowledge diffusion is important for total factor productivity, it is also important for international competitiveness. In consequence, knowledge diffusion should be regarded as one of the companies' core competencies.

BACKGROUND

Although interest in how knowledge diffusion plays a role during the network economy era is relatively new, considerable work has been done in the past on related topics. The study of knowledge diffusion and technology transfer is rooted in agriculture, the military, and education (Backer, 1991; Glaser, Abelson, & Garrison, 1983; Rogers, 1983, 1988, 1995). Perhaps one of the best known of technology transfer formulations is Rogers's (1983, 1995) "Diffusion of Innovations" theory. Diffusion is the process by which an innovation is communicated through certain channels over time among the members of a social system" (Rogers, 1995, p. 5) The field of knowledge diffusion and technology transfer explores the strategies by which knowledge is disseminated and put to use, its benefits and shortcomings, and the policy and practice implications stemming from its application (Backer, 1991). This field represents a cross-disciplinary body of work that has produced an estimated

10,000 literature citations (Backer, 1991) and is widely used in the public health, education, and agricultural fields (Rogers, 1995). Initially conceptualized as a linear process, theories of diffusion and technology transfer have been modified to reflect the dynamic, interactive nature of knowledge dissemination and application (Smale, 1993). Moreover, the knowledge diffusion field has developed a number of important premises or conceptual frameworks. Chat can be useful in addressing the ways in which innovations or new technology is spread. Dunn, Holzner, and Zaltman (1985), backed by a body of literature and experiences in the field of knowledge diffusion dating back to Merton (1968), formulated the following four premises: (1) knowledge use is interpretative, (2) knowledge use is socially constrained, (3) knowledge use is systemic, and (4) knowledge use is transactive.

Network Economy and Knowledge Diffusion

The network economy means that, in view of the widespread use of computer networks in the socioeconomic era, all economic activities are based on the unification of the information transmission and processing in Internet platform, and the economic information cost sharply drops down. This phenomenon is leading to the idea that the information which replaces capital plays a dominant role in economy management and eventually becomes a globalization economic form of the core economic resources. It does not narrowly refer to the industries that are centering on the computer networks, or vigorous developing industries concerned, or the emerging industries. It also includes the combination and infiltration of computer networks and traditional industries, as well as the economic form that is reducing production and transaction costs and increasing productivity level; the result is information has turned to the most important power of industrial development and innovation. The greatest advantage of the network economy lies in accelerating the flow of information and reducing information costs. This influence penetrates the economic life of production, exchange, distribution, and consumption, which have changed the cost structure and other features of these links.

In the process of endogenous growth of knowledge, the endogenous economic growth model stressed the role of the transfer of knowledge. But many of the current studies focused on the role of technology transfer; it has not paid enough attention to the knowledge—the origin of technology. In terms of the implication of the knowledge economy, it includes four basic economics areas: knowledge production, knowledge accumulation, knowledge exchange, and knowledge distribution. These four basic aspects are inseparable from knowledge diffusion. The nature of the knowledge determines the knowledge production bred in the process of the dissemination and the use of knowledge. The knowledge exchange is only a typical state of knowledge diffusion, while the distribution and accumulation of knowledge is only the result of the knowledge diffusion.

There is an authoritative view that nobody will be able to develop better resources and have more wealth without more and better knowledge. Knowledge is not only a symbol of wealth, but also a source of wealth. Only when people can use their own comprehensive grasp of scientific knowledge can knowledge be transformed into wealth.

Tapscott, Lowy, and Ticoll (1998) thought the operational system of the network economy had the following characteristics:

- It is the knowledgeable and digital economic network that is gradually changing the economic metabolism of the world, changing the type of the organization and the institution and nature of economic activities.
- It is the molecular formula structure network.
- All stratifications of the network economic society already transformed from centralized form to discrete form.
- The individual dynamic portfolio gradually substitutes for the old large enterprise, and companies are weaving increasingly complex webs for each other in order to obtain more wealth.
- It is the globalization innovation network and the integration of production and consumption.
- The communication and the cooperation own the instantaneity.

In brief, “the network” and “the knowledge” already became the fundamental mode and the core soul of the network economy.

Network Effects of Knowledge Diffusion

Knowledge may be classified into various categories depending on the purpose of its use. Polanyi (1962) classified knowledge into explicit and tacit knowledge. Explicit knowledge refers to knowledge that is codified in formal, systematic language (encoded knowledge). It is knowledge that can be combined, stored, retrieved, and transmitted with relative ease and through various mechanisms. Tacit knowledge refers to knowledge that is so deeply rooted in the human body and mind that it is hard to codify and communicate. It is knowledge that can only be expressed through action, commitment, and involvement in a specific context and locality. Tacit and explicit knowledge are often treated as separate entities, but it is unlikely that a piece of knowledge will be exclusively explicit or tacit. Knowledge can exist in both forms simultaneously throughout an organization. Knowledge diffusion occurs routinely within organizations.

Knowledge is not static, but fluid; it is absorbed by individuals who interpret, modify, and use it for their own purposes. In particular, two patterns of knowledge diffusion have been documented. First, knowledge flows are geographically localized (Jaffe, Trajtenberg, & Henderson 1993). Second, knowledge diffuses more easily within a firm than between firms (Kogut & Zander, 1992).

Knowledge diffusion has three parts: besides the two parts of knowledge transfer (Davenport, Prusak, 1998)—transmission (sending knowledge to a recipient) and absorption (assimilation and use of knowledge by recipient)—there is a retransfer process. If absorption did not take place, knowledge cannot be said to have successfully transferred. Not to be ignored is that innovation occurred during the whole process of knowledge diffusion. As a result of the difference of the environment, knowledge foundation, principal part of knowledge exchange, innovation occurred during the process of knowledge diffusion; the process of knowledge diffusion is not only the transfer of originality but also the promotion of the second diffusion at the same time. The network effect precisely plays its effectiveness in the knowledge diffusion process. Knowledge value in the network has the accumulation and the transfer effect. The scattered, one-sided, disorderly materials and data may be processed by knowledge according to the users' requirements to review, analyze, and synthesize, thus forming the effective information resource. When the scope of knowledge use is large enough, knowledge networks utilize a special system that will allow each behavior to use the network, or contact the network automatically available and automatically integrated in the network. The sources of knowledge change into integrated knowledge of spontaneous generation or even a higher level, greater value. In addition to the cumulative effect, knowledge also has transfer effect. If knowledge average cost is fixed, the scope of knowledge use is larger and the benefits produced are greater. The online knowledge self-accumulation increment and transfer effect, as well as the work experience, can promote "learn by doing." A predecessor's research indicated that the cumulative effects caused by enterprise investment in information and knowledge produce a spillover effect on other enterprises and even the entire economy. Under certain conditions, marginal returns of knowledge unceasingly increase.

Positive feedback, network effects, and economies of scale are always based on the question of compatibility and network standards. For a network as an information technology, the larger the compatibility, the more transitional costs there are and the stronger are lock-in effects. The diffusion of human knowledge—following the self-expansion of the tongue and interpersonal media, the language and print media, and the digital and electronic media—realizes the optimal resource allocation and diversion and cooperation, and saves plenty of cost. People can share more information, and efficiency would be added. The faster the diffusion, the more expensive the value of the knowledge and corresponding media, even that becoming the most common standards. Media networks include the print media carrying language and electronic media carrying voices and pictures, as well as interpersonal media (face-to-face communications and friendly intercourses). Joining such a network is valuable precisely because many other households and businesses obtain components of the overall system. Diffusion is a process that transforms from the old knowledge network to the new knowledge network through the media, the large network that both types of knowledge share and which is compatible with the foundation environment of knowledge.

To realize the strategy of the network effects of knowledge diffusion requires the following two aspects. From the static aspect, the compatible strategy and tactics of revolution can be adopted. We can weigh and balance the relationship between function and compatibility, and open up and monopolize knowledge diffusion strategies in different market structures. Based on the relationship, there are four different strategies triggered by the new knowledge diffusion to the market that can stimulate the network effect: monopoly transfer, function performing, open-up transfer, and interruption.

From the dynamic aspect, we can find a complete knowledge diffusion process. Firstly, design the market strategies of knowledge diffusion, demonstrate the prominent function to corner the market. Secondly, improve compatibility and others' acceptance through repeated explanations and the establishment of extensive alliances. Finally, lead people to innovate the new knowledge. With the market changes, the strategies change responsively. Through the implementation of such strategies, a knowledge diffusion network will effectively transform knowledge into value, promote innovation, and accelerate the development of the knowledge economy.

FUTURE TRENDS

Peter Drucker (1991) has described the economy of the future as a network society. Business networks are not entirely new, but there has been a rapid evolution in their number, form, and complexity:

- Business networks are replacing traditional markets and vertically integrated companies.
- Global competition is pushing companies to focus on their core competitive competencies.
- IT is lowering transaction costs and providing tools to manage increasingly complex inter-company collaboration.
- Networks are better adapted to knowledge-rich environments because, compared with hierarchical orga-

nizations, they have superior information processing capacity and flexible governance.
- Empowered by new digital media, network organizations are expected to take a lead in creating economic and social innovations.

Therefore, firms are weaving increasingly complex webs of production and customer service, and of innovation and knowledge creation. Knowledge is becoming the most important source of growth as well as productivity. Information means competitive advantage, and knowledge leads to progress. The keys to the strong economic and cultural growth of a nation's future are successful generation, acquisition, diffusion, and exploitation of knowledge.

CONCLUSION

This article describes how knowledge diffusion plays a positive role in the network economy. First, this article analyzes the relationship between network economy and knowledge diffusion, and discusses the media network and characteristics of knowledge diffusion. Furthermore, this article carries on the analysis with the knowledge diffusion network effects by static analysis and dynamic analysis. Finally, the article discusses how to realize the network effect of knowledge diffusion. In conclusion, the elaborate integration of the network economy with knowledge diffusion to create network effects is proposed. This research can provide new vision for information technology to develop in the knowledge economy era.

The prevailing demands of the knowledge economy are challenging organizations worldwide to harness knowledge capital more extensively and innovatively to create greater socioeconomic value. For the coming, distinctively knowledge-based millennium, leaders have singled out intensive knowledge-driven innovation as the decisive success factor for all organizations. It should be reckoned that effective knowledge diffusion will enhance the benefits arising from strategic alliances and ensure enterprises achieve the strategic objectives of existing and future investment activities during the network economy.

KEY TERMS

Knowledge: Derived from individuals transforming data and information in a processing hierarchy that enables action (Wilson, 1996).

Knowledge Diffusion: The adaptations and applications of knowledge documented in scientific publications and patents.

Knowledge Economy: Based on the production, the assignment, and the application of knowledge and information.

Knowledge Innovation: A process to utilize experimental research and development activities and empirical practice activities to promote the knowledge that the technical innovation and the system innovation need.

Knowledge Management: Creating, acquiring, interpreting, retaining, and transferring knowledge to improve performance by purposefully modifying behavior based on new knowledge.

Knowledge Transfer: The process by which knowledge is transmitted to, and absorbed by, a user.

Network Economy: All economic activities based on the unification of information transmission and processing in an Internet platform.

Network Effect: A phenomenon whereby a service becomes more valuable as more people use it, thereby encouraging ever-increasing numbers of adopters.

Network Worms

Thomas M. Chen

INTRODUCTION

Internet users are currently plagued by an assortment of malicious software (malware). The Internet provides not only connectivity for network services such as e-mail and Web browsing, but also an environment for the spread of malware between computers. Users can be affected even if their computers are not vulnerable to malware. For example, fast-spreading worms can cause widespread congestion that will bring down network services.

Worms and viruses are both common types of self-replicating malware but differ in their method of replication (Grimes, 2001; Harley, Slade, & Gattiker, 2001; Szor, 2005). A computer virus depends on hijacking control of another (host) program to attach a copy of its virus code to more files or programs. When the newly infected program is executed, the virus code is also executed. In contrast, a worm is a standalone program that does not depend on other programs (Nazario, 2004). It replicates by searching for vulnerable targets through the network, and attempts to transfer a copy of itself. Worms are dependent on the network environment to spread. Over the years, the Internet has become a fertile environment for worms to thrive.

The constant exposure of computer users to worm threats from the Internet is a major concern. Another concern is the possible rate of infection. Because worms are automated programs, they can spread without any human action. The fastest time needed to infect a majority of Internet users is a matter of speculation, but some worry that a new worm outbreak could spread through the Internet much faster than defenses could detect and block it. The most reliable defenses are based on attack signatures. If a new worm does not have an existing signature, it could have some time to spread unhindered and complete its damage before a signature can be devised for it.

Perhaps a greater concern about worms is their role as vehicles for delivery of other malware in their payload. Once a worm has compromised a host victim, it can execute any payload. Historical examples of worms have included:

- **Trojan horses:** Software with a hidden malicious function, for example, to steal confidential data or open a backdoor;
- **Droppers:** Designed to facilitate downloading of other malware;
- **Bots:** Software to listen covertly for and execute remote commands, for example, to send spam or carry out a distributed denial of service (DDoS) attack.

These types of malware are not able to spread by themselves, and therefore take advantage of the self-replication characteristic of worms to spread.

This article presents a review of the historical development of worms, and an overview of worm anatomy from a functional perspective.

BACKGROUND

The term "worm" was created by John Shoch and Jon Hupp at Xerox PARC in 1979, inspired by the network-based multisegmented "tapeworm" monster in John Brunner's novel, *The Shockwave Rider* (Shoch & Hupp, 1982). They were aware of an earlier self-replicating program, Creeper, written by Bob Thomas at BBN, which propelled itself between nodes of the ARPANET. They invented a worm to traverse their internal Ethernet LAN seeking idle processors after normal working hours for the purpose of distributed computing. Because the worms were intended for beneficial uses among cooperative users, there was no attempt at stealth or malicious payload. Their worms were designed with limited lifetimes, and responsive to a special "kill" packet. Despite these safeguards, one of the worm programs believed to have been accidentally corrupted ran out of control and crashed several computers overnight.

The most famous worm incident was the Morris worm in November 1988 that disabled 6,000 computers in a few hours (Spafford, 1989). Robert Morris Jr. was a student at Cornell University at the time. The damage was caused by the worm re-infecting computers that were already infected, until the computers slowed down and crashed. It was probably the first worm to use a combination of methods to spread quickly. First, it attempted to crack password files on Unix systems. The password file was encrypted but publicly readable. The worm could encrypt password guesses and compare them to the contents of the password file. Second, it exploited

the debug option in the Unix sendmail program. Third, it carried out a buffer overflow exploit taking advantage of a vulnerability in the Unix finger daemon program.

Worm development was relatively slow until 1999, when e-mail became a popular infection vector. In March 1999, Melissa spread to 100,000 computers in 3 days, setting a new record and shutting down e-mail for many companies using Microsoft Exchange Server (CERT advisory CA-1999-04, 1999). It was a Microsoft Word macro that used the functions of Word and Outlook e-mail to propagate. When the macro is executed in Word, it launched Outlook and sent itself to 50 recipients found in the address book. Additionally, it infected the Word normal.dot template, so that any Word document created from the template would carry the infection.

In the summer of 1999, the PrettyPark worm propagated as an e-mail attachment called "Pretty Park.exe" with the icon of a character from the television show "South Park." If executed, it installed itself into the system folder and modified the registry to ensure that it ran whenever any .exe program was executed. It e-mailed itself to addresses found in the address book. Another worm, ExploreZip, appeared to be a WinZip file attachment in e-mail but was not really a zipped file. When executed, it displayed an error message but the worm secretly copied itself into the systems folder and loaded itself into the registry. It e-mailed itself using Outlook or Exchange to recipients found in unread messages in the inbox. It monitored all incoming messages and replied to senders with a copy of itself.

The summer of 2000 saw more mass mailing worms. In May 2000, the Love Letter worm appeared with the subject line "I love you" and encouraged the recipient to read the attachment which was a Visual Basic script (CERT advisory CA-2000-04, 2000). When executed, the worm installed copies of itself into the windows and system directories and modified the registry to ensure that it would be run during bootup. It infected various types of files (.vbs, .jpg, .mp3, etc.) on local drives and networked shared directories. If Outlook is installed, the worm e-mailed copies of itself to anyone found in the address book. In addition, the worm sent copies of itself via IRC channels.

Appearing around the same time, NewLove was a Visual Basic script worm. It was interesting as a polymorphic worm that tried to change its appearance in every copy. The worm forwarded itself with a file name chosen randomly from "recent documents" to all addresses in the Outlook address book. The e-mail has no text but has a subject line including the new file name.

In October 2000, the Hybris worm spread as an e-mail attachment (CERT incident note IN-2001-02, 2001). If executed, it modified the "wsock32.dll" file in order to track all Internet traffic at the infected host. For every e-mail sent, it subsequently sent a copy of itself to the same recipient. It had the interesting capability to receive plug-ins dynamically by connecting to a preprogrammed newsgroup. The plug-ins were encrypted and updated the worm code. This capability is potentially dangerous because the worm functionality can be changed at any time by the worm author.

A new wave of more sophisticated worms began in early 2001. In March 2001, the Lion worm spread among Linux computers using the "pscan" application, a freely distributed network port scanner written in Perl. The worm used this port scanner in combination with the "randb" program to scan class B hosts listening on TCP port 53 that were vulnerable to the BIND buffer overflow vulnerability. It then attacked these hosts using an exploit called "name." After a system was compromised, the worm stole password files and other sensitive information (IP address, accounts) and sent these by e-mail. It also installed several things: the t0rn rootkit to evade detection, the DDoS agent TFN2K, a Trojanized version of SSH to listen on port 33568, and backdoor root shells on TCP ports 60008 and 33567.

In May 2001, the Sadmind worm first exploited a buffer overflow vulnerability in Sun Solaris systems. These compromised systems were then used to carry out an attack to compromise Microsoft IIS (Internet Information Services) Web servers.

In July 2001, the Code Red worm caused major damages by exploiting a buffer overflow vulnerability discovered in Microsoft IIS Web servers about a month earlier (Berghel, 2001; Moore, Shannon, & Brown, 2001). Specifically, the Index Server ISAPI vulnerability allowed a remote attacker to gain full system level access (Microsoft Security Bulletin MS01-033, 2001). The first version of the Code Red worm appeared on July 12. On infected systems, it set up 100 parallel threads, each an exact replica of the worm, in order to spread faster. It attempted to generate pseudorandom IP addresses but used a static seed which (apparently unintentionally) resulted in identical lists of IP addresses. Although 200,000 hosts were infected in 6 days, the worm was slowed down by the fact that the same targets were getting hit repeatedly. A second version of Code Red appeared on July 19. This version spread much faster because the static seed had been changed to a random seed, ensuring that each copy of the worm generated different IP addresses. More than 359,000 computers were reportedly infected by Code Red version 2 within 14 hours. By design, the worm stopped by itself on July 20. On August 4, a new worm self-named Code Red II used the same buffer overflow exploit but a different payload. It generated random IP addresses but they are not completely random; about 1 out of 8 are completely random; 4 out of 8 addresses are within the same class A range of the infected host's address; and 3 out of 8 addresses are within the same class B range of the infected host's address. On infected systems, it activated 300 parallel threads to spread faster. The enormous number of parallel threads created a flood of scans, resulting in serious network congestion.

In September 2001, the Nimda worm used a combination of five methods to spread quickly: e-mail to addresses from the host's Web cache and default MAPI mailbox, with random subject lines and an attachment named "readme.exe"; attacked random Microsoft IIS Web servers though a buffer overflow vulnerability published a year earlier; copied itself across open network shares; added Javascript to Web pages to infect Web browsers; and looked for backdoors left by previous Code Red II and Sadmind worms. It was able to spread to 450,000 hosts within 12 hours. Although none of the methods was new, the combination of so many methods in one worm was unusually complex.

In November 2002, the Winevar worm was an example showing the capability to protect itself by disabling antivirus software. It used a list of keywords to scan memory to stop recognized antivirus processes and scan the hard drive to delete associated files.

In January 2003, the SQL Slammer (or Sapphire) worm spread among Microsoft SQL servers (Moore et al., 2003). Interestingly, the worm consists simply of a 376-byte payload in a single 404-byte UDP packet. This is advantageous for fast spreading because infected hosts can generate these short UDP packets quickly. Unlike TCP, UDP is connectionless and does not require a host to wait for a connection set up. Infected hosts were put into a simple loop to send UDP packets to randomly generated IP addresses as fast as possible. The packets carried an exploit for a buffer overflow vulnerability in Microsoft SQL Server discovered 6 months earlier (Microsoft Security Bulletin MS02-039, 2002).

The week of August 11, 2003, has been called one of the worst weeks in worm history. First, the Blaster (or Lovsan) worm exploited a DCOM RPC (distributed component object model remote procedure call) vulnerability in Windows 2000 and Windows XP systems. On vulnerable systems, the worm opened a remote shell process that transfers a file "msblast.exe" from an infected host. Seven days later, the Welchi (or Nachi) worm used the same exploit along with an exploit for a WebDAV vulnerability in Microsoft IIS 5.0 servers. Interestingly, Welchi attempted to remove Blaster from infected systems and applied the Microsoft patch for the RPC vulnerability. It was programmed to self terminate on January 1, 2004. One day after Welchi, the Sobig.F worm, the fifth variant of the original Sobig.A worm discovered in January 2003, spread by mass mailing. It spoofed the "from" address in e-mails with a randomly chosen address found on the victim's computer. It had the capability to download arbitrary files to an infected computer. It was used to set up spam relay servers and steal confidential system information. At preprogrammed times, it contacted a number of master servers to get download instructions. Around the same day, the Dumaru worm pretended to be a Microsoft patch "patch.exe" attachment in e-mail. If opened, the worm copies itself into the system directory and installs a Trojan horse that listens to an IRC channel for commands from the worm author.

2004 was notable for a conflict between the authors of MyDoom, Netsky, and Bagle, evidenced by messages embedded in the worm codes. The MyDoom.A worm appeared in January. It e-mailed itself to addresses harvested from various types of files on the infected host, along with various subject lines and attachment names. The payload contains a DDoS agent and a backdoor to download arbitrary files. Soon afterward, the Bagle worm spread similarly by e-mail and installed a Trojan horse that opened a backdoor to allow remote control. The Netsky family of worms, also mass mailers, appeared shortly afterward with comments embedded in its code directed at the authors of MyDoom and Bagle, and some variants contained code to remove them from infected hosts.

Although worms have continued to evolve since 2004, there have not been "big" worm outbreaks on the scale of Slammer or Code Red. Worm writers have seemed to be spending more efforts toward exploring new infection vectors, such as instant messaging, Internet relay chat (IRC), peer-to-peer file sharing, or SMS/MMS (short message service/multimedia messaging service). It could be said that worms are still perceived as a major threat but fading in importance compared to other emerging malware threats. Since 2005, concern has been gradually shifting away from worms toward other types of malware, namely bots, spyware, and rootkits.

Worm Anatomy

Worms must have certain functions in their code for self replication:

- **Target identification:** To locate new targets
- **Infection mechanism:** To compromise a new target
- **Replication:** To transfer a worm copy to a target.

Optionally, worms might contain timing control and a payload. Timing might be controlled for self termination; downloading plug-ins or worm code updates; downloading new malware to infected systems; or activation of the payload.

Worms do not always carry a payload, and payloads can be virtually anything. Payloads such as a DDoS agent might be activated by the timing control (e.g., to start flooding at the same time) (Mirkovic, Dietrich, Dittrich, & Reiher, 2004).

Target Identification

The simplest method to find new targets is randomly chosen IP addresses (essentially 32-bit numbers). However, this approach is not efficient. As more hosts become infected,

the spreading rate slows down due to infected hosts hitting targets that are already infected. This inefficiency creates excessive traffic in the network, which slows down the spreading rate further.

Worms such as Blaster and Code Red II have used more complicated algorithms for IP addresses. Blaster chose a random IP address only 60% of the time; at other times, it attempted to find an address in the same local network as the infected victim. Code Red II chose random IP addresses 1 out of 8 times; 4 out of 8 addresses were within the same class A range; and 3 out of 8 addresses were within the same class B range as the infected host.

Another popular method is to harvest e-mail addresses from the victim host. Early mass mailing worms starting with Melissa found addresses from the address book. More sophisticated worms such as MyDoom can harvest e-mail addresses from many types of files located on a victim. The rationale for targeting addresses found from a victim is that recipients are more likely to read e-mail if it was apparently sent from an acquaintance.

Infection Vectors

It is apparent from the historical review that worms can spread by any number of ways. Since 1999, e-mail has been one of the most popular infection vectors because: worms often carry their own SMTP engine; e-mail can take advantage of social engineering; messages can be easily forged and mutated; e-mail can take advantage of social connections which may be more effective than random contacts.

Worms can also exploit vulnerabilities. The most common type of exploit is a buffer overflow because: it can usually be done remotely; it can give complete control over a target; and buffer overflow vulnerabilities are found in many operating systems and applications (Foster, Osipov, & Bhalla, 2005). Even the early Morris worm used a buffer overflow exploit.

Worms such as Lirva and Fizzer were able to spread by file sharing, namely the KaZaa peer-to-peer network. The worm resides in a shared folder, usually with a harmless name.

Worms can spread by messaging via instant messaging or IRC (Internet relay chat). The 2003 Lirva worm was able to spread by IRC. An infected file or URL is sent to a chat channel. In March 2005, the Kelvir family of worms began to spread by instant messaging via MSN Messenger. Random looking messages contained a link to a Web site which attempted to download files. When downloaded and executed, the worm continues to spread by sending instant messages to all found MSN messenger contacts.

Additional infection vectors include: password cracking (e.g., Morris worm); copy to open network shares; modification of Web sites for drive-by downloading; taking advantage of backdoors left by previous worms or Trojan horses (e.g., Nimda worm); and spreading by Bluetooth, SMS/MMS (short message service/multimedia messaging service), or other wireless connections (Hypponen, 2006).

Payloads

The optional payload of a worm is executed after a new victim has been compromised. Some worms have no payloads, and the reason is not known for certain. A payload could be virtually anything. In past cases, common payloads have included: bots to control a group of infected hosts as a bot net (Schiller & Binkley, 2007); spam relay servers to generate spam; backdoors to allow covert remote access; DDoS agents such as TFN2K; spyware, key loggers, and other Trojan horses; and rootkits to evade detection. While destructive payloads are entirely possible, it might be counterproductive, resulting in slower spreading and more attention from security experts.

The payload is often considered to be a clue to the worm author's motivations. When a payload is absent, the worm might be a proof of concept (e.g., to see how fast it could spread). Payloads for spamming or stealing personal information suggests a profit motive.

FUTURE TRENDS

Although widespread outbreaks of fast-spreading worms have been less common since 2003, worms are still a serious threat according to most surveys of organizations. The nature of the threat has simply continued to evolve.

First, worms continue to expand to new infection vectors. For example, the Cabir worm in June 2004 was the first to spread by Bluetooth between Symbian smartphones (Hypponen, 2006). This was followed by the ComWar worm in March 2005 using MMS as the infection vector. ComWar was followed shortly by the Mabir worm which was able to spread by both MMS and Bluetooth.

Second, there has been a growing prevalence of payloads oriented toward control (bots, backdoors, rootkits) and financial profit (spyware, keyloggers). Anti-spyware and rootkit detection programs are quickly becoming essential protection for computer users. These other types of malware do not have to be delivered by worms. For example, malware can spread by drive-by-downloading at a malicious Web site. But worms continue to be a popular vehicle to deliver a variety of malware.

Third, social engineering continues to be common. Malware writers have been quick to take advantage of interest in current events to entice e-mail recipients to read spam. Another example is one of the most prevalent worms in 2006 was the Nyxem (or Blackmal or "Kama Sutra") worm which offered sexually provocative subject lines and body texts.

CONCLUSION

Worm evolution has progressed from early experimentation to sophisticate vehicles for other types of malware. Worms are commonplace on the Internet and threaten to expand to other networking environments such as wireless.

Unfortunately, the nature of the worm threat is essentially similar to other criminal activities. Worms are created by criminals, and it is impossible to predict how new worms will be invented. Thus, defenses are always catching up to new attacks. There are natural questions that may always be somewhat uncertain. For instance, when will another major worm outbreak happen? How fast could a worm spread and what damage will be caused? Continued research is needed to address these questions.

KEY TERMS

Computer Virus: A set of program instructions capable of self replication by attaching to a normal host file or program.

Exploit: Code written to take advantage of a specific vulnerability.

Infection Vector: The transmission channel for spreading an infection.

Malicious Software (malware): The broad variety of software containing a harmful function, such as viruses, worms, and Trojan horses.

Payload: The part of a virus or worm that is executed after a target host has been successfully compromised and infected.

Social Engineering: A type of attack taking advantage of human gullibility.

Vulnerability: A weakness or bug in software programs that could lead to a security compromise if exploited.

Worm: An automated standalone program capable of self replication by copying itself to vulnerable hosts through a network.

Networked Virtual Environments

INTRODUCTION

The inherent need of humans to communicate acted as the moving force for the formation, expansion and wide adoption of the Internet. The need for communication and collaboration from distance resulted in the evolution of the primitive services originally offered (i.e., e-mail) to advanced applications, which offer a high sense of realism to the user, forming a reality, the so-called virtual reality. Even though virtual environments were first introduced as stand alone applications, which could run on a single computer, the promising functionalities of this new form of representation and interaction as well as the familiarity of the users with it drew increased research interest. This fact resulted in virtual reality to be viewed as the solution for achieving communication and collaboration between scattered users, in various areas of interest, such as entertainment, learning, training, etc. This led to the creation of Networked Virtual Environments (NVEs). In particular, NVEs were first introduced in the 1980's and the first areas that exploited the newborn technology were military and entertainment applications. In particular, the U.S Department of Defense played an important role to the direction of applications, protocols and architectures for this promising technology. In the 1990's, where academic networks became a reality, NVEs drew increased academic research interest and a variety of applications and platforms were developed. In particular, the academic community has reinvented, extended, and documented what the Department of Defense has done. The evolution and the results extracted by research on this field were widely adopted from multiple areas of interest, with main representative the entertainment area.

Since 2000, where virtual reality technology, processing power of computers and the network were significantly improved, a wide variety of systems, protocols and applications were developed. In particular, the familiarization the end users with the Internet and the promising advantages and opportunities of Virtual Reality contributed to currently view NVEs as an effective tool for supporting communication and collaboration of scattered users. Currently, the application areas of NVEs have been widely expanded and their use can be found at military and industrial team training, collaborative design and engineering, multiplayer games (Zyda, 2005), mobile entertainment, virtual shopping malls, online tradeshows and conferences, remote customer support, distance learning and training, science, arts, industry, etc. Summarizing, NVEs nowadays tend to consist a powerful tool for communication and collaboration, with applications ranging from entertainment and teleshopping to engineering and medicine. To this direction, in the recent years important active research on this topic in both academic and industrial research is taking place.

BACKGROUND

NVE is a twofold term. Even though the "Virtual Environments" part prevails, the "networked" substance changes the meaning and nature of these environments. Regarding the Virtual Environment, it can be considered as a simulation generated by a computer, which can simulate either an imaginary or real world. Even though Virtual Environments can be two-dimensional, the term is mainly related to three-dimensional environments that aim at providing to the users a high sense of realism by incorporating realistic 3D graphics and stereo sound, to create an immersive experience. As far as it concerns the "networked" part of the term, this dimension is mainly related to the support of multiple concurrent users, scattered around the globe, even though NVEs can be single user applications. A definition provided by Singhal and Zyda (1999) states that "NVEs are software systems that can support multiple users, which can interact both with each other and with the environment in real time and aim at providing to the users a high-sense of realism by incorporating 3D graphics and multimedia."

The concept of a NVE is simple. Two or more users can view the Virtual Environment (VE) on their computer, having their own local copy of the virtual world. For achieving

high-sense of realism and maintaining consistency, when a user performs actions on one computer, these actions are propagated through the network to other participating computers for keeping all copies of the VE synchronized. The participants constitute active parts of the VE, usually represented by human-like entities, called avatars for enhancing the awareness (Joslin, Pandzic & Thalmann, 2003).

As mentioned earleir, the network constitutes the core of NVEs. However, NVEs can be further categorized by their architectural model or the nature, in terms of the kind of application they plan to support (Macedonia, 1997). In particular, regarding the architectural model, the most popular category of NVEs are the Distributed Virtual Environments (DVEs), where active parts of the virtual environment are scattered to different computers, which are connected through the network. Accordingly, in respect to the nature of these environments, one of the major categories are the Collaborative Virtual Environments (CVEs), where the users have the ability to meet and interact with others, with agents and the objects of the virtual environment.

MAIN ISSUES AND CONCEPTS IN NVES

A NVE constitutes a computer system, which generates virtual worlds, where the users can interact both with the system and the other connected users in real time. The users are connected to the Internet and working on different computers, access the same virtual scene. The simulation of the virtual scenes is realized through distributed and heterogeneous computational resources. The evolution of the software applications and services in combination to the melioration of the network allows for the development of networked applications, which are characterized by the enhancement and combination of many advanced features. For NVEs in particular, where the achievement of high realism constitutes a key concept, the realistic and detailed representation of the provided information is of high importance. Therefore, the potentialities that technology presents in combination to the increased needs of the users result in NVEs to adopt rich representation for the information in terms of graphics and media.

Despite the fairly simple concept, the design of NVE systems involves a complex interaction of several domains of Computer Science. In particular the interacting domains are the following: (a) networking, which is related to the transmission of various types of data with different requirements in terms of latency, bitrate, and so forth, (b) simulation, which is related to the virtual environment and involves visual database management and rendering techniques with real time optimizations, (c) human-computer interaction, which is related to the support of various types of devices, (d) virtual human simulation, which is related to the avatar's realistic representation in terms of facial expressions, motions, and so forth, and (e) artificial intelligence involving decision making processes and autonomous behaviors (Joslin et al., 2003).

This section will present the basic issues related to NVEs, in terms of the basic features they need to support, the components necessary, in terms of the hardware needed for their operation and interaction with the users, the most common architectures adopted for supporting such environments, the technologies and protocols for their development as well as the issues and factors that should be taken into account for assuring a good performance.

Basic Characteristics

As mentioned above, NVEs can represent either a real or imaginary world. Thus, the structure, the space, the objects and the functionalities provided in such an environment may significantly vary in respect to the concept they aim to support. However, for achieving a high sense of realism, NVEs are characterized by some common features. In particular, these environments should provide: (a) a shared sense of space, in terms of creating the illusion to the users that they are being located in the same place, (b) a shared sense of presence, which is mainly related to the virtual representation of the users that is commonly realized through human-like personas called avatars as well as to the visibility of others participants entering or leaving the environment, (c) a shared sense of time, in terms of being able to see other participants' actions when they occur, (d) a way to communicate, which can be achieved through gestures, typed text and voice and finally (e) a way to share, in terms of being able to interact realistically not only with other participants but also with the virtual environment itself (Singhal & Zyda, 1999). The support of the above-mentioned characteristics is critical for the successful simulation of reality and vital for the effective communication and collaboration of the participating users.

Basic Components

In terms of the hardware needed for NVEs, four components are found necessary for the correct and successful operation of these environments. In particular the components needed are: (a) graphics engines and displays, which constitute the cornerstone of the user interface and the users' "window" to the environment, (b) communication and control devices (e.g., keyboard, mouse, joystick, dataglove, head mounted display, motion detectors in full-body immersive environments), which allow and support the manipulation of the objects of the environment as well as the navigation and interaction of the user with the environment, (c) processing systems for computing and determining the transmission of the events that take place within a virtual environment and

last but not least (d) data network for the actual communication, transmission of information and sharing of data. The components work together for achieving and maintaining the sense of realism among the scattered users.

Architectures

From a more technical point of view, the architectures that support these types of software systems usually fall into one of the following cases: (a) client-server architectures, where the clients communicate their changes to one or more servers and these servers, in turn, are responsible for the redistribution of the received information to all connected clients and (b) peer-to-peer architectures, where the clients communicate directly their modifications and updates of the world to all connected clients (McGregor, Kapolka, Zyda & Brutzman, 2003). The case of the client-server model is the most simple but it is cannot support high scalability as there is a central point of failure, the server. As far as it concerns the peer-to-peer model the scalability is restricted by the network. It should be mentioned that hybrid solutions can be adopted, in regard to the specific needs and the type of the application that each system aims to support. However, there are hybrid architectures, which adopt the simple client-server model with peer-to-peer communication among groups of servers or with server hierarchies, where certain servers act as clients to others. In addition, the client-server and peer-to-peer structures can be integrated into peer-server architectures, where some data packets are transmitted through certain nodes using peer-to-peer while other data are transmitted though a server.

Technologies and Protocols

This subsection presents some of the commonly used technologies for the creation of 3D content as well as the protocols available for the support of the networking feature of the NVEs.

3D Internet Technologies for NVEs

There is a large number of technologies for the development of 3D content, each of which provides certain functionality. Some of the most know 3D technologies are (Diehl, 2001): VRML, Extensible 3D (X3D) and Java3D API. These technologies vary on the way an object/model is represented, on their ability to support animations, whether they provide a programming interface, whether they support streaming, and so forth. It becomes clear that the selection of an appropriate technology depends on the needs and requirements of the application developed. The main standard in this area is X3D, which is the open standard for Web-delivered three-dimensional graphics. It specifies a declarative geometry definition language, a run-time engine, and an application programming interface (API) that provide an interactive, animated, real-time environment for 3D graphics (Daly & Brutzman, 2007). As described in Bouras, Panagopoulos, and Tsiatsos (2005) there are some X3D enabled NVEs platforms as well as possible solutions for migrating from a VRML based multiuser platform to X3D available.

Protocols

The protocols used for the support of NVEs depend mainly on the networking solution that each system adopts. For NVEs the protocols most commonly used are the following: at the network layer the Internet Protocol (IP) and at the Transport Layer the Transmission Control Protocol (TCP), the User Datagram Protocol (UDP) and the Multicast IP protocol. It should also be mentioned that for Distributed Virtual Environments, which constitute a subset of NVEs there are additional protocols, which meet the specific needs of this type of applications and are the following: the Distributed Interactive Simulation (DIS) protocol, the Distributed Worlds Transfer and Communication Protocol (DWTP) (Broll, 1997), the Multi-User 3D Protocol (Mu3D) (Galli & Luo, 2000) and the Virtual Reality Transfer Protocol (VRTP) (Brutzman, Zyda, Watsen & Macedonia, 1997). As stated in (Diehl, 2001) there is no protocol able to serve all types of applications equally. Thus, based on the type and requirements of the developed application the appropriate protocol should be adopted for optimized performance and results.

Design and Development Challenges

The complexity of NVEs is mainly related to the need and desire to achieve a high-sense of realism. This fact results in applications that need to include multiple traditional software types, rich graphics, and compatibility with other applications. The networked nature of these environments is an additional factor that affects their complexity, in terms both of the development and deployment. In particular, NVE development is a difficult balancing act of trade-offs, as there are a number of factors that should be taken into account for optimizing the networking performance of the system (Diehl, 2001). These factors are: (a) the network bandwidth, which constitutes a limited resource and therefore the allocation of its capacity should be carefully determined, (b) heterogeneity, which is related to the quality of service that users with diverse equipment (e.g., processing system, network connection, graphic resolution) can achieve, (c) distributed interaction, which is related to the fact that the system must provide each user with the illusion that the entire environment is located on the local machine and that the actions of the users have a direct and immediate impact on the environment, (d) the real-time system design and resource management,

which defines the process and thread architecture of the application, (e) the failure management that concerns the reaction of the system in a possible failure and its impact on the users' view, (f) the scalability, which is related to the need for supporting a larger number of concurrent users and finally (g) the deployment and configuration, in terms of how the software will be accessible by the end users. It is very difficult to determine a formula that can satisfy all the aforementioned factors and resolve the limitations that each of them introduces, as the dependency among them is strong and improving one's behavior can affect other component's behavior as well (Singhal & Zyda, 1999). Therefore, based on the specific type of the application as well as its target group the developers need to specify their priorities for the design and development.

FUTURE TRENDS

As stated previously, NVEs are complex systems, which incorporate a number of applications and different technologies. In particular, the NVEs currently developed are prototyping the information infrastructure of the next century in terms of advanced networking, virtual reality, high performance computing, data mining, and human/computer interactions. Thus, there is a wide range of areas that can be further developed and improved for the optimization of these environments and their wider adaptation. Based on the fact that NVEs allow multiple participants to collaborate using high-speed networks connecting heterogeneous computing resources and large data stores, NVEs could further extend the human/computer paradigm so as to include human/computer/human collaborations. Another direction that draws increased interest for NVEs is the ability to efficiently support large-scale applications. The term "large-scale" refers both to the data size (in terms of virtual space and graphics) as well as to the concurrent number of users that can participate (Bouras, Giannaka, Panagopoulos & Tsiatsos, 2006). To this direction, research has already begun producing techniques and algorithms for achieving this challenging task. Moreover, the need for an advanced sense of realism seems to emerge, especially where the relationship between the virtual world and the everyday physical world is concerned (Benford, Greenhalgh Rodden & Pycock, 2001) while ubiquitous, mobile, and wearable computing promises to make access to digital information universal and continual. Finally, many ideas and technological solutions could be adopted by 3D games technology in order to use these environments to support other applications. As Zyda (2007) said, "the same technology that makes interactive 3D games so entertaining in the physical action domain is just as effective in education, training, and other more serious applications."

CONCLUSION

In this chapter we presented the basic issues of NVEs. The areas covered were: the basic characteristic and components of NVEs, the architectures, technologies and protocols available for their development as well as some design and development issues that should be taken into account when designing and developing a NVE. It is obvious that, as technological challenges are overcome, NVE systems tend to become more and more powerful communication and collaboration tools on various fields of interest.

KEY TERMS

CVE: Collaborative Virtual Environment is an extension of a NVE which aims at a collaborative task. CVEs aim to provide an integrated, explicit and persistent context for cooperation that combines both the participants and their information into a common display space. These objectives create the potential to support a broad range of cooperative applications such as training.

DIS: Distributed Interactive Simulation is an open standard for conducting real-time platform-level wargaming across multiple host computers and is used worldwide especially by military organizations but also by other agencies such as those involved in space exploration and medicine.

DVE: Distributed Virtual Environment is an NVE where active parts of the virtual environment are scattered to different computers, which are connected through the network.

HLA: High Level Architecture is a general purpose architecture for distributed computer simulation systems. Using HLA, computer simulations can communicate to other computer simulations regardless of the computing platforms.

Java 3D API: The Java 3D API is a hierarchy of Java classes which serve as the interface to a sophisticated three-dimensional graphics and sound rendering system. Java 3D provides high-level constructs to create and manipulate 3D geometry, and to build the structures used to render that geometry.

NVE: Networked Virtual Environment is a virtual environment that allows a group of geographically separated users to interact in real time

X3D: Extensible 3D is the open standard for Web-delivered 3D graphics. It specifies a declarative geometry definition language, a run-time engine, and an application programming interface that provide an interactive, animated, real-time environment for 3D graphics.

VE: Virtual Environment is a computer-generated simulation with which the user can interact in such a way that he receives real time feedback aiming to provide its users with a sense of realism.

VR: Virtual reality is a technology which allows a user to interact with a computer-simulated environment.

VRML: Virtual Reality Modeling Language is a standard file format for representing 3D interactive vector graphics, designed particularly with the World Wide Web in mind.

Neural Networks for Automobile Insurance Pricing

Ai Cheo Yeo
Monash University, Australia

INTRODUCTION

In highly competitive industries, customer retention has received much attention. Customer retention is an important issue, as loyal customers tend to produce greater cash flow and profits, are less sensitive to price, bring along new customers and do not require any acquisition or start-up costs.

BACKGROUND

Various techniques have been used to analyse customer retention. Eiben, Koudijs and Slisser (1998) applied genetic programming, rough set analysis, Chi-square Automatic Interaction Detection (CHAID) and logistic regression analysis to the problem of customer retention modelling, using a database of a financial company. Models created by these techniques were used to gain insights into factors influencing customer behaviour and to make predictions on customers ending their relationship with the company. Kowalczyk and Slisser (1997) used rough sets to identify key factors that influence customer retention of a mutual fund investment company. Ng, Lui and Kwah (1998) integrated various techniques such as decision-tree induction, deviation analysis and multiple concept-level association rules to form an intuitive approach to gauging customers' loyalty and predicting their likelihood of defection.

Mozer and his co-researchers (2000) explored techniques from statistical machine learning to predict churn and based on these predictions to determine what incentives should be offered to subscribers of wireless telecommunications to improve retention and maximise profitability of the carrier. The techniques included logit regression, decision trees, neural networks and boosting. Besides Mozer and his co-researchers, others have also applied neural networks to churn prediction problems. Behara and Lemmink (1994) used the neural network approach to evaluate the impact of quality improvements on a customer's decision to remain loyal to an auto-manufacturer's dealership. Wray and Bejou (1994) examined the factors that seem to be important in explaining customer loyalty. They found that neural networks have a better predictive power than the conventional analytic techniques such as multiple regression. Smith, Willis and Brooks (2000) also found that neural networks provided the best results for classifying insurance policy holders as likely to renew or terminate their policies compared to regression and decision tree modelling.

PREDICTING RETENTION RATES

We have also used neural networks to learn to distinguish insurance policy holders who are likely to terminate their policies from those who are likely to renew in order to predict the retention rate prior to price sensitivity analysis. Policy holders of an Australian motor insurance company are classified into 30 risk groups based on their demographic and policy information using k-means clustering (Yeo, Smith, Willis & Brooks, 2001, 2003). Neural networks are then used to model the effect of premium price change on whether a policy holder will renew or terminate his or her policy. A multilayered feedforward neural network was constructed for each of the clusters with 25 inputs and 1 output (whether the policy holder renews or terminates the contract).

Several experiments were carried out on a few clusters to determine the most appropriate number of hidden neurons and the activation function. Twenty hidden neurons and the hyperbolic tangent activation function were used for the neural networks for all the clusters. A uniform approach is preferred to enable the straight-forward application of the methodology to all clusters, without the need for extensive experimentation by the company in the future. Input variables that were skewed were log transformed.

Some of the issues we encountered in using neural networks to determine the effect of premium price change on whether a policy holder will renew or terminate his or her policy were:

- Determining the threshold for classifying policy holders into those who terminate and those who renew
- Generating more homogenous models
- Clusters that had too few policy holders to train the neural networks

Determining Threshold

The neural network produces output between zero and one, which is the probability that that a policy holder will ter-

minate his or her policy. Figure 1 shows the probability of termination of Cluster 11. A threshold value is used to decide how to categorise the output data. For example a threshold of 0.5 means that if the probability of termination is more than 0.5, then the policy will be classified as terminated. Usually the decision threshold is chosen to maximise the classification accuracy. However, in our case we are more concerned with achieving a predicted termination rate that is equal to the actual termination rate. This is because we are more concerned with the performance of the portfolio (balancing market share with profitability) rather than whether an individual will renew or terminate his or her policy. The actual termination rate for cluster 11 is 14.7%. To obtain a predicted termination rate of 14.7%, the threshold was set at 0.204 (see Figure 1). The confusion matrix for a threshold of 0.204 is shown in Table 1. The overall classification accuracy is 85.3%.

Generating more homogeneous models

The confusion matrix provides the prediction accuracy of the whole cluster. It does not tell us how a given percentage change in premium will impact termination rates. To determine how well the neural networks were able to predict termination rates for varying amounts of premium changes, the clusters were then divided into various bands of premium as follows: decrease in premiums of less than 22.5%, premium decrease between 17.5% and 22.5%, premium decrease between 12.5% and 17.5% and so on. The predicted termination rates were then compared to the actual termination rates. For all the clusters the prediction accuracy of the neural networks starts to deteriorate when premium increases are between 10% and 20%. Figure 2 shows the actual and predicted termination rates for one of the clusters (Cluster 24).

In order to improve the prediction accuracy, the cluster was then split at the point when prediction accuracy starts to deteriorate. This is to isolate those policy holders with a significant increase in premium. It is believed that these policy holders behave differently due to a greater number of these policy holders who have upgraded their vehicles. Two separate neural networks were trained for each cluster. The prediction accuracy improved significantly with two neural networks as can be seen from Figure 3. The average absolute deviation decreased from 10.3% to 2.4%.

Combining Small Clusters

Some of the smaller clusters had too few policy holders to train the neural networks. We grouped the small clusters that had fewer than 7,000 policies. The criterion for grouping was similarity in risk. Risk in turn is measured by the amount of claims. Therefore the clusters were grouped according to similarity in claim cost. The maximum difference in average claim cost per policy was no more than $50. For the combined clusters, prediction ability is also improved by having two neural networks instead of one for each cluster.

PRICE SENSITIVITY ANALYSIS

Having trained neural networks for all the clusters, sensitivity analysis was then performed on the neural networks to determine the effect of premium changes on termination rates for each cluster. There are several ways of performing the sensitivity analysis:

One approach is based on systematic variation of variables (SVV). To determine the impact that a particular input variable has on the output, we need to hold all the other inputs to some fixed value and vary only the input of interest while we monitor the change in outputs (Anderson, Aberg & Jacobsson, 2000; Bigus, 1996).

A more automated approach is to keep track of the error terms computed during the backpropagation step. By computing the error all the way back to the input layer, we have

Figure 1. Determining the threshold value of the neural network output

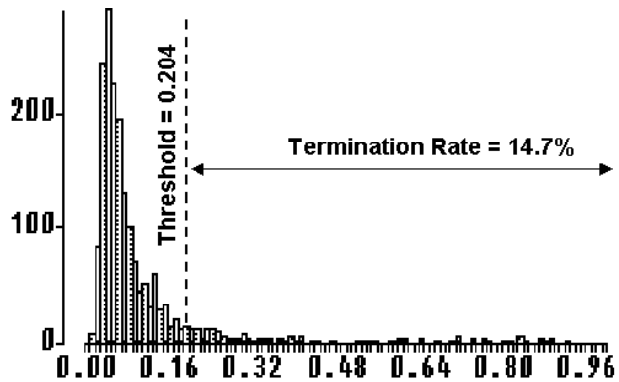

Table 1. Confusion matrix for cluster 11 with decision threshold = 0.204

	Classified as		
Actual	Terminated	Renewed	Total
Terminated	841 (50.0%)	842 (50.0%)	1,683
Renewed	845 (8.6%)	8,935 (91.4%)	9,780
Total	1,686	9,777	11,463
Overall Accuracy			85.3%

Figure 2. Prediction accuracy for one neural network model of cluster 24

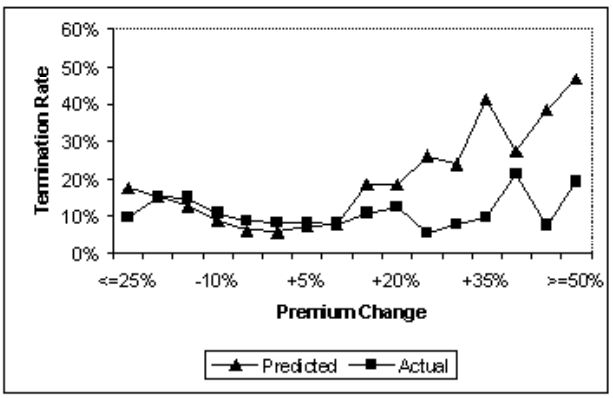

Figure 3. Prediction accuracy for two networks model of cluster 24

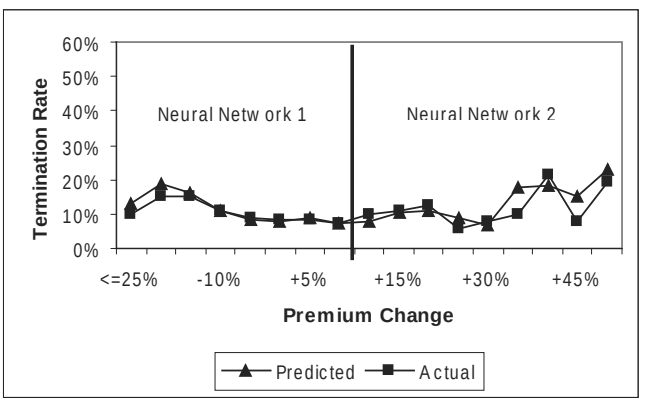

Table 2. Price sensitivity analysis – effect on termination rate (Cluster 24)

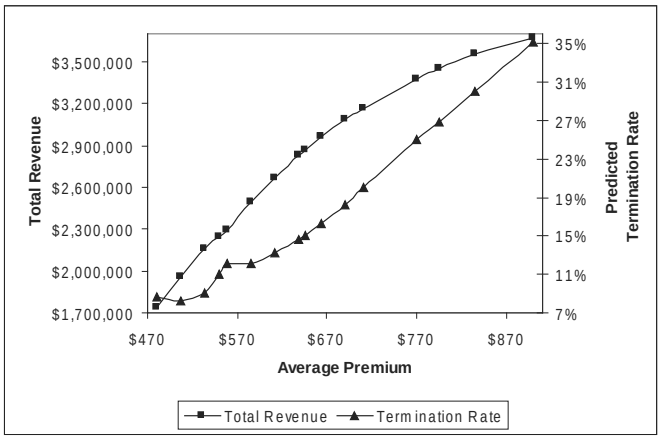
Scored Against	Average Change in Premium	Average Premium Amount ($)	Termination Rate
Neural Network 1	-8.3%	481	8.6%
	-3.3%	507	8.3%
	1.7%	533	9.1%
	6.7%	559	12.2%
Neural Network 2	11.7%	585	12.1%
	16.7%	612	13.2%
	21.7%	638	14.6%
	26.7%	664	16.3%
	31.7%	690	18.2%
	51.7%	795	26.9%
	71.7%	900	35.1%

Figure 4. Price sensitivity analysis - effect on termination rate and revenue (Cluster 24)



a measure of the degree to which each input contributes to the output error (Bigus, 1996).

The third approach is based on sequential zeroing of weights (SZW) of the connection between the input variables and the first hidden layer of the neural network (Anderson et al., 2000).

In their research, Anderson and his co-researchers (2000) found that neural networks are suitable not only for function approximation of nonlinear relationship but are also able to represent to a high degree the nature of input variables. The information generated about the variables using the SVV and SZW methods can serve as a guide to the interpretation of influence, contribution and selection of variables. We performed price sensitivity using the SVV approach by varying the premium information and holding all other inputs constant.

Separate data sets were created from each "half" cluster with all variables remaining unchanged except the new premium and related variables (change in premium, percentage change in premium and ratio of new premium to new sum insured). For example, cluster 24 was split into two "halves"; policy holders with premium decreases or increases of less than 10% and policy holders with premium increases of more than 10%. Data sets with varying percentage changes in premium were created and scored against the trained neural networks to determine the predicted termination rates. Results of price sensitivity analysis for Cluster 24 are shown in Table 2 and Figure 4 as an example. They show that as premiums increase the termination rates also increase.

CONCLUSION AND FUTURE RESEARCH

We randomly selected a few clusters to carry out experiments to determine the appropriate neural network architecture for the prediction of retention rates. More experiments could be

performed to find an appropriate neural network architecture for each of the clusters so that prediction accuracy could be improved. However, the insurance industry is unlikely to implement the proposed approach if it is difficult to implement. We have therefore adopted a straightforward approach that requires minimal fine tuning for specific data. While this research has been focused on premium pricing within the insurance industry, the methodology developed is quite general. In fact, the approach can be applied to any industry concerned with setting prices for products in competitive environments. This includes sectors such as retail and telecommunications.

KEY TERMS

Activation Function: Transforms the net input of a neural network into an output signal, which is transmitted to other neurons.

Association Rules: Predict the occurrence of an event based on the occurrences of another event.

Backpropagation: Method for computing the error gradient for a feedforward neural network.

Boosting: Generates multiple models or classifiers (for prediction or classification), and to derive weights to combine the predictions from those models into a single prediction or predicted classification.

Chi-Square Automatic Interaction Detection (CHAID): A decision tree technique used for classification of a data set. CHAID provides a set of rules that can be applied to a new (unclassified) data set to predict which records will have a given outcome. CHAID segments a data set by using chi square tests to create multi-way splits.

Confusion Matrix: Contains information about actual and predicted classifications done by a classification system.

Decision Trees: Tree-shaped structures that represent sets of decisions. These decisions generate rules for the classification of a dataset.

Deviation Analysis: Locates and analyses deviations from normal statistical behavior.

Genetic Programming: Search method inspired by natural selection. The basic idea is to evolve a popula-

tion of "programs" candidates to the solution of a specific problem.

K-means Clustering: An algorithm that performs disjoint cluster analysis on the basis of Euclidean distances computed from variables and randomly generated initial seeds.

Logistic/Logit Regression: A technique for making predictions when the dependent variable is a dichotomy, and the independent variables are continuous and/or discrete.

Multi-Layered Feedforward Network: A layered neural network in which each layer only receives inputs from previous layers.

Multiple Concept-Level Association Rules: Extend association rules from single level to multiple levels. Database contents are associated together to the concepts, creating different abstraction levels.

Multiple Regression: A statistical technique that predicts values of one variable on the basis of two or more other variables.

Neural Network: Non-linear predictive models that learn through training and resemble biological neural networks in structure.

Neural Network Architecture: A description of the number of layers in a neural network, each layer's transfer function, the number of neurons per layer, and the connections between layers

Neuron: The basic processing element of a neural network.

Regression Analysis: A statistical technique used to find relationships between variables for the purpose of predicting future variables.

Rough Sets: Rough sets are mathematical algorithms that interpret uncertain, vague, or imprecise information.

Sequential Zeroing of Weights: A sensitivity analysis method that involves sequential zeroing of weights of the connection between the input variables and the first hidden layer of the neural network.

Statistical Machine Learning: An approach to machine intelligence that is based on statistical modeling of data.

Systematic Variation of Variables: A sensitivity analysis method whereby the input of interest is varied while holding all other inputs to some fixed value to determine the impact that particular variable has on the output.

Weights: Strength of a connection between two neurons in a neural network.

Neural Networks for Intrusion Detection

Rui Ma
Beijing Institute of Technology, China

INTRODUCTION

With the rapid expansion of computer networks, network security has become a crucial issue for modern computer systems. As an important and active defense technology, the intrusion detection system (IDS) plays an important role in defensive systems. IDSs provide real-time protection from interior attacks, exterior attacks, and invalid operations, and it can intercept intrusions and respond whenever the network system integrity is violated (Ma, 2004). Many intrusion detection approaches have been deeply researched and some widely deployed. But the diversification, complexity, and scale of intrusions raise new demands for IDSs. Neural networks are tolerant of imprecise data and uncertain information. With their inherent ability to generalize from learned data they seem to be an appropriate approach to IDSs (Hofmann, Schmitz, & Sick, 2003). This article discusses the detection of distributed denial-of-service (DDoS) attacks using artificial neural networks techniques. The implementation of a distributed intelligent intrusion detection system (DIIDS) is described, including both the data processing technique and neural networks approaches adopted.

BACKGROUND

Intrusion Detection System

Many IDSs are based on the general model proposed by Denning (1987). This model is independent of platform, system vulnerability, and type of intrusion. It maintains a set of historical profiles for users, matches an audit record with the appropriate profile, updates the profile whenever necessary, and reports any attacks detected.

IDSs can be divided into two types: (1) host-based IDSs and (2) network-based IDSs. Host-based IDSs evaluate information found on a single or multiple host systems, including contents of operating systems, system logs and application files. Network-based IDSs evaluate information captured from network communications, by analyzing the stream of packets traveling across the network. Packets are captured through a set of sensors placed at strategic points in the network (Jean & Philippe, 2001).

Intrusion detection schemes can be classified into two general categories (Ghosh, 1999a): (1) misuse detection and (2) anomaly detection. Misuse detection techniques assume that all kinds of intrusion behavior can be described as specific patterns, thus allowing the identification of intrusive behavior by comparing current user activity with specific patterns that have been observed previously during an attack. The most significant advantage of misuse detection techniques is that known attacks can be detected fairly reliably and with a low false positive rate. However, the key limitation of misuse detection techniques is that they cannot detect novel attacks.

Anomaly detection techniques assume that all kinds of intrusion behavior differ from normal user activities. Any current user behavior sufficiently deviant from the normal user activities will be flagged as anomalous and hence considered as a possible attack. The most significant advantage of anomaly detection techniques is that it directly addresses the problem of detecting novel attacks against systems. However, the most notable disadvantage of anomaly detection techniques is the high rates of false alarm.

In order to detect known attacks, subtle variations of known attacks, and novel attacks efficiently, IDSs should selectively combine aspects of both misuse detection techniques and anomaly detection techniques (Chen, 2004).

Neural Networks

An artificial neural network consists of a collection of processing elements that are highly interconnected and that transform a set of inputs to a set of desired outputs. The result of the transformation is determined by the characteristics of the elements and the weights associated with the interconnections among them. By modifying the connections between the nodes, the network is able to adapt to the desired outputs.

The neural network gains the necessary experience initially by being trained to correctly identify preselected examples of a problem. The response of the neural network is reviewed and the configuration of the system is refined until the neural network's analysis of the training data reaches a satisfactory level. In addition to the initial training period, the neural network also gains experience over time as it conducts analyses on data related to the problem.

The training algorithms of neural networks can be classified into two general categories: (1) supervised and (2) unsupervised. In the learning phase, a supervised algorithm

learns the desired output for a given input or pattern. Whereas an unsupervised algorithm learns without specifying the desired output (Jean & Philippe, 2001).

Neural Network Intrusion Detection Systems

Neural networks have capabilities of self-learning, self-organization, and self-adaptivity; as well as a capability to analyze fuzzy, nonstructured, imprecise, incomplete data and to generalize from previously observed behaviors. With the continuous development of network technologies and increasing multiplicity and novelty of network attacks, IDSs must be more flexible and efficient. Artificial neural networks offer the potential to resolve a number of the problems encountered by the other approaches to intrusion detection.

Various approaches to using neural networks for intrusion detection have been advocated. One approach is to create keyword, count-based, misuse detection systems with neural networks (Lippmann & Cunningham, 1999; Ryan, Lin, & Miikkulainen, 1998). The data that are presented to the neural network consist of attack-specific keyword counts in network traffic. Such an approach is close to a host-based IDS. Some researchers created a neural network to analyze program behavior profiles instead of user behavior profiles (Ghosh, 1999b). This method identifies the normal system behavior of certain programs and compares it to the current system behavior. Cannady (1998) developed a network-based neural network IDS in which packet-level network data were retrieved from a database and then classified according to the packet characteristics before being presented to a neural network.

In the case of DIIDS, three basic artificial neural networks approaches are described: (1) neural network expert system, which is mainly used to detect known attacks by using forward parallel inference which improves inference efficiency; (2) back-propagation neural network; and (3) adaptive resonance theory neural network, which are used to detect not only known attacks, but variations of them or indeed, unknown attacks. Finally, based on the neural network approaches just described, cooperative intrusion detection approaches are discussed.

NEURAL NETWORKS IN INTRUSION DETECTION SYSTEMS

The Distributed Intelligence Intrusion Detection System

DIIDS is based on neural networks techniques and is characterized by the following constituent components: data collection; detection and analysis; console; and database. DIIDS can be deployed in a distributed or integrated manner. In particular, DIIDS combines the capability of host-based and network-based IDSs and uses artificial neural networks as detective techniques.

The console is responsible for the management, monitoring, and reporting status of the system. Storage of feature data and detection results is undertaken by the database. Data collection assembles and processes both network-based and host-based data before identifying feature data. Detection and analysis then determines if the attack occurs through three basic neural networks approaches: (1) neural network expert system; (2) back-propagation neural network; and (3) adaptive resonance theory neural network. In addition, the cooperative intrusion detection technique is also used.

Data Processing

Three levels of data processing are conducted. Initially, data is selected from the available data set by the data collection component. The data collection component comprises a network engine, a host agent, and a data fusion facility. The network engine collects all data packages flowing in the network and then resolves them into the feature data set for the network. Eight elements of the feature data garnered from the network are: (1) protocol type, (2) source IP address, (3) destination IP address, (4) source port, (5) destination port, (6) sequence number, (7) acknowledgement number, and (8) raw data. The host agent collects the data that characterizes system performance, for example, network traffic, memory, and CPU usage. These form the original feature data. A second phase converts the data elements such as protocol type, source, and destination IP address into a standardized numeric representation. The third part is that the process concerns the association processing.

By analyzing the feature data, both the spatial and temporal associate relationships between intrusion behaviors can be determined. Some attacks, which originate from different sources and try to attack the same specific goal, send many packages which have identical destination IP addresses and different source IP addresses. The relationship of these packages is called the *spatial associate relationship*. The *temporal associate relationship* points to many packages which have same source IP address but try to attack the same specific goal in a certain time period. In order to embody the spatial and temporal associate relationship in a concrete detective record, the associate detection algorithm (Figure 1) must be used. This algorithm processes associate information of feature data and converts the stochastic associated attributes into the detection associated attributes. Based on a variable, continuous, and sliding temporal window, the algorithm calculates the count of any distinct value of stochastic associated attributes during this time. Then the algorithm compares the maximum count with the threshold to determine the value of the associate attributes (Lee, 1999). This approach can

effectively detect the associate relationship between intrusion behaviors, reduce the complexity of intrusion detection algorithms, and improve the intrusion detection capability. After the smooth transition of the original data, a total of 13 elements of the feature data are obtained which are in turn used by each neural networks approach.

The Neural Network Expert System Approach

The neural network expert system (Alpaslan & Tolun, 1994) intrusion detection approach converts the AND nodes and OR nodes in the rule-based system into the corresponding AND nodes and OR nodes represented by neural networks and constructs the neural network that is equivalent to the original rule set. The value of the weight is 1 if and only if the correspondence input node participates in the AND/OR operation. Otherwise, the value is 0. The threshold of the AND node is the total number of all input nodes that participate in the AND operation, whereas the threshold of the OR node is the invariable value 1.

From an architectural perspective, the neural network expert system is a three-layered feed forward network with full interconnection between layers. The three layers are the input layer, the hidden layer, and the output layer. The nodes in the input layer correspond to the detective feature data. The nodes in the hidden layer correspond to the "then-clause" of rules. All hidden nodes are AND nodes. The nodes in the output layer correspond to the different kinds of attacks. All output nodes are OR nodes.

The neural network expert system solves the problem by using forward parallel inference which improves inference efficiency. This approach achieves better results when behavior is normal and the attack is of a known type. However, it is not so effective when attacks are of a kind that have not been encountered previously.

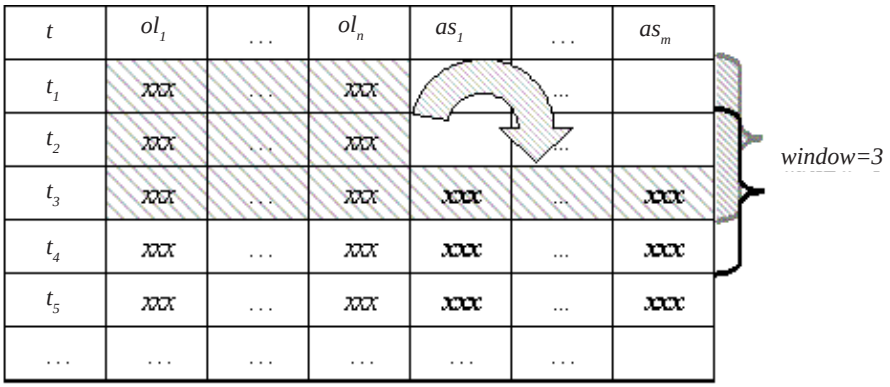
The Back-Propagation Neural Network Approach

The Back-Propagation (BP) neural network intrusion detection approach has the capability of both self-learning and self-adaptivity and can distinguish intrusion behaviors, albeit imprecisely, for both known and unknown attacks. The architecture of the BP neural network intrusion detection approach is the three-layered feed forward network with full interconnection between layers. Again, the three layers are the input layer, the hidden layer, and the output layer. There are 13 nodes in the input layer that correspond to the 13 elements of the detective feature data. There are 25 nodes in the hidden layer, which were determined by experiment. There are two nodes in the output layer that detect if an attack occurs.

First, the BP neural network translates the input feature values into continuous values using fuzzy functions. Then, it is trained using the supervised and improved BP algorithm (Hagan et al., 2002), which improves the rate of convergence through restricting the output of the sigmoid function and adjusts all weight values and thresholds separately. When the anticipant outputs are achieved, the approach calculates the distance between the real output and the anticipant output to decide which attack has occurred.

After the BP neural network is trained, it can be used to detect attacks online. This approach achieves better results for normal behavior and known attacks, but can also detect some variations of known attacks.

Figure 1. The associate detection algorithm



Legend: t-time, ol-original data with associate relationship, as-achieved associate data, window-time window

The Adaptive Resonance Theory 2 Neural Network Approach

The *adaptive resonance theory 2* (ART2) neural network (Carpenter & Grossberg, 1987) intrusion detection approach uses unsupervised learning; possesses the capabilities of self-learning and self-adaptivity; demonstrates better stability-plasticity trade-off; and can detect attacks, even unknown attacks, in real time.

The ART2 neural network intrusion detection approach adopts the competition and self-stabilization principle. It contains both attention subsystems and orienting subsystems. Attention subsystems establish the internal representation of familiar activities, while orienting subsystems respond to unfamiliar activities. Attention subsystems accomplish a competed selection from the bottom-up vectors, and a match comparison between bottom-up vectors and up-bottom vectors. Orienting subsystems verify the similarity between input vectors and anticipant output vectors. When a match value exceeds the vigilance parameter, the corresponding node is the winner.

In the ART2 neural network, there are 13 input nodes which correspond to the detective feature data, and five output nodes of which three correspond to the normal behavior and two kinds of known attacks, one to unknown attack, and one is reserved. This approach translates the input feature values into continuous values using fuzzy functions and classifies the output by adjusting the value of the vigilance parameter. This approach achieves better results during normal behavior, known attacks, and unknown attacks. However, it is particularly effective in unknown attack scenarios.

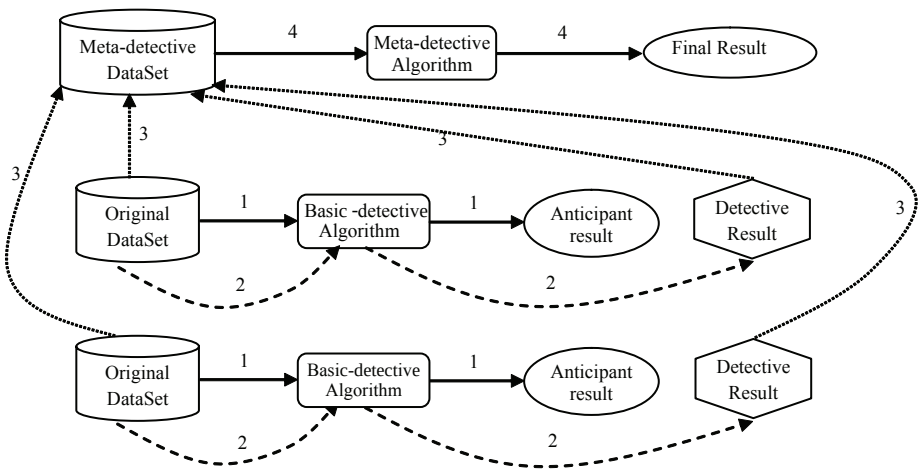
The Cooperative Intrusion Detection Approach

Any of the aforementioned detection approaches have advantages and disadvantages and can be successfully utilized for different attack modes. In order to utilize the characteristic of different detection approaches, the cooperative intrusion detection approach (Chan, 1996; Lee & Heinbuch, 2001; Parikh, 2001) is proposed (Figure 2). The kernel of the cooperative intrusion detection approach is the metadetection algorithm.

In this approach, the three individual neural network detection approaches are referred to as the basic intrusion detection algorithms. Every basic intrusion detection algorithm is a metadetector which has distributiveness, parallelism, independence, and an inherent separation of training and detection. The input data of the metadetection algorithm are the results obtained from metadetectors. The algorithm employs several detection strategies: voting, arbitration, and combing. Different metadetection algorithms are formed from combinations of these basic strategies.

Two categories of the cooperative intrusion detection approach exist: (1) local data-based and (2) the global data-based. The metadetectors in the local data-based approach are trained using local data. Instead of using global training data, the global data-based approach shares metadetectors (Figure 3). These metadetectors are trained by local data in one area and then used to detect attacks in another area. In this case, the metadetectors are referred to as remote metadetectors. Depending on the characteristics of neural networks, especially the ART2 neural network, the global data-based approach shares the global training data when it shares the

Figure 2. The architecture of cooperative intrusion detection approach



training results of the remote metadetectors. This approach solves the scalability issue and achieves good results.

FUTURE TRENDS

The most effective learning algorithms of neural networks need to be considered. The neural network expert system should have a learning capability. It is necessary to reduce the retraining time of the BP neural network when user behavior changes.

In order to have a highly adaptive capability to detect unknown attacks, research in self-organizing maps (SOMs) which offer an increased level of adaptability are needed. ART2 and SOM should be compared, and an improvement in both adaptability and detection capability for unknown attacks is required.

Because of the extensive number of vulnerabilities in computer systems and the creativity of attackers, intrusions have become increasingly diverse and complex. Using the cooperative intrusion detection approach as a basis, it is planned to develop a hierarchical IDS and research how efficiency may be improved.

CONCLUSION

The distributed intelligence intrusion detection system has been deployed in a small test network. After collecting and analyzing the feature data, it was characterized into four parts: (1) normal, (2) Trinoo attack, (3) TFN2K attack, and (4) unknown attacks. Normal means there is no attack. Trinoo and TFN2K are known attacks and have appeared in the training data. Unknown attacks have not appeared in the training data. The results show that known attacks can be detected better by the neural network expert system; unknown attacks can be detected better by the BP neural network and the ART2 neural network, especially the ART2. In the cooperative intrusion detection technique, the global data-based approach achieves promising results.

KEY TERMS

Adaptive Resonance Theory: This is a kind of neural network. The basic ART system is an unsupervised learning model and typically consists of comparison and recognition fields (one each) of neurons, a vigilance parameter, and a reset module. There have been several types. ART2 supports continuous inputs.

Artificial Neural Networks: A type of artificial intelligence that attempts to imitate the way a human brain works. Rather than using a digital model, in which all computations manipulate zeros and ones, a neural network works by creating connections between processing elements, and the organization and weights of the connections determine the output.

Back-Propagation Neural Network: This is a kind of feed forward neural network. It consists of multiple layers of computational units and is fully interconnected between layers. Each neuron in one layer has directed connections to the neurons of the subsequent layer. It usually applies the sigmoid function as an activation function.

Distributed Denial of Service Attack (DDoS): A DDoS attack is an attack on a computer system or network that causes a loss of service to users, typically the loss of network connectivity and services by consuming the bandwidth of the victim network or by overloading the computational resources of the victim system.

Intrusion Detection System (IDS): An IDS is a security system that monitors computer systems and network traffic. It analyzes the traffic for possible hostile attacks originating from outside the organization as well as for system misuse, and attacks originating from inside the organization.

Neural Network Expert System: Expert systems are an artificial intelligence application that uses a knowledge base of human expertise for problem solving. In a neural network expert system, the knowledge is encoded in the weight, and the artificial neural network generates inference rules.

Tribe Flood Network 2000 (TFN2K): This is a kind of distributed DDoS attack. TFN2K uses a client/server mechanism where a client issues commands simultaneously to a set of TFN2K servers. The servers then conduct the DDoS attacks against the victim(s).

Trinoo: This is a kind of distributed DDoS attack. Trinoo is the attack server. Trinoo waits for a message from a remote system and, upon receiving the message, launches a DDoS attack against a third party.

Neural Networks for Retail Sales Forecasting

G. Peter Zhang
Georgia State University, USA

INTRODUCTION

Forecasting of the future demand is central to the planning and operation of retail business at both macro and micro levels. At the organizational level, forecasts of sales are essential inputs to many decision activities in various functional areas such as marketing, sales, and production/purchasing, as well as finance and accounting (Mentzer & Bienstock, 1998). Sales forecasts also provide basis for regional and national distribution and replenishment plans. The importance of accurate sales forecasts for efficient inventory management has long been recognized. In addition, accurate forecasts of retail sales can help improve retail supply chain operations, especially for larger retailers who have a significant market share. For profitable retail operations, accurate demand forecasting is crucial in organizing and planning purchasing, production, transportation, and labor force, as well as after sales services.

Barksdale and Hilliard (1975) examined the relationship between retail stocks and sales at the aggregate level and found that successful inventory management depends to a large extent on the accurate forecasting of retail sales. Agrawal and Schorling (1996) and Thall (1992) also pointed out that accurate demand forecasting plays a critical role in profitable retail operations, and poor forecasts would result in too-much or too-little stocks that directly affect revenue and competitive position of the retail business. The importance of accurate demand forecasts in successful supply chain operations and coordination has been recognized by many researchers (Chopra & Meindl, 2007; Lee, Padmanabhan, & Whang, 1997).

Retail sales often exhibit both seasonal variations and trends. Historically, modeling and forecasting seasonal data is one of the major research efforts, and many theoretical and heuristic methods have been developed in the last several decades. Different approaches have been proposed, but none of them has reached consensus among researchers and practitioners. Until now, the debate is still not abated in terms of what the best approach to handle the seasonality is.

On the other hand, it is often not clear how to best model the trend pattern in a time series. In the popular Box-Jenkins approach to time series modeling, differencing is used to achieve stationarity in the mean. However, Nelson and Plosser (1982) and Pierce (1977) argued that differencing is not always an appropriate way to handle trend, and linear detrending may be more appropriate. Depending on the nature of the non-stationarity, a time series may be modeled in different ways. For example, a linear or polynomial time trend model can be used if the time series has a deterministic trend. On the other hand, if a time series exhibits a stochastic trend, the random walk model and its variations may be more appropriate.

In addition to controversial issues around the ways to model seasonal and trend time series, one of the major limitations of many traditional models is that they are essentially linear methods. In order to use them, users must specify the model form without the necessary genuine knowledge about the complex relationship in the data. This is the main reason for the mixed findings reported in the literature regarding the best way to model and forecast trend and seasonal time series.

One non-linear model that recently received extensive attention is the neural network (NN) model. The popularity of the neural network model can be attributed to their unique capability to simulate a wide variety of underlying non-linear behaviors. Indeed, research has provided theoretical underpinning of neural network's universal approximation ability. In addition, few assumptions about the model form are needed in applying the NN technique. Rather, the model is adaptively formed with the real data. This flexible data-driven modeling property has made NNs an attractive tool for many forecasting tasks, as data are often abundant while the underlying data generating process is hardly known.

In this article, we provide an overview on how to effectively model and forecast consumer retail sales using neural network models. Although there are many studies on general neural network forecasting, few are specifically focused on trending or seasonal time series. In addition, controversial results have been reported in the literature. Therefore it is necessary to have a good summary of what has been done in this area and more importantly to give guidelines that can be useful for forecasting practitioners.

It is important to note that the focus of this article is on time series forecasting methods. For other types of forecasting methods used in retail sales, readers are referred to Dominique (1998), Green (1986), and Smith, McIntyre, and Dale (1994).

BACKGROUND

Neural networks are computing models for information processing. They are very useful for identifying the func-

tional relationship or pattern in the retail sales and other time series data. The most popularly used neural network model in practice for retail sales is the feedforward multi-layer network. It is composed of several layers of basic processing units called neurons or nodes. For an in-depth coverage of NN models, readers are referred to Bishop (1995) and Smith (1993). A comprehensive review of the NNs for forecasting is given by Zhang, Patuwo, and Hu (1998).

Before it can be used for forecasting, the NN model must be built first. Neural network model building (training) involves determining the order of the network (the architecture) as well as the parameters (weights) of the model. NN training typically requires that the in-sample data be split into a training set and a validation set. The training set is used to estimate the parameters of some candidate models, among which the one that performs the best on the validation set is selected. The out-of-sample observations can be used to further test the performance of the selected model to simulate the real forecasting situations.

The standard three-layer feedforward NN can be used for time series forecasting in general and retail sales in particular. For one-step-ahead forecasting, only one output node is needed. For multiple-step forecasting, more output nodes should be employed. For time series forecasting, the most important factor in neural networks modeling is the number of input nodes, which corresponds to the number of past observations significantly auto-correlated with the future forecasts. In a seasonal time series such as the retail sales series, it is reasonable to expect that a forecasting model should capture the seasonal autocorrelation that spans at least one or two seasonal periods of, say, 12 or 24 for monthly series.

Therefore, in modeling seasonal behavior, it is critical to include in the input nodes the observations separated by multiples of seasonal period. For example, for a quarterly seasonal time series, observations that are four quarters away are usually highly correlated. Although theoretically, the number of seasonal lagged observations that have autocorrelation with the future value can be high, it is fairly small in most practical situations, as empirical studies often suggest that the seasonal autoregressive order be one or at most two (Box & Jenkins, 1976).

There are many other parameters and issues that need to be carefully considered and determined in neural network model building for retail and other time series. These include data preparation, data division and sample size, network architecture in terms of number of hidden and input nodes, training algorithm, model evaluation criteria, and so forth. Practical guidelines can be found in many references in the literature including Adya and Collopy (1998), Kaastra and Boyd (1996), and Zhang et al. (1998).

MAIN FOCUS OF THE ARTICLE

Modeling seasonal and trend time series has been one of the main research endeavors for decades. In this article, we provide a review of the research work on trend and seasonal time series forecasting with a focus on recent studies for retail sales time series with neural networks. In the early 1920s, the decomposition model along with seasonal adjustment was the major research focus due to Persons (1919) work on decomposing a seasonal time series. Different seasonal adjustment methods have been proposed, and the most significant and popular one is the Census X-11 method developed by the Bureau of the Census in the 1950s and 1960s, which has evolved into the current X-12-ARIMA program. Because of the *ad hoc* nature of the seasonal adjustment methods, several model-based procedures have been developed. Among them, the work by Box and Jenkins (1976) on the seasonal ARIMA model has had a major impact on the practical applications to seasonal time series modeling. This model has performed well in many real world applications and is still one of the most widely used seasonal forecasting methods. More recently, neural networks have been widely used as a powerful alternative to traditional time series modeling.

In neural network forecasting, little research has been done focusing on seasonal and trend time series modeling and forecasting. In fact, how to effectively model seasonal time series is a challenging task not only for the newly developed neural networks, but also for the traditional models. One popular traditional approach to dealing with seasonal data is to remove the seasonal component first before other components are estimated. Many practitioners in various forecasting applications have satisfactorily adopted this practice of seasonal adjustment. However, several recent studies have raised doubt about its appropriateness in handling seasonality. Seasonal adjustment has been found to lead into undesirable non-linear properties, severely distorted data, and inferior forecast performance (Ghysels, Granger, & Siklos, 1996; Plosser, 1979). De Gooijer and Franses (1997, p. 303) pointed out that "although seasonally adjusted data may sometimes be useful, it is typically recommended to use seasonally unadjusted data." On the other hand, mixed findings have also been reported in the limited neural network literature on seasonal forecasting. For example, Sharda and Patil (1992) found that, after examining 88 seasonal time series, NNs were able to model seasonality directly and pre-deseasonalization is not necessary. Alon, Qi, and Sadowski (2001, p. 154) also found that NNs are able to "capture the dynamic non-linear trend and seasonal patterns, as well as the interactions between them." However, Farway and Chatfield (1995) and Nelson, Hill, Remus, and O'Connor (1999), among others, found just the opposite. Their findings suggest that neural networks are not able to directly model

seasonality, and pre-deseasonalization of the data is necessary to improve forecasting performance.

Chu and Zhang (2003) compared the accuracy of various linear and neural network models for forecasting aggregate retail sales. Using multiple cross-validation samples, they found that the non-linear models outperform their linear counterparts in out-of-sample forecasting, and prior seasonal adjustment of the data can significantly improve forecasting performance of the neural network model. The overall best model is the neural network built on deseasonalized time series data. While seasonal dummy variables can be useful in developing effective regression models for predicting retail sales, the performance of dummy regression models may not be robust. In addition, they found that trigonometric models are not useful in aggregate retail sales forecasting.

Zhang and Qi (2005) examined the issue of how to use neural networks more effectively in modeling and forecasting a seasonal time series with a trend component. The specific research questions they addressed are (1) whether neural networks are able to directly model different components of a seasonal and trend time series and (2) whether data pre-processing is necessary or beneficial. Instead of focusing solely on the seasonal component alone as in previous studies (e.g., Nelson et al., 1999), they took a systematic approach on the data preprocessing issue to study the relevance of detrending and deseasonalization. Using a large number of simulated and real time series, they evaluated the effect of different data preprocessing strategies on neural network forecasting performance. Results clearly show that without data preprocessing neural networks are not able to effectively model the trend and seasonality patterns in the data, and either detrending or deseasonalization can greatly improve neural network modeling and forecasting accuracy. A combined approach of detrending and deseasonalization is found to be the most effective data preprocessing that can yield the best forecasting result.

Therefore, it is recommended that data preprocessing is performed before building neural network models for retail sales data that contain seasonal and trend components. If the time series contains only the seasonal variation, deseasonalization should be the best choice. However, if both trend and seasonal fluctuations are evident, a combined approach of detrending and deseasonalization should be used.

FUTURE TRENDS

Sales forecasting is critical for most business operations. Developing new forecasting methods and models will continue to be an important endeavor in the future. Although neural networks provide an excellent modeling tool for forecasting researchers and practitioners, there are still many ways to improve their performance in the future. For example, while this article focuses on time series approaches, it may be valuable to consider both time series and cross-sectional data in building sales forecasting models. Many external factors including both micro- and macro-variables can be useful in sales forecasting. In addition, combining multiple models to improve forecasting accuracy is an important area to explore.

CONCLUSION

Neural networks become an important tool for retail sales forecasting. Due to complex nature in model building for retail sales, it is necessary to preprocess the data first. Several recent studies strongly suggest that for retail sales that contain both trend and seasonal variations, it is not appropriate to directly model sales time series with neural networks. Rather, both seasonal effect and trend movement can have significant effect in accurately modeling retail sales. In order to build the best neural network model, forecasters should use a combined approach of deseasonalization and detrending to removing the seasonal and trend factors first. Another benefit with both seasonality and trend removed is that more parsimonious neural networks can be constructed.

KEY TERMS

Box-Jenkins Approach: A very versatile linear time series modeling approach that can model trend, seasonal, and other behaviors by using moving averages, autoregression, and difference equations.

Census II X-11: A method that systematically decomposes a time series into trend, cyclical, seasonal, and error components. It was developed by the Bureau of the Census of the Department of Commerce and is widely used in deseasonalizing economic data.

Deseasonalization: Sometimes also called seasonal adjustment. A process of removing seasonality from the time series. Most governmental statistics are seasonally adjusted to better reflect other components in a time series.

Detrending: A process of removing trend from the time series through either differing of time series observations or subtracting fitted trends from actual observations.

Feedforward Neural Network: A special type of neural network where processing elements are arranged in layers and the information is one directional from input layer to hidden layer(s) to output layer.

Neural Networks: Computing systems that are composed of many simple processing elements operating in parallel

whose function is determined by network structure. They are used mainly to model functional relationship among many variables.

Retail Sales: A measure of the total receipts of retail stores. Retail sales data provide valuable information about consumer spending. Aggregate retail sales are reported monthly by the Commerce Department.

Seasonality: Periodic pattern that typically occurs within a year and repeats itself year after year. Most retail data exhibit seasonal variations that repeat year after year.

Trend: Long-term movement in a time series that represents the growth or decline over an extended period of time.

New Perspectives on Rewards and Knowledge Sharing

INTRODUCTION

Of the 260 responses from a survey of European multinationals, 94% believed that knowledge management requires employees to share what they know with others within the organization (Murray, 1999). Among the processes of knowledge management—creation, sharing, utilization and accumulation of knowledge—sharing is what differentiates organizational knowledge management from individual learning or knowledge acquisition.

However, the process of sharing knowledge is often unnatural to many. Individuals will not share knowledge that is regarded to be of high value and importance. In fact, the natural tendency for individuals is to hoard knowledge or look suspiciously at the knowledge of others. Thus, incentive schemes—where employees receive incentives as a form of compensation for their contributions—are common programs in many organizations. Such schemes have met their fair share of success as well as failure in the field of knowledge management. On the one hand, the carrot and stick principle used in Siemens' ShareNet project turned out to be a success (Ewing & Keenan, 2001). On the other hand, the redemption points used in Samsung Life Insurance's Knowledge Mileage Program only resulted in the increasingly selfish behavior of its employees (Hyoung & Moon, 2002).

Furthermore, despite the plethora of research on factors affecting knowledge sharing behavior, little concerns discovering effective ways to encourage individuals to voluntarily share their knowledge. Early studies on knowledge management began by trying to discover key factors pertaining to knowledge management in general, instead of knowledge sharing in particular, as summarized in Table 1. Although research on knowledge sharing started around the mid 1990s, it focused mainly on knowledge sharing at the group or organizational level in spite of the fact that knowledge itself actually originates from the individual. Even at the group or organizational level, most studies dealt with a specific knowledge type, such as best practices (Szulanski, 1996) or a specific context, such as between dispersed teams (Tsai, 2002). In addition, factors such as trust, willingness to share, information about the knowledge holder, and the level of codification of knowledge were considered in abstract. Although these factors are valuable, they require further empirical research before they could be used to explain the individual's fundamental motivation to share knowledge. Thus, this study aims to develop an understanding of the factors that support or constrain the individual's knowledge sharing behavior in the organization, with a special interest in the role of rewards. This is done according to Fishbein and Ajzen's (1975) Theory of Reasoned Action (TRA), a widely accepted social psychology model that is used to explain almost any human behavior (Ajzen & Fishbein, 1980).

BACKGROUND

Due to the fact that knowledge is a resource that is locked in the minds of humans, knowledge sharing does not occur with the sole implementation of information systems. As such, an investigation into the individual's motivation behind knowledge sharing behavior, coupled with a firm foundation in social psychology, should take precedence. Accordingly, the TRA is adopted so as to provide a well-established explanation for such volitional, rational, systematic decision logic as that of knowledge sharing.

The TRA assumes that human beings are usually rational in thinking, and would systematically use available information (Fishbein & Ajzen, 1975). In the TRA, the individual's attitude toward and subjective norm regarding a behavior jointly determine the behavioral intention that results in the individual's decision to engage in a specific behavior. In this study, we focus only on the salient beliefs that affect the knowledge sharing attitude because knowledge sharing behavior is assumed to be motivated and executed mainly at the individual level. Since the TRA can be applied to almost any behavior, the nature of the beliefs operative for a particu-

lar behavior are left unspecified. Following the elicitation recommendations suggested by Fishbein and Ajzen (1975), free response interviews to elicit five to nine salient beliefs were conducted with chief knowledge officers (CKO) and chief information officers (CIO) of the subject population in April 1999. Once these salient beliefs surfaced, the research model was developed.

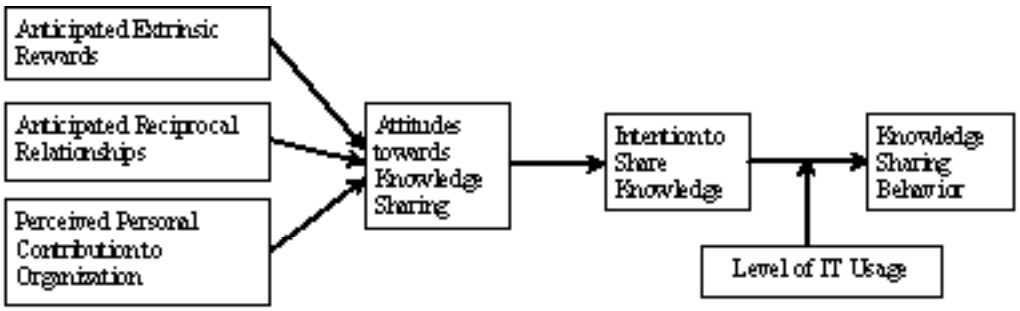
We propose three factors that are consistently emphasized throughout the interviews: anticipated extrinsic rewards, anticipated reciprocal relationships, and perceived personal contribution to the organization, as the antecedents of the attitudes towards knowledge sharing. According to the interdependence theory, individuals will behave according to rational self-interest. Knowledge sharing occurs when the rewards exceed the costs (Constant, Keisler & Sproull, 1994; Kelley & Thibaut, 1978), implying that anticipated extrinsic rewards will positively affect the individual's attitude. Concerning intrinsic rewards, the social exchange theory states that social exchanges entail unspecified obligations (Blau, 1967). As employees are seen to believe that their relationship with others can be improved through sharing knowledge, the anticipated reciprocal relationships positively affect the individual's attitude. In addition to these, the self-motivation theory (Deci, Connell & Ryan, 1989; Iaffaldano & Muchinsky, 1985; Schwab & Cummings, 1970) finds that feedback from others on shared knowledge can form a self-motivational factor and serve as another major determinant of the attitude toward knowledge sharing. Eisenberger and Cameron (1996) note that one's sense of competence actually increases due to the feedback concerning the quality of one's output. Employees who are able to link instances of past knowledge sharing with an understanding of how these actions contribute to others' work, and/or improvements in organizational performance are likely to develop more favorable attitudes toward knowledge sharing than employees who are unable to construct such linkages. Finally, following Fishbein and Ajzen's (1975) argument about the possibility of several external variables affecting intention to perform a behavior, we introduced an aspect of information technology (IT) into our model. Since IT is considered to be an important enabler in knowledge management (O'Dell & Grayson, 1998; Ruggles, 1998), we examined how the individual's level of IT usage affects knowledge sharing behavior.

Data were collected through the utilization of a survey. A total of 900 questionnaires were distributed in October and November 1999 to employees in 75 departments of four large government-invested organizations in South Korea. Of this total number, 861 responses were received, of which 467 were usable. We found that the anticipated reciprocal relationship provided for the individual's positive attitude towards knowledge sharing, and resulted in a positive influence of intention and behavior. However, contrary to many researchers' expectations, anticipated extrinsic rewards were found to have a negative effect on such an attitude.

FUTURE TRENDS

This negative correlation—which might prove important for future research—can be explained with the results of research in the pay-performance area. Kohn (1993) found that there is either no relationship or a negative relationship

Figure 1. Research model



between rewards and performance, although many assume that people will do a better job if they are promised some form of reward. Kohn cited six reasons as to why rewards fail, three of which can also be considered within the knowledge-sharing context.

First, rewards are seen to have a punitive effect because, as compared to outright punishment, they are manipulative in nature. Not receiving an expected reward is seen to be indistinguishable from being punished. Both result in movement, but not motivation (Herzberg, 1968). Rewards are seen to destroy relationships because for any one winner, many others would feel that they have lost. When there exists a limited number of rewards, competition between employees will ensue. Second, rewards are at times used as a simpler alternative to addressing underlying issues, such as the lack of an ideal knowledge-sharing culture within the organization. The ideal culture mentioned should include providing useful feedback, social support, and room for self-determination. Third, rewards could be an undermining factor towards intrinsic motivation. Interest in knowledge sharing would decrease with an increase in one's perception of being controlled (Levinson, 1973). Employees might assume that the task at hand is not something they would want to do if they have to be bribed to do it. As such, with the increase in incentive offered, the negative perception towards the task at hand becomes greater.

Another explanation can also be found in organizational citizenship behavior literature. According to Katz and Kahn (1966), any critical voluntary behavior that is beyond the scope of one's job description is a direct result of one's identification with and internalization of individual and organizational values, rather than the involvement of any external factors. Furthermore, Constant et al. (1994) stated that experienced workers perceive the process of sharing knowledge as part of normal business activity. These workers hold a negative view of any extrinsic rewards given in return for sharing knowledge. With such strong support for the negative effect view of extrinsic rewards on the attitude towards knowledge sharing, would it be right to completely discard extrinsic rewards?

Eisenberger and Cameron (1996) found that extrinsic rewards could both positively and negatively influence motivation—knowledge sharing in this case. They find that rewards can be divided into two broad types, namely task-contingent and quality-dependent rewards. Quality-dependent rewards positively influence organization initiatives, as they do not reduce one's intrinsic motivation. In fact, due to the feedback concerning the quality of one's output, one's sense of competence actually increases. Task-contingent rewards, on the other hand, undermine any task because of their negative influence on intrinsic motivation. A possible design for such a scheme is a knowledge market where "buyers and sellers of knowledge negotiate a mutually satisfactory price for the knowledge exchanged" (Ba, Stallaert & Whinston, 2001, p. 232). In this way, the reward of individuals would be based on the usefulness of their knowledge, thus ensuring the creation of high-quality knowledge.

In addition, a reward that is less than what employees feel their performance justify could threaten their self-esteem. This is due to the fact that the self-ratings done by employees are usually higher than those done by the management. According to Meyer (1975), a common way for employees to cope with such a problem is to "downgrade the importance of the activity on which the threat is focused" (p. 44). Hence, an incentive scheme should be well-designed so as to reward individuals who are deemed deserving, as the rewarding of contributors aids in positively influencing the sharing of knowledge. Additionally, the scheme's design should discourage self-centered behavior, which is detrimental to the organization's health (Michailova & Husted, 2003); otherwise, the scheme would only produce temporary compliance, and might decrease an individual's intrinsic motivation (Deci, 1971,1972a). When intrinsic interests exist among employees for a particular task, the attachment of

incentives to the performance of the task only results in the decrease of that interest (Deci, 1972b). "When pay becomes the important goal, the individual's interest tends to focus on that goal rather than on the performance of the task itself" (Meyer, 1975, p. 41), thus resulting in employees striving to increase incentives at the cost of output quality.

Furthermore and most importantly, an incentive scheme needs to be incorporated with proper organization norms (Markus, 2001). If the norms are not in place, employees will not share their knowledge even if there is in place, a comprehensive incentive scheme. According to O'Dell and Grayson (1998), "if the process of sharing and transfer is not inherently rewarding, celebrated and supported by the culture, then artificial rewards [will not] have much effect and can make people cynical" (p. 168). Husted and Michailova (2002) also stated that "unless knowledge sharing is built into the expectation of the individual and is reflected in the reward mechanism, sharing will not take place".

CONCLUSION

In summary, of the two views posed by past research, our recent study to discover the influence of extrinsic rewards in knowledge sharing supports the negative view. This implies that, when the management of an organization is motivated to embrace knowledge sharing but its employees are not, using incentives to influence knowledge sharing would only result in the employees placing emphasis on the incentives. This could result in the sharing of low-quality knowledge and undermine the whole knowledge-sharing effort. Furthermore, the continuous use of incentives "could actually be encouraging hoarding behavior and competitive actions, diminishing the free flow of knowledge in the organization" (Wasko & Faraj, 2000, p. 162). Therefore, extrinsic rewards should be coupled with other factors, such as organizational norms, to bring about benefits. The reconciliation of this disparity in views should provide new grounds for future research.

KEY TERMS

Explicit Knowledge: Knowledge that has been captured and codified into manuals, procedures, and rules, and is easy to disseminate (Stenmark, 2000).

Extrinsic Rewards: Incentives that are mediated outside of a person, such as praises and monetary compensation (Deci, 1972b).

Implicit Knowledge: Knowledge that can be expressed in verbal, symbolic, or written form but has yet to be expressed (Bock, Zmud, Kim, & Lee, 2003).

Intrinsic Rewards: Incentives that are mediated within a person, such as satisfaction (Deci, 1972b).

Knowledge Management System: A knowledge repository, shared knowledge base or knowledge based system, which is a class of information systems developed to support and enhance the organizational processes of knowledge creation, storage / retrieval, transfer and application (Alavi & Leidner, 2001).

Knowledge Sharing: Voluntary activities of transferring or disseminating knowledge between people or groups in an organization (Bock, Zmud, Kim & Lee, 2003).

Organizational Norm: Organization culture or climate, which consists of the shared values, beliefs and practices of the people in the organization (McDermott & O'Dell, 2001).

Tacit Knowledge: Knowledge that cannot be easily articulated, and thus only exists in people's minds, and is manifested through their actions (Stenmark, 2000).

New Technologies in Hospital Information Systems

Dimitra Petroudi
National and Kapodistrian University of Athens, Greece

Nikolaos Giannakakis
National and Kapodistrian University of Athens, Greece

INTRODUCTION

A hospital information system (HIS), variously also called clinical information system (CIS), is a comprehensive, integrated information system designed to manage the administrative, financial, and clinical aspects of a hospital. This encompasses paper-based information processing as well as data processing machines.

As an area of medical informatics, the aim of an HIS is to achieve the best possible support of patient care and administration by electronic data processing.

It can be composed of one or few software components with specialty specific extensions, as well as of a large variety of subsystems in medical specialties (e.g., laboratory information system, radiology information system).

CISs are sometimes separated from HISs in that the former concentrate on patient and clinical state-related data (electronic patient record), whereas the latter keeps track of administrative issues. The distinction is not always clear, and there is contradictory evidence against a consistent use of both terms.

Types of HIS

1. Central or exocentric: The difference is supported in whether the information is kept in central computer or is distributed in other computers in all the hospital.
2. Oriented or not to the patient: Even if both of this two types deal with the data of patient, the orientation of HIS can influence the processes and the general "character of" HIS.
3. With terminals or workstations: They are two appliances that resemble and usually are not separated. Terminals are electronic appliances that allow the users to communicate with the computer. Generally, they are connected with mini-computers or mainframes that can find themselves far or near. If they are alone, they have few possibilities, and generally they are not capable to make anything if they are not connected with a functional computer. Workstations are computers drawn for professional use from an individual each time. They are completely functional computers, and they can be connected with other workstations, mainframes, or mini-computers.

An HIS can be placed:

1. Next to the bed of patient: Its placement next to the patient's bed is essential for the monitor and control appliances. For the recording of situation of patient, nevertheless, there is no advantage. In a study, the results were the recording of data was not improved when the system was found next to the patient, since the bigger part of recording was done outside the room, or in the rooms of other patients. Nevertheless, its placement in this point improved the use of automated drawings of care, the calculation of situation of patient, and the pricing for the care of services.
2. In the corridor near the patient's bed: Its placement in the corridor is continuously increasing. It allows the nurses to record, very shortly afterwards, their removal from the patient, without the detachment of attention from the presence of patient and the potential requirement of attention. However, there is danger for the safety, since someone can receive information about the situation of a patient simply looking at, indiscreetly, the hour of recording.
3. In a staff's room: Its placement in regions, where the staff is only allowed, has the advantage of bigger safety. However, it is uncomfortable and time consuming, since the staff should walk enough each time it needs information.
4. Other possibilities: Electronic clipboards. The unique disadvantage is found in that the users perhaps forget where they left it.

Expected profits from the hospital information systems

1. Reduction or repression of registrations
2. Reduction of office duties for the medical and nursing staff

3. Easier access to the medical data
4. Reduction of duration of staying in the hospital
5. Minimisation the insufficient medical recipes
6. Minimisation of errors in the recording of results
7. Redeployment, reorientation or reduction of staff
8. Improvement of quality of registrations
9. Improvement of quality of care
10. Better communication
11. Reduction of hospital cost
12. Increase of satisfaction of nurses
13. Growth of common hospital database
14. Improvement of perception of patients on their care
15. Improvement of general appearance of hospital

HARDWARE TECHNOLOGIES

The patients entrust the organisms of healthcare in order to offer them the higher level of care with the smaller probability of error. The existing technologies help standards of health to be strengthened, but the hardware solutions will save an important cost, also measured in money and in time. Solutions, such as electronic forms, can exclude the problems that come up in a handwritten system. These technologies give the doctors/nurses, and the other clinical, a lot of time in order to focus in what they know better.

Bar Coding

The bar coding is a low risk technology (cost, application) that makes it a practical choice for a organisation. Also, in order to be used effectively, it does not need intensive education. The positive results of bar code in the safety of patient are widely acceptable in the healthcare system.

The initiative of FDA (Food and Drug Administration) for the safety of the patient was completed in February 2004, and it will ask for the hospitals to use bar codes in the hospitals the next 3 years. The technology uses bar code for the patients, the medicines, the blood, and the vaccines. A tool collects all the codes, and is immediately connected with the medical file of patient. Following the system with the bar codes, the FDA calculated that this will involve economy of 3-9 billion dollars.

The solution offers:

- Effectiveness
- Safety
- Reduction of cost
- Reciprocity
- Correctness
- Precision

Touch Screen Technology

This technology allows a nurse to easily export conclusions for the patients using a friendly environment (touch screen). The nurse simply touches upon the screen that she/he wishes. The button in the screen shows the room number at the same time as the name of patient. In this easy two-step access, the nurse shows the category from which she/he asks information.

This solution offers:

- Easy to use
- Precision in the import of data
- Efficient administration
- Easy completion of data.

Browser-Based Technology

Three factors should appear for using the browser-based technologies. Firstly, the technology should contribute to the cost decrease. Secondly, the technology should have competitive advantage. Finally, the technology should have an impact in the improvement of patient. An installation with this technology needs only a Web browser, such as Internet Explorer, Netscape, Mozilla, for running the software.

The solution offers:

- Portability - the browser-based software offers an easy access to the information with point and click
- Easy access each hour (day-night), from everywhere (office, home, everywhere Internet exists)
- Less hour of employment - It is decreased because the system functions permanently all day
- Friendly to the user - does not need learning new applications only point and click.

Document Imaging

The solution offers:

- Focus to the customer service - the important data can be easily filed. The solution allows the hospital to vindicate the medical data
- Decreased of printing - All the information is stored in a filed system that is fast approachable
- Easy Web access - the doctors, as long as the other users can have always access and from everywhere via Web
- Not other lost files - the e-files give the possibility to the hospital to compose an electronic recording of all given data and afterwards, place the disk in a database

- Completed copy of HIS - the medical directives can immediately be placed in a filed e-file with easy access and reuse
- Better functional space - Better management of existing spaces in the hospital and utilisation of these for more effective ways.

Mobile Carts

They make the worker feel comfortable with the utilisation of technology. The professionals can be hesitant in the use of the technology if the programs are not easily used. The unwillingness can be obvious in each employee, which can decrease his/her productivity or increase the overtime and create an unpleasant working environment. With a portable workstation, the aim is for the workers to feel comfortable. The solution offers:

- Faculty of transport
- Flexibility.

Pen Tablets

This technology helps hospitals to decrease the functional costs and the handwritten work, as well as to improve the healthcare. In this technology, there is a pen that is used as the mouse. Pen tablets allow the professionals of health to store information fast and easily, allow them to focus on the patient and spend less time in tedious debits. The professionals, with this technology, can collect the vital points, statistical data, and other information near to patient's bed.

The solution offers:

- Decreased handwritten work
- It improves the provided healthcare
- It increases the productivity.

E-Forms

E-forms allow the health professionals to organise their registrations without the enormous volume of paper that is usually in the bookshelves of an office.

The solution offers:

- Bigger flow - e-forms give the opportunity to the hospital for research, decreasing the repeated exit for handwritten work.
- Correctness (precision) - the solution increases the safety of patient by decreasing the errors that exist in a handwritten system.
- It improves the flow of work - E-forms offer to the hospital processes in order to improve the effectiveness. It releases the personnel from tedious obligations.
- Seamless integration - the solution offers completion to the hospital without extra programs and maintenance.
- It increases the professionalism - Improving the appearance and the drawing of medical forms can improve the picture of hospital for the public.

Wireless Technology

The medical community continues searching ways in order to maintain the precision, as well as to improve the functional efficiency. For example, the doctors can have access and renew the medical file using computers that are found next to the patient's bed. The portable computers, the PDA, the Pen Tablets and the mobile telephones were proved a new powerful tool for the improvement of efficiency and effectiveness of services that are provided in the hospital environment. The information with regard to the patient, his/her care, and the programmed examinations is immediately available to the professionals of health in any place in the hospital. More important is the fact that with the import of data straight in the network of hospital, are limited the double written data and errors are decreased at the copy of data.

The solution offers:

- Mobility
- Flexibility
- Speed
- Safety

BENEFITS

For the patients:

- It builds an electronic medical file
- It improves the quality of care

For the hospital doctors:

- It helps the decision-making via the easier access in the information
- It is capable to program and record the clinical activities

For the governors:

- It provides the comprehensive daily lists of activity
- It simplifies the planning of energies for the care of patient
- It improves the communication with the colleagues

For the management:

- It helps with the required reports at the meetings
- It improves the efficiency via the automation
- It helps with the improvement of management of staff

CONCLUSION

The future of HIS depends on many factors, like: 1) the hardware becomes cheaper, 2) the software does not become more expensive, 3) the money spent by the government is not increased, 4) there have not been determined the models for the storage and exchange of data, and 5) it demands the education of the staff.

KEY TERMS

Barcode (also **bar code**): A machine-readable representation of information in a visual format on a surface.

Hardware: The general term that is used to describe physical artifacts of a technology.

Laboratory Information System (LIS): A class of software that handles receiving, processing, and storing information generated by medical laboratory processes.

Radiology Information System (RIS)**:** Used by radiology departments to store, manipulate, and distribute patient radiological data and imagery.

Software Component: A system element offering a predefined service and able to communicate with other components.

Touch Screens, **Touch Panels:** Display overlays that have the ability to display and receive information on the same screen.

Next-Generation Enterprise Systems

Charles Møller
Aalborg University, Denmark

INTRODUCTION

"ERP is dead - long live ERP II" was the title of a path breaking research note from Gartner Group (Bond, Genovese, Miklovic, Wood, Zrimsek, & Rayner, 2000). In this research note, Gartner Group envisions how the ERP vendors respond to market challenges and how ERP and ERP strategies evolved by 2005. Gartner Group defines ERP II as a transformation of ERP (Enterprise Resource Planning), and today the major vendors have adopted this concept in their contemporary ERP packages.

ERP (Enterprise Resource Planning) is an important concept to industry. Enterprises are increasingly implementing packaged ERP systems. A recent study confirmed that over 90% of the 500 largest Danish enterprises have adopted one or more ERP system. Further, the study found the systems to be of an average age of 2.8 years and decreasing (Møller, 2005a).

ERP is a standardized software package designed to integrate the internal value chain of an enterprise (Klaus, Rosemann, & Gable, 2000). In 2002, the five major ERP vendors were: (i) SAP; (ii) Oracle; (iii) Peoplesoft; (iv) SAGE; and (v) Microsoft Business Solutions. They controled almost 50% of the ERP market (c.f. Table 1) and consequently the corporate infrastructure is dominated by the design of these systems and the vendors. By 2006, the market is consolidated and many of the smaller vendors have been merged with larger vendors. Oracle acquired PeopleSoft and JD Edwards and the global market seems to be dominated by SAP, Oracle and Microsoft.

According to Nah (2002) the American Production and Inventory Control Society (APICS) defines ERP as: "a method for the effective planning and controlling of all the resources needed to take, make, ship and account for customer orders in a manufacturing, distribution or service company." This definition expresses ERP as a tool but ERP is also a management vision and an agency of change and ERP has been attributed to almost any good or bad that IT may bring about in business.

In the late 1990s, the ERP hype was primarily motivated by companies rushing to prepare for Y2K (Calloway, 2000). Then, after a short recession the adoption of ERP has continued. Davenport's sequel on enterprise systems (Davenport, 1998, 2000; Davenport & Brooks, 2004) illustrates the changing business perspective on ERP and the ERP hype.

Davenport (1998) sums up the first wave of experiences from implementing ERP systems in a much cited paper on "putting the enterprise system into the enterprise," and points to the new potential business impact of the ERP systems. The discussion evolved over the first enthusiastic expectations, continued over a growing number of horror stories about failed or out-of-control projects, toward a renewed hype of expectations on e-business and SCM.

The ERP II concept is the software industry's perception of the new business challenges and the vision addresses the issues of e-business integration in the supply chain. ERP II is the next-generation ERP concept and in a few years from now the ERP II vision is going to be institutionalized into the infrastructure of most enterprises. This article will portray the conceptual framework of ERP II.

Table 1. Top 5 worldwide ERP software application new license revenue market share estimates for 2002. Source: Gartner Dataquest (June 2003)

Vendor	*2002 Market Share (%)*	*2001 Market Share (%)*
SAP AG	25.1	24.7
Oracle	7.0	7.9
PeopleSoft	6.5	7.6
SAGE	5.4	4.6
Microsoft Business Solutions	4.9	4.6
Others	51.1	50.3
Total Market Share	100.0	100.0

Table 2. Enterprise systems in retrospective

Decade	Concept	Function
1950s	Inventory Control Systems (ICS)	Forecast and inventory management
1960s	Material Requirement Planning (MRP)	Requirement calculations based on Bill-of-Material (BoM)
1970s	Manufacturing Resource Planning (MRP/II)	Closed-loop planning and capacity constraints
1980s	Computer Integrated Manufacturing (CIM)	Automation, Enterprise models
1990s	Enterprise Resource Planning (ERP)	Integrated processes

BACKGROUND: THE EMERGENCE OF THE ERP CONCEPT

The ERP II concept may be understood by taking a closer look at the development of the ERP concept. Enterprise systems have often been explained through the historical evolution of ERP (Chen, 2001; Klaus, Rosemann & Gable, 2000; Wortmann, 1998). The concept of Enterprise Systems (ES) has evolved over almost 50 years, driven by the changing business requirements, the new information technologies, and by the software vendor's ability to provide standardized solutions.

The fundamental structure of ERP has its origin in the 1950s and in the 1960s with the introduction of computers into business. The first applications were automating manual tasks such as bookkeeping, invoicing and reordering. The early Inventory Control (ICS) systems and Bill of Material (BOM) processors gradually turned into the standardized Material Requirements Planning (MRP). The legacy of the IBM's early COPICS specifications can be found in the structure of the systems even today.

The development continued in the 1970s and in the 1980s with the MRP II and the CIM concept. During the 1970s MRP caught on like wildfire, and was fueled by the "MRP Crusade" of the American Production and Inventory Control Society (APICS). But gradually industry came to the understanding that neither of these concepts was able to meet the expectations. Even though the CIM ideas failed in many aspects, the research, for example, on IS development (ISD) and enterprise models, provided the background for gradually integrating more areas into the scope and of the information systems (Wortmann, 2000). This development peaked in early 1990s with the advent of the Enterprise Resource Planning (ERP) systems, often embodied in SAP R/3 (Bancroft, Seip, & Sprenge,l 1997), along with the other major vendors: Oracle, Peoplesoft, JD Edwards and Baan; the so-called JBOPS. Although the ERP systems have other legacies like accounting, the prevailing planning and control philosophy is deeply rooted in manufacturing and in MRP.

ENTERPRISE RESOURCE PLANNING II

The ERP market experienced a hype based on the Y2K problem, but after Y2K the ERP market soured. It was doubted that traditional ERP could meet the e-business challenge (Mabert, Soni, & Venkataramanan, 2001). New vendors of the "bolt-on" systems like, for example, i2 Technology with SCM and Siebel with CRM emerged on the scene (Calloway, 2000) and Application Integration (EAI) became a critical issue (Evgeniou, 2002). New delivery and pricing methods like ASP (Application Service Provider) and ERP rentals were conceived (Harell, Higgins, & Ludwig, 2001) and the traditional ERP vendors were challenged.

The ERP II concept is a vision original conceived by Gartner Group in 2000. Gartner Group, who also put the name on the ERP concept, defines ERP II as: "a business strategy and a set of industry-domain-specific applications that build customer and shareholder value by enabling and optimizing enterprise and inter-enterprise, collaborative-operational and financial processes" (Bond et al., 2000).

ERP II builds on ERP and thus the concept excludes the "bolt-on" vendors like i2 or Siebel from this vision (Mello, 2001). AMR Research does not restrict their competing vision on Enterprise Commerce Management (ECM) to the ERP vendors and define ECM as: "a blueprint that enables clients to plan, manage, and maximize the critical applications, business processes and technologies they need to

support employees, customers, and suppliers" (http://www.amrresearch.com/ECM). GartnerGroup has later resigned on this requirement and today ERP II is a framework which includes enterprise systems based on "Best of Breed" systems and EAI (Light, Holland, & Willis, 2001) as well as "Single Vendor" solutions.

ERP II includes six elements that touch business, application and technology strategy: (i) the role of ERP II, (ii) its business domain, (iii) the functions addressed within that domain, (iv) the kinds of processes required by those functions, (v) the system architectures that can support those processes, and (vi) the way in which data is handled within those architectures. With the exception of architecture, these ERP II elements represent an expansion of traditional ERP. ERP II is essentially componentized ERP, e-business and collaboration in the supply chain (Bond, 2001).

Throughout the ERP industry, the new philosophies of e-business was gradually incorporated into the legacy ERP systems, and system architectures were redesigned and modularized, for example, like SAP did with their NetWeaver platform. Consequently, the contemporary standard systems today incorporate the ERP II vision. The ERP industry survived the challenge and a recent market analysis does not render any signs of market fragmentation, but rather a consolidation. Today, we see an ERP market consisting of one dominant actor, a handful of major vendors and a larger number of vendors of minor significance (also c.f. Table 1).

Today, all the major vendors have adopted the ERP II concept, either partly or to the full extent. The evolution has been driven by the emerging business requirements and by the possibilities offered by the new information technology, exactly the same as the evolution of the ERP concept.

The new technologies are not necessarily inventions of the ERP vendors, but rather the technologies emerge as stand alone systems and after a while they are adopted by the major vendors and then incorporated into the standard systems. That happened to, for example, application frameworks (.NET or J2EE), the databases (Oracle or MS SQL) or Decision-Support Systems (DSS). Business Intelligence (BI) is an example of an analytical DSS technology previously associated with add-ons, like Data warehouse systems based on OLAP tools, and are now integrated into the core of the standard databases. BI refers to a broad category of analytical applications that helps companies make decisions based on the data in their ERP systems. Another example is the Internet standards like XML, originally conceived outside the control of the major vendors but gradually adopted into the infrastructure of the ERP systems. Other examples are the Supply Chain Management (SCM) systems or the Customer Relationship Management (CRM) systems from third-party vendors like i2 or Siebel. Those third-party vendors experienced a short explosive growth, but then when the technologies are incorporated into the standard ERP system the potential business benefit increases.

FUTURE TRENDS: THE NEXT-GENERATION ERP

There is an emerging pattern of stable generic application architectures which we choose to portray as the ERP II con-

Table 3. The four layers of ERP II

Layer		*Components*
Foundation	Core	Integrated Database (DB) Application Framework (AF)
Process	Central	Enterprise Resource Planning (ERP) Business Process Management (BPM)
Analytical	Corporate	Supply Chain Management (SCM) Customer Relationship Management (CRM) Supplier Relationship Management (SRM) Product Lifecycle Management (PLM) Employee Lifecycle Management (ELM) Corporate Performance Management (CPM)
Portal	Collaborative	Business-to-consumer (B2C) Business-to-business (B2B) Business-to-employee (B2E) Enterprise Application Integration (EAI)

cept. Calloway (2000) and Weston (2003) have attempted to frame this overall development and partial aspects have further been dealt with, for example, by Wortmann (2000) and by Møller (2005b). The conceptual framework of ERP II illustrated in Figure 1 consists of four distinct layers, as exhibited in Table 3: (i) the foundation layer, (ii) the process layer; (iii) the analytical layer and (iv) the e-business layer consisting of the collaborative components.

Core Components

The foundation layer consists of the core components of ERP II. The core components shape the underlying architecture and provide a platform for the ERP II systems. ERP II does not need to be centralized or monolithic. One of the core components is the **integrated database**, which may be a distributed database. Another core component is the **application framework,** likewise potential distributed. The integrated database and the application framework provide an open and distributed platform for ERP II.

Central Components

The process layer of the concept is the central component of ERP II, and this layer reflects the traditional transaction-based systems. ERP II is **Web-based open and componentized**. This is different from being Web-enabled, and the ultimate ERP II concept may be implemented as a set of distributed Web services.

Enterprise Resource Planning (ERP) is one of the central components in the ERP II conceptual framework. The backbone of ERP is the traditional ERP modules like financials, sales and distribution, logistics, manufacturing, or HR. ERP still makes up the backbone of ERP II along with the additional integrated modules aimed at new business sectors outside the manufacturing industries.

The ERP II concept is based on **Business Process Management** (**BPM**). ERP has been based on "Best-practice" process reference models but ERP II systems build on the notion of the process as the central entity and ERP II include tools to manage processes: design (or orchestrate) processes, to execute and to evaluate processes (Business Activity Monitoring) and in ERP II redesigning processes will have effect in real-time.

The BPM component allows for ERP II to be accommodated to suit different business practices for specific business segments that otherwise would require problematic customization. ERP II further includes vertical solutions for specific segments like apparel and footwear or the public sector. Vertical solutions are sets of standardized preconfigured systems and processes with "add-ons" to match the specific requirements in, for example, a business sector.

Corporate Components

The analytical layer consists of the corporate components that extend and enhance the central ERP functions by providing decision support to manage relations and corporate issues. Corporate components are not necessarily synchronized with the integrated database and the components may easily be "add-ons" acquired by third-party vendors. The most common components such as Supply Chain Management (SCM) systems and Customer Relationship Management (CRM) systems are listed in Table 3 and illustrated in Figure 1, and they will further be explained under the terms and definitions at the end of this article.

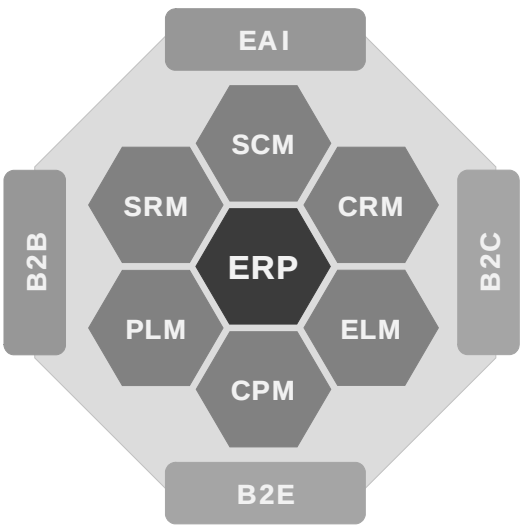
In the future, we can expect new breeds of corporate components. Product Lifecycle Management is already established as the R&D equivalence to ERP and Employee Lifecycle Management is emerging as an example of a people-oriented component.

Collaborative Components

The e-business layer is the portal of the ERP II systems and this layer consists of a set of collaborative components. The collaborative components deal with the communication and the integration between the corporate ERP II system and actors like customer, business partners, employees, and even external systems.

The most common and generic components are listed in Table 3 and illustrated in Figure 1, and will further be explained under the terms and definitions at the end of this article.

Figure 1. The conceptual framework for ERP II



CONCLUSION

ERP II is a vision of the next-generation ERP and the conceptual framework for ERP II is a generic model of the emerging architecture of the contemporary enterprise systems. All major ERP vendors have implemented major parts of this concept (SAP NetWeaver, Oracle Fusion and Microsoft Dynamics). ERP II is aimed at extending the reach of integration into the supply chain and the business benefits of the systems are only realized when the integration occurs (Davenport, Harris, & Cantrell, 2004). Business managers will therefore need to consider their entire range of enterprise systems into a supply chain integration context, and future research will deal with interorganizational integration based on the ERP II.

KEY TERMS

Enterprise Resource Planning (ERP) II systems are second generation ERP systems. ERP II extends on the ERP concept (see Figure 1). The ERP II vision is framed by Gartner Group and in practice defined by the contemporary systems of the major ERP vendors.

Supply Chain Management (**SCM**) systems provide information that assist in planning and managing the production of goods. For instance, SCM assists in answering questions such as where the good is to be produced, from what the parts are to be procured and by when it is to be delivered.

Customer Relationship Management (**CRM**) systems facilitate the managing of a broad set of functions relating to managing customers relations that primarily include the categories of customer identification process and customer service management.

Supplier Relationship Management (**SRM**) is the vendor side analogy to CRM aimed at the effective management of the supplier base. SRM facilitates the management of the supplier relations in its entire life-cycle.

Product Lifecycle Management (**PLM**), including Product Data Management (PDM), enables enterprises to bring innovative and profitable products to market more effectively, especially in the evolving e-business environment. PLM enables enterprises to harness their innovation process through effective management of the full product definition lifecycle in their extended enterprises.

Employee Lifecycle Management (ELM) is the integration of all aspects of information and knowledge in relation to an employee from the hiring to the retirement from the company. ELM enables enterprises to effectively manage their portfolio of competencies.

Corporate Performance Management (CPM), or sometimes Enterprise Performance Management (EPM), is an umbrella term that describes the methodologies, metrics, processes and systems used to monitor and manage an enterprise's business performance. Thus, CPM provides the managements with an overall perspective on the business.

Consumer to business (B2C), or e-commerce systems, deals with the carrying out of commercial transactions with businesses or with individual customers by using the Internet as an electronic medium. This requires an extensive infrastructure of which the main features are a catalogue, online ordering facilities and status checking facilities.

Business to business (B2B), or e-procurement systems, improves the efficiency of the procurement process by automating and decentralizing the procurement process. The traditional methods of sending Request for Quotes (RFQ) documents and obtaining invoices and so forth, are carried out over the Web through purchasing mechanisms such as auctions or other electronic marketplace functions, including catalogues.

Business to employee (B2E), intranets or knowledge management systems, provide the employee with an updated personalized portal to the enterprise on his desktop. The perspectives of the intranet and knowledge management systems increase in the context of the ERP II concept.

Enterprise Application Integration (EAI), or extranets, provides the ERP II system with a portal and a platform for integration with other systems inside or outside the corporation. EAI provides the support for automating processes across various IT platforms, systems and organizations.

The Nomological Network and the Research Continuum

Michael J. Masterson
USAF Air War College, USA

R. Kelly Rainer, Jr.
Auburn University, USA

INTRODUCTION

Social science and management information systems (MIS) research have been criticized for failure to integrate theory construction and theory testing (see e.g., Subramanian & Nilakanta, 1994). In particular, concerns with MIS as a cohesive research discipline have long included inadequate construct development and lack of valid, reliable measuring instruments for those constructs (Keen, 1980). Understanding the theoretical basis of constructs and how they are developed and tested across the research continuum are fundamentals of a cohesive academic discipline. To provide a common research framework for the growth of MIS as a scientific discipline, this chapter proposes a framework for an integrated research continuum across the life cycle of the research process.

BACKGROUND

The growth of any scientific discipline entails the development of a system of specialized, abstract concepts that define the lawful relationships (or hypotheses) that represent a discipline's theories. Scientists recognize underlying concepts in observed phenomena and build those concepts into the lawful relationships of a scientific theory (Blalock, 1982, Hempel, 1952).

This search for lawful relationships among natural events is the primary function of science, and focuses on two objectives: (1) describing specific events, objects, or phenomena in the world of experience and (2) establishing theories, or general principles, to explain or predict the specified events, objects, or phenomena (Feigl, 1970 Hempel, 1952).

Theories of a science must support explanation and prediction. If a scientific discipline lacks explanatory and predictive theories, no connection can be established between descriptions of different events, objects, or phenomena. Such a nontheory based discipline is unable to predict or prepare for future occurrences. The lack of explanatory principles permits no use of theory for practical application. Practical application requires theories or principles that explain what particular effects occur when specific changes occur in a given system. In addition, comparability tests of the theory by other researchers would be impossible (Blalock, 1982).

SCIENTIFIC THEORY AS A SPATIAL NETWORK AND THE RESEARCH CONTINUUM

To develop precise theories of wide scope and high empirical confirmation, scientific disciplines create and evolve comprehensive systems describing lawful relationships of theoretical constructs (Hempel, 1952). Some variables of interest within these theoretical constructs cannot be directly observed. Thus, constructs contain theorized unobservable, latent factors measured by empirically observed indicators (Nunnally, 1978).

A comprehensive scientific theory can be represented as a spatial network in which hypotheses use correspondence rules to link theoretical constructs to derived and observed empirical concepts, which acquire meaning through operational definitions. The unobservable (latent) theoretical constructs are anchored to the empirical environment by rules of interpretation (the correspondence rules). By virtue of these interpretive connections, the network can function as a scientific theory (Blalock, 1982). The ability to interpret unobservable, underlying constructs transforms a theoretical, spatial network into an empirically testable theory.

An important implication of this view of the structure of theory is that the integration of theory construction and theory testing across the research continuum is of major importance (Feigl, 1970; Hempel, 1952; Hughes, Price, & Marrs, 1986; Trochim, 1996). Figure 1 (below) is a graphic depiction of this spatial framework, developed from the work of Hempel (1952), Blalock (1982), and Trochim (1996).

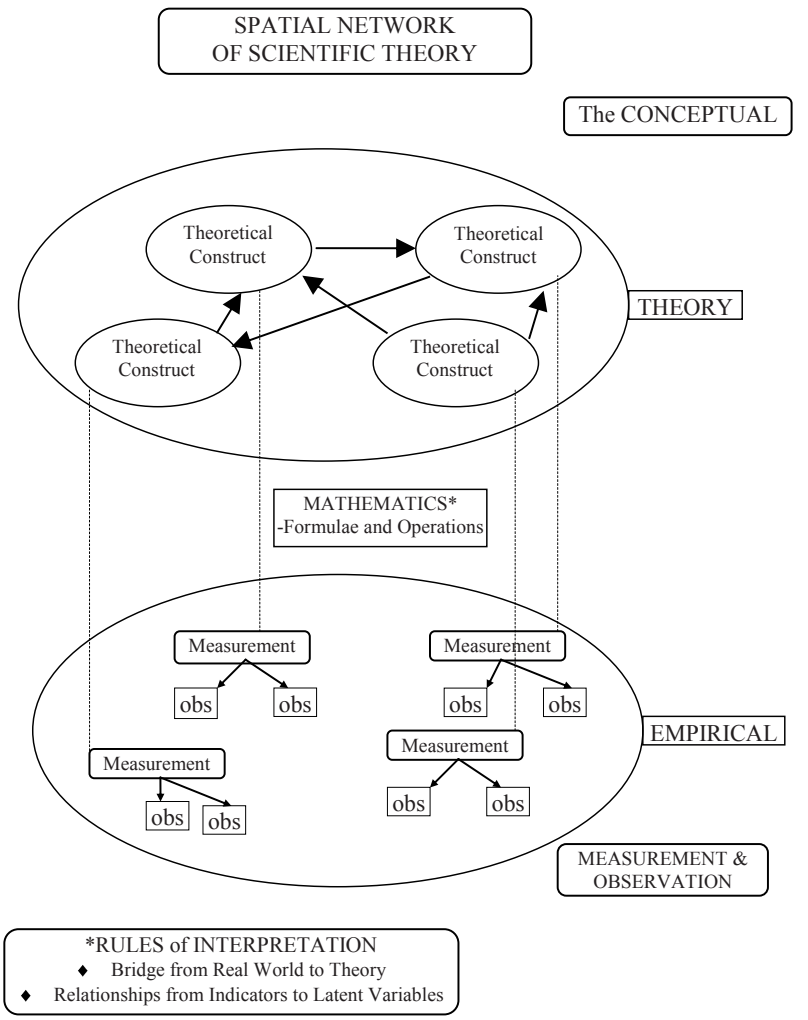
Figure 1 represents a 1:1 correspondence between theoretical constructs and measurements, which is not always the case. Observable measurements, which are qualitatively different in the empirical world, can overlap or measure the same thing if their positions in this spatial network link them to the same theoretical construct. Also, a measurement may serve as the interpretive link to multiple theoretical

constructs, though the researcher would specify the operative definition in use for that interpretive relationship, for example, measuring self-esteem requires accounting for elements of self-image and ego (Cronbach & Meehl, 1955; Hempel, 1952; Trochim, 1996).

In a spatial network of theory and observation, internal principles define basic entities (concepts and constructs) of the theory, and the hypotheses describe interrelationships of these theoretical constructs, either within the same theory or with other theories. (see "The CONCEPTUAL" in Figure 1). Bridge principles are the mathematical formulae and operations, stated as the rules of interpretation, that link the processes proposed by the theory to empirical phenomena (measures and observations). Bridge principles enable a theory to be used for explanations and/or prediction (see "EMPIRICAL" and "RULES of INTERPRETATION" in Figure 1). Without these principles, a theory has no explanatory power or practical application, and no empirical test is possible.

A fundamental requirement of science is that a statement of fact from an appropriate theory made by one scientist must be independently verifiable by other scientists. This principle of scientific generalization gains wide belief and support for any theory and is central to all scientific work (Nunnally, 1978).

Figure 1.



Unlike the physical sciences, social and behavioral sciences study living organisms to define and classify behavior, and the hypotheses linking behavior to conditions that control it. Psychological measurement, or psychometrics, is inseparable from this process (Nunnally, 1978). Evaluating the adequacy of a theoretical spatial network requires judging empirical testability (Popper, 1959), verifiability (Dodd, 1968), and confirmability (Clark, 1969). Meeting these standards requires a clear and explicit specification of theoretical construct definitions and operationalizations across the research continuum (Hughes et al., 1986). Statistics is the area of mathematics used in evaluations of theoretical constructs.

Scientific behavioral studies begin with observations or questions about some object, event, or phenomenon, in a search for the functional relationships, the laws, and the principles of behavior. This behavior must be described in a manner that fully communicates all observations to others so that they may verify the observation. (Blalock, 1982).

The Nomological Network. Cronbach and Meehl (1955) defined a nomological network as the interlocking system of hypotheses, principles, and laws linking the constructs that constitute any theory. A nomological network encompasses the theoretical constructs being measured, how the concept is going to be measured, and the specification of the interrelationships between the theoretical and empirical planes (see Figure 1). All three aspects of the spatial network are present in a nomological network: constructs, empirical observations/measures, and the mathematical rules of interpretation that link theory to observation. Scientifically, the purpose of the nomological network is to clarify all parts of a theory, so a theory's laws of explanation and prediction can be exploited.

As a standard for tests of social and behavioral constructs, the nomological network focuses on sampling statistics of content (test items), not sampling statistics of people. As empirical measures of a theory are developed, the theory formulation that guides the development of the mathematical formulae and operations focuses on sampling content (Blalock, 1982; Nunnally, 1978). The goal of sampling content is to generalize findings over populations of test items. The researcher addresses what, not who, is being measured (Cronbach, 1975). Thus, the specific focus of the nomological network is not the subject. Rather, the nomological network measures observable properties, the relationship of different theoretical constructs to each other, and the relationship of the theoretical constructs to the observable properties via the mathematical rules of interpretation (Cronbach, 1975; Cronbach & Meehl, 1955). Also, at least some of the laws in the nomological network must involve observables, otherwise no bridge could exist to the theoretical constructs. (Cronbach & Meehl, 1955; Trochim, 1996).

Cronbach and Meehl (1955) defined construct validity as the process of following all these principles of the nomological network to ensure generalizability of scientific principles. Construct validity specifically addresses the question, "Does the test measure the attribute it is said to measure?" Construct validation identifies theoretical constructs defined by a network of relations, all of which are anchored to observables, making the constructs testable (Cronbach, 1975). This process is a direct identification of the spatial network (see Figure 1) and the nomological network, including the constructs (concepts) of interest in a theory, their observable manifestations, and the interrelationships among the constructs, measures, and observations.

The social and behavioral sciences, including MIS, face difficulties that vary considerably from those encountered in the physical sciences. These difficulties stem from two fundamental issues, which are:

1. the relationship between theory and research, and
2. the development of theoretically defined constructs and measurement procedures.

When the phenomena of interest cannot be directly observed, the development of latent constructs and instruments to operationalize them provide the theoretical basis for research in a discipline (Venkatraman & Grant, 1986). To meet this basic criterion of science, the focus must be on generalizability and the comparability of one's measurements across diverse settings (Hughes et al, 1986; Nunnally, 1978). Blalock (1982) identifies this focus as one of conceptualization and measurement, where

1. Conceptualization refers to the theoretical process by which researchers move from ideas or constructs to suggesting appropriate research operations.
2. Measurement refers to the linkage process between the physical operation, on the one hand, and a mathematical language on the other.

Systems theory is commonly used as a generic concept to represent the elements represented in this triple linkage (Blalock, 1982; Trimmer, 1950). The essential point in connecting theoretical constructs, physical measurement operations, and mathematical formulae and operations, is that the basic concepts or variables be specified with sufficient clarity so that

1. the "systems" or unit to which they are intended to refer is known;
2. it is clear how to distinguish them from other stimuli, properties, or responses with which they are likely to be confounded;

3. it has been specified how concepts that refer to one type of system are related definitionally, or by some presumed causal law, to at least some concepts that refer to any other systems that are also expected to play important roles in substantive theories.

This last specification implies that it is often desirable to use information provided at one level of analysis (e.g., about individual behaviors) to support, refute, or clarify theories formulated at other, unobservable levels. Psychologists successfully integrated the methodological tools of empirically minded investigators presented in the scaling and measurement literature. Unfortunately, this has resulted in an imbalance between theory development and methods of measurement, with development of measures occupying a much larger place in the research process than conceptualization of theory (Ackoff, 1984). This creates the necessity for explicit theoretical formulations that clearly state which theoretical assumptions are being made in each measurement decision across the research continuum (Blalock, 1982).

The Research Continuum. The life cycle of the research process functions as an integrated continuum moving from the most exploratory, descriptive kinds of observation, to generalization, and finally to experimental applied research focused on complete, specific answers (Ackoff, 1984; LaMott, 1997; Vandendorpe, 1997). The clear focus on the nonhierarchical developmental aspect of basic research supports a model of the research continuum in which phases of the research life cycle are integrated, rather than performed separately. This holistic approach lets the researcher determine research strategy, orientation, and criteria (Cronbach & Meehl, 1955; Yin, 1994). A researcher determines the type of research strategy by choosing one of the following familiar series of questions to ask: "who," "what," "where," "how," and "why" (Hedrick et al., 1993; Yin, 1994).

"What" questions are exploratory and deal with conceptual discussions and initial theory formulation examining observed phenomena. "Who" and "where" questions favor survey strategies or analysis of archival records to seek generalizable patterns. Frameworks (i.e., a taxonomy of classification based on standard guidelines) are developed to explain, organize, and manage identified patterns (see e.g., Kochen, 1986; Merrill & Tenneyson, 1977). Frameworks in the field of MIS, for example Nolan and Wetherbe (1980), are typically validated by mapping MIS research publications to the framework to determine if the framework properly classifies the published material. This method organizes the research and enables recognition of conceptual patterns. These strategies support research goals that are either descriptive or predictive. "How" and "why" questions are more explanatory, and lead to the use of single or multiple case studies and experiments as the preferred research strategy. The experiments could be either field experiments or laboratory experiments, again determined by the researcher's orientation (Latane & Darley, 1969; Yin, 1994).

Surveys help researchers generalize their findings. One survey development example in MIS research is the development of the end-user computing construct (Rainer & Harrison, 1993), which used Churchill's (1979) survey development process.

When researchers focus on specific "how" and "why" criteria, field experiments are in order. Data are collected from subjects in the environment where the construct of interest exists. Finally, with the proper constructs of interest (e.g., computer skills) identified, researchers set up laboratory experiments to obtain observable outcomes (see e.g., Miller, 1994).

Theory building takes place in the exploratory and generalization phases of the research process, while theory testing occurs in the generalization and experimental phases. This blending of phases, where theory development or testing are accomplished, demonstrates the integration of research across the continuum, as depicted in Figure 2. The research continuum (LaMott, 1997; Yin, 1994) supports theory building and theory testing in an interactive model.

The process of basic research as a complex, pluralistic feedback model integrates the research life cycle across a broad continuum. Research does not follow a rigidly structured, waterfall life cycle. Instead, a researcher can spiral across and down the continuum on a specific research track. In this spiral process, different strategies and phases of the research process are determined by the orientation and criteria set by the researcher. This process includes the peculiarity of an observation being applied, in practice, with no theoretical foundation (Kochen, 1986).

In 1997, *R&D Magazine*'s basic research survey of 4,000 researchers, 67.3% stated that the most critical element of basic research developed an understanding of scientific principles or phenomena. They noted that the second most critical element was creation of a foundation for future development. These two critical elements point out the importance and currency of the spatial network of theory development and the nomological network (Vandendorpe, 1997).

Different strategies can be employed across the research continuum. The changing orientation and criteria of the researcher determines strategy. The nature of the following components and dimensions of the research continuum become more specific and increase in importance in moving from conceptual studies to laboratory experiments (Blalock, 1982; Nunnally, 1978):

1. knowledge of subjects and environment;
2. questions and objectives and data collection procedures;
3. knowledge of and accuracy in operationalizing variables and relationships;
4. potential internal validity;

Figure 2.

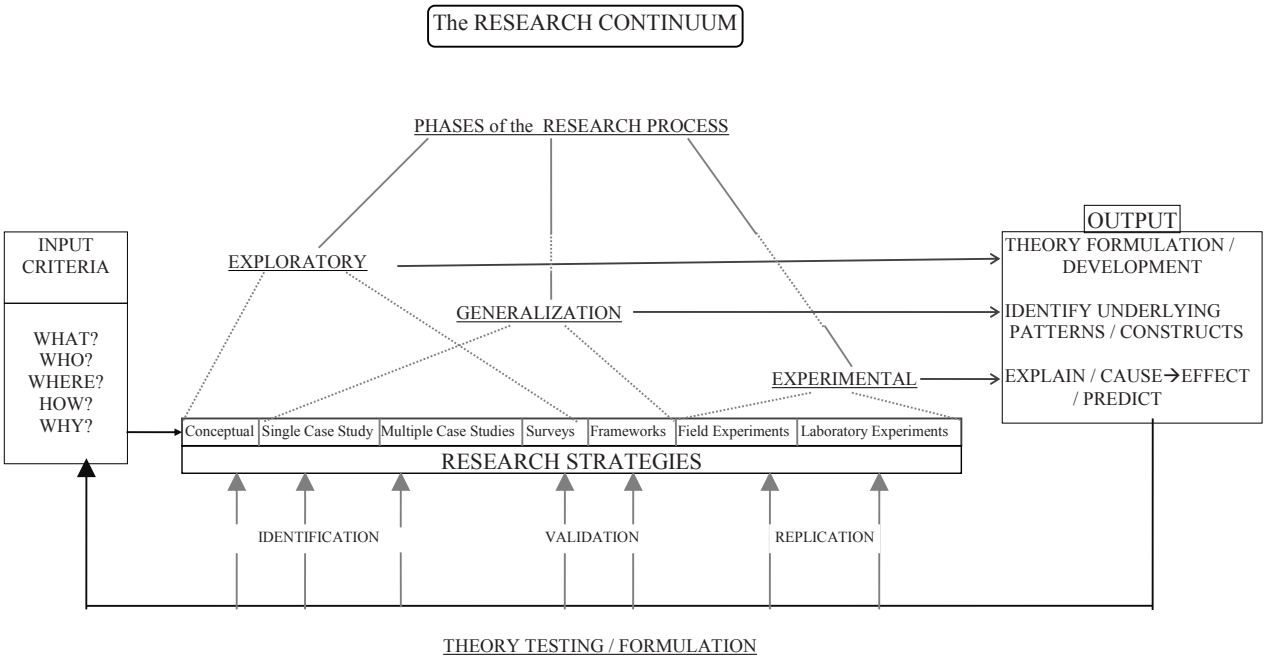


Figure 3.

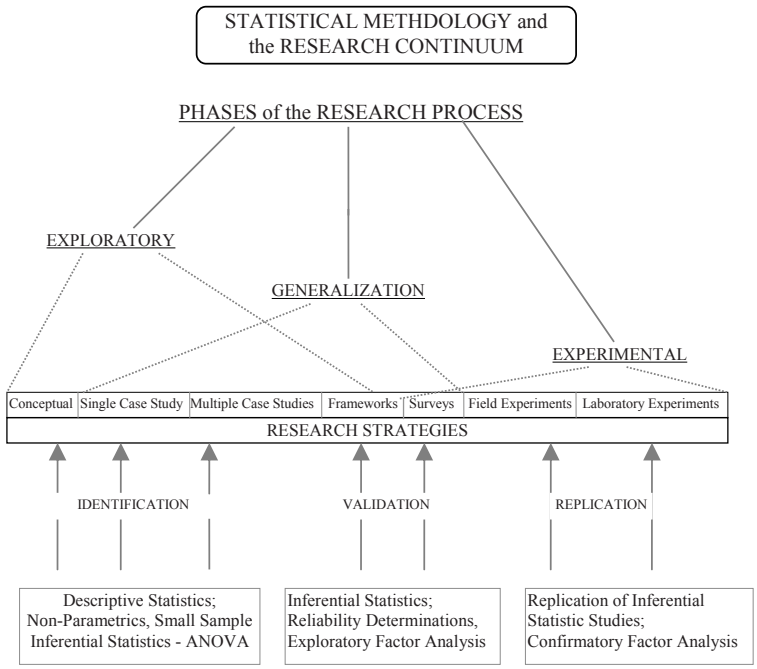

5. potential external validity;
6. potential reliability;
7. possible sources of bias.
8. ability to predict;
9. ability to uncover causal models.

Also, the statistical methodologies employed by a researcher change across the research continuum from conceptual studies to laboratory experiments (see Figure 3). The change is from descriptive to inferential statistics, from initial descriptive identification of observations to independent confirmation and replication critical to the process of scientific generalization.

FUTURE TRENDS

Although the spatial, nomological network and the research continuum have high face validity, more work needs to be done in these areas. It is interesting to note that the references here are relatively old. The fact is that researchers have not done recent work in these areas.

One direction for future research would be to validate the nomological network and research continuum proposed here. Researchers could take a subject area in a discipline (e.g., decision support systems in MIS), map its constructs to the nomological, spatial network and map its published articles to the research continuum.

CONCLUSION

Social and behavioral sciences face two very different issues from those encountered in the physical sciences: (1) the relationship between theory and research, and (2) the development of theoretically defined constructs and measurement procedures. By understanding the integrated and interactive nature of the research continuum across the life cycle of research, and the fundamental requirement for development of theory out of that research, investigators can advance the rigor of their chosen academic disciplines, and build a testable body of work to support and grow their chosen scientific discipline.

This research continuum, grounded in the triple linkage depicted in the spatial network, is robust and flexible. However, the challenge in not having readily observable and measurable data outcomes across the research continuum makes the operationalization and measurement of constructs for a researcher difficult, challenging, and tedious (Blalock, 1982). Understanding the theoretical basis of a construct, how it is developed and tested within a nomological network, and the interplay across the research continuum, are fundamental in contributing to the establishment and future development of MIS and social sciences as cohesive academic disciplines.

KEY TERMS

Basic Research: Research performed without thought of practical ends, producing general knowledge and an understanding of nature and its laws.

Bridge Principles: Mathematical formulae and operations, stated as the rules of interpretation, that link the processes proposed by the theory to empirical phenomena (measures and observations).

Conceptualization: Refers to the theoretical process by which researchers move from ideas or constructs to suggesting appropriate research operations.

Construct Validity: Identifies theoretical constructs defined by a network of relations, all of which are anchored to observables, making the constructs testable.

Internal Principles: Define basic entities (concepts and constructs) of the theory and the lawful relationships, hypothesized as part of theory, describing interrelationships of these theoretical constructs, either within the same theory or with other theories.

Measurement: Linkage process between the physical operation, on the one hand, and a mathematical language on the other.

Measurement by Proclamation: Theoretical claims of lawful relationships with no link to empirical tests (Blalock, 1982).

Nomological Network: Interlocking system of hypotheses, principles, and laws linking the constructs that constitute any theory.

Theories: General principles to which individual events, objects, or phenomena conform, and by which the occurrence of these events, objects, or phenomena is systematically anticipated.

Nonlinear Approach to Brain Signal Modeling

Tugce Balli
University of Essex, UK

Ramaswamy Palaniappan
University of Essex, UK

INTRODUCTION

Biological signal is a common term used for time series measurements that are obtained from biological mechanisms and basically represent some form of energy produced by the biological mechanisms. Examples of such signals are electroencephalogram (EEG), which is the electrical activity of brain recorded by electrodes placed on the scalp; electrocardiogram (ECG), which is electrical activity of heart recorded from chest, and electromyogram (EMG), which is recorded from skin as electrical activity generated by skeletal muscles (Akay, 2000).

Nowadays, biological signals such as EEG and ECG are analysed extensively for diagnosing conditions like cardiac arrhythmias in the case of ECG and epilepsy, memory impairments, and sleep disorders in case of EEG. Apart from clinical diagnostic purposes, in recent years there have been many developments for utilising EEG for brain computer interface (BCI) designs (Vaughan & Wolpaw, 2006).

The field of signal processing provides many methods for analysis of biological signals. One of the most important steps in biological signal processing is the extraction of features from the signals. The assessment of such information can give further insights to the functioning of the biological system.

The selection of proper methods and algorithms for feature extraction (i.e., linear/nonlinear methods) are current challenges in the design and application of real time biological signal analysis systems. Traditionally, linear methods are used for the analysis of biological signals (mostly in analysis of EEG). Although the conventional linear analysis methods simplify the implementation, they can only give an approximation to the underlying properties of the signal when the signal is in fact nonlinear. Because of this, there has been an increasing interest for utilising nonlinear analysis techniques in order to obtain a better characterisation of the biological signals.

This chapter will lay the backgrounds to linear and nonlinear modeling of EEG signals, and propose a novel nonlinear model based on exponential autoregressive (EAR) process, which proves to be superior to conventional linear modeling techniques.

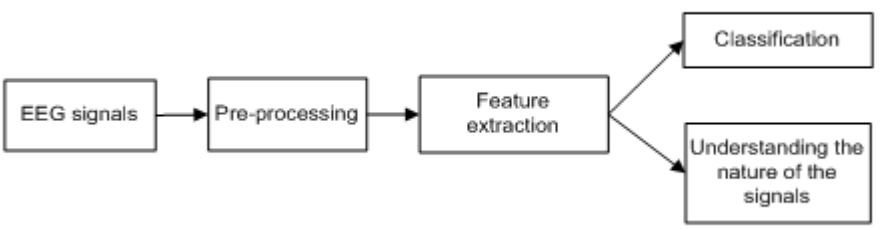
BACKGROUND INFORMATION

EEG Signal Processing

In recent years, the field of biological signal processing has seen an explosive growth. In particular, there have been many research studies on EEG signals for:

- Diagnosis of certain neurological conditions such as sleep disorders, memory impairments and epilepsy;
- Extracting relevant features for classification of different mental states;

Figure 1. The basic steps in EEG signal analysis



- Understanding the dynamics and underlying mechanisms of the brain.

Figure 1 shows the basic steps in the analysis of EEG signals, these are: *preprocessing* which includes the removal of noises such as the baseline noise, powerline interference and eye blink contamination; *feature extraction,* which extracts representative values of the signals through modeling techniques, and *classification,* where the extracted features are classified in specific for the application, such as discrimination between different mental states or neurological conditions. Note that the feature extraction step is not necessarily followed by classification—the features can also be used in understanding the nature and underlying dynamics of the signals, for example in investigating a certain brain disorder. The selection of appropriate feature extraction methods for obtaining a better representation of the EEG signals is the most challenging step in EEG signal processing. This can be approached in two ways namely the linear and nonlinear modeling techniques.

Utilising Linear Modeling Techniques for Analysis of EEG Signals

Since its discovery by Hans Berger in 1929 (Sanei & Chambers, 2007) the EEG signals have been used extensively in research studies for diagnosis of certain neurological conditions (such as memory impairments, sleep disorders, and epilepsy). Traditionally linear modeling techniques like autoregressive (AR) modeling and power spectral estimation (PSD) have been extensively used for the analysis of EEG signals (Sanei & Chambers, 2007).

Palaniappan (2005) used second order AR model coefficients as features for the classification of EEG signals recorded from alcoholic and control subjects. The EEG signals were recorded from subjects while they were exposed to visuals selected from Snodgrass and Vanderwart picture set. The feature sets were classified using three different classification algorithms namely the simplified Fuzzy ARTMAP (SFA) neural network (NN), multilayer-perceptron trained by the backpropagation algorithm (MLP-BP) and Linear Discriminant (LD). The results of this study indicated that the classifiers were able to discriminate the alcoholic and control subjects with average discrimination error of 2.6%, 2.8% and 11.9% for LD, MLP-BP and SFA classifiers respectively.

In another study, Subasi, Kiymik, Alkan, and Koklukaya (2005) characterised and classified EEG segments recorded from epilepsy patients and healthy subjects using PSD values as feature sets. Two different methods were utilised for PSD estimation namely the AR spectral estimation and FFT-based spectral estimation. The feature sets were classified using multilayer feedforward neural network with backpropagation algorithm (MLP-BP). The results of this study indicated an average classification accuracy of 92.3% for AR spectral estimation and 91.6% for FFT-based spectral estimation. The authors also suggested that utilizing nonlinear methods instead of the conventional linear methods would improve the classification accuracy.

Apart from diagnostic purposes, in the last decade there has been an increasing interest in utilising EEG for Brain Computer Interface designs. Keirn and Aunon (1990) were one of the first groups that suggested using EEG as an alternative mode of communication between disabled people and their environment. The different pairs of mental tasks were classified (i.e., baseline, maths, letter composing, geometric figure rotation, and visual counting) using a Bayesian quadratic classifier. They used power asymmetry ratio for creating the feature sets since the mental tasks were identified as belonging to right or left hemisphere of the brain. In addition, they used AR model coefficients as feature sets. Their study showed that the AR method was superior to asymmetry ratios where the most significant result was 84.6% classification accuracy for discrimination of two different mental tasks.

Utilising Nonlinear Modeling Techniques for Analysis of EEG Signals

The individual neurons in the brain behave in a nonlinear manner. There are many research studies reporting more or less successful attempts to apply nonlinear methods to biological time series data (Babloyantz, Salazar & Nicolis, 1985; Bukkapatnam et al, 2002; Gautama, Van Hulle & Mandic, 2003; Lehnertz, Mormann, Kreuz, Anderzak, Rieke & David, 2003; Stepien, 2002).

One of the first studies on nonlinear EEG analysis was by Babloyantz et al. (1985). In this study it was shown that certain nonlinear measures (i.e., Correlation Dimension) change during low-wave sleep patterns. In other words, different sleep stages could be discriminated using these nonlinear measures. After this study the nonlinear methods began to attract the interest of many researchers. Nonlinear methods have been applied mainly to areas such as diagnosis of epileptic seizures and sleep disorders (Chippa & Bengio, 2003).

Bukkapatnam (2007) characterized and classified two different mental conditions from EEG signals using the theory of nonlinear dynamical systems. In this study, 64 channel signals of length 256 samples recorded from 20 people were used. Out of 20 EEG signals used, 10 were obtained from people under alcoholic influence and the remaining ten were recorded from people in a normal (non-alcoholic) condition. The feature sets were created by calculating the correlation dimension of the EEG segments (where this measure quantifies the nonlinear complexity of the signals) (Sanei & Chambers, 2007). The created feature sets were used as an input to a two layer back propagation neural network. The

classifier was able to distinguish between subjects under alcoholic influence and the control subjects with 90% accuracy. The results of this study indicated that EEG signals could be described as noise-contaminated, nonlinear, and perhaps chaotic dynamic systems.

In Stepien et al. (2002), an analysis of spontaneous EEG of 21 healthy subjects recorded when they were resting was conducted. The EEG signals were tested if they were generated by a nonlinear process using surrogate data method (Theiler, Eubak, Longtin, Galdrikian & Farmer, 1992), where the nonlinear prediction error was used as a test statistic. Out of 336 (from 21 subjects with 16 channels) EEG segments, only 17 (5%) of them were found to be nonlinear. The results of this study indicated very low percentage of nonlinearity in the EEG signals recorded from healthy subjects. However, the existence of nonlinearity in various pathological states like epilepsy is indicated by Lehnertz et al. (2003) and Gautama et al. (2003). The existence of this distinguishing feature between normal and diseased cases would allow improved classification of EEG signals using nonlinear methods.

In another previous study done by Gautama et al. (2003), the nonlinearity of EEG signals recorded from healthy and epilepsy patients was investigated. In total, five sets of EEG data were utilised where the sets A and B were recorded from healthy subjects with eyes open and closed, the sets C and D were recorded from epilepsy patients during seizure-free interval from epileptogenic zone and from outside of epileptogenic zone, respectively. And the set E contained the EEG segments recorded from epilepsy patients during seizure activity recorded from seizure generating areas. The nonlinearity of the EEG segments was assessed by surrogate data method (Theiler et al., 1992) where the delay vector variance, third order autocorrelation and asymmetry due to time reversal methods were used for the characterisation of time series (Gautama et al., 2003). The results of this study indicated that the percentage of nonlinearity is lower for EEG segments recorded from healthy subjects (i.e., with eyes open and closed: sets A and B) compared to epilepsy patients (i.e., during seizure and seizure free intervals: sets C, D, and E). These results show that there are clear differences in dynamical properties of the electrical activity of the brain recorded from different physiological and pathological brain states.

Lehnertz et al. (2003) indicated in his article that there are plenty of evidences in the literature that nonlinear EEG analyses are able to characterize the neuronal behavior in the brain and provide a tool for detecting the preictal state in the epilepsy patients. However the sufficiency of sensitivity[a] and specificity[b] of these analysis techniques are still subject to current research. The development of new time series analysis techniques that will sufficiently represent the nonlinear, chaotic and multidimensional behavior of the EEG signals will improve the understanding of the brain dynamics. Once enough specificity and sensitivity is obtained from these analysis techniques, more extensive clinical studies and the implementation of such systems can be considered in the future.

EXPONENTIAL AUTOREGRESSIVE MODEL–A RECENT NONLINEAR MODELING TECHNIQUE FOR ANALYSIS OF EEG SIGNALS

Haggan and Ozaki (1981) introduced EAR algorithm for modeling nonlinear fluctuations in time series. They stated that the analysis of stochastic processes have been mostly done using some form of linear time series modeling and this can only provide an approximation to the underlying properties of the signals. Besides, it is found that many signals exhibiting random vibrations display nonlinear behavior; hence a nonlinear model that gives a good approximation to the underlying properties of a signal is required.

The EAR model exhibits certain features of random vibrations that do not occur in linear models namely the amplitude-dependent frequency, jump phenomena and limit cycle (Haggan & Ozaki, 1981).

An EAR model of order p is defined by;

$$x_t = \sum_{k=1}^{p} (\varphi_k + \pi_k \cdot e^{-\gamma x_{t-1}^2}) \cdot x_{t-k} + e_t \tag{1}$$

where φ, π, γ are autoregressive coefficients, x_t is data at sampled point t, p is the model order and e_t is Gaussian white noise with mean zero.

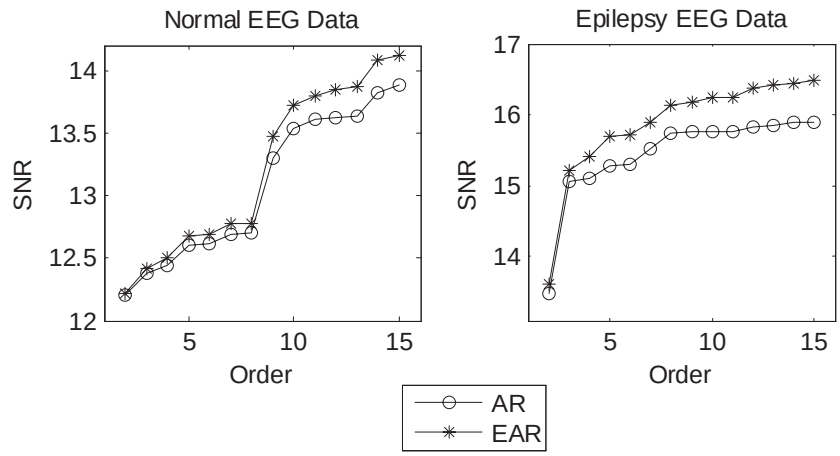
The nonlinearity of the EAR model comes from the exponential term, $e^{\gamma \cdot x(n-k)^2}$, which makes the series globally nonlinear. If nonlinear parameter γ is set to 0, the equation will become an ordinary linear AR model with coefficients $a_p = \varphi_p + \pi_p$ such that;

$$x_t = \sum_{k=1}^{p} a_k \cdot x_{t-k} + e_t \tag{2}$$

The estimation of the $2p$+1 coefficients $\{\gamma, (\varphi_i, \pi_i, i=1,2,\ldots,p)\}$ of the EAR model is a nonlinear optimisation problem, hence is complicated especially with increasing model order. In order to achieve this task, binary genetic algorithms (BGA) hybridized with recursive least squares (RLS) algorithm can be used (Shi & Aoyama, 1997).

Genetic algorithms are search algorithms inspired by the natural selection and natural genetics which can be used to solve optimisation problems. Initially, there is a population of candidate solutions to the optimisation problem and the solutions evolve toward better solutions according to the

Figure 2. Example of SNR result when linear/nonlinear methods were applied to EEG modeling



principles of natural selection (i.e., survival of the fittest) (Goldberg, 1989). For the selection of the fittest chromosome, a fitness function that measures the performance of a chromosome in the population must be defined according to the optimisation problem to be solved.

In our study here, the nonlinear coefficient γ of the EAR model is determined by BGA and once the nonlinear coefficient is obtained, the model will become a linear regression problem in which the linear coefficients, $\{\varphi_i, \pi_i, i=1,2,\ldots,p\}$ will be determined by RLS algorithm. Moreover, the model order is selected as the order with minimum Akaike Information Criterion (AIC) value (Akaike, 1974).

Figure 2 shows an example of signal to noise ratio (SNR) results obtained by applying conventional linear AR modeling and EAR modeling to EEG data from a healthy subject and an epilepsy patient. Note that the SNR values were calculated by reconstructing time series with corresponding AR coefficients (for both AR and EAR modeling techniques) and calculating the SNR between original and reconstructed signals. The figure clearly indicates an improved modeling when EAR was used.

These initial results are promising since it appears that the EAR method can provide an improved characterisation of time series. It is hoped that this method will lead to a better representation of the EEG signals when used in various applications.

FUTURE TRENDS

The preliminary results obtained from EAR model are promising since they indicated an improved modeling of EEG signals recorded from healthy subjects and epilepsy patients. However, further experiments should be conducted to investigate the representative ability of EAR method for the classification of different classes of EEG data (i.e., EEG data from epilepsy patients during seizure and seizure free intervals, EEG data from healthy subjects, mental task EEG data, etc).

The proposed improved EAR method could also be explored for other biological signal analysis applications, such as electrophysiological analysis of cognitive processes, prediction of epilepsy onset, abnormal heart sound and beat detection, heart rate variability monitoring, and so forth.

CONCLUSION

The characterisation (i.e., feature extraction) of EEG signals is one of the most challenging steps towards the design of a real time biological signal analysis system. In order to achieve that task, knowledge of the underlying dynamics of the EEG signals is necessary so that suitable modeling techniques could be utilised for characterisation of the EEG signals. In recent years, nonlinear time series analysis techniques in particular largest Lyapunov exponent, correlation dimension and nonlinear prediction error measures along with surrogate data method were repeatedly applied to some of the biological signals (specifically, EEG) in order to understand the nature of the signals. The results of these studies suggested presence of highly significant nonlinearities in EEG signals, especially the signals recorded from patients with neurological disorders. However the sensitivity and specificity of the utilized nonlinear measures are still subject to current research. It is believed that the development of new time series analysis techniques that will sufficiently represent the nonlinear, chaotic and multidimensional behavior of the EEG signals will improve the understanding of the brain dynamics.

KEY TERMS

AR: Autoregressive model, a linear prediction model where each data point in time series is defined to be linearly related to its previous data points.

EAR: Exponential Autoregressive model, a nonlinear extension of Autoregressive model.

Linear Regression: A technique that attempts to model a set of data points by fitting a linear equation to the data.

Linear System: A system f(·) that obeys the superposition and scaling property is said to be linear such that; for $a, b \in R : f(a \cdot x + b \cdot y) = a \cdot f(x) + b \cdot f(y)$.

Linear Signal: A linear signal is generally defined as the output of a linear shift invariant system that is driven by Gaussian white noise.

Nonlinear Signal: A nonlinear signal is generally defined as the signal generated by the system that does not obey superposition and scaling properties.

Power Spectral Density: Power spectral density shows the power per unit frequency of a signal.

Shift-Invariant System: A shift-invariant system is known as a system that input-output relationship does not vary with time such that; let $y[n]$ be the response of the system to input $x[n]$, for any delay t, the response of the system to input $x[n-t]$ will be $y[n-t]$.

Stochastic (Random) Process: Opposite of deterministic processes in which the future states of the system can not be predicted precisely. In other words, even if the initial states of

the process are known there are many states that the process can go where some states are more probable than others.

White Noise: A random signal that has equal amount of power at all frequency bands.

ENDNOTES

[a] Sensitivity is a statistical measure of how well a classification test correctly identifies a condition.

[b] Specificity is a statistical measure of how well a classification test correctly identifies the negative cases, or those cases that do not meet the condition under study.

INTRODUCTION

Visual and auditory imagery combination offers a way of presenting and communicating complex events that emulate the richness of daily experience (Kendall, 1991). It is notable that sound events arise from the transfer of energy to a sound object in everyday life. Even in childhood, we learn to take the following attitudes about the sound events:

- Recognize the occurrence of sound events and relate them to physical events.
- Classify and identify heterogeneous sound events through a lifetime of experience.

Important distinctions in the data can be communicated by exploiting simple categorical distinctions of sound events. Taste, smell, heat, and touch are not suitable channels for data presentation because our perception of them is not quantitative. However, the auditory system constitutes a useful channel for data presentation (Yeung, 1980).

Furthermore, sounds play an important role in the study of complex phenomena through the use of auditory data representation according to Buxton (1990) and Kendall (1991). It is known that our ears and brains can extract information from nonspeech audio that cannot be, or is not visually displayed (Buxton, 1990).

BACKGROUND

Nonspeech Audio

According to Wall and Brewster (2006), nonspeech audio can be delivered in a shorter time than synthetic speech. Synthetic speech audio can be laborious and time consuming to listen to and compare many values through speech alone. So, nonspeech audio can be a better means at providing an overview of the data.

Researchers, such as Bronstad, Lewis, and Slatin (2003) have investigated whether the use of nonspeech audio cues can reduce cognitive workload to users performing very complex tasks that they would otherwise find impossible.

Nonspeech audio researchers have investigated sounds more complex than ubiquitous interrupting beeps to provide information about spatial structure to computer users. In this way, the vOICe Learning Edition (Jones, 2004) is an actual example of interface that translates arbitrary video images from an ordinary camera into nonspeech sounds. However, the artificial sounds adopted by the vOICe have no analogs in everyday listening. So, this kind of interfaces has required extensive trials from users before their effective use.

Everyday Listening

According to Buxton (1990) and Gaver (1988), everyday listening is the experience of listening to events rather than sounds. This experience is different than that enjoyed by traditional psychoacoustics. It consists of hearing which things are important to avoid and which might offer possibilities for action. Instead of perceiving attributes, such as frequency, spectral content, amplitude of sounds, everyday listening is concerned with the attributes of events in the world. Examples of events are the speed of an approaching automobile, the force of a slammed door, and the direction of a walking person (Gaver, 1988). Everyday tasks, such as driving and crossing the street, are examples due to everyday listening. Listening to airplanes, water, birds, and footsteps are other examples of everyday listening. Also, Gaver (1993) has investigated several studies of everyday listening based on the ecological perspective.

Surprisingly, everyday listening skills have been virtually ignored in computer-based interfaces. Listening to events is not well understood by traditional audition approaches.

Studies suggest that a comprehensive account of everyday listening has yet to emerge. We have investigated a first study on comprehensive account of everyday listening by using nonspeech sounds as events (Nomura, Utsunomiya, Tsuchinaga, Shiose, Kawakami, Katai, & Yamanaka, 2007a).

We have concentrated on such everyday listening and ecological approach to perception in our previous works (Nomura, Shiose, Kawakami, Katai, & Yamanaka, 2004; Nomura, Yamanaka, Katai, Kawakami, & Shiose, 2004; Shiose, Ito, & Mamada, 2004). One of the works concerned with perceiving an approaching automobile is useful in understanding the scope of an ecological approach to perception (Shiose et al., 2004). The auditory system captures the experience of everyday listening by the idea that a given sound provides information about the interaction of materials at a location in an environment. Also, alterations in loudness caused by alterations on distance from a source may also provide information about time-to-contact in an analogous fashion to alterations in visual texture (Shaw, McGowan, & Turvey, 1991).

Echolocation

Spallanzani discovered that blinded bats could fly, avoid obstacles, land on walls and ceiling, and survive in nature as well as sighted bats. However, this discovery remained unanswered as how bats possess a sixth sense for orientation and navigation (Raghuram & Marimuthu, 2005). Griffin answered the question in 1938 and called this sixth sense "echolocation" (Griffin, 1958).

Some bat-like sonar systems have been developed using echolocation (Barshan & Kuc, 1992; Bitjoka & Takougang, 2007; Waters & Vollrath, 2003).

On the other hand, Daniel Kish (Roberts, 2006), as an example of human echolocation, lost his sight as an infant and taught himself to "see" with sonar by clicking his tongue. He learned to see without sight.

In our recent work (Nomura, Chiba, Honda, Shirakawa, Shiose, Katai, Kawakami, & Yamanaka, 2008), we looked at the possibility to emerge a comprehensive account of human echolocation that enables spatial structure perception of the environment using acoustics.

Virtual 3-D Acoustic Environment

Virtual 3-D acoustic environments created by computers are an emerging technology that may be used to teach blind children in actual acoustic environment (Inman, Loge, & Cram, 2000).

Advantages of using virtual 3-D acoustic training environments are to provide learners with guided and unguided practice controlling audio parameters by software. The parameters can be adjusted to suit the specific needs of a learner's auditory experience (Inman, Loge, & Cram, 2001).

The virtual 3-D acoustic environment is modeled on the binaural human hearing system (Inman, Loge, & Cram, 2001) and described by a complex response function (head-related transfer function - HRTF) (Mφller, Sφrensen, Hammershφi, & Jensen, 1995). HRTFs contain all the information about the sound source's location (its direction and distance from the listener), and can be used to generate binaural cues (interaural time differences - ITDs; interaural intensity differences - IIDs). Consequently, measured and implemented HRTFs can generate virtual 3-D acoustic environments.

In our previous work (Nomura, Utsunomiya, Tsuchinaga, Shiose, Kawakami, Katai, & Yamanaka, 2007b), we have investigated an approach to enhance spatial conceptualization performances of subjects using the virtual 3-D acoustic environment system.

WORK'S PURPOSE

We propose novel nonspeech audio-based user interfaces to provide visually impaired and elderly people with the opportunity to perceive and conceptualize spatial structure through echolocation. We hope that the users have opportunities to freely access the available facilities and friendly interaction with these targets (spatial structures) without depending on such expert systems as pattern recognizer, spoken language converter, or voice synthesizer.

Also, the purpose is not only or simply based on converting inaudible ultrasound echoes into audible sounds like the sonar system modeled by Bitjoka and Takougang (2007).

In this way, we believe that the user may take advantage of the similar skills employed by bats in everyday listening through echolocation. For example, the association of reverberations with empty environment is a kind of such skill. When a room is reverberant, it means that it is spacious, considering all other things equal. The idea is that the users can utilize their experience and familiarization with everyday listening to friendly conceptualizing spatial structure information without hard cross-modal training. The strategy is based on skill transfer process (Shiose, Sawaragi, Nakajima, & Ishihara, 2004) to embody the cues for spatial structure conceptualization process by avoiding heavy computational load, due to the previously mentioned expert systems (like the vOICe).

We suppose that the eventual interface users can embody the skills employed in everyday tasks by navigating and training in a virtual 3-D acoustic environment. Then, we experimentally evaluate performances of subjects on tasks to perceiving spatial structures represented by various aural surfaces in the 3-D acoustic environment.

EXPERIMENTAL APPROACH

Figure 1 presents a schematic overview of our experimental approach toward nonspeech audio-based interfaces to support users on spatial structure (target) perception and conceptualization.

The apparatus of the experimental approach is constituted by an ultrasound system and a 3-D acoustic environment system, described in the following sections.

Ultrasound System

The ultrasound system is represented by a conventional Pioneer robot, as shown in Figure 2. The robot is constituted by a panel with eight ultrasonic (transmitter and receiver) sensors in a line at its front. This set of sensors is responsible for getting spatial structure information, such as distance from the target.

In this work we do not use ultrasounds to convert them into audible sounds, as done in conventional approaches.

Figure 1. Schematic overview of the experimental approach

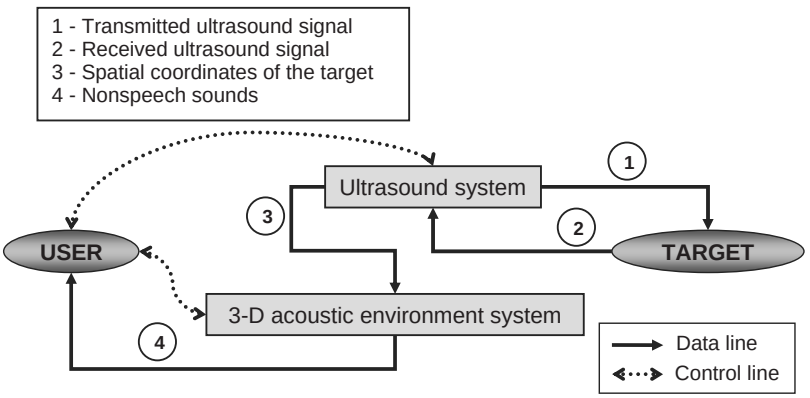

Figure 2. Conventional Pioneer robot with a panel of ultrasonic sensors

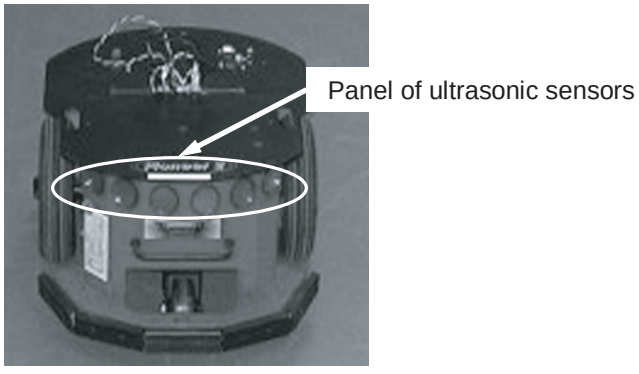

We only take advantage of the Pioneer robot to detect and obtain spatial structure coordinates of a target. According to Figure 1, the ultrasound system interacts with the target by transmitting (line 1) and receiving (line 2) ultrasound signals.

3-D Acoustic Environment System

The second part of the experimental apparatus consists of a 3-D acoustic environment system mainly based on sound space processors to add necessary effects such as movement, reflection, reverberation into sound source. In this way, the system creates different sets of experiments characterized by different virtual acoustic environments with nonspeech sounds.

A front view of devices that compose the 3-D acoustic environment system is presented in Figure 3.

Figure 4 presents a schematic overview of the 3-D acoustic environment system with a list of devices and their respective models. According to this schematic overview, the nonspeech sound generation process occurs as follows:

- The audio recorder (AR) plays a fan noise representing the sound source of nonspeech sounds in everyday world. This sound source was saved using precise microphones (Nomura, et al., 2007).
- The sound space processor (SSP) adds effects such as movement, reverberation, and reflection into this sound source. The movement of each sound is guided by the spatial coordinates as output of the ultrasound system (first part of our experimental approach). According to the previous work (Shiose, Ito, & Mamada, 2004), reverberation and reflection levels were adjusted to -30 dB to generate nonspeech sounds and create the virtual hallways described in Figure 5.
- The sounds with effects are mixed by mixing devices (MXP and MXC).
- Then, the resulting sounds are heard by the subjects wearing headphones (DSH) during the experiments.

The apparatus to create the virtual 3-D acoustic environment is only for training, enabling, and simulating echolocation skill transfer process (Shiose, Sawaragi, Nakajima, & Ishihara, 2004) by subjects. The system does not represent a prototype to be implemented on the eventual interface devices.

Virtual Hallways

The upper view of a typical virtual hallway created by the experimental approach is shown in Figure 5. The virtual hallway is formed by aural surfaces, and each aural surface is constituted by the generated nonspeech sounds with the experimental approach.

The interval (e) corresponds to the part of hallway, measured in meters, where there are no alterations on aural surfaces during the navigation task by subjects.

The value of this interval is given by the following equation:

$$e = v.t, \quad (1)$$

Figure 3. Front view of devices composing the 3-D acoustic environment system (Nomura, Tsuchinaga, Nojima, Shiose, Kawakami, Katai, & Yamanaka, 2007)

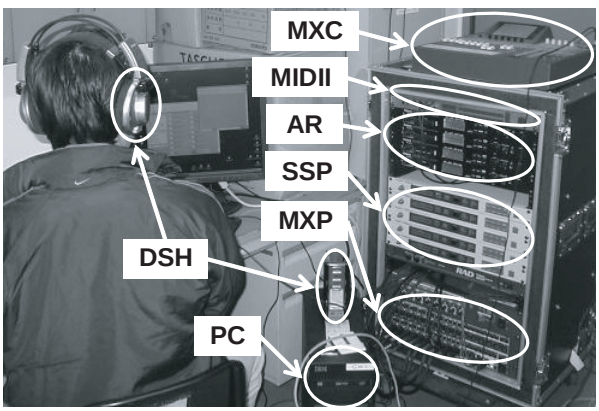

Figure 4. Schematic overview of the apparatus

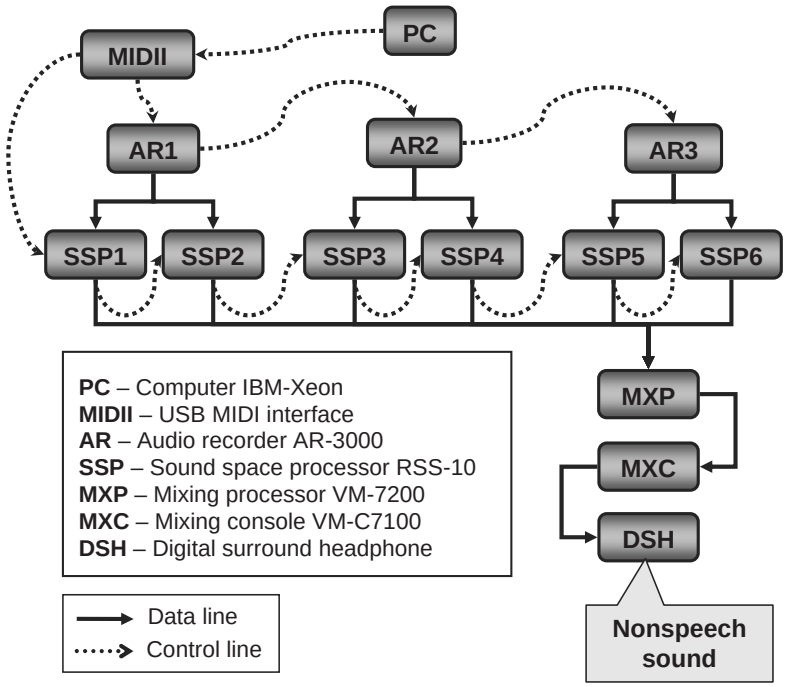

Figure 5. Detailed upper view of a virtual hallway

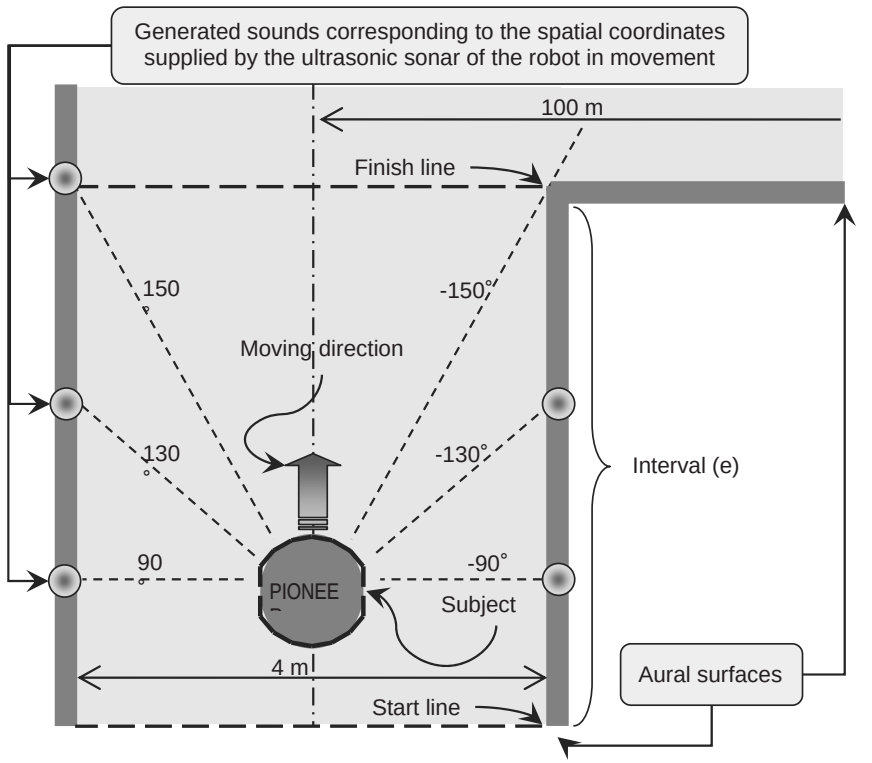

Figure 6. Types of virtual hallways modified by different appearances of aural surfaces

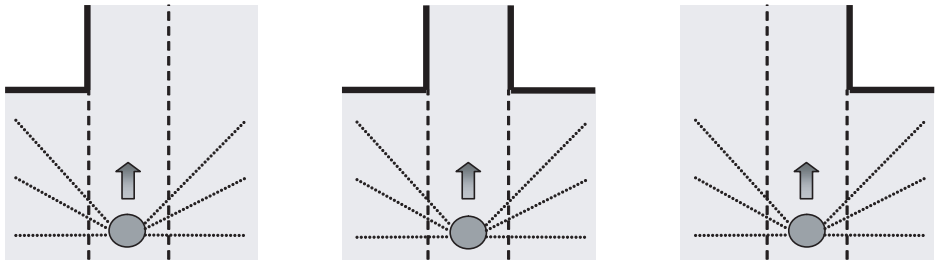

Figure 7. Types of virtual hallways modified by different disappearances of aural surfaces

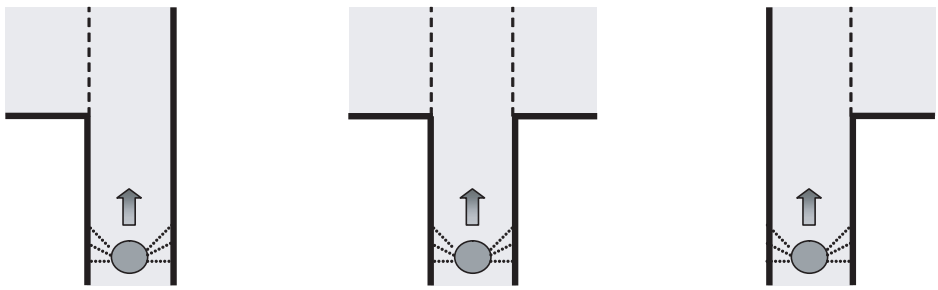

where v represents the moving speed in km/h and t represents the time in seconds that is randomly set during the experiments.

The virtual hallways created by left (A1), left and right (A2), and right (A3) appearances of aural surfaces are shown in Figure 6. Figure 7 shows the virtual hallways created by left (D1), left and right (D2), and right (D3) disappearances of aural surfaces.

EXPERIMENTS

The experiments aim to evaluate performances of subjects on tasks to perceiving alterations on aural surfaces belonging to a virtual hallway. They used their auditory system skills to hear nonspeech sounds as events. In this way, the subjects' task consisted of navigating virtual hallways created by the experimental approach.

Fourteen subjects participated in the following two sets of experiments:

- Set 1 characterized by appearances of aural surfaces representing the types A1, A2, and A3 of virtual hallways.
- Set 2 forming the types D1, D2, and D3 for virtual hallways modified by disappearances of aural surfaces.

All subjects had no audition problems. No visual information was necessary to participate in the experiments.

The experiments consisted of two sessions as follows:

- A training session provided subjects' familiarization with the three types of appearances for set 1 and the other three types of disappearances for set 2.
- A testing session got results from subjects traveling the different types of virtual hallways and trying to categorize the type of the traveling hallway by anticipation.

In the testing session, we instructed the subjects in pressing a key on a keyboard as follows:

- "←" when they perceive that the left aural surface is going to appear as shown in Figure 6(A1) for experimental set 1, or disappear as shown in Figure 7(D1) for set 2.
- "↓" when they perceive that the left and right aural surfaces are going to appear as shown in Figure 6(A2) for experimental set 1, or disappear as shown in Figure 7(D2) for set 2.
- "→" when they perceive that the right aural surface is going to appear as shown in Figure 6(A3) for experimental set 1, or disappear as shown in Figure 7(D3) for set 2.

Also, in this testing session, an important point is that the subjects should anticipate the type of the traveled virtual hallway. In other words, they should make a decision by the period randomly selected from the set {3.0, 3.5, 4.0, 4.5, 5.0, 5.5, 6.0} in seconds. This period corresponded to the time spent by the subject to move from start to finish lines as indicated in Figure 5. The moving speed was set at 4 km/h in all the experiments.

Then, the experimental results correspond to anticipatory times. To obtain these results, we just have computed the values (negative ones) related to the decisions made by the subjects before crossing the finish line.

Results

In Table 1, we verify that the subjects found serious difficulties in anticipating and perceiving the virtual hallways modified by disappearances of aural surfaces. The averaged performance rate was equal or less than 30%.

However, Table 2 shows that the subjects achieved successful performances on anticipating and perceiving appearances of aural surfaces as virtual hallways. We verify that the averaged performance rate was equal or more than 96%.

FUTURE TRENDS

In this work we have concentrated on investigating a nonspeech audio-based interface that does not require instrumentation of the environment with tags or any additional communication infrastructure in contrast to the conventional user interfaces.

Table 1. Performances of subjects in tasks to perceive disappearances of aural surfaces

	D1	D2	D3
Averaged anticipatory time (s)	-0.58	-1.11	-0.72
Maximum anticipatory time (s)	-1.25	-2.00	-2.20
Averaged performance (%)	21.4	20.0	30.0

Table 2. Performances of subjects in tasks to perceive appearances of aural surfaces

	A1	A2	A3
Averaged anticipatory time (s)	-2.45	-2.29	-2.44
Maximum anticipatory time (s)	-2.75	-2.70	-2.75
Averaged performance (%)	100.0	96.0	100.0

It is relevant that sighted and nonsighted people can get remarkable echolocation abilities to use reflected or reverberated sound patterns to move around and locate their position in rooms and corridors in spite of such irregularities. In other words, users can also locate moving and nonmoving sound-producing objects as well as non-sound-producing obstacles in the environment, and they can often describe the size, shape, and texture of these targets from the pattern of the perceptual consequences.

In the future, we hope to contribute with design of eventual user interfaces that take advantage of a low computational cost provided by the proposed concept. We believe in the realistic practicalities of our proposed concept on future aural user interfaces.

CONCLUSION

Experimentally, we evaluated the subjects' ability to anticipate and perceive alterations on aural surfaces of virtual hallways by generating nonspeech sounds in a 3-D acoustic environment.

Early experimental results showed that more exhaustive experiments could be useful to accurately evaluate how sensitive a subject is to anticipating and perceiving alterations on aural surfaces of virtual hallways.

Surprisingly, the subjects performed well in anticipating and perceiving alterations on aural surface of virtually created hallways without hard cross-modal training. Comparison of experimental results concerning the sets of experiments showed that subjects performed better in tasks conceptualizing virtual hallways modified by appearances of aural surfaces. A possible reason for this difference could be explained by an ecological psychology approach based on direct perception of everyday listening events. We had two event situations in the sets of experiments. First, an event started in a silent situation (without sound) corresponding to the aural surface appearance of experimental set 1. Second, an event stopped in a noisy situation (with initial nonspeech sounds) corresponding to the aural surface disappearance of experimental set 2. Then, we could infer that a starting sound event was easier to be perceived by the subject inserted in first situation. In this situation, there was no initial nonspeech sound to disturb the direct perception of events.

We found that the comprehensive account of everyday listening by taking advantage of subjects' experience to listening to events, rather than sounds, was primordial for achieving these results.

The results were promising to conclude that the exploration of auditory perceptual skills, using nonspeech sounds as events, can be a great alternative to developing novel nonspeech audio-based interfaces. In this way, we believe that upcoming interface users, such as visually impaired or elderly people, have the opportunity to friendly recover the freedom to access the existing public environment. We hope that they can access the facilities without depending on help from others or additional instruments into the infrastructure.

Furthermore, we expect to contribute to the request of impaired persons that do not like to be wired to the complex expert systems of conventional interfaces requiring mental workload and hard training. An immediate contribution can be into the development of applications such as "driving a car in the dark" or "detecting room layouts in the dark" systems.

KEY TERMS

Aural Surface: It consists of a kind of virtual wall constituted by the generated nonspeech sounds in the 3-D acoustic environment.

Conceptualization: It is the result of spatial structure categorization after processing the visual, aural, or echo information captured in nonspeech audio cues.

Echolocation: It is based on the principle that listeners can process the returning echo information when they emit sound waves and listen to the echoes that return from a target.

Everyday Listening: It is the experience of listening to events rather than sounds. Listening to airplanes, water, birds, and footsteps are some examples of everyday listening. Everyday tasks such as driving and crossing the street are examples due to everyday listening too.

Nonspeech Audio: It can be delivered in a shorter time than synthetic speech. It is a better means at providing an overview of the data. Since nonspeech audio can be heard from 360 degrees, auditory information is better captured than visual information.

Spatial Structure Perception: It refers to perception of size, shape, and texture of targets (objects) by processing the returned echoes through echolocation.

3-D Acoustic Environment: It provides learners with guided and unguided practice controlling audio parameters by software. These parameters can be adjusted to suit the specific needs of a learner's auditory experience during a computer simulation.

Virtual Hallway: It is a kind of virtual corridor in the 3-D acoustic environment where a listener travels to anticipate and perceive alterations on aural surfaces during the navigation task. There are three types of virtual hallways characterized by appearances of aural surfaces and another three types corresponding to disappearances.

Object Classification Using CaRBS

Malcolm J. Beynon
Cardiff Business School, UK

INTRODUCTION

The notion of uncertain reasoning has grown relative to the power and intelligence of computers. From sources which are uncertain information and/or imprecise data, it is importantly the ability to represent uncertainty and reason about it (Shafer & Pearl, 1990). A very general problem of uncertain reasoning is how to combine information from independent and partially reliable sources (Haenni & Hartmann,forthcoming). With data mining, understanding the confirming and/or conflicting information from characteristics describing objects classified to given hypotheses is affected by their reliability. Further, the presence of missing values compounds the problem, since the reasons for their presence may be external to the incumbent reliability issues (Olinsky, Chen, & Harlow, 2003; West, 2001).

These issues are demonstrated here using the classification technique: Classification and Ranking Belief Simplex (CaRBS), introduced in Beynon and Buchanan (2004) and Beynon (2005). CaRBS operates within the domain of uncertain reasoning, namely in its accommodation of ignorance, due to its mathematical structure based on the Dempster-Shafer theory of evidence (DST) (Srivastava & Mock, 2002). The ignorance here encapsulates incompleteness of the data set (presence of missing values), as well as uncertainty in the evidential support of characteristics to the final classification of the objects.

This chapter demonstrates that a technique such as CaRBS, through uncertain reasoning, is able to uniquely manage the presence of missing values by considering them as a manifestation of ignorance, as well as allowing the possible unreliability of characteristics to be inherent. Importantly, the described process removes the need to falsely transform the data set in any way, such as through imputation (Huisman, 2000).

The example issue of credit ratings considered here has become increasingly influential since its introduction in around 1900 with the Manual of Industrial and Miscellaneous Securities (Levich, Majnoni, & Reinhart, 2002). The rating agencies shroud their operations in particular secrecy, stating that statistical models cannot be used to replicate their ratings (Singleton & Surkan, 1991), hence advocating the need for alternative analyses, including those utilising uncertain reasoning.

BACKGROUND

DST is a methodology for evidential reasoning, manipulating uncertainty, and capable of representing partial knowledge (Kulasekere, Premaratne, Dewasurendra, Shyu, & Bauer, 2004; Scotney & McClean, 2003). Early after its introduction it was considered as a generalisation of Bayesian theory.

The traditional terminology within DST begins with a finite set of hypotheses Θ (frame of discernment). A *mass value* (basic probability assignment) is a function $m: 2^{\Theta} \rightarrow [0, 1]$ such that: $m(\varnothing) = 0$ and $\sum_{A \in 2^{\Theta}} m(A) = 1$ (2^{Θ} the power set of Θ). Any $A \in 2^{\Theta}$, for which $m(A) > 0$ is called a *focal element* and represents the exact belief in the proposition depicted by A. From one source of evidence, a set of focal elements (and mass values) is defined as a body of evidence (BOE).

To collate two or more sources of evidence, DST provides a method to combine them, using Dempster's rule of combination. If $m_1(\cdot)$ and $m_2(\cdot)$ are independent BOEs, then the function $m_1 \oplus m_2: 2^{\Theta} \rightarrow [0, 1]$, defined by:

$$[m_1 \oplus m_2](y) = \begin{cases} 0 & y = \varnothing \\ (1-k)^{-1} \sum_{A \cap B = y} m_1(A) m_2(B) & y = \varnothing \end{cases}$$

where $k = \sum_{A \cap B = \varnothing} m_1(A) m_2(B)$, is a mass value associated with $y \subseteq \Theta$. The term $(1 - k)$ can be interpreted as a measure of conflict between the sources (Murphy, 2000) and is made up of one minus the sum of the products of mass values from the two pieces of evidence with empty intersection (often the k is also called the level of conflict and not $1 - k$). The associated problem with conflict is the larger the value of k the more conflict in the sources of evidence, and subsequently the less sense there is in their combination (Murphy, 2000).

To demonstrate DST, the example of the murder of Mr. Jones is considered, where the murderer was one of three assassins, Peter, Paul, and Mary, so Θ = {Peter, Paul, Mary}. There are two witnesses. Witness 1, is 80% sure that it was a man, the concomitant BOE, defined $m_1(\cdot)$, includes m_1({Peter, Paul}) = 0.800. Since we know nothing about the remaining mass value it is allocated to Θ, m_1({Peter, Paul, Mary}) = 0.200. Witness 2, is 60% confident that Peter was leaving on a jet plane when the murder occurred, a BOE defined

Table 1. Intermediate combination of BOEs $m_1(\cdot)$ and $m_2(\cdot)$

$m_2(\cdot) \setminus m_1(\cdot)$	$m_1(\{\text{Peter, Paul}\}) = 0.800$	$m_1(\{\text{Peter, Paul, Mary}\}) = 0.200$
$m_2(\{\text{Paul, Mary}\}) = 0.600$	{Paul}, 0.480	{Paul, Mary}, 0.120
$m_2(\{\text{Peter, Paul, Mary}\}) = 0.400$	{Peter, Paul}, 0.320	{Peter, Paul, Mary}, 0.080

$m_2(\cdot)$, includes $m_2(\{\text{Paul, Mary}\}) = 0.600$ and $m_2(\{\text{Peter, Paul, Mary}\}) = 0.400$.

Defining the combination of these sources of evidence the BOE $m_3(\cdot)$, using Dempster's combination rule, the intermediate set intersections of focal elements of the two BOEs and multiplication of the respective mass values are given in Table 1.

In Table 1, the noticeable result is that no intersections of focal elements produce the empty set, so $k = \sum_{A \cap B = \varnothing} m_1(A) m_2(B) = 0$. It follows, with the measure of conflict $(1 - k) = (1 - 0) = 1$, then the values in Table 1 identify the combined BOE $m_3(\cdot)$ has the form, $m_3(\{\text{Paul}\}) = 0.480$, $m_3(\{\text{Peter, Paul}\}) = 0.320$, $m_3(\{\text{Paul, Mary}\}) = 0.120$ and $m_3(\{\text{Peter, Paul, Mary}\}) = 0.080$. This combined evidence has a more spread-out allocation of mass values to varying subsets of {Peter, Paul, Mary}. Further, there is a general reduction in the level of ignorance associated with the combined evidence. Smets (2002) offers a comparison of a variation of this example with how it would be modelled using traditional probability and Transferable Belief Model.

MAIN THRUST

The main thrust of this chapter is the description and application of the CaRBS system for object classification (Beynon, 2005), which operates in the DST environment. It operates on n_O objects (o_1, o_2, …), each described by n_C characteristics (c_1, c_2, …) and classified to a given hypothesis x or its compliment $\neg x$. For the object o_j ($1 \leq j \leq n_O$) and i^{th} characteristic c_i ($1 \leq i \leq n_C$), a *characteristic* BOE, defined $m_{j,i}(\cdot)$, has the mass values, $m_{j,i}(\{x\})$, $m_{j,i}(\{\neg x\})$ and $m_{j,i}(\{x, \neg x\})$. Following Gerig, Welti, Guttman, Colchester, and Szekely (2000), they are given by:

$$m_{j,i}(\{x\}) = \frac{B_i}{1-A_i} cf_i(v), \quad \frac{A_i B_i}{1-A_i} \quad m_{j,i}(\{\neg x\}) = \frac{-B_i}{1-A_i} cf_i(v) + B_i$$

and $m_{j,i}(\{x, \neg x\}) = 1 - m_{j,i}(\{x\}) - m_{j,i}(\{\neg x\})$,

where $cf_i(v) = \frac{1}{1+e^{-k_i(v-\theta_i)}}$ is the confidence value associated with a characteristic value supporting evidence on the association of objects to the given hypothesis and its complement, and k_i, θ_i, A_i and B_i are incumbent control variables. Importantly, if either $m_{j,i}(\{x\})$ or $m_{j,i}(\{\neg x\})$ are negative they are set to zero, and the respective $m_{j,i}(\{x, \neg x\})$ then calculated. In Figure 1, a characteristic value v is shown to be first transformed into a confidence value (Figure 1a), then deconstructed into its characteristic BOE (Figure 1b) and finally represented as a single simplex coordinate $p_{i,j,i,v}$ in a simplex plot (Figure 1c).

The group of characteristic BOEs $m_{j,i}(\cdot)$ $i = 1, \ldots, n_C$ associated with an object o_j and its classification to x and $\neg x$ can be combined using Dempster's combination rule into an *object* BOE, defined $m_j(\cdot)$, from which its final classification can be found.

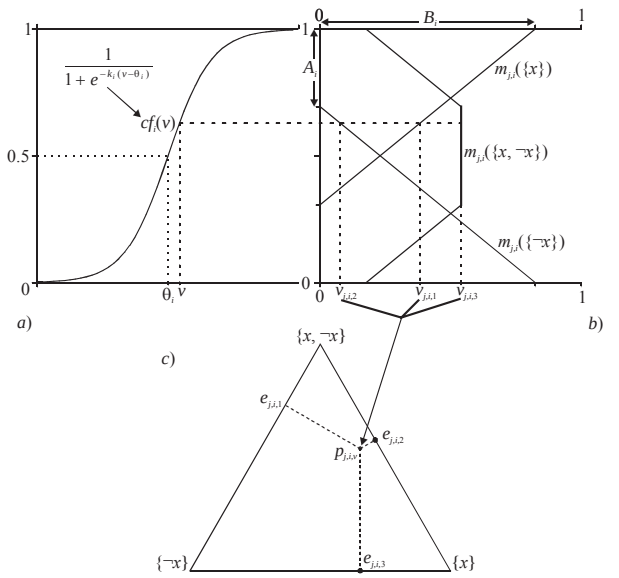
The CaRBS system depends on the assignment of values to the incumbent control variables (with standardised characteristic values, their example domains are; $-1 \leq k_i \leq 2$, $-1 \leq \theta_i \leq 1$, $0 \leq A_i < 1$ and $B_i = 0.4$, see Beynon, 2005). The configuration process then becomes a constrained optimisation problem, solved here using Trigonometric Differential Evolution (TDE) (Fan & Lampinen, 2003), with operation parameters; amplification control $F = 0.99$, crossover constant $CR = 0.85$, trigonometric mutation probability $M_t = 0.05$ and number of parameter vectors $NP = 360$. In summary, TDE develops possible optimum solutions by perturbing previous solutions with the differences between two other previous solutions.

The employed objective function (OB) attempts to minimise the ambiguity in the classification of objects but not the inherent ignorance. For sets of objects making up the equivalence classes, $E(x)$ and $E(\neg x)$, namely those associated with the hypothesis and not the hypothesis, respectively, the optimum solution is to maximise the weighted difference values $(m_j(\{x\}) - m_j(\{\neg x\}))$ and $(m_j(\{\neg x\}) - m_j(\{x\}))$, respectively. The subsequent OB is given by:

$$\text{OB} = \frac{1}{4}\left(\frac{1}{|E(x)|} \sum_{o_j \in E(x)} (1 - m_j(\{x\}) + m_j(\{\neg x\})) + \frac{1}{|E(\neg x)|} \sum_{o_j \in E(\neg x)} (1 + m_j(\{x\}) - m_j(\{\neg x\})) \right)$$

which has domain $0 \leq \text{OB} \leq 1$. Each $(m_j(\{x\}) - m_j(\{\neg x\}))$ and $(m_j(\{\neg x\}) - m_j(\{x\}))$ difference value measures the ambiguity in each classification, there is no attempt to minimise the $m_{j,i}(\{x, \neg x\})$ values so no inclination to directly minimise the concomitant ignorance in each objects' classification. Correct classification is graphically defined by which side of the vertical dashed line down from the $\{x, \neg x\}$ vertex, in a simplex plot, an object BOE's simplex coordinate is positioned (classifying to x (right) and $\neg x$ (left)).

Figure 1. Graphical representation of stages in CaRBS for a characteristic value



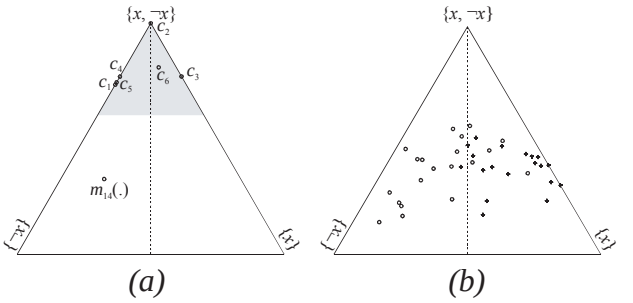
The example results briefly presented concern the Bank Financial Strength Rating (BFSR) of banks in the U.S. (Moody's, 2004). Here, a sample of 40 U.S. banks is considered, described by the six characteristics: (1) Net Income Revenue/Average Assets (c_1); (2) Non Interest Expense/Average Assets (c_2); (3) Equity/Assets (c_3); (4) Net Loans/Assets (c_4); (5) Loan Loss Reserves/Gross Loans (c_5); and (6) Dividend Pay-Out (c_6). The binary classification of the individual banks is based on the rating groups: "B– and above" (x - 20 banks) and "C+ and below" ($\neg x$ - 20 banks).

The first results shown are based on the optimisation of the classification of the 40 banks, using all their characteristic values and known BFSR ratings, see Figure 2.

In Figure 2(a), the classification results of a single bank are shown, namely o_{14}, known to have a BSFR rating "C+ and below." The shaded region denotes the domain that each characteristic BOE can exist in (constrained by $B_i = 0.4$). The simplex coordinates of the characteristic BOEs describing it (labelled c_1, …, c_6), in this case those to the left and right of the vertical dashed line are offering confirming and conflicting evidence, respectively. Its final object BOE, defined $m_{14}(\cdot)$, is to the left of the vertical line again suggesting "C+ and below," the correct classification in this case.

In Figure 2(b), the final classification of all 40 banks is presented, each cross and circle representing banks known to be "B– and above" and "C+ and below," respectively. Pertinent to this investigation, the different heights in the simplex plots that the circles and crosses are found demonstrate the different levels of ignorance associated with the predicted classifications of the banks (their $m_j(\{x, \neg x\})$ mass

Figure 2. Simplex plot representations of results for 40 banks (with no missing values)



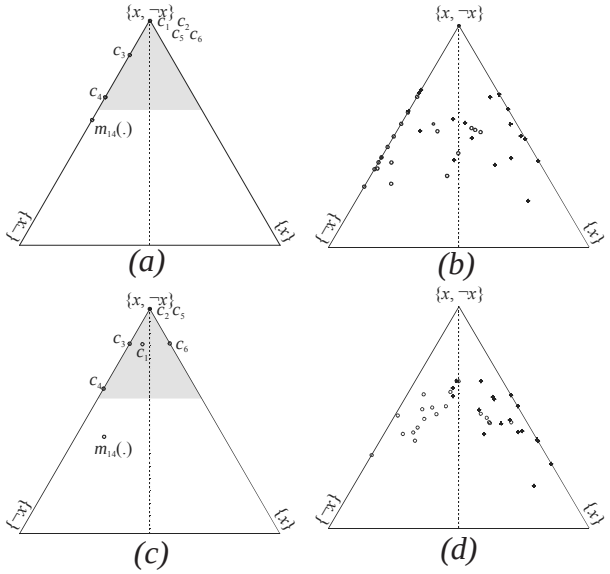
values). Inspection of these results shows an overall 85.0% classification accuracy.

An incomplete data set with missing values causes a problem in data mining due to the uncertainty in what to do with their presence, since most data analysis techniques were not designed for their presence (Schafer & Graham, 2002). Moreover, any imputation-based management of their presence alters the data set considered and mitigates the interpretive power of the concomitant results. In the case of the CaRBS system, there is no requirement to manage the missing values, instead they are retained and considered ignorant values, a direct consequence of its basis on uncertain reasoning.

To illustrate, 50% of the characteristic values in the bank data set are removed and defined as missing. With data mining, this would be a critical situation (Shen & Lai, 2001), since any traditional management dramatically alters the data set considered. All those missing values offer ignorant evidence for which their associated characteristic BOEs are made up of; $m_{j,i}(\{x\}) = 0$, $m_{j,i}(\{\neg x\}) = 0$ and $m_{j,i}(\{x, \neg x\}) = 1$. As with the complete data set, a CaRBS system was configured on this incomplete data, see the top row of simplex plots in Figure 3.

The results in Figure 3(b) show many of the object BOEs are further up the simplex plot indicating more ignorance associated with their final BFSR classifications, a consequence of the number of missing values present which now only confer ignorance evidence. Many of the simplex coordinates are towards the edges of the simplex plots, due to the reduced number of character values that may offer conflicting evidence to a banks BFSR classification (overall 77.5% classification accuracy). In Figure 3(a), for the bank o_{14}, it is noticeable that the characteristic BOEs of c_1, c_2, c_5 and c_6 are at the $\{x, \neg x\}$ vertex, due to them being missing in this case.

Figure 3. Simplex plot representations of results for banks (with missing values retained [top row] and managed using mean imputation [bottom row])



By way of comparison, the missing values in the incomplete data set are replaced through mean imputation (Huisman, 2000): see the bottom row of simplex plots in Figure 3. The results in Figure 3(c) show the inhibiting information of the c_1 and c_6 imputed characteristic values (previously missing), which illustrates the effect of transforming an incomplete data set. That is, since they now are considered to have numerical values (not missing now instead the mean of the characteristic values still present), the optimisation process to assign values to the control variables means they now contribute some evidence rather than just ignorance as previously mentioned.

The results in Figure 3(d) indicate 77.5% classification accuracy, with less simplex coordinates of the object BOEs at the edges of the simplex plot, a consequence of more conflicting evidence from the characteristics, since all characteristic values are not missing. The classification accuracies when there are missing values present are the same, and only slightly worse than when there were no missing values. Importantly when the missing values are retained the rich analysis is on the original data and allows further interpretability unlike when the missing values are imputed.

FUTURE TRENDS

The development of data mining techniques is for the improvement of understanding aspects of everyday life. General uncertain reasoning-based methodologies, such as DST, fuzzy set theory, and rough set theory, offer novel opportunities for evolving the nature of intelligent modelling, bringing different advantages to the subsequent analyses. In the case of DST, the concomitant Transferable Belief Model is taking the theoretical issues forward (Smets, 2005), with particular techniques such as CaRBS utilising the DST environment practically when undertaking the more applied data mining. Perhaps the future lies in the collaboration of the general methodologies (like those previously mentioned), which could augment the advantages, hence realism that subsequent techniques can utilise.

CONCLUSION

The nascence of the CaRBS system described and employed in this chapter illustrates how the development of data mining techniques is an ongoing process. With its underlying mathematical structure being based around the DST of evidence, the utilisation of uncertain reasoning here allows the classification of objects that is allowing for the presence of ignorance in the results.

The advantageous traits associated with the CaRBS system also highlight the incumbencies of effective data mining. Firstly the interpretability of the results, be it with a consistent visual domain (such as the simplex plot), and secondly the lack of a need to externally manage the presence of missing values. This second point is particularly pertinent since perhaps there exists a too relaxed attitude toward their management without real concerns for the effects to real interpretation that can be afforded.

KEY TERMS

Confidence Value: A function to transform a value into a standard domain, such as between 0 and 1.

Equivalence Class: A set of objects considered the same subject to an equivalence relation (e.g., those objects classified to *x*).

Evolutionary Algorithm: An algorithm that incorporates aspects of natural selection or survival of the fittest.

Focal Element: A finite nonempty set of hypotheses.

Imputation: Replacement of a missing value by a surrogate.

Mass Values: A positive function of the level of exact belief in the associated proposition (focal element).

Objective Function: A positive function of the difference between predictions and data estimates that are chosen so as to optimise the function or criterion.

Simplex Plot: Equilateral triangle domain representation of triplets of nonnegative values which sum to one.

Uncertain Reasoning: The attempt to represent uncertainty and reason about it when using uncertain knowledge, imprecise information, and so forth.

Object-Oriented Software Reuse in Business Systems

Daniel Brandon, Jr.
Christian Brothers University, USA

INTRODUCTION

"Reuse [software] engineering is a process where a technology asset is designed and developed following architectural principles, and with the intent of being reused in the future" (Bean, 1999). "If programming has a Holy Grail, widespread code reuse is it with a silver bullet. While IT has made and continues to make laudable progress in our reuse, we never seem to make great strides in this area" (Grinzo, 1998). "The quest for that Holy Grail has taken many developers over many years down unproductive paths" (Bowen, 1997). This article is an overview of software reuse methods, particularly object oriented, that have been found effective in business systems over the years.

BACKGROUND

Traditional software development is characterized by many disturbing but well documented facts, including:

- Most software development projects "fail" (60%) (Williamson, 1999).
- The supply of qualified IT professionals is much less than the demand (www.bls.gov).
- The complexity of software is constantly increasing.
- IT needs "better," "cheaper," "faster" software development methods.

Over the years, IT theorists and practitioners have come up with a number of business and technical methods to address these problems and improve the software development process and results thereof. Most notable in this sequence of techniques are CASE (computer-aided software engineering), JAD (joint application development), prototyping, 4GL (fourth generation languages), and Pair/Xtreme programming. While these methods have often provided some gains, none have provided the improvements necessary to become that "silver bullet." CASE methods have allowed development organizations to build the wrong system even faster, "wrong" in the sense that requirements are not met and/or the resulting system is not maintainable or adaptable. JAD methods tend to waste more of everyone's time in meetings. While prototypes can help better define user requirements, the tendency (or expectation) that the prototype can be easily extended into the real system is very problematic. The use of 4GL languages only speeds up the development of the parts of the system that were easy to make anyway, while unable to address the more difficult and time consuming portions. Pair programming has some merits but stifles creativity and often requires more time and money.

The only true "solution" has been effective software reuse. Reuse of existing proven components can result in the faster development of software with higher quality. Improved quality results from both the use of previous "tried and true" components and the fact that standards (technical and business) can be built into the reusable components (Brandon, 2000). This improved quality results in lower lifecycle maintenance costs, and since two thirds of software product lifecycle costs are in post-delivery maintenance, this cost savings aspect of reusability is the most rewarding (Schach, 2005). There are several types of reusable components that can address both the design and implementation process. These come in different levels of "granularity" and in both object oriented and non-object oriented flavors.

Software reuse received much attention in the 1980s but did not catch on in a big way until the advent of object oriented languages and tools" (Anthes, 2003). In Charles Darwin's theory of species survival, it was the most adaptable species that would survive (not the smartest, strongest, or fastest). In today's fast moving business and technical world, software must be adaptable to survive and be of continuing benefit. Object oriented software offers a very high degree of adaptability. "Object technology promises a way to deliver cost-effective, high quality and flexible systems on time to the customer" (McClure, 1996). "IS shops that institute component-based software development reduce failure, embrace efficiency and augment the bottom line" (Williamson, 1999). "The bottom line is this: while it takes time for reuse to settle into an organization—and for an organization to settle on reuse—you can add increasing value throughout the process" (Barrett & Schmuller, 1999). We say "object technology" not just adopting an object oriented language (such as C++, Java, or PHP), since one can still build poor, non-object oriented, and non-reusable software, even using a fully object oriented language.

TYPES AND APPLICATIONS OF REUSE

Radding (1998) defines several different types of reusable components, which form a type of "granularity scale":

- **GUI Widgets:** Effective, but only provide modest payback.
- **Server-Side Components:** Provide significant payback but require extensive up-front design and an architectural foundation.
- **Infrastructure Components:** Generic services for transactions, messaging, and database … require extensive design and complex programming.
- **High-Level Patterns:** Identify components with high reuse potential.
- **Packaged Applications:** Only guaranteed reuse—may not offer the exact functionality required. This includes COTS (commercial off the shelf software).

An even lower level of granularity is often defined to include simple text files that may be used in a number of code locations such as "read-me" and documentation files, "help" files, Web content, business rules, XML schemas, test cases, and so forth. Among the most important recent developments of object oriented technologies is the emergence of design patterns and frameworks, which are intended to address the reuse of software design and architectures (Xiaoping, 2003). The reuse of "patterns" can have a higher level of effectiveness over just source code reuse. Current pattern level reuse includes such entities as a J2EE Session Façade or the .Net Model-View-Controller pattern.

Reuse has two types. The first is called opportunistic (or accidental) reuse, where developers realize that a component from a previous project could be used in the current project. The second is systematic (or deliberate) reuse, where components are built to be reused (Schach, 2005). Reusing code also has several key implementation areas: application evolution, multiple implementations, standards, and new applications. The reuse of code from prior applications in new applications has received the most attention. However, just as important is the reuse of code (and the technology embedded therein) within the same application.

Application Evolution

Applications must evolve even before they are completely developed, since the environment under which they operate (business, regulatory, social, political, etc.) changes during the time the software is designed and implemented. This is the traditional "requirements creep." Then after the application is successfully deployed, there is a constant need for change.

Multiple Implementations

Another key need for reusability within the same application is for multiple implementations. The most common need for multiple implementations involves customizations, internationalization, and multiple platform support. Organizations whose software must be utilized globally may have a need to present an interface to customers in the native language and socially acceptable look and feel ("localization"). The multiple platform dimension of reuse today involves an architectural choice in languages and delivery platforms.

Corporate Software Development Standards

Corporate software development standards concern both maintaining standards in all parts of an application and maintaining standards across all applications. "For a computer system to have lasting value it must exist compatibly with users and other systems in an ever-changing information technology (IT) world" (Brandon, 2000). As stated by Weinschenk and Yeo, "Interface designers, project managers, developers, and business units need a common set of look-and-feel guidelines to design and develop by" (Weinschenk & Yeo, 1995). In the area of user interface standards alone, Appendix A of Weinschenk's book presents a list of these standards; there are over 300 items (Weinschenk, Jamar, & Yeo, 1997). Many companies today still rely on some type of printed "Standards Manuals."

EFFECTIVE SOFTWARE REUSE

Only about 15% of any information system serves a truly original purpose; the other 85% could be theoretically reused in future information systems. However, reuse rates over 40% are rare (Schach, 2004). "Programmers have been swapping code for as long as software has existed" (Anthes, 2003). Formal implementation of reuse in various forms of software reuse has been a part of IT since the early refinements to 3GLs (Third Generation Languages). COBOL had the "copy book" concept, where common code could be kept in a separate file and used in multiple programs. Most all modern 3GL's have this same capability, even today's Web-based languages like HTML and JavaScript on the client side, and PHP (on the server side). HTML has "server side includes"; JavaScript has ".js" and ".css" files; and PHP has "require" files (".inc"). Often used in conjunction with these "include" files is the procedure capability where some code is compartmentalized to perform a particular task, and that code can be sent arguments and possibly also return arguments. In different 3GLs this might be called "subroutines"

or in modern languages "functions." A function "library" is a separate file of one or more functions and depending on the language may be pre-compiled.

Object oriented methods are concerned with the design and construction of modules of code that can exhibit certain characteristics. The key characteristics are encapsulation, composition, genericity, inheritance (generalization and specialization), and polymorphism. The code modules are typically called "object types" at the design level and "classes" at the implementation level. These classes contain both form (data) and functionality (functions). Encapsulation involves public "access functions" mediate access to the private data of a class to preserve both data security and integrity. Object oriented methods foster reusability in several ways:

- A class can be "composed" of other classes, and this provides one form of code reuse.
- Generic classes (or templates) can be created, which provide generic definitions and functionality that are common to a number of specific classes, and this is often used to implement types of data structures.
- Interfaces can be specified that define, but do not implement, functionality. Using interfaces, one can design common functionality that may be realized (implemented) by a number of classes (Arlow & Neustadt, 2005).

A class (or interface) can also be derived from another class (a more general "super" or "base" class). Derived classes (more specific classes) inherit the form and functionality of their base class and can add additional form or functionality and also modify functionality; this is the polymorphism aspect. This principle of "inheritance" is the cornerstone of reusability in object oriented systems (Oestereich, 1999).

As an example of object oriented application, consider a large GUI application that may have hundreds of windows. Suppose the corporate design is to have each window show the company name on the top left and the date/time on the top right. Later a new boss decides he or she wants the company name on the top right and the date/time on the top left. If the application had been written in a non-object oriented language, then we would have to go back and modify hundreds of windows. If instead we had used an environment that supported inheritance (such as C++, Java, or PHP) and we had derived all our windows from a base window class, then we would only have to change the one base class. If we used only an "include file" from which to get the company name, that would allow us to easily change the company name, but not to change the place where the name appeared in the window (unless we had clairvoyantly foreseen such a possibility, and designed a name location parameter in our include file).

In most organizations, software reusability is still a goal that is very elusive, as said by Bahrami (1999), "a most difficult promise to deliver on." Radding (1998) stated, "Code reuse seems to make sense, but many companies find there is so much work involved, it's not worth the effort. … In reality, large scale software reuse is still more the exception than the rule." Bean (1999) in "Reuse 101" states that the current decreased "hype" surrounding code reuse is likely due to three basic problems:

- Reuse is an easily misunderstood concept.
- Identifying what can be reused is a confusing process.
- Implementing reuse is seldom simple or easy to understand.

Grinzo (1998) also listed several reasons and observations on the problem of reuse, other than for some "difficult to implement but easy to plug-in cases" such as GUI widgets: a "nightmare of limitations and bizarre incompatibilities," performance problems, "thorny psychological issues" involving programmers' personalities, market components that are buggy and difficult to use, fear of entrapment, component size, absurd licensing restrictions, or lack of source code availability.

Schach (2005) lists and describe the impediments to reuse as:

- Too many IS professionals would rather rewrite than reuse.
- Many IS professionals are skeptical on the safety and quality of using components built for other applications.
- Reuse artifacts are not stored and cataloged in a useful manner.
- Reuse can be expensive (building a reuse process, maintaining the reuse library, and verifying the fitness of the artifact for the new application).
- Legal issues may arise with contract software.
- COTS products are seldom available in source code format.

Some organizations try to promote software reusability by simply publishing specifications on class libraries that have been built for other in-house applications or that are available via third parties; some dictate some type of reuse, and other organizations give away some type of "bonus" for reusing the class libraries of others (Bahrami, 1999). But more often than not, these approaches typically do not result in much success. "It's becoming clear to some who work in this field that large-scale reuse of code represents a major undertaking" (Radding, 1998). "An OO/reuse discipline entails more than creating and using class libraries. It requires *formalizing* the practice of reuse" (McClure, 1996).

There are generally two key components to *formalizing an effective software reuse practice* both within an applica-

tion development and for new applications (Brandon, 2002). These components are:

1. Defining a specific "Information Technology Architecture" within which applications would be developed and reuse would apply
2. Defining a very specific object oriented "Reuse Foundation" that would be implemented within the chosen IT architecture

Once the technical issues of an architecture and a reuse foundation are addressed, then management issues need to resolved, namely "procedures, disciplines, and tools for tracking, managing, searching, and distributing software assets" (Anthes, 2003). Procedures and disciplines have to be formulated and enforced as part of the software development management and organizational "culture." Software can be built or procured to handle the searching, tracking, cataloging, and distribution issues.

FUTURE TRENDS

Several future trends will be key to the continuing success of software reuse. The first trend is for companies to adopt the necessary management principles that foster reuse including programming incentives. Programmers must be rewarded for reusing software, and also producing software that can be reused.

The initial design of systems in an object oriented manner will include several reuse considerations. Lee and Tepfenhart (2002) itemize the basic steps in identifying the system object types as:

- Using the things to be modeled
- Using the definitions of objects, categories, and types
- Using object decomposition (composition)
- Using generalization (working up an inheritance hierarchy)
- Using subclasses (working down the inheritance hierarchy)
- Using domain analysis (reusing domain level functionality)
- Reusing an application framework
- Reusing class hierarchies (including template classes)

Another trend is for software to be developed that facilitates "library" functions for reusable components. Vendors and products in this area today include CMEE (Component Manager Enterprise Edition) from Flashline (http://www.ejbean.com), Logidex byLogicLibrary, and Component Manager by Select Business Solutions (www.selectbs.com). International standards like UML (Unified Modeling Language) and RAS (Reusable Asset Specification) (www.rational.com) will make these tools more interoperable. As well as "library" type tools, other technologies and tools will facilitate reuse that is based on standards such as "Web services" and other messaging technologies, which will let software be reused "where it sits."

Still another trend is for companies to devote programming resources specifically to developing reusable components, while other programmers use the components built by this devoted group.

CONCLUSION

"If you want reuse to succeed, you need to invest in the architecture first" (Radding, 1998). "Without an architecture, organizations will not be able to build or even to buy consistently reusable components." In terms of general IT architectures for business systems, there are historically several types as Central Computer, File Services, Two or Three Tier Client Server, and Two or Three Tier Internet- (Browser-) based. Various transaction processing and database vendors have their own "slants" on these basic approaches, which may depend upon how business logic and the database are distributed.

Today companies are mainly interested in the last of these categories. Internet-based applications are becoming the preferred way of delivering software-based services within an organization (intranets), to the worldwide customer base via browsers and "net appliances" (Internet), and between businesses (extranets). Vendor independent and "open" architectures are often preferred, and the "multiple platform"

Figure 1.

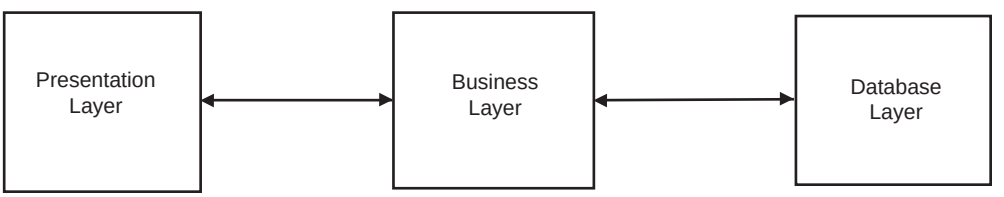

Figure 2.

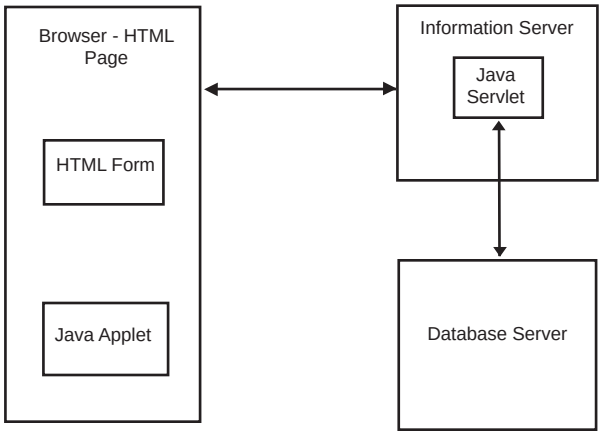

Figure 3.

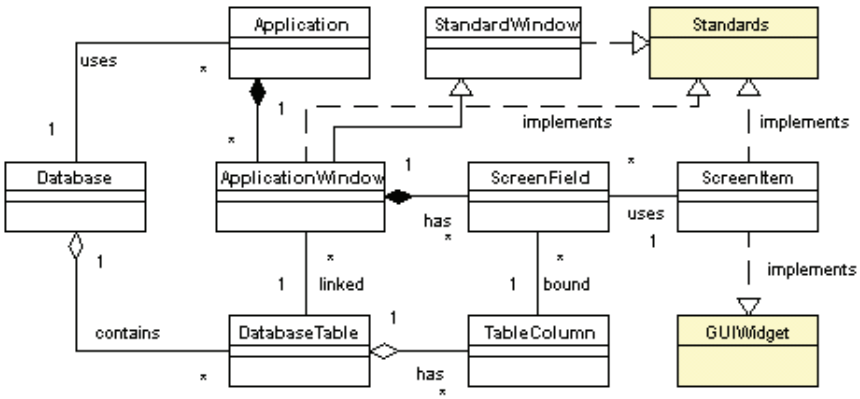

Figure 4.

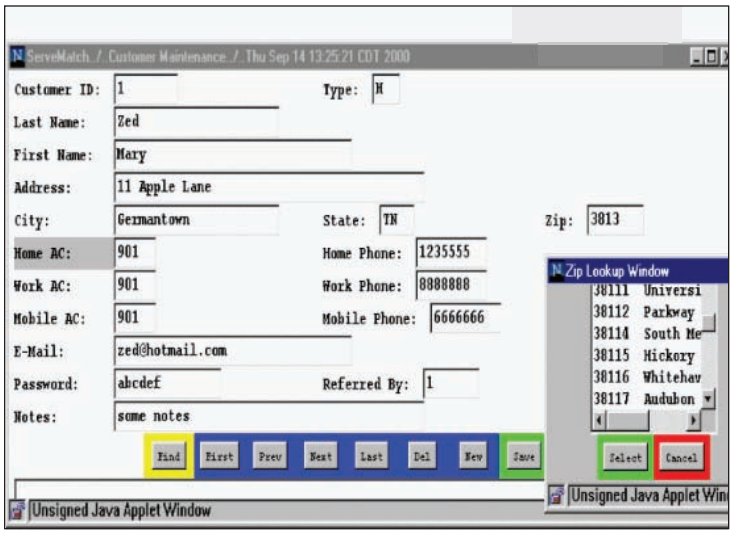

dimension of reusability is handled by using server generated HTML and JavaScript (via Java or PHP programs on the server).

As has been concluded by several authors, "A reuse effort demands a solid conceptual foundation" (Barrett & Schmuller, 1999). One such foundation was presented by Brandon (2002). It is based on the key object oriented principles of inheritance and composition. By establishing this foundation, an organization can effectively begin to obtain significant reusability since programmers must inherit their class from one of the established classes, and they must only compose their class of the established pre-built components.

KEY TERMS

Class: A program construct representing a type of thing (abstract data type), which includes a definition of both form (information or data) and functionality (methods).

Composition: A new class in an objected programming language that is composed of other classes.

Encapsulation: The ability to insulate data in a class so that both data security and integrity is improved.

Framework: A software foundation that specifies how a software system is to be built. It includes standards at all levels both internal construction and external appearance and behavior.

Function: A programming construct where code that does a particular task is segregated from the main body of a program; the function may be sent arguments and may return arguments to the body of the program.

Implementation: The code placed inside of methods. For some languages this code is pre-compiled or interpreted.

Include: Some code stored separately from the main body of a program so that this code can be used in many programs (or multiple places in the same program).

Inheritance: A feature of object oriented languages that allows a new class to be derived from another class (a more general class); derived classes (more specific classes) inherit the form and functionality of their base class.

Interface: The specification for a method ("what" a method does); how that function is called from another program. Interfaces are provided in source form as opposed to implementations, which are secure. This allows one to use a method without regard for "how" that method is coded. It also allows multiple implementations of the same interface.

Libraries: A group of functions and/or classes stored separately from the main body of the main program; an "include" file consisting of functions and/or classes.

Method: A function defined inside of a class.

Packages: Similar to a library, but just containing classes.

Patterns: A software library for a common business scenario. A framework may be a design framework (possibly expressed in UML) or an implementation framework (possibly in C++, Java, or PHP).

Polymorphism: The ability of object oriented programs to have multiple implementations of the same method name in different classes in an inheritance tree. Derived classes can override the functionality defined in their base class.

Reuse: Reuse (software) is a process where a technology asset (such as a function or class) is designed and developed following specific standards, and with the intent of being used again.

Separation: The separation of what a method does (interface) from how the method does it (implementation).

Observations on Implementing Specializations within an IT Program

Erick D. Slazinski
Purdue University, USA

INTRODUCTION

With a projected 2.26 million additional jobs to fill in various computer fields by the year 2010, there are and will continue to be ample job opportunities in the computer industry. However, the computer field is far too broad for one individual to be an expert in the entire field. Therefore it may be more useful for students to have the opportunity to concentrate their studies in a specific interest area within a broader Information Technology (IT) degree.

IT educators throughout the United States (US) have paid attention to the needs and demands of the IT industry. To address the need for IT graduates with specialized skills, many of the leading universities have created programs which allow undergraduate students to specialize or focus their studies.

This chapter will discuss findings on the state of IT programs with regards to their course offerings. One area of specialization, or track, is presented as an example. It will be noted that even within a specialty area, there can be further specializations. In addition to supporting the students pursuing the specialty area, general knowledge courses must also be offered to those pursuing other specialty areas.

BACKGROUND

The Bureau of Labor Statistics reported 2.9 million computer-related jobs in 2000, with an expected 4.89 million computer jobs by the year 2010. Considering new jobs as well as replacements, over 2.26 million additional people will be needed to fill these jobs (Hecker, 2001). The fluid nature of the IT industry makes generalizations difficult. Therefore, skills are often categorized or grouped together into skill sets (or job descriptions). The most common clustering of skills has been summarized in Table 1.

Of these pathways (or specialization tracks), two of the top occupations (as predicted by the US Dept of Labor) are systems analysis and database administrators (which have been grouped in the EDC Information Support and Service Pathway). See Table 2 for a listing of the top growth occupations.

WHERE ARE THE SPECIALIZED IT PROGRAMS?

Published curriculum from the institutes who attended the Conference for IT Curriculum (CITC) II held in April of 2002 were used as the sample set. The conference attendees were primarily IT educators from around the US, who had an interest in IT curriculum issues. An IT curriculum is focused on the application of technologies to solve problems. To differentiate, a traditional Computer Science curriculum is focused on algorithm design.

Table 3 illustrates, that out of the 28 programs studied, 50% (14) had some specialization available for students. Of the 14 programs that offered specializations, 45% (6) of those offered at least a database specialization similar to our sample track.

NEED FOR A DATABASE TRACK

The same data from the Bureau of Labor Statistics (Hecker, 2001) indicates there were 106,000 jobs for database administrators (DBAs) in 2000, with a projected 176,000 openings to fill by the year 2010. In addition to DBAs, there are also

database professionals who specialize in database architecture and database programming.

ANATOMY OF A DATABASE TRACK

Though there are various job titles given to database activities in the workplace, such as these listed on the ITWORKS-OHIO website: Data Analyst, Database Administrator, Database Analyst, Database Developer, and Database Specialist—many others exist in the marketplace. However, based on the author's opinion, when the job descriptions are examined, one can find that there are really three, inter-related roles. Figure 1 illustrates these roles using the structure of a house as an example. The DBA (as the foundation) keeps a database available, secure, and healthy. Without the DBA, the rest of the database team could not function. The database developer (as the framing of the house) encodes the business logic in the database. Additionally the database developer often develops the interface layer between the system software and the database engine. Lastly, the database architect (as the roof of the house) is often a senior staff member. Typical

Table 3. Programs and specializations

INSTITUTION NAME	SPECIALAZATION	DATABASE SPECIALIZATION

University of Cincinnati-Clermont	NO	
USCS	NO	

duties include determining the amount of business logic to be encoded in the database, developing the database design (including distribution of data, data flows, etc.) and often overseeing the implementation of the database. Like the components of a house, all three roles are co-dependant and necessary. In addition to the specific duties, each member must maintain several lines of communication within the development team and organization.

The database administrator must often work with the system/network administrators when it comes to the purchasing of hardware, determining network traffic and bandwidth requirements, coordinating the use of backup devices, etc. They often work with the database architects in providing recommendations for physical implementation issues. For the database developer, they must interact with the database architect (they are implanting the design from the architect) as well as the system developers and ensure that the developers have access to the data they need while maintaining the integrity of the database. The database architect must work with the software architect. Together they determine how to partition the business logic of the system. The database architect works with the DBA in determining the best physical implementation of the supporting database. And lastly the architect often coordinates the activities of the database developers.

Based on these responsibilities and communication channels, the database track was designed to produce students prepared for these multi-faceted jobs. During the first two years of our program, all students gain a broad overview of the Information Technology field, taking introductory courses in programming, Internet technologies, architectures, telecommunications, database, and systems analysis and design

- **Introduction to Application Development:** Introduction to system development using MS Access.
- **Introduction to Computer Programming:** Application development using Visual Basic.
- **Internet Foundations and Technologies:** Web page development using XHTML.
- **Information Technology Architectures:** Explores the history, architecture, and development of the Internet and the World Wide Web.
- **Systems Software and Networking:** Introduction to data communications and Network Operating systems.
- **Programming for the Internet:** Internet application development using scripting languages.
- **Database Fundamentals:** Normalization, SQL, and application interfaces to databases.
- **Systems Analysis and Design Methods:** Introduction to information systems development.

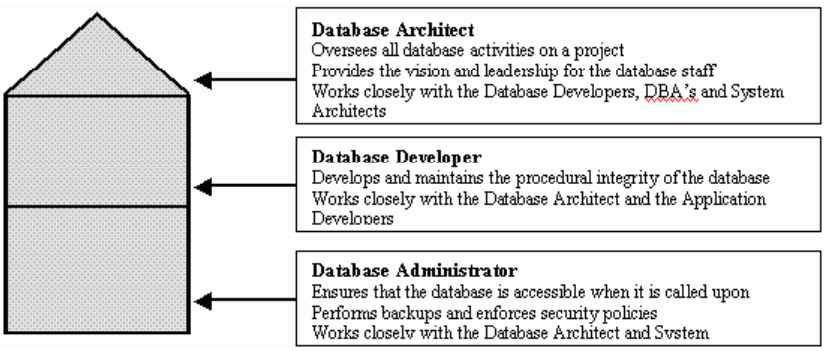
COURSES IN THE DATABASE TRACK

Students specializing in the database area must complete an additional 25 credit hours of technical courses focused on getting the database student prepared for one of the three roles described above. The progression of the courses is shown in Figure 2. Then it will be shown how these courses, in combination with other technical electives, prepare our students for future jobs.

A brief description of these database courses follows.

- **Introduction to Application Development (all students):** Introduces the development of information systems through the use of a database. Topics include business information systems, system and application development, database management systems, problem solving, logic, data types, and programming using database technology. Given a database design and application requirements, students design, construct, and test a personal computer information system.
- **Database Fundamentals (all students):** Looks at relational database concepts, including data design,

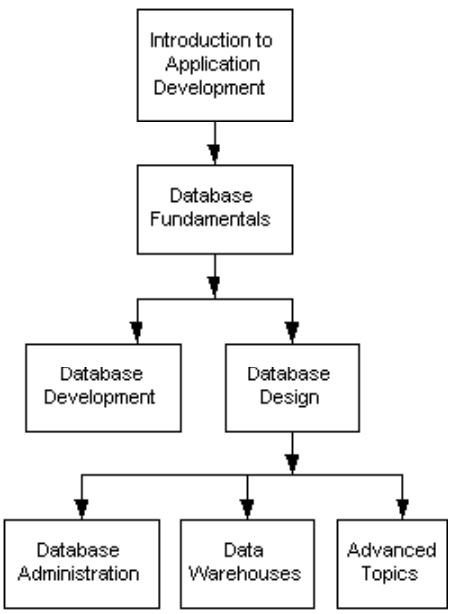
Figure 1. Database roles



modeling and normalization. Students use SQL to query, define, populate, and test a database. Expands on previous courses by accessing databases from programs and the Web, and discusses practical issues that database developers must handle.

- **Database Development:** Explores some of the programmatic extensions to SQL supported by leading Relational Database Management Systems (RDBMS) vendors. Topics include stored procedure and trigger design and implementation, query optimization to enhance performance, and data transformation to enhance interoperability of data.
- **Database Design and Implementation:** Deals with advanced design techniques and physical issues relating to enterprise-wide databases. Topics include advanced normalization, data distribution, distributed database design and replication, storage estimation and allocation, usage analysis, partitioning of very large tables, metadata analysis, data conversion, and load techniques.
- **Database Administration (elective):** Explores tools and techniques for managing an organization's database technology. Topics include database architecture, database technology installation, database creation and maintenance, RDBMS operations and troubleshooting, and database performance tuning.
- **Data Warehousing (elective):** Studies the design and implementation of data warehouses (including data marts and operational data stores) using current database technologies. Topics include data modeling for warehouses, data warehousing infrastructure and tool selection, data exploration, data synthesis and reduction, organizational metadata, and data warehouse administration.
- **Advanced Topics in Database Technology (elective):** Explores contemporary issues in the database arena. These issues may be related to new or breakthrough concepts, technologies, or techniques.

Figure 2. Database courses



Rounding Out the Students

Since database development has a significant analysis and design component, students are required to take a Systems Requirements Discovery and Modeling course, offered by our systems analysis group. Likewise many database personnel are often relegated to a distinct group with a project that has management requirements, so a Project Management course is also required. To support the further specialization into the database architect, database programmer and database administrator roles, two separate selective areas - database management selectives and database technology selectives - were defined. The students must choose a minimum of six credit hours (two courses) in each of the selective areas. The database management selectives are the elective courses listed with the database course flow in Figure 2 (above) – database administration, data warehousing and advanced topics in database management, as well as any graduate level database course offered during the student's senior year. The database technology selectives provide additional areas of exploration on topics that piqued the students' interest in their first two years. Again they are allowed to choose any two courses from the following:

- **Object-Oriented Programming:** use object-oriented programming languages (Java) in the development of modern, business applications.
- **Advanced Design Techniques:** advanced study of system design methods and techniques used by systems analysts to develop information systems.
- **Software Development Methodologies:** methodologies and practices commonly used in contemporary software development projects.
- **Enterprise Application Development:** component development and reuse, distributed object technologies, multi-tier applications.
- **Senior Software Development Project:** integrates the software development technologies and techniques taught in prior courses.
- **E-Commerce:** components of e-commerce.
- **Automatic identification and data capture:** real-time data feeds.
- Any other database management selective course(s) not already taken.

MODEL CURRICULA

At the time this chapter was written, there are at least three curricula models available from which to build from: the IEEE/ACM Computing Curricula; the EDC Academic Foundations and Pathways (EDC, 2002) and the ACM SIG ITE Curriculum Proposal. These models share more similarities than differences and selecting a model may be more a matter of preference of one set of authors over another. Considering the most mature model, the author has chosen to compare the specified database track against the IEEE / ACM Computing Curricula 2001.

The most recent IEEE / ACM Computing Curricula report, available at the ACM Web site, identifies Information Management (IM) as a knowledge area within their Computing Curricula 2001. The IM area of knowledge includes 14 components. Three are considered core, and 11 are viewed as electives. The courses in our database track provide significant coverage of the IM areas identified. Additionally, a Database Administration course that is beyond the model is offered. Table 4 shows the mapping from the IM components to our DB-track courses.

FUTURE TRENDS

For our University, the new curriculum implementing the track concept started in Fall 2001. In Spring 2003 the first cohort of Freshmen (who entered the program with the tracks in place) were required to select their track of interest. However, as news of the program's availability became known, students under the old plan of study transferred to the new plan of study. Additionally, transfer students were admitted under the new plan of study. These students plus an enthusiastic faculty caused the transition to the new course models to occur immediately after the new program (with tracks) was ratified by the University curriculum committee instead of waiting until the Spring 2003 semester.

This caused several registration issues which our counselors had to handle: multiple plans of studies; multiple course equivalencies (as courses were being brought online and retired); and pre-requisite issues. Of these the issue of tracking pre-requisites has been the most challenging because certain courses exist in multiple curriculums whose content has changed every time the curriculum has changed. Often counselors would have to have professors validate that a student had the appropriate pre-requisite knowledge. This often led to questions such as "who taught this pre-requisite course?" or "did you cover this topic?"

CONCLUSION

Since the IT field is too broad to be comprised of only generalists, the IT workforce is becoming increasingly specialized. In response to this, IT educators have started offering areas of specialization or tracks that meet industry's needs. However, designing and implementing a tracked curriculum is a demanding task. The implementation costs may be higher than first estimated. If students are to get

Table 4. Comparison of model curricula to database track courses

IM Knowledge Areas	DB Track
IM1: Information Models and Systems (core)	In 1st year course
IM2: Database Systems (core)	In 1st year course
IM3: Data Modeling (core)	2nd year: Database Fundamentals 3rd year: Database Design
IM4: Relational Databases (elective)	2nd year: Database Fundamentals 3rd year: Database Design
IM5: Database Query Languages (elective)	2nd year: Database Fundamentals (not OO queries)
IM6: Relational Databases Design (elective)	2nd year: Database Fundamentals 3rd year: Database Design
IM7: Transaction Processing (elective)	2nd year: Database Fundamentals 3rd year: Database Development
IM8: Distributed Databases (elective)	3rd year: Database Design 4th year Data Warehousing
IM9: Physical Database Design (elective)	3rd year: Database Design
IM10: Data Mining (elective)	4th year Data Warehousing
IM11: Information Storage and Retrieval (elective)	4th year Data Warehousing (partial)
IM12: Hypertext and Hypermedia (elective)	Candidate for 4th year Adv Topics
IM13 Multimedia Information and Systems (elective)	Candidate for 4th year Adv Topics
IM14: Digital Libraries (elective)	Candidate for 4th year Adv Topics

through a curriculum with multiple tracks in a reasonable time frame, the number of courses that need to be offered every semester can increase. This increase will require more resources could put a drain on other departmental offerings (such as service/graduate courses).

KEY TERMS

DBA: The title database administrator (DBA) represents an IT professional who ensures the database is accessible when it is called upon, performs maintenance activities, and enforces security policies.

IT Discipline: The ***intellectual gap*** in our educational frameworks for students who are interested in computing careers but find computer science too narrow, mathematical, and physical-science oriented, while MIS is insufficiently deep in technical content and too focused on traditional business topics and culture (Finkelstein, 2002).

Knowledge Area: Represents a particular sub-discipline that is generally recognized as a significant part of the body of knowledge that an undergraduate should know (IEEE, 2001).

Relational Database Management System (RDBMS): A suite of programs which typically manages large structured sets of persistent data, offering ad hoc query facilities to many users, which is based on the relational model developed by E.F. Codd (FOLDOC).

Selective List: A set of courses, grouped together for the purpose of filling an educational skill gap.

Systems Analysis: The design, specification, feasibility, cost, and implementation of a computer system for business (FOLDOC).

Systems Design: The approach used to specify how to create a computer system for business (FOLDOC).

Track: A series of courses designed around a topical area which is structured in a manner to efficiently develop a student's skill set.

Offshore Software Development Outsourcing

OFFSHORE SOFTWARE DEVELOPMENT OUTSOURCING EVOLUTION

Until the global economic downturn of the new millennium, demand for information technology (IT) professionals exceeded supply mostly due to specific skill sets such as integrating legacy applications with Web development, project management, telecommunications, mobile commerce, and enterprise resource planning. More firms are turning externally not only to local vendors but also to services across the globe (Carmel, 1999). Staff supplementation from domestic contractors has evolved to a sophisticated model of partnering with offshore/nearshore software development firms. Many of these relationships evolved from a short-term project need for select skills to a long-term commitment of resources, cultural diversity efforts, and dependencies that integrate vendors as partners.

The most pervasive IT project, Year 2000 (Y2K), had constraints of skill sets, time, and budget. IT managers had to look at many alternatives for achieving compliance. Firms that planned as early as the mid-1990s had time to experiment and build new relationships. With governmental sanction and support, some countries and their business leaders recognized the competitive advantage their labor force could offer (O'Riain, 1997; Heeks, 1999; Trauth, 2000). An unusual need for services because of Y2K, economic disparity within a global workforce, and proactive efforts of some governments led to the fostering of offshore software development.

Early companies to outsource offshore were software vendors. Managing offshore development smoothly took years and a certain type of project management expertise in addition to a financial commitment from executives. The activity involved new applications and integrating software development with existing domestically built applications. The Y2K investment and intense cultural communication paid off for firms willing to work through the challenges. Not only did initial offshore projects provide a solution to the skill shortage, they also yielded substantial cost savings when compared to outsourcing the work domestically. Such factors resulted in these relationships continuing past Y2K, where some companies now regard their offshore arm as partners.

The IT outsourcing market was estimated at over US$100 billion by 2001 (Lacity and Willcocks, 2001). Although outsourced IT services can include call centers and facilities management, this discussion focuses on outsourcing software development. "Offshore" software development typically refers to engaging workers from another continent. Examples are U.S. companies using Indian contractors. "Nearshore" software development refers to vendor firms located in nearby countries often on the same continent, for example Dutch firms engaging Irish software developers. For our purposes, discussion of offshore software development issues is assumed to apply to nearshore outsourcing, since most of the issues are the same.

Most firms already have had experience supplementing their staff. Dealing with offshore firms, however, is relatively new for firms whose main business is not software development. Distance, time zones, language and cultural differences are some key issues that differentiate offshore software development from the use of domestic contractors or consultants (Carmel, 1999). Nearly 1 million IT-jobs will move offshore from the United States by 2017 (Gaudin, 2002).

The most common reasons for outsourcing are cost reduction, shortages of IT staff, reduced development time, quality of work, and internationalization (see Table 1).

APPROACHES TO OFFSHORE SOFTWARE DEVELOPMENT

The approaches taken to offshore development describe the basic features of how firms have structured their relationships with offshore software developers. The basic dimensions include the type of organization that provides offshore services, the nature of the working relationship that clients have with that organization, and whether offshore staff are on a defined project or in a staff augmentation role.

Type of Organization Providing Offshore Development

An important dimension for describing the relationship with foreign software developers would be the basic types of

Table 1. Reasons for engaging in offshore software development

- Cost reduction - due primarily to lower wages and secondarily from tax incentives. Accounting for indirect costs, such as travel and teleconferencing, overall average savings may be close to 25% (Overby, 2001).
- Access to a global pool of talent - quicker staffing thereby enabling faster time to delivery.
- 24×7 Productivity – the global delivery model allows a "follow-the sun" approach for round-the-clock handing-off of work to developers in different time zones.
- Quality – rigorous requirements of certifications (CMM, ISO) or cultural dedication to detail and quality.
- Localization - adapting software to local requirements may be best handled by resources in or near the target location.

organizations with which client firms form an outsourcing arrangement. The basic options are to contract directly with an offshore IT services firm, to engage a domestic IT services firm with offshore capabilities, or to set up a wholly owned software development center in an offshore location.

- Direct contract with an offshore firm – The client firm contracts directly with the offshore software firm. This option represents a range of alternatives.

  • Long-distance contracting – the offshore firm maintains no permanent staff in the country of their clients. Clients and offshore firms use long distance communications technologies such as phone, e-mail, and short-term visits.
  • Limited presence – Offshore firms locate some staff in client countries by setting up satellite offices in one or more cities. Most of the work is performed offshore, but a local project manager and a small local team answers questions and function as liaisons to solve problems.
  • Integrated on-site – the export firm provides a mix of extensive onsite expertise to handle business and requirements analysis, system design, and project management, and coordinates with offshore staff, normally working closely with client management. As many as 70 firms from Ireland have set up subsidiaries in the U.S. with Irish government financial support (Cochran, 2001).

- Contract with a domestic IT services firm with offshore capabilities – Many domestically-based IT services firms have the ability to send work offshore. This may take the form of an IT firm that acts as an intermediary, or a firm that itself owns an offshore satellite location. Some domestic firms employ both approaches. An intermediary acts as a liaison with offshore software firms, and already has subcontracting or partnering arrangements with them. The IT services firm works with clients in much the same way as other domestic IT services firms, but differs in that it uses offshore resources for some of the software development. Intermediaries may negotiate a cut of the cost savings their clients achieve by going offshore. The advantage in giving up the full savings of dealing directly with outsourcers is that the intermediaries buffer clients from most aspects of dealing with offshore providers. For small to midsize companies new to outsourcing, brokers offer the big benefit of offshore projects—good work done more cheaply, but without cross-cultural, long–distance, vendor management headaches.

- Wholly owned Satellite – The firm operates in an offshore location to directly hire IT professionals to become its employees. This is model is almost exclusively used by companies that sell software or by companies whose products have a large software component.

Length of Relationship and Type of Project

The working relationship between clients and vendors can be described by whether the relationship is short or long term, and the type of work the vendor performs.

Relationships with an offshore IT services firms can range from a few months to many years. Short-term relationships may be a single-hit project with no plan for follow-up projects. Long-term relationships may become important business partnerships where an offshore firm is responsible for an ongoing stream of projects.

The nature of work given to offshore vendors can range from well-defined projects to relatively unstructured ones. Typical examples of well-defined projects are technical design, implementation, maintenance, or software conversion. In other cases, vendors may take on significant responsibility

for project initiation, requirements determination, and project management involving new systems or major enhancements to existing systems that have strategic impact to the firm.

Carmel and Agarwal (2002) propose a four-stage model of offshore outsourcing that can be described in terms of time frame and nature of work. They describe firms moving from short-term structured engagements to longer-term structured engagements, and finally to long-term unstructured engagements as a maturation process. A company, however, may have outsourcing efforts that fall into different categories. For example an organization may engage offshore firms for both an ongoing stream of structured and unstructured projects, while at the same time evaluating other vendors, or outsourcing special needs projects on a one-time basis.

Defined Project vs. Staff Augmentation

The previous discussion of offshore development focused on contracting with the outsourcer for the delivery of a defined product. It's possible to tap some outsourcing firms as sources for augmenting staff. Companies contract outsourcing services on the basis of developer time instead of a fixed price software deliverable. Offshore staff may travel to the client's site and be managed closely by the client or may remain in the offshore location managed remotely. Offshore firms in this case have limited responsibility for managing projects.

SOFTWARE EXPORTING COUNTRIES

Table 2 lists dominant players by order of reported revenues, industry software organizations, and their Web sites. Many reports of exports are not standardized. It is not clear what is included in sales figures and who is reporting them. Even if these figures were comparable, the projection for evaluating different countries is not. Some countries are producing more software with fewer developers than others. The types of applications delivered may not compare. Converting a legacy customer database is not similar to customizing an enterprise system. More importantly, within a country there may be many development vendors and generalizations that are not applicable to each company.

CRITICAL ISSUES OF OFFSHORE SOFTWARE DEVELOPMENT

Challenges associated with offshore development are different than domestic development. In most cases the issues lead to creative solutions that some companies have tackled and incorporated to their advantage. Special circumstances of offshore development present factors that practitioners have found to be of special importance in achieving success.

Quality Certification

The Software Engineering Institute's Capability Maturity Model (CMM) (CM-SEI, 2002) or the International Organization for Standardization's ISO9001: 2001 standard (ISO, 2002) serves as an independent evaluation of the quality of a vendor's development processes. Certification should not be taken at face value. Investigation can clarify its meaning. When it was acquired? Was it qualified by project or by subsidiary? Who provided the evaluation? Was it self-assessed? There are a number of questions to raise.

Table 2. Information Technology Industry Organizations by Country (Enterprise Ireland promotes Irish exports, including software services.)

Canada	Information Technology Association of Canada	www.itac.ca
Mexico	AMITI - Mexican Association for the Information Technologies Industry	www.amiti.org.mx/

Onsite Presence

Despite the ability to operate virtually, the tenuous nature of offshore development is optimized when face-to-face contact, handshaking, and social/professional relationships nurture the engagement. The limited presence and integrated on-site approaches address the distance resistance.

Managing Globally

The downside of being productive 24×7 is that some part of the team is often not available for real-time contact because they are not at work at the same time. Travel by someone is a necessity in almost all offshore arrangements. The nature of the relationship will dictate how many and how often, from where to where. Sometimes this may involve extended stays.

Trust and Confidence

Relationship management is the overriding success factor when minimal levels of other factors are in place. IT services firms accent their marketing on these traits. For offshore firms to be seen as important business partners and take on work beyond routine development work, clients need to have a high level of trust and confidence in the outsourcers' abilities and intentions.

Political Environment

The stability of the offshore country's government prevents some firms from exploring offshore outsourcing (Nicholson and Sahay, 2001). Israel's thriving development curtailed with the Palestinian war. The Pakistan-India border disputes caused the U. S. State Department to ban travel to India. Although firms contract with a software firm and not the country, political environment of the country can influence the feasibility of working with firms located there.

Intellectual property concerns are usually dissuaded due to protection by law. Most countries have laws that are comprehensive enough to deal with software as ownership. However, having laws in place does not mean that governments enforce them.

Cultural Awareness and Integration

Close working relationships between offshore vendors and clients from another culture may require significant time, not only for becoming aware of each others' cultures, but to integrate it in practice. Firms with close working relationships not only achieve integration in software methods and delivery but also achieve integration in social aspects of team building.

Nationalism

Organizations that hire offshore developers may have to justify why they are not hiring domestically when many people are unemployed. Issuing of U.S. H1-B visas raised concern as many Americans became unemployed. The IT community was sensitive to the impact of hiring foreigners with special skills. Although visas are no longer granted as they once were, many organizations have had to deal with the same issue that arises with offshore software development. Human rights and workers' ability to earn a living wage are not comparable to client countries' workers—but no published reports of abuse or exploitation surfaced. Offshore software development offers governments ways to gain power and enhance their standing in the world.

Capacity of the Workforce

The availability of human resources to deliver IT demand is debatable. There is mixed evidence about the ability to meet demand (Overby, 2001; Carmel and Agarwal, 2002). Determining capacity is tricky. One must not only review population numbers but the educational, telecommunications, and managerial infrastructure that allows growth.

Risk Management

The most obvious threat relates to the political environment. Because some firms perceive security breaches as more vulnerable using offshore developers, outsourcers probably take extra precaution to sell their services. Y2K and September 11th reinforced the need for business continuity planning.

Risk management can also affect selection of firms in part on the basis of location. Developing relationships with a geographically diverse portfolio of outsourcers could minimize the risk of regional political and economic disturbances.

FUTURE TRENDS

Increased Offshore Outsourcing of Higher-Level System Life Cycle Tasks

Greater experience in using offshore developers on the part of client firms coupled with the maturation of technologies and methodologies for global software delivery allow firms to outsource more high-level development and realize the benefits of outsourcing across a wider variety of IT work.

Emergence of Major Contenders to India

India has been by far the major destination for offshore software development outsourcing, with Israel and Ireland usually considered "major players." China, Philippines, and Russia are often noted as potential contenders. Outsourcing industries are emerging in a number of unexpected locations such as Viet Nam, Mexico, Ukraine, and Iran due to low entry costs.

Increasing Use of Offshore Workers by Domestic Software Firms

To remain competitive, domestic IT outsourcing firms increasingly use offshore developers either through wholly-owned development centers offshore, or by subcontracting or partnering with foreign outsourcing firms (Overby, 2001).

Increased Sensitivity to Outsourcing Domestic Jobs

Reduced employment in importing countries creates a potential for a backlash. Ensuing restrictive changes in visas for foreign workers could limit higher-level work outsourced offshore since it requires greater onsite presence.

Increased Use of Third-Party Offshore Software Development Suppliers

Rather than bear project management costs directly, more importers will engage third-part consultants to act as a buffer and minimize relationship costs

CONCLUSIONS

Offshore software development outsourcing potentially provides considerable benefits. Some businesses are in the early stages of offshore experimentation, while others have formed mature business partnerships with offshore software firms. Many businesses will outsource more IT work offshore in order to cut costs and reduce time to market in addition to the benefits of quality. An increasing share of the IT work being outsourced is found at higher levels. These forces, however, may be compensated by factors such as political agenda of domestic employment, a desire to avoid negative public relations, and visa limitations that increase the challenges for offshore firms to provide on-site staff.

KEY TERMS

Capability Maturity Model (CMM): A methodology used to evaluate an organization's software development process. The model describes a five-level evolutionary path

of increasingly organized and systematically more mature processes.

Global Delivery Model: To distribute and manage software development across multiple global locations. GDM requires infrastructure, project management, cultural sensitivity, and process guidelines to support communication and coordination between locations.

Intellectual property rights: Laws and enforcement mechanisms to afford the creator of an intellectual property (e.g., software) the means of controlling how their work is used, and ensuring that the creator is properly rewarded and recognized for their work**.**

ISO 9001:2001: Provides standards used to assess an organization's ability to meet its customer's requirements and achieve customer satisfaction. Software firms use it as an alternative to CMM.

Localization: The process of adapting software to a particular language, culture, and desired local "look-and-feel". This may include local sensitivities, geographic examples, and adhering to local legal and business requirements.

Staff Augmentation: When an employee of an outsourcing firm is lent to a client company for work. Normally a staff augmentation employee works at the client's worksite with the technical direction coming from the client company.

OMIS-Based Collaboration with Service-Oriented Design

Kam Hou Vat
University of Macau, Macau

INTRODUCTION

The success of today's enterprises, measured in terms of their ability to learn and to apply lessons learned, is highly dependent on the inner workings and capabilities of their information technology (IT) function. This is largely due to the emergence of the digital economy (Ghosh, 2006; Turban, Leidner, McLean, & Wetherbe, 2005), characterized by a highly competitive and turbulent business environment, inextricably driven by the intra- and inter-organizational processes and the knowledge processing activities they support. One consequence is the increase in organizations' efforts to deliberately manage knowledge (Tapscott, 1997), especially the intellectual capital (Stewart, 1997) of their employees (De Hoog, van Heijst, van der Spek, et al., 1999), which necessarily deals with the conceptualization, review, consolidation, and action phases of creating, securing, combining, coordinating, and retrieving knowledge. In fact, such efforts must be instrumental to creating an efficient organization model based on some innovative initiative, and then enable the organization to launch and learn. In a knowledge-creating organization (Nonaka & Takeuchi, 1995), employees are expected to continually improvise, and invent new methods to deal with unexpected problems and share these innovations with other employees through some effective channels of communications or knowledge transfer mechanisms. The key is collaboration, implying that organizational knowledge is created only when individuals keep modifying their knowledge through interactions with other organizational members. The challenge that organizations now face is how to devise suitable information systems (IS) support to enable such collaboration, namely, to turn the scattered, diverse knowledge of their people into well-documented knowledge assets ready for reuse to benefit the whole organization. This article presents some service-oriented perspectives of employee-based collaboration through the design of specific IS support called the Organizational Memory Information System (OMIS) in light of the peculiar open-source development initiative of Wiki technology (Leuf & Cunningham, 2001).

BACKGROUND

Lately, an organization's ability to learn is often considered a process of development to organizational memory. By organizational memory (Walsh & Ungson 1991), we are referring to various structures within an organization that hold knowledge in one form or another, such as databases and other information stores, work processes, procedures, and product or service architecture. As a result, organizational memory (OM) must be nurtured to assimilate new ideas and transform those ideas into action and knowledge, which could benefit the rest of the organization (Ulrich, Von Glinlow, & Jick 1993). Through understanding the important components of the OM (Vat, 2001), an organization can better appreciate how it is currently learning from its key experiences, to ensure that relevant knowledge becomes embedded within the future operations and practices of the organization. In practice, creating and using an OM is a cooperative activity necessarily involving many members of an organization. If those individuals are not adequately motivated in contributing to the OM initiative, and the organizational culture does not support knowledge sharing (Orlinkowski, 1992), it is not likely to turn the scattered, diverse knowledge present in various forms into well-structured knowledge assets ready for deposit and reuse in the OM.

Consequently, it is important to distinguish between the organizational memory (OM encompassing people) and the OMIS that captures in a computational form only part of the knowledge of the organization. The OM captures the knowledge of the organization. The associated OMIS makes part of this knowledge available either by providing direct access to it (e.g., codified knowledge assets such as experience reports) or indirectly by providing knowledge maps (e.g., tacit knowledge assets such as personnel with specific expertise). Managing the OM deals first of all with the question of "Which knowledge should go into the OMIS?" Answering this question requires determining what knowledge is owned by the members of the organization, what knowledge is needed now, what is going to be needed in the future, and for what purposes. This helps the organization to define not only a strategy for acquiring the needed knowledge, but also to establish validation criteria in relation to the defined goals. Besides, we also need to deal with "who needs the knowledge, when and why," as well as the policies for accessing and using the OMIS. This contextualization of the OMIS with respect to the organization's ability to learn is essential to implement the mechanisms of organizational knowledge transfer, examples of which are discussed in Vat (2006). In fact, in this modern age of information technology and swift change, learning has become an integral part of

the work of an organization run along principles intended to encourage constant reshaping and change. An OMIS-based organization can be characterized as one that continuously transforms itself by developing the skills of all its people and by achieving what Argyris (1992) has called *double-loop learning,* which helps transfer learning from individuals to a group, provide for organizational renewal, keep an open attitude to the outside world, and support a commitment to knowledge. One of the missions of the OMIS is to facilitate and bring about the fundamental shifts in thinking and interacting and the new capabilities needed in the organization.

SERVICE-ORIENTED DESIGN FOR OMIS

When designing an OMIS to nurture an organization's ability to learn (Vat, 2001, 2002), we consider the following modes of learning behavior: (1) individual, (2) group, and (3) repository. Individual learning is characterized by knowledge being developed, and possibly the result of combining an insight with know-how from other sources in the organization, but it is often not distributed and is not secured for reuse. Group learning is centered around the concept of communication in two possible modes: supply-driven or demand-driven. The former is characterized by an individual who has found a way to improve the work process and communicates this to one's coworkers. The latter refers to a worker who has recognized a problem in the current process and asks fellow workers whether they have a solution for this problem. In each case, knowledge is developed, distributed, and possibly combined with knowledge from other parts of the organization, but it is seldom secured. In repository learning, the communication element is replaced by collection, storage, and retrieval of knowledge items. Namely, it is typified by storing lessons learned in some information repository so that they can be retrieved and used when needed. Overall, in repository learning, knowledge is developed, secured, distributed, and is possibly the result of knowledge combination. It is convinced that the requirements of an OMIS design should be formulated in terms of some typical usage scenarios. Namely, an OMIS should facilitate individual workers to access the knowledge required by combination, to submit a lesson learned, and to decide which of the coworkers would be interested in a lesson learned. Also, there should be criteria to determine if something is a lesson learned, how it should be formulated and where it should be stored, and how to distribute some newly asserted knowledge piece to the workers in need. The perceived technical issues, nevertheless, could include the following: How are we to organize and index the OM to enhance its diffusion? How does an organization retrieve relevant elements of the OM to answer a user request or proactively push relevant elements towards users? How does an organization adapt the answer to users, in particular to their tasks, according to the knowledge contexts? These problems are largely related to the OM framework for knowledge distribution, whose goal is to improve organizational learning, with the aid of the previously mentioned OMIS support whose discussion through the idea of service-orientation is our major concern in the following section.

The Context of Service-Orientation

The term "service" has existed for some time (Chesbrough & Spohrer, 2006), and its attendant "service-oriented" connotation has also been used in different contexts and for different purposes (Rust & Miu, 2006). According to Erl (2005), one constant characteristic of this term currently identified among the research community is that it represents a distinct approach for separating concerns. Simply stated, the effort or logic required to solve any problem can be better constructed, executed, and managed if it is decomposed into a collection of smaller, related pieces. Each of these pieces addresses a concern or a specific part of the problem. Indeed, this thinking is not new and it does transcend technology and automation solutions, especially in the IT field, but what distinguishes the service-oriented approach to separating concerns is the manner in which it achieves separation. Consider our city that is full of service-oriented businesses, each of which provides a distinct service that can be used by multiple consumers. Collectively, these businesses comprise a community, decomposable into specialized, individual outlets, providing all possible business services. More importantly, individual outlets are encouraged to interact and leverage one another's services. Nonetheless, we want to avoid a model in which outlets form tight connections that result in constrictive inter-dependencies. Preferably, businesses are empowered to self-govern their individual services so as to evolve and grow relatively independent of each other. Meanwhile, it is also important to ensure that service providers must adhere to certain baseline conventions that standardize key aspects of each business for the benefit of the consumers without significantly imposing on the individual provider's ability to exercise self-governance.

The Promise of Service-Oriented Computing

With the rapid increase of software applications for the daily running of modern businesses, service-oriented computing (SoC) (Dijkman & Dumas, 2004) is emerging as a promising paradigm for enabling the flexible interconnection of autonomously developed applications operating within and across organizational boundaries (Alonso, Casati, Kuno, & Machiraju, 2003). Under the SoC paradigm, the functionality of existing applications can be expressed as services or a network of services called service compositions (Casati & Shan,

2001; Benatallah, Sheng, & Dumas, 2003). Currently, the SoC paradigm is mainly associated with enabling technology founded on such standards as SOAP (Simple Object Access Protocol), WSDL (Web Services Description Language), WS-Security, and BPEL (Business Process Execution Language). Such technology enables businesses to describe the services they offer, to publish these descriptions online, to find other services based on their descriptions, and to build applications using those services. The term "service-oriented design" was coined by Dijkman and Dumas (2004) to represent the set of modeling languages, methods, and techniques used to design such services, to verify the conformance of services to their requirements, and to enable a model-driven approach to service development and composition.

The Challenge in Service-Oriented Design

In anticipation of the emerging service opportunities to provide enterprise solutions that can extend or change on demand, Dimmermann, Krogdahl, and Gee (2004) enumerated three major levels of abstractions to be managed within the service-oriented design process:

- **Operations:** These are transactions that represent single logical units of work (LUWs). Execution of an operation will typically cause one or more persistent data records to be read, written, or modified. SoC operations are typically comparable to object-oriented (OO) methods. They have a specific, structured interface, and return structured responses.
- **Services:** These represent logical groupings of operations. For example, if we consider *KnowledgePortfolio* as a service, then *Lookup knowledge objects by reference number, List knowledge item by name and call reference,* and *Save data for new knowledge* represent the associated operations.
- **Business Processes:** These represent a long-running set of actions or activities performed with specific business goals in mind. Business processes typically encompass multiple service invocations. Examples include: *Initiate New Student, Create StudentPortfolio, Showcase StudentPortfolio,* or *View StudentPortfolio.* In SoC terms, a business process consists of a series of operations executed in an ordered sequence according to a set of business rules. The sequencing, selection, and execution of operations is termed a service or process choreography. Typically, choreographed services are invoked in response to business events.

From a modeling standpoint, the challenge in service-oriented design for OMIS is how to characterize in a well-specified manner those operations, services, and process abstractions systematically for such architectural components as individual learning, organizational learning, and intellectual property management.

FUTURE TRENDS

Much of earlier literature review (Ghosh, 2006; Badaracco 1991; Hamel & Prahalad 1994; Quinn 1992; Pinchot & Pinchot 1994) supports the supposition that intellectual material in the form of information, knowledge, and any other form of intellectual property is a valued organizational asset, and organizations are increasingly dependent on information technology (IT) for the transfer of knowledge and information. Conspicuously missing, however, is often a discussion of collaboration (Tabaka, 2006; Schrage 1990) as a regenerative source of ideas that will advance organizations to learn, change, and excel (Menon, 1993; Stewart, 1994). To collaborate is to work in a joint intellectual effort, to partition problem solving to produce a synergy such that the performance of the whole exceeds that of any individual contributor. The central issue in organizational learning is how individual learning is transferred to the organizational level. In this regard, the use of Wiki technology (*www.wiki.org*) as a collaborative tool within an organizational setting renders an excellent example. Yet, only with a clear understanding of the transfer process can we manage learning processes consistent with organizational goals, issues, and values. If this transfer process was indeed actualized in the design and practice of the OMIS, we could well have a knowledge organization with the capability of capturing learning in its different paths and incorporating that learning into the running of its daily operations.

The Service-Oriented Aspects of Wiki Technology

Wiki technology is based on open-source software. The software that operates any Wiki is called a Wiki engine (Kille, 2006). A variety of free Wiki engines (also known as Wiki clones) are available from the Web (*www.wiki.org*). There are also Wiki hosts offering Wiki service with a minimal fee, such as the Seedwiki (*www.seedwiki.com*), and JotSpot (*www.jot.com*). The first Wiki application invented by Ward Cunningham in 1995 was to publish information collaboratively on the Web (Leuf & Cunningham, 2001), and this first Wiki Web site (*c2.com/cgi/wiki*) is still actively maintained today. Leuf and Cunningham (2001, p. 14) define a Wiki (Hawaiian word meaning *quick*) as a freely expandable collection of interlinked Web pages, a hypertext system for storing and modifying information. Cunningham's original vision was to create a Wiki as the simplest online database that could possibly work. Today, Wikis are interactive Web sites that can offer numerous benefits to users (Wagner, 2004), in the form of a simple editing and publishing interface that can

be used and understood easily. Anyone can create a new Wiki page, add or edit content in an existing Wiki page, and delete content within a page, without any prior knowledge or skills in editing and publishing on the Web. In fact, the major distinguishing factor between Wikis and regular Web sites is the ability of Wiki users to easily edit all aspects of a Wiki Web site. Fuchs-Kittowsk and Kohler (2002, p. 10) interpret a Wiki as an open author system for a conjoined construction and maintenance of Web sites. They suggest that Wiki technology can facilitate cooperative work and knowledge generation in such contexts as content management systems, discussion boards, and other innovative forms of groupware. Indeed, members of a Wiki community can build and develop meaningful topic associations by creating numerous links among Wiki pages. To make the Wiki technology useful for collaborative work in organizations, Wagner (2004, p. 270) suggested 11 principles that govern the functional design of a Wiki application:

- **Open:** If a Wiki page is found to be incomplete or poorly organized, any reader can edit it as he or she sees fit.
- **Incremental:** Wiki pages can cite other pages, including pages that have not been written yet.
- **Organic:** The structure and text content of the site is open to editing and evolution.
- **Mundane:** A small number of (irregular) text conventions will provide access to the most useful but limited page markup.
- **Universal:** The mechanisms of editing and organizing are the same as those of writing, so that any writer is automatically an editor and organizer.
- **Overt:** The formatted (and printed) output will suggest the input required to reproduce it.
- **Unified:** Page names will be drawn from a flat space so that no additional context is required to interpret them.
- **Precise:** Pages will be titled with sufficient precision to avoid most name clashes, typically by forming noun phrases.
- **Tolerant:** Interpretable (even if undesirable) behavior is preferred to error message.
- **Observable:** Activity within the site can be watched and reviewed by any other visitor to the site. Wiki pages are developed based on trust.
- **Convergent:** Duplication can be discouraged or removed by finding and citing similar or related content.

The Potential Benefits as a Collaborative Tool

According to Wagner (2004) and Raman, Ryan, and Olfman (2005), the use of Wiki technology can address some knowledge management goals for collaborative work and organizational learning. Here, a knowledge management system refers to any IT-based system that is developed to support and enhance the organizational processes of knowledge creation, storage, retrieval, transfer, and application (Alavi & Leidner, 2001, p. 114). In particular, any Wiki clone can be designed to support such basic functions as searching and indexing capabilities for effective retrieval and storage of knowledge attributes. The most often cited benefits of using Wikis to support collaborative work thereby include the simplicity of learning and working with the technology, and the free download through the Wiki engines of all the necessary knowledge items of interest throughout the organization. More importantly, Davenport and Prusak (1998) provide three essential reasons why organizations need such a technology to implement its knowledge management systems:

1. To enhance visibility of knowledge in organizations through the use of maps, hypertexts, yellow pages, and directories;
2. to build a knowledge-sharing culture, namely, to create avenues for employees to share knowledge; and
3. to develop a knowledge infrastructure, not confined solely to technology, but to create an environment that permits collaborative work.

CONCLUSION

If designed and implemented effectively, Wiki technology can support a portion of an organization's collaboration and knowledge management requirements — specifically, knowledge sharing, storing, and support for the communication process within organizations. A key advantage of using Wikis to support knowledge management initiatives is that the technology is free. Nonetheless, issues such as sufficient user training, the availability of resources and skills to support the technology, and effective customization of Wiki features must be considered before the value of using the technology to support collaborative work within any organization is to be realized. Meanwhile, the use of service-oriented design is yet to be explored in terms of a more systematic methodology to enable enterprises to describe, publish, and compose application services (in the specific area of collaborative work and knowledge management), and to communicate with applications of other enterprises according to their service descriptions. The current development of SoC (Quartel, Dijkman, & Sinderen, 2004) promises to deliver the methods and technologies to help business partners link their software applications. This should facilitate the introduction of richer and more advanced applications (other than the Wiki applications), thereby offering new collaborative opportunities. Currently, we consider service-oriented design as the process of designing application support for one or more

intra- and/or inter-organizational processes using the SoC paradigm, which is characterized by the explicit identification and description of the externally observable behavior (service) of an application. Thereby, applications can then be linked, based on the description of their externally observable behaviors. According to this paradigm, developers in principle do not need to have any knowledge about the internal functioning of the applications being linked. This peculiar feature of separation of concerns forms the basis of service-orientation that has been elaborated in this article as a promising means of designing collaborative work within an organizational setting in the immediate future.

KEY TERMS

Collaboration: To facilitate the process of shared creation involving two or more individuals interacting to create shared understanding where none had existed or could have existed on its own.

Double-Loop Learning: Together with single-loop learning, describes the way in which organizations may learn to respond appropriately to change. Single-loop learning requires adjustments to procedures and operations within the framework of customary, accepted assumptions, but fails to recognize or deal effectively with problems that may challenge fundamental aspects of organizational culture, norms, or objectives. Double-loop learning questions those assumptions from the vantage point of higher-order, shared views, in order to solve problems.

Knowledge Management: The broad process of locating, organizing, transferring, and using the information and expertise within the organization, typically by using advanced information technologies.

Learning Organization: An organization that focuses on developing and using its information and knowledge capabilities to achieve the following: to create higher-value information and knowledge, to modify behaviors to reflect new knowledge and insights, and to improve bottom-line results.

Organizational Learning: A process of leveraging the collective individual learning of an organization to produce a higher-level organization-wide intellectual asset. It is a continuous process of creating, acquiring, and transferring knowledge accompanied by a modification of behavior to reflect new knowledge and insight, and produce a higher-level asset.

Organizational Memory: A learning history that tells an organization its own story that should help generate reflective conversations among organizational members. Operationally, an organizational memory has come to be a close partner of knowledge management, denoting the actual content that a knowledge management system purports to manage.

Organizational Memory Information System (OMIS): An information system supporting the development of organizational memory, whose design philosophy is often organization specific. An example philosophy is to consider the OMIS as a meaning attribution system in which people select certain resource items out of the mass potentially available and get them processed to make them meaningful in a particular context in order to support their purposeful actions.

Service-Oriented Computing: A field of research focusing on the development of such technology that enables enterprises to describe the services they offer in a textual, mostly XML-based form, to publish these descriptions online and find services of other enterprises according to these descriptions, to compose services into new services, and to communicate with applications of other enterprises according to their service descriptions.

Service-Oriented Design: The process of designing software application support for one or more business processes, using the service-oriented computing paradigm.

Wiki Technology: Technology based on open-source software in the form of a Wiki engine. The Hawaiian word "Wiki" means "quick," with the connotation that this technology is easy to use once installed. Wikis run over the World Wide Web and can be supported by any browser. The technology is governed by an underlying hypertext transfer protocol (HTTP) that determines client and server communication. Wikis are able to respond to both requests for data (GET) and data submission (POST), in a given Web front, based on the HTTP concept.

On a Design of Narrowband FIR Low-Pass Filters

Gordana Jovanovic Dolecek
INSTITUTE INAOE, Puebla, Mexico

Javier Diaz Carmona
INSTITUTE ITC, Celaya, Mexico

INTRODUCTION

Stearns and David (1996) states that "for many diverse applications, information is now most conveniently recorded, transmitted, and stored in digital form, and as a result, digital signal processing (DSP) has become an exceptionally important modern tool." Typical operation in DSP is digital filtering. Frequency selective digital filter is used to pass desired frequency components in a signal without distortion and to attenuate other frequency components (Smith, 2002; White, 2000). The pass-band is defined as the frequency range allowed to pass through the filter. The frequency band that lies within the filter stop-band is blocked by the filter and therefore eliminated from the output signal. The range of frequencies between the pass-band and the stop-band is called the transition band and for this region no filter specification is given.

Digital filters can be characterized either in terms of the frequency response or the impulse response (Diniz, da Silva & Netto, 2002). Depending on its frequency characteristic, a digital filter is either low-pass, high-pass, band-pass, or band-stop filters. A low-pass (LP) filter passes low frequency components to the output, while eliminating high-frequency components. Conversely, the high-pass (HP) filter passes all high-frequency components and rejects all low-frequency components. The band-pass (BP) filter blocks both low- and high-frequency components while passing the intermediate range. The band-stop (BS) filter eliminates the intermediate band of frequencies while passing both low- and high-frequency components.

In terms of their impulse responses digital filters are either infinite impulse response (IIR) or finite impulse response (FIR) digital filters. Each of four types of filters (LP, HP, BP, and BS) can be designed as an FIR or an IIR filter (Ifeachor & Jervis, 2001; Mitra, 2005; Oppenheim & Schafer, 1999).

The design of a digital filter is carried out in three steps (Ingle & Proakis, 1997):

- Define filter specification
- Approximate given specification
- Implement digital filter in hardware or software.

The topic of filter design is concerned with finding a magnitude response (or, equivalently, a gain) which meets the given specifications. These specifications are usually expressed in terms of the desired pass-band and stop-band edge frequencies ω_p and ω_s, the permitted deviations in the pass-band (pass-band ripple) R_p, and the desired minimum stop-band attenuation A_s, (Mitra, 2005). Figure 1 illustrates a typical magnitude specification of a digital low-pass filter.

In many applications it is often advantageous to employ FIR filters, since they can be designed with exact linear phase, and exibits no stability problems. However FIR filters have a computationally more intensive complexity compared to IIR filters. During past several years, many design methods have been proposed to reduce complexity of the FIR filters, (Chen, Chang and Vinod, 2006; Jovanovic-Dolecek & Mitra, 2007; Lian and Yang, 2001; Rodrigues & Pai, 2005; Yang and Lian, 2003;Yang and Lian, 2006; Zou & Saramaki, 2004).

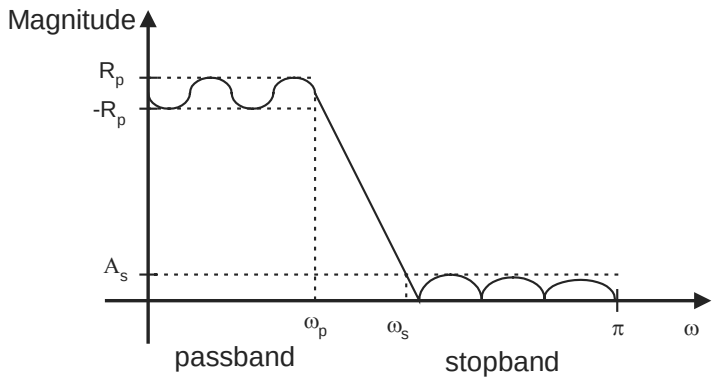
This chapter describes a class of digital filters, called IFIR (interpolated finite impulse response filters), that can implement narrowband low-pass FIR filters with a significantly reduced computational complexity.

The IFIR filter $H(z)$ is a cascade of two filters, an expanded shaping or model filter $G(z^M)$ and an interpolator or image suppressor $I(z)$. In this manner, the narrowband FIR prototype filter $H(z)$ is designed using lower order filters, $G(z)$ and $I(z)$. For more details on the IFIR structure see Neuvo, Cheng, and Mitra (1984) and Jovanovic Dolecek (2003).

An increase in the interpolation factor results in the increase of the interpolation filter order as well as in the decrease of the shaping filter order.

The proposal in Jovanovic Dolecek and Diaz-Carmona (2003) decreases the shaping filter order as much as possible, and efficiently implements the high order interpolator filter. To do so, in Jovanovic Dolecek and Diaz-Carmona (2005) the use of a sharpening recursive running sum (RRS) is proposed as an interpolator in the IFIR structure. The transfer function of an RRS filter with length M is given by

Figure 1. Low-pass filter magnitude specification



$$H_{RRS}(z)=\left(\frac{1}{M}\sum_{k=0}^{M-1}z^{-k}\right)^{L}=\left(\frac{1}{M}\frac{1-z^{-M}}{1-z^{-1}}\right)^{L} \qquad (1)$$

where L is the number of stages. The RRS filter is a linear-phase low-pass filter that requires no multipliers and two additions per output sample, but it has a high pass-band droop and a low stop-band attenuation. The filter sharpening technique, (Hartnett & Boudreaux, 1995; Kaiser & Hamming, 1984; Samadi, 2000), can be used to improve the frequency characteristic of the RRS filter.

We describe here how to find the interpolation factor M, and the number of the stages L, for a given sharpening polynomial, so that the specifications are satisfied with as low as possible complexity.

BACKGROUND

Filter Sharpening

The sharpening technique, which was first proposed by Kaiser and Hamming (1984), attempts to improve both the pass-band and stop-band of a linear FIR filter by using multiple copies of the same filter. This technique is based on the use of a polynomial approximation which maps a transfer function before sharpening, to a new transfer function. The sharpening polynomial is obtained using the closed formula proposed by Samadi (2000). The polynomial coefficients are always integers, which can be implemented as Shift-and-Add multipliers (Parhi, 1999).

Algorithm Description

This section exposes the algorithm for computing the main design parameters for the design of a narrowband low-pass filter using an IFIR structure, where the interpolator filter is the sharpening recursive running (RRS) filter.

The algorithm is based on an iterative design of the model filter G(z) using following specifications:

$$\omega_{Gp}=M\omega_p,\quad \omega_{Gs}=M\omega_s,$$
$$\delta_{Gp}=\alpha\delta_p,\quad \delta_{Gs}=\delta_s, \qquad (2)$$

where ω_{Gp} and ω_{Gs} are the normalized pass-band and stop-band frequencies, respectively, δ_{Gp} the maximum pass-band ripple and δ_{Gs} the minimum stop-band attenuation of the model filter $G(z)$, and ω_p, ω_s, δ_p and δ_s are the corresponding design specifications of the desired filter. The parameter α is a key factor in this design. The higher value of α the smaller model filter order, and vice versa. For a given value of M the maximum value of α is determined by the sharpened RRS filter pass-band droop. Our experience says that it is useful to take the values of α in the range $0.5 \le \alpha \le 0.9$.

In Figure 2 is shown the flow diagram of the algorithm. At first step, the maximum possible interpolation factor, $M = M_{max} = \pi/\omega_s$ and the minimum possible number of RRS stages $L = 1$, are selected. The choice of M is a key factor to satisfy the pass-band specification, while the choice of L is a key factor to satisfy the stop-band specification of the designed overall filter. Consequently, in the next steps the factor M is increased until the pass-band specification is satisfied, interpolation factor searching loop, while the parameter L is increased until the stop-band specification is reached, RRS stages searching loop. If as a result, an even

value of M and an odd value of L are obtained from these searching loops, the factor M is reduced by one to avoid a branch fractional delay in the sharpened RRS filter (Webb & Munson, 1996). In the following steps the algorithm looks for a possible further model filter order reduction by increasing the model pass-band ripple δ_{Gp}, while keeping satisfied the given overall filter specification.

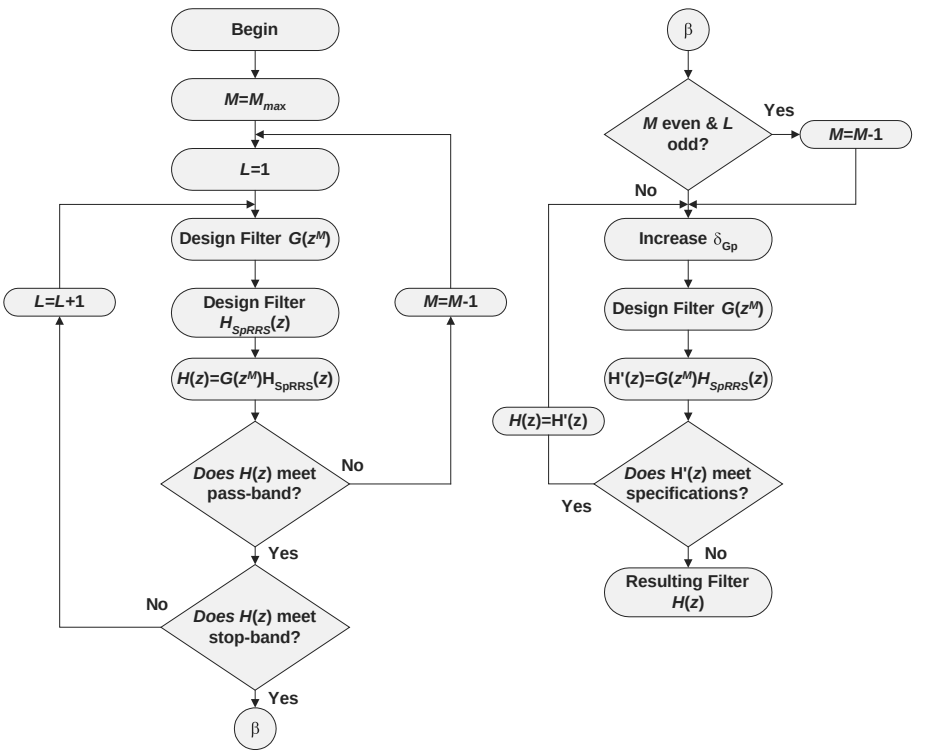
The algorithm complexity, number of operations performed, is strongly determined by the interpolation factor and RRS stages searching loops, this is the number of iterations required to meet the desired pass-band and stop-band specifications, respectively. The main iteration computational workload is the design of both the model filter, by Parks McClellan algorithm, and the sharpened RRS filter, by the sharpening polynomial. Hence the total algorithm complexity depends on how fast the parameters are found for both pass-band and stop-band specifications. This speed is determined basically by two factors:

1. Desired filter specifications: in this sense the narrower pass-band the smaller number of iterations in the interpolation factor searching loop, and the smaller stop-band attenuation the smaller number of iterations in the RRS stages searching loop.
2. Sharpening polynomial structure: due the sharpening polynomial modifies the RRS pass-band and stop-band frequency magnitude response. For instance the higher the sharpening polynomial improves the RRS pass-band the smaller number of iterations in the interpolation factor searching loop, and the higher the sharpening polynomial improves the RRS stop-band the bigger number of iterations in the RRS stages searching loop.

Accordingly to the algorithm there can be possible no convergence cases:

1. Any interpolation factor M meets the pass-band specification.
2. The increment of L in the RRS stages searching loop causes a not pass-band meeting for any M in the interpolation factor searching loop. If the design is limited to narrowband filters the first case is completely avoided and the second case is less prone to occur. Both no convergence cases are detected with a fixed maximum number of iterations.

Figure 2. Flow diagram of the algorithm



Design Example

The described algorithm was implemented in MATLAB and different filters have been designed in a PC PIV at 1.7 GHz. We show as design example the low-pass linear-phase FIR filter, proposed in Saramaki, Neuvo, and Mitra (1988), with next specifications: ω_p=0.05π, ω_s=0.1π, δ_p=0.01, δ_s=0.001. According to the proposal by Mehrnia and Willson (2004) the optimal interpolation factor M=4, results in the total number of products per output sample of 25 and the total number of additions of 47.

The design parameters obtained using the described algorithm for the sharpening polynomial with σ =δ =0, m=n=1 and α = 0.6 are: L= 2, M= 3 with a number of floating point operations of 112885030 FLOPS and a computation time of 3.4 seconds. The model filter order is N_G = 35. The design parameters for the sharpening polynomial with σ =δ = 0, m= 2, n = 1 and α = 0.6 are: L=3, M= 5, a number of floating point operations of 106420351 FLOPS and a computation time of 4.0 seconds. In this case we have N_G = 21. In Figures 3 and 4 are shown the frequency magnitude responses for both cases.

As a matter of filter complexity comparison Table 1 shows the total number of products per output sample NPS_T, the total number of additions per out sample NAS_T, and the total delay units $NDel_T$ required for the proposed algorithm, and for algorithms proposed in (Gustafsson, Johansson & Wanhammar, 2001; Saramaki et al., 1988; Webb & Munson, 1996). Note that the smallest total number of products is obtained with the proposed algorithm using the sharpening polynomial with the parameters m= 2, n= 1. The method in (Saramaki et al., 1988) with three stages exhibits lower complexity than the proposed method with the sharpened polynomial m= n=1. However, the method (Saramaki et al., 1988) does not propose how to choose the design parameters.

FUTURE TRENDS

The use of IFIR filter design techniques is now a rather well-developed topic in the field of digital filters. Nonetheless, an analytical technique for obtaining a design employing the minimum number of filter-tap multipliers has not previously appeared and presents an important research task (Mehrnia & Willson, 2004). The future research also includes a multistage design and finding an optimal choice of the corresponding interpolation factors.

Another important issue that needs to be addressed is how to choose the sharpening polynomials (as a trade-off between the values of tangencies m and n and the number of cascaded basic RRS filters) that will yield an improved characteristic of the RRS filter and a decreased complexity of the overall design.

CONCLUSION

A direct algorithm to find the design parameters of an IFIR structure with a low complexity has been described, where the interpolation filter is a sharpened RRS filter. The proposal is based on an iterative design of the model filter $G(z)$ and the sharpened RRS filter until the filter desired specifications are met. As shown in the design example for a given sharpening polynomial, the proposed algorithm finds the maximum interpolator factor and the minimum number of RRS stages to meet desired specifications with small number of products per output sample. The proposed method is useful for narrowband FIR filter design.

KEY TERMS

Digital Filter Design: It is carried out in three steps: Definition of filter specification, approximation of given specification, and implementation of digital filter in hardware or software.

Expanded Filter: Expanded filter $G(z^M)$ is obtained by replacing each delay z^{-1} in the filter $G(z)$ with M delays z^{-M}. In the time domain this is equivalent to inserting M-1 zeros between two consecutive samples of the impulse response of $G(z)$.

FLOPS: Measure of the computational complexity of an algorithm expressed in terms of Floating Point Operations per second.

Frequency Selective Filters: Digital filters which pass desired frequency components in a signal without distortion and attenuate other frequency components.

Interpolator: The filter $I(z)$ which is used to eliminate the unwanted spectrum introduced by expansion of the model filter in an IFIR structure.

Model or Shaping Filter: The filter $G(z)$ in the IFIR structure which has M times higher both the pass-band and the stop-band frequencies, than the prototype filter.

MPS: Measure of the computational complexity of a digital filter expressed in terms of Multipliers per Output Sample.

Pass-Band: The frequency range allowed to pass through the filter.

Pass-Band Ripple: The permitted deviation in the pass-band.

Stop-Band: The frequency band that is blocked by the filter.

Stop-Band Attenuation: The desired minimum attenuation in the stop-band.

Transition Band: The range of frequencies between the pass-band and the stop-band.

One Organization, One Strategy

Kevin Johnston
University of Cape Town, South Africa

INTRODUCTION

Most organizations have multiple levels of strategic plans (de Kluyver & Pearce, 2006), one of which is the Information Technology (IT) strategic plan. The alignment of an organization's business strategy with its IT strategy has been a concern of CIOs (Benson & Standing, 2008; Croteau & Bergeron, 2001; Johnston, Muganda, & Theys, 2007; Luftman Kempaiah, & Nash, 2006), CEOs (Armstrong, Chamberlain, Moore, & Hart, 2002; O'Brien & Marakas, 2006), academic researchers (Henderson & Venkatraman, 1999; Kangas, 2003; Pearlson & Saunders, 2004; Reich & Benbasat, 2000), and research companies (Broadbent, 2000; Croteau & Bergeron, 2001; Meta Group, 2001) since the age of vacuum tubes. The Society for Information Management (SIM) studies reveal that 'IT and Business Alignment' was the number one management concern in 2003, 2004 and 2005, and has been one of the top 10 concerns since 1983(Luftman et al., 2006).

IT and business strategies should not be separate or aligned; organizations should simply have one business strategy: one organization, one strategy.

BACKGROUND

Organizations need to recognize changing business climates, fluctuating resources, and the need to expand or grow (Bocij, Chaffey, Greasley, & Hickie, 2006). Organizations that plan, and then move in the right direction at the right time, survive. "Strategic planning enables a company to focus on what is important" (Benson & Standing, 2008, p. 207). All factors including IT must be considered and taken into account holistically to create value (de Kluyver & Pearce, 2006).

Key tasks of most managers within an organization are to acquire, develop, and allocate the organization's resources, and to develop and exploit the organization's capacity for innovation (Burgleman, Maidique, & Wheelwright, 2001). The acquisition, development, allocation, and exploitation of IT should be part of any business strategy. Many new products/services and ideas like e-commerce and BPR have been based on IT (Benson & Standing, 2008).

IT can contribute to the overall performance of the organization in many ways, including making/saving money, quality improvements, productivity gains, and providing new services/functions (McKeen & Smith, 2004). Strategic, management, operational, and functional support benefits can and do arise from the IT contribution (Ward & Daniel, 2006). It is unlikely that these contributions and possible innovations will occur by chance; they need to be planned.

O'Brien and Marakas (2007, p. 42) state that IT is more than a support for business, and that IT is "no longer an afterthought in forming business strategy." Linear planning is useless; organizations must plan holistically (Hartman, Sifonis, & Kador, 2000) or harmoniously in order to survive. Organizations should have a single strategic plan.

WHERE, WHY, WHAT, HOW?

Strategy is about creating options; strategic thinking focuses on taking different approaches, on choosing different sets of activities, on choosing a unique competitive position (de Kluyver & Pearce, 2006). Strategy is about choice, change and conclusions, where to do business (location and industry), why (reasons), what to do/offer, what not to do/offer, and how to do it.

Where should an organization do business, locally, nationally, or internationally, and in which industries? Organizations should be thinking in terms of where it makes good business sense, where the organization will survive.

A vision stating the goals of the organization (provides broad future focus) and which provides guidance and motivation needs to be developed (de Kluyver & Pearce, 2006) and communicated to all staff.

A business strategy needs to be defined which includes all the capabilities (forces/tools/resources) of an organization, so that approved plans may be executed as effectively as possible (Henderson & Venkatraman, 1999). Strategy articulates ways in which opportunities can be exploited using the organization's capabilities and resources (Burgleman et al., 2001). Strategy without capabilities is meaningless (Burgleman et al., 2001), and excluding the IT capability from the organizations strategy renders the strategy less effective at best. Similarly, having capabilities without strategy makes them aimless (Burgleman et al., 2001). The IT strategy and capability must therefore be an integral part of the overall strategy, or IT will become an aimless capability of the organization or at best will be run according to the CIO's aims. Managing the IT resource is a basic business function (Burgleman et al., 2001), which should be the responsibility of all managers within an organization.

Organizations create a strategy to anticipate change beyond the control of the organization, so changes within the organization (such as to business processes and organizational structure) can be initiated and controlled (Ivancevich & Matteson, 1999). A number of forces must fit together in a balanced way in order for an organization to function effectively. The framework developed by Scott Morton (1991) illustrates the interrelationship between strategy and four other forces, namely business processes, organizational structure, people, and IT. External environments (socioeconomic and technological) influence the organization. Changes in any one or more of these forces upsets the equilibrium of the organization (Turban, McLean, & Wetherbe, 2004); a change in any one force may require changes in some or all of the forces. Essentially, Scott Morton's framework implies that strategy should be developed in a holistic fashion, taking all forces into consideration. So IT (and business processes, organizational structure, people, and their roles) should not be merely aligned with the overall strategy or be there to support the overall strategy, they each contribute and form an essential part of one organizational strategy.

Organizations need to define exactly where they are going, why they wish to go there, what resources they will use to get there, and how they will utilize the resources to get there. Management needs to ensure that all stakeholders are aware of the plan.

IT STRATEGY

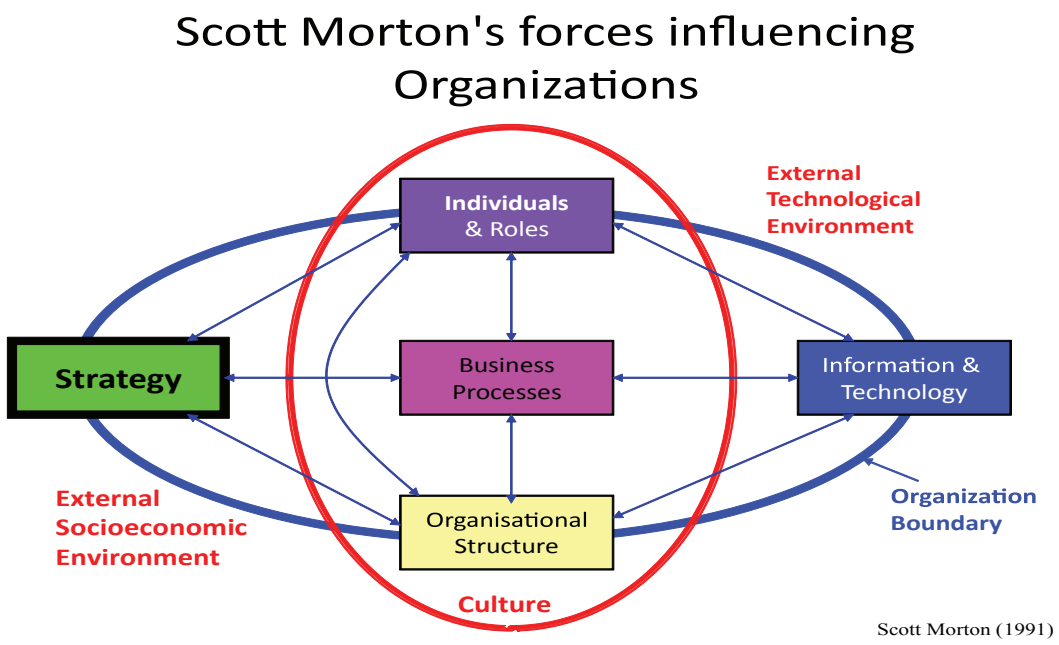
Several authors (Boddy, Boonstra, & Kennedy, 2005; Bocij et al., 2006; Burgleman et al., 2001; Croteau & Bergeron, 2001; McKeen & Smith, 2003; Reich & Benbasat, 2000; Ward & Daniel, 2006) agree that it is important to align IT strategy with the organization's business strategy. Although the importance of strategic alignment of IT is acknowledged and widely accepted, it remains an issue within many organizations (Armstrong et al., 2002; McKeen & Smith, 2003).

Gates (1999) wrote: "It is impossible to align IT strategy with business strategy if the CIO is out of the business loop." Lucas (2005) wrote that in many organizations the CIO is "kept in the dark about corporate strategy."

The lack of IT alignment with business can result in late market entry, lost market opportunities, or an unsustainable market advantage (Conarty, 1998) or business failure (Bocij et al., 2006).

Some authors (Benson & Standing, 2008; Bocij et al., 2006; Ward & Daniel, 2006) view IT strategy and business strategy as two distinct strategies, with IT strategy either supporting or influencing business strategy. Ward and Peppard (2002) suggested guidelines to align business and IT strategies. Huber, Piercy, and McKeown (2008) state that the different strategic views within an organization need to be interlinked. Pukszta (1999) stressed that IT strategy must

Figure 1



Scott Morton (1991)

be completely and seamlessly integrated (co-adapted) with business strategy at all organizational levels. O'Brien and Marakas (2007) compare the two approaches (alignment and co-adaptation).

IT and business strategies should not be aligned; organizations should have one harmonious strategy. IT strategy (and other strategies such as e-business, supply-chain, technology, etc.) must lose its distinctness; in this way it will gain prominence and exert greater influence (Pukszta, 1999; O'Brien & Marakas, 2007) within organizations. Each organization should have one harmonized strategy: one organization, one strategy.

IT planning should be in harmony, not merely aligned with business strategy.

CONFIGURATION

Organizations need to decide on internal structures, processes, and people that optimize the strategic plan. Structure, processes, and order are necessary for the survival of the organization.

"A gap has developed between the power and choice enjoyed by individuals as consumers and citizens on the one hand, and that available to them in the workspace on the other" (Chowdhury, 2000). This gap must be reduced. Employees have to be included in decisions regarding the strategy, structure, and business processes of organizations.

Organizational design and structure have always been important factors that influence the behavior of groups and individuals. It is through structure that management establishes expectations of achievements for individual employees and departments, and decides how the organization's strategy is to be measured. The purpose of structure is to regulate, or reduce, uncertainty in the behavior of employees (Ivancevich & Matteson, 1999). Where and how IT is placed in the organizational structure determine the role and influence of IT.

Each organization requires a structure, and when that is ignored, the organization will not be able to crawl, much less fly! No organization will last if everyone acts independently; a structure needs to be developed preferably with the employees, which will enhance the strategy and vision of the organization.

Employees cannot survive alone within an organization; they need to be in some sort of formation. Organizations only 'fly' when all the employees are in formation.

Organizations need tradition, ritual, and structure to retain their identity. A department in which the author worked had a daily meeting in which all employees met each other and offered encouragement, support, guidance, and feedback. The meetings were stand-up, 15- to 30-minute affairs, with a fixed regular program. On Mondays, projects and work for the week ahead were discussed; Tuesdays were thinking days and employees had to solve puzzles in groups; Wednesdays were learning days where one employee had to teach the others something; Thursdays were to announce and discuss change; and Fridays were for external focus or external speakers. Each employee had an opportunity to lead a Tuesday and Wednesday meeting. In organizations where there is encouragement, involvement, and participation, the production is much greater. Goleman (2007, p. 312) states that all people believe warm human relationships to be the core feature of 'optimal human existence'. Human relationships drive people's ability to be and work at optimal levels (Goleman, 2007). It is therefore imperative that organizations involve and include all employees in debates and decisions about strategy, IT, business processes, organizational structures, and people.

Organizations need to fly with employees who want to be in the organization, who feel part of the organization, who know where the organization is headed, and who want to fly in formation.

TIMING

Organizations understand that they cannot change or fight the seasons. Organizations need to develop strategies anticipating 'winter' and unseasonal changes. Organizations must develop rapid responses to external demands; be able to adapt their organizational structures, IT, and business processes; and involve their employees to achieve competitive advantage.

Organizations need to understand that IT change is only one factor that affects competitive position. In order to survive, organizations need to adapt to change in a timely manner. Therefore strategic planning must be a dynamic process, and IT and IT change must form part of the process, as must other changes such as people and structural changes. Successful organizations balance a well-defined business focus with the willingness, and the will, to undertake major and rapid change.

Organizations need to be ready to respond to continual changes. Prerequisites are leadership, governance, competencies, and technology (Hartman et al., 2000). The first prerequisite is leadership; outstanding companies are associated with their leaders (such as Welch, Gates, and Bezos). Leaders create a vision that is shared and accepted within the organization. Governance is the operating model that defines the organization. The formation or structure of the organization must be clear. People's roles, responsibilities, and authority levels must be defined. Organizations need to have methods for assessing, selecting, allocating, and monitoring resources. Competencies are the ways in which the organization responds to change, exploits available resources and opportunities, and accommodates reality. Technology needs to be robust and comprehensive.

"The reality of a strategy lies in its enactment, not in those pronouncements that appear to assert it" (Burgleman et al., 2001). Strategic intent needs to be converted into strategic action to be meaningful.

Organizations need strategies to deal with obstacles, and may in some cases need to revise their strategies in order to be successful.

SUCCESS

The organization must expect some casualties, but if the organization has survived and looks likely to continue surviving, the strategy was successful. To succeed, the energy, creativity, and resources of the organization must have been used. If there are parts of the organization that have not being used, the question must arise, why are they in the organization?

Burgleman et al. (2001) ask and answer the question: "What strategies, policies, practices, and decisions result in successful management of high-technology enterprises?" Six themes of success are listed: (1) business focus, (2) adaptability, (3) organizational cohesion, (4) entrepreneurial culture, (5) sense of integrity, and (6) hands-on top management. All are controlled or influenced by the organizational strategy. Unless each and every one of the organizations' resources are in harmony, an organization cannot have succeeded. If IT strategy and all other strategies are harmonized into a single business strategy, then the organization can claim to have a holistic business focus, to have organizational cohesion, and to have a sense of integrity. A disharmonized strategy certainly cannot be regarded as being honest, fair, or open—other attributes of integrity.

FUTURE TRENDS

Organizations will develop a single evolving harmonized strategy, to which all employees have contributed. The organizational strategy will be a continual, changing, probing, never-ending cycle involving all in the organization. Organizations will have one integrated strategy that has involved all employees.

CONCLUSION

Organizational success must include the ability to harmonize the organization and mobilize the workforce (Reich & Benbasat, 2000). Organizations and individuals can only realize their potential for greatness and goodness when they join the flock, fly in formation, and contribute something for the common good. Business and IT strategies will be in harmony when IT is seen as contributing positively to the organization's business strategy. IT strategy must form a harmonized part of the organization's overall strategy (Ward & Peppard, 2002).

KEY TERMS

Alignment: The arrangement or position of different, separate elements (strategies) in relation to each other.

Business Process: A collection of business activities that take several inputs and create one or more outputs.

Business Strategy: A description of the plans, actions, or steps an organization intends to take in order to strengthen and grow itself.

CIO (Chief Information Officer): The head of the IS department in an organization.

Harmony: A pleasing combination of elements in a whole. The combination of elements intended to form a connected whole, as opposed to alignment where the elements remain separate.

IT (Information Technology): A collection of all systems in an organization**.**

IT Strategy: A description of the plans, actions, or steps an organization intends to take in order to make the best use of IT within itself.

Strategy: Plans to create and manage change, and exploit opportunities.

Online Communities and Community Building

Martin C. Kindsmüller
Berlin University of Technology, Germany

Berlin University of Technology, Germany

Leon Urbas
Berlin University of Technology, Germany

INTRODUCTION

"Online community" is one of today's buzzwords. Even though superficially it is not hard to understand, the term has become somewhat vague while being extensively used within the e-commerce business. Within this article, we refer to online community as being a voluntary group of users who partake actively in a certain computer-mediated service. The term "online community" is preferred over the term "virtual community," as it denotes the character of the community more accurately: community members are interacting online as opposed to face to face. Furthermore, the term "virtual community" seems too unspecific, because it includes other communities that only exist virtually, whereas an online community in our definition is always a real community in the sense that community members know that they are part of the community.

Nevertheless, there are other reasonable definitions of online community. An early and most influencing characterization (which unfortunately utilizes the term "virtual community") was coined by Howard Rheingold (1994), who wrote: "…virtual communities are cultural aggregations that emerge when enough people bump into each other often enough in cyberspace. A virtual community is a group of people […] who exchanges words and ideas through the mediation of computer bulletin boards and networks" (p. 57). A more elaborated and technical definition of online community was given by Jenny Preece (2000), which since then, has been a benchmark for developers. She stated that an online community consists of four basic constituents (Preece, 2000, p. 3):

1. Socially interacting people striving to satisfy their own needs.
2. A shared purpose, such as interest or need that provides a reason to cooperate.
3. Policies in the form of tacit assumptions, rituals, or rules that guide the community members' behavior.
4. A technical system that works as a carrier that mediates social interaction.

Not explicitly mentioned in this characterization but nevertheless crucial for our aforementioned definition (and not in opposition to Preece's position) is voluntary engagement.

BACKGROUND

Just because everybody is now talking about them, online communities are, historically seen, neither an implication of the World Wide Web — which dates back to 1991 (Berners-Lee et al., 1992) — nor dependent on the Internet as a transport infrastructure. In fact, online communities emerged at times when ARPAnet—the predecessor of the Internet — was still restricted to military-funded institutions. They were based on computerized bulletin boards first introduced by Christensen and Suess (1978). Their system was called CBBS (computerized bulletin board system) and followed the idea of a thumbtack bulletin board hosted electronically on a computer. Other computer hobbyists were able to connect with their home computers via a dial-up modem connection and could "pin" messages to a shared "board." The first online communities developed through other participants responding to those messages, creating ongoing discussions. At that time, computer hobbyists and scientists were more or less the only ones who owned computers and modems. Therefore, most topics on CBBS were within the realm of computers, but in the long run, the discussions broaden. Within the 1980s, similar systems appeared that were now subsumed as BBS (bulletin board system). The most well known were "The Well" (Whole Earth 'Lectronic Link) and FidoNet (Rheingold, 2000).

Apparently, at the very same time, the technological and social environment was ready for online communities, as there were at least two other independent developments concerning this matter:

1. The Usenet was invented by computer science students at Duke University and the University of North

Carolina, using a simple scheme by which these two computer communities could automatically exchange information via modems at regular intervals.

2. The first MUDs appeared at the University of Essex (UK) creating playful and imaginative online communities. MUDs (short for Multi-User Dungeon/Dimension/Domain) are computer-implemented versions of text-based role-playing games, in which multiple persons can take virtual identities and interact with one another. Early MUDs were adventure games played within old castles with hidden rooms, trapdoors, etc.

Nowadays, most online communities are using the Internet as carrier, and most of them are Web based, using HTTP as a protocol for transportation and the DHTML standard for presentation. But there are still communities that employ other systems and protocols, like newsreaders using NNTP and mail-groups using SMTP or IRC (Internet relay chat) based chatting systems (IRC). Some online communities even use multiple systems and protocols to communicate and cooperate.

ONLINE COMMUNITIES

The conditions in pure online communities highly differ from a computer-mediated communication situation within a company. Whereas employees in a computer-supported cooperative work (CSCW) context usually meet online as well as face-to-face, members of online communities have, as a general rule, never met each other. Working in a highly standardized company context, employees have to focus on task fulfillment within a certain time frame. Superiors evaluate their achievements, and they are accordingly paid by the company. Online communities thrive on volunteers. Usually none of the community members can be forced to do something, and there are no tangible incentives. Basic research in motivation psychology (Franken, 2001) even shows that incentives tend to be counterproductive.

Community members usually show a high degree of intrinsic motivation to participate actively in the development of an online community. It is still open to discussion where this motivation comes from. Simple rules like "It's all based on trying to maximize the potential personal benefit" seem to fail, as long as one has a simplistic concept of the term "personal benefit." As the attention-economy-debate (i.e., Aigrain, 1997; Ghosh, 1997; Goldhaber, 1997) shows that personal benefit is a complex entity if one relates it to online activities in the World Wide Web.

The likelihood of taking an active part in a community increases with the potential personal benefit that could be gained within that community. This is directly related to the quality of the contents offered. As, e.g., Utz (2000) stated, the likelihood of submitting high quality contributions increases with the quality and the manifoldness of the existing entries. Appropriate solutions of these quality assurance aspects are rating systems.

A "killer-feature" for such an application generates immediate benefit for a user as soon as he or she contributes to the community, even without anybody else contributing. In addition to such a feature, or even as a partial replacement, one can follow best practices. After analyzing numerous well-working online communities, Kollock (1999) came to the conclusion that there are basically two states of motivation: self-interest (what seems to be the common motivation found) and altruism. Self-interest as a motivational state is linked to expectation of reciprocity: people are willing to help or cooperate with others if they can expect a future quid pro quo.

A widely discussed issue in the context of community building is the so-called public goods dilemma: if people can access public goods without restriction, they tend to benefit from these goods and, therefore, from others' contributions without contributing in the same way. If, on the other hand, most members of a community are led into temptation, the public good will vanish (Kollock & Smith, 1996). The main problem is to keep the balance between the individual and common interest: an individually favorable and reasonable behavior turns out to be harmful for the others, and in the long run, disastrous for the community (Axelrod, 1984; Ostrom, 1990).

Owing to these circumstances, it is not surprising that a great deal of all online community building projects fail, even though much effort has been put into these projects due to the high profit opportunities within the field as, for instance, Hagel and Armstrong (1997) predicted.

ONLINE COMMUNITY BUILDING

Recipe-based fabrication of online communities is, at least, a bold venture if not an illusionary enterprise. Social relationships and group momentum are particularly hard to predict. As Rheingold (2000) explicated, online communities grow organically and tend to follow their own rules. Therefore, controlling efforts always have to be adjusted to the current group context. Nevertheless, some well-approved principles could be derived from findings that were discussed in the last paragraph.

According to Kollock (1999), cooperation within an online community can only be successful if individuals:

1. Can recognize each other, i.e., they are not operating anonymously within the community.
2. Have access to each others interaction history.
3. Share the presumption of a high likelihood of a future encounter within the online community.

This leads to the conclusion that online communities have to offer possibilities of creating and managing relationships by supporting continuous interaction between their members. Therefore, it is advantageous if the system has a memory, in the sense that every community member and every item stored in the system holds a personal history.

People tend to act from self-interest if they are aware that their actions have effects on their reputations: high-quality contributions, impressive knowledge, and the perception of being willing to help others enhance the prestige of the community member. Although altruism as a motivational state for taking part in an online community is less common in comparison with self-interest, it is still frequent enough to be addressed if one thinks about community building. People with altruistic motivation try to meet the needs of the group or certain group members. This motivational state can be satisfied by establishing a public space where these needs can be stated, communicated, and discussed.

Considering the public goods dilemma, it is essential to introduce a role concept to clearly communicate the borderline between being in a group and out of a group. To get full access to all group resources, one has to join the group. Several functionalities are only accessible for registered and authorized users. The commitment that is required to join the group leads to a comprehensible demarcation between members and nonmembers, who, in turn, facilitate the togetherness of the group and the identification of the members within the group. Three further selective measures address the public goods dilemma: personal presence, personal responsibility, and personal history. Anonymity and lack of continuity among the members promotes egoistic behavior. Therefore, modifying actions should be tagged with users' login names, which, in turn, should be associated with records of personal data. Tagging entries and actions with user login names makes it easy to recognize people and enhances the constitution of personal relationships and online cooperation among the community members. Seeing all modifying actions supports the actors' personal responsibility. If the system has a memory of every action, this gives a personal history to every community member, as well as to the community's artifacts. Information about past interactions of the members again increases personal responsibility, whereas information about interaction with the artifacts facilitates getting up-to-date within a new area of interest and familiarizing new members with the online community's etiquette and who-is-who.

"Content is king" is commonplace for virtually all Web-based efforts. This is notably true for online communities operating on a user-as-editors base. To implement a reasonable quality assurance system, it is crucial to apply technical as well as social means. Technically, this can be done by employing a content rating system. Employing a "tiger team" of highly motivated volunteers can, on the other hand, help the online community to start up by delivering good content. For all content producers, it has to be as easy as possible to feed new content into the system. The best way of avoiding barriers is through continuous usability testing.

Introducing dedicated and active moderators seems to be the most important step to nourish motivation of the community members. Moderators can enhance group activities and increase the efficiency of the group. They are responsible for communicating the group standards (etiquette), acting as confessors for new community members, and helping in preserving continuity. Rojo (1995) showed that an active moderator can, to some extent, compensate for the lack of active members in an online community.

As opposed to face-to-face communities, where only members can start a conversation, online communities can initiate communication. This opportunity should be brought into play by implementing change awareness functions as software agents that collect relevant information for users and present it in e-mails and personalized portal pages. An important item in using profiles for personalized services is keeping profiles up-to-date. Experience shows that interests continuously change over time. Profile setting dialogues are often accessed once and then forgotten. Thus, there is risk for personalized services to decrease subjectively in quality over time. Hence, it is important to monitor user behavior and let the agents ask from time to time if interpretations of observations of, for example, changing interests, are correct.

The open-source movement has become very successful in recruiting new developers who start their own projects or join existing software development efforts. Today, most if not all open-source software development communities use online services for cooperation. In the remainder of this section, the application of the requirements for software supporting online community building is demonstrated with examples of open-source software development communities:

- **"Killer-feature":** Open-source projects are often founded to solve an existing problem, i.e., the killer-feature is the product of the online community. When others join the project, the work becomes even more effective.
- **Recruitment:** Open-source communities produce software systems that are not only intended for use by themselves but also for external clients. These external users, i.e., users not actively involved in the open-source online community, can be made active developers that modify the source and give it back to the project. To foster this process of developer recruitment, online communities should provide transparent rules for becoming actively involved. The projects that do not seem to be hermetic have better chances of growing their developer base.

- **Transparency:** The most important possibility of gaining transparency is through a public archive of the project's mailing lists. Because it is often not easy to scan large e-mail archives, open-source communities should provide text documenting guidelines and standards.
- **Policy:** The Debian community that maintains an open-source Linux distribution is a good example of a growing community that has given itself a substantial set of roles, rules, and guidelines. They achieve transparency of their standards by publication of documents on their Web server — other projects, such as UserLinux, use a Wiki for that purpose which makes such standards more vivid and activates community members' attendance.
- **Trust:** Debian has a twofold quality assurance system. There are no anonymous additions to the system, and approved maintainers electronically sign all modifications. Bugs are reported by all users. The bug lists are available to the public.
- **Cooperation and usability:** Cvs is a configuration management software for source code trees in distributed development teams. cvs is an example of cooperation software and its usability issue: Based on rcs (revisions management for single files), it is efficient to use for everyday tasks in open-source software development.
- **Awareness:** Workflows can provide awareness. Examples include automated e-mail distribution of users' bug reports and e-mail notifications of cvs commits.

This exploration into open-source projects and their online coordination and cooperation tools reveals that a voluntary community approach works, and the infrastructures and supporting tools of these projects can be taken as a best practice reference case.

FUTURE TRENDS

Recently, the term "socialware" was proposed for software systems dedicated to enhance social relations. According to Hattori et al. (1999), socialware are systems which aim to support various social activities by means of computer networks. This is done by linking people with others, fostering communication within a community and connecting the community's information. Initially intended for CSCW systems that are used by stable communities, the socialware approach seems suitable for implementing software for online communities as well. It uses rules of interpersonal communication and transfers these structures into software. The technical concept associated with socialware is a multiagent system architecture. The CSCW functionality is achieved through coordination and cooperation of a distributed set of software entities (agents). Users of a community system have personal agents for gathering and exchanging information, visualizing contexts, and supporting decisions. Personal agents and the users they belong to are seen as personal units. Personal units interact with community agents that have the function of providing shared information and mediating communication between personal units. This approach also makes it possible to link several partially overlapping online communities.

A current development in online communities is the transformation of the virtuality of computer networks into the real world. There are different enabling technologies for mobile and ad hoc communities. An important factor is localizability in cellular phone networks or with global positioning systems (GPSs). Using the localization information as part of the application context allows for mobile communities. They are often based on asynchronous communication, like Internet online communities. An example for such a mobile community is the petrol station price comparison community. In 2000, the German Research Center for Information Technology offered car drivers a location aware service for obtaining the locations of petrol stations together with their prices, in exchange for other stations' current petrol prices.

The availability of new short-range radio networking technologies, such as Bluetooth or wireless LAN, enables new synchronous mobile communities. This gives users the ability to connect devices ad hoc (i.e., without a server infrastructure), permitting mobility and interaction. As with other Internet online communities, besides professional applications such as disaster management (Meissner et al., 2002), game playing is an important technology driver, e.g., pervasive group games are being developed (Pennanen & Keinänen, 2004) that could build up social structures in some ways comparable to online communities.

CONCLUSION

Advanced software solutions like the aforementioned socialware approach can help to build and maintain stable online communities. In the long run, though, it is not the technology, it is the people that make an online community work. The most advanced technology is neither sufficient nor, as early BBS/MUD approaches show, necessary for stable online communities. People will always make creative use of technology by using it in other ways than were originally intended by the designers. This will, once in a while, generate possibilities for new online communities.

Nevertheless, the most important factor for successful online communities is providing awareness about changes in the communities' databases to members. Awareness functions provide an understanding of the others' activities and

the communities' goals and progress to relate and evaluate the users' own activities accordingly (Dourish & Bellotti, 1992).

KEY TERMS

Community Building: All activities related to building and maintaining online communities.

CSCW (Computer-Supported Cooperative Work): Software tools and technology as well as organizational structures that support groups of people (typically from different sites) working together on a common project.

Online Community: An online community is a voluntary group of active users that partake actively in a certain computer-mediated service.

Socialware: Socialware aims to support various social activities on a network. Rules of interpersonal communication are used and transferred into community software.

UaE (User-As-Editors) Approach: The community members are responsible for supplying new content and for the quality assurance of existing content, as well as for creating and maintaining the etiquette of the community.

Virtual Community: A featureless and, therefore, often misleading term usually regarded as synonymous to online community. The term "online community" is preferable, as it denotes the character of the community more accurately.

Wiki: Internet service based on HTTP and HTML providing "open editing" of Web pages with a Web browser. Hyperlinks between documents are supported with simple textual references. By default, everybody is allowed to edit all available pages.

This work was previously published in Encyclopedia of Information Science and Technology, edited by M. Khosrow-Pour, pp. 2203-2208, copyright 2005 by Information Science Reference, formerly known as Idea Group Reference (an imprint of IGI Global).

Online Communities and Online Community Building

INTRODUCTION

In this article, we define and describe the concept of online communities, outline the essential conditions under which they emerge and present some means that foster the building of online communities.

"Online community" is one of the buzzwords in the age of Web 2.0. Within this article, we refer to online community as a voluntary group of users who partake actively in a certain computer-mediated service. The term "online community" is preferred over the term "virtual community," as it denotes the character of the community more accurately: community members are interacting online as opposed to face-to-face. Furthermore, the term "virtual community" seems too unspecific, because it includes other communities that only exist virtually, whereas, an online community in our definition is always a real community in the sense that community members know that they are a part of their community.

Nevertheless, there are other reasonable definitions of online community. An early and most influencing characterization (which unfortunately utilizes the term "virtual community") was coined by Howard Rheingold (1994). He wrote: "…virtual communities are cultural aggregations that emerge when enough people bump into each other often enough in cyberspace. A virtual community is a group of people […] who exchanges words and ideas through the mediation of computer bulletin boards and networks" (p. 57). A more elaborate and technical definition of online community is given by Jenny Preece (2000), which acts as a benchmark for developers since then. She states that an online community consists of four basic constituents (Preece, 2000, p. 3):

- Socially interacting people striving to satisfy their own needs;
- A shared purpose like an interest or need that provides a reason to cooperate;
- Policies in the form of tacit assumptions, rituals, or rules that guide the community members' behavior; and
- A technical system that works as a carrier that mediates social interaction.

Not explicitly mentioned in this characterization, but nevertheless crucial for our aforementioned definition (and not in opposition to Preece's position), is voluntary engagement (see also Janneck, Finck, & Oberquelle, 2005).

As Preece's (2000) definition indicates, the basic constituents of online communities include individual issues, group-related issues, as well as technology-related issues. Online communities thus comprise the participants' basic individual motivation, the social interaction processes entailed to "bundle" individual needs to increase efficiency, and the implemented technical functions that support these processes.

In the light of the aforementioned role of social processes, it is not surprising that, with respect to online communities, findings from voluntary groups of active user communities outside computer-based systems are also a highly relevant source of information (see e.g., Baumeister & Bushman, 2008). In the section devoted to online community building, we will present Kraut's (2003) suggestion of a highly-sophisticated application of social psychology theory to address some well-known problems in online communities.

BACKGROUND

Just because everybody is now talking about them, online communities are historically seen neither as a repercussion of the World Wide Web—which dates back to 1991 (Berners-Lee, Cailliau, Groff, & Pollermann, 1992)—nor as dependent on the Internet as a transport infrastructure. In fact, online communities emerged at the time when ARPAnet—the predecessor of the Internet—was still restricted to military-

funded institutions. Some of these online communities were based on computerized bulletin boards first introduced by Christensen and Suess (1978). Their system was called CBBS (computerized bulletin board system) and followed the idea of a thumbtack bulletin board hosted electronically on a computer. Other computer hobbyists were able to connect with their home computers via a dial-up modem connection and could "pin" messages to a shared "board." The first online communities developed when other participants responded to those messages and created ongoing discussions. At that time, computer hobbyists and scientists were more or less the only ones who owned computers and modems. Therefore, most topics on CBBS were within the realm of computers, but in the long run, the topics of discussion broadened. By the 1980s, similar systems appeared that were now called BBS (bulletin board system). The most well known BBSs were "The Well" (Whole Earth 'Lectronic Link) and FidoNet (Rheingold, 2000).

Apparently, at the very same point in time, the technological and social environment was ready for online communities, as there were at least two other independent developments emerging:

1. The Usenet was invented by computer science students at Duke University and the University of North Carolina. They used a simple scheme by which these two computer communities could automatically exchange information via modems at regular intervals.
2. The first MUDs appeared at the University of Essex (UK) creating playful and imaginative online communities. MUDs (Multi-User Dungeon/Dimension/Domain) are computer-implemented versions of text-based role-playing games, in which multiple gamers can take virtual identities and interact with one another. Early MUDs were adventure games played in a labyrinth of dark dungeons with hidden rooms, trapdoors, and so forth.

Nowadays, most online communities are using the Internet as a carrier. Most of them are Web-based, using HTTP as a protocol for transportation and a combination of XHTML, CSS and JavaScript for presentation. But there are still communities that employ other systems and protocols, like newsreaders using NNTP and mail-groups using SMTP- or IRC- (Internet relay chat) based chatting systems. Some online communities even use multiple systems and protocols to communicate and cooperate.

A multiple group of new Web-based services like instant messaging, forums, chats, Web logs (or blogs), wikis, social bookmarking services and several types of other sharing services (e.g., for photos, videos, audio-files, or files in general) has recently been developed. Some of these services like instant messaging, forums or chats are typical applications within the field of computer-mediated communication and therefore foster online communities. Other types of services like, for example blogs, are at first sight not made to be platforms to house online communities. But as soon as these services are enriched with comment functions, RSS feeds and linkbacks (linkbacks are means to obtain notifications when other documents are linked to a certain document) they can be used as such. The latest developments are platforms like Facebook or MySpace, often summarized under the somewhat vague label Web2.0. They typically combine several of the aforementioned services to create rich communication media that could be used by online communities.

ONLINE COMMUNITIES

The conditions in pure online communities highly differ from a computer-mediated communication situation within companies and corporations. Whereas employees in a computer-supported cooperative work (CSCW) context usually meet online as well as face-to-face, members of online communities have, as a general rule, never met each other. Working in a highly standardized company context, employees have to focus on task fulfillment within a certain timeframe. Superiors evaluate their achievements, and they are accordingly paid by the company.

Online communities live from their volunteers. Usually none of the community members can be forced to do something, and there are no tangible incentives. Basic research in motivation psychology (Franken, 2001) even shows that incentives tend to be counterproductive.

Community members usually show a high degree of intrinsic motivation to participate actively in the development of an online community. It is still open to discussion where this motivation comes from. Simple rules like "It's all based on trying to maximize the potential personal benefit" seem to fail, if the concept of the term "personal benefit" is too simplistic. The attention-economy-debate (e.g., Aigrain, 1997; Ghosh, 1997; Goldhaber, 1997) shows that personal benefit is a complex entity if one relates it to online activities in the World Wide Web.

The likelihood of taking an active part in a community increases with the potential personal benefit that could be gained within that community. This is directly related to the quality of the contents offered. As Utz (2000) stated, the likelihood of submitting high quality contributions increases with the quality and the manifoldness of the existing entries. Appropriate solutions for quality assurance are rating systems.

A "killer feature" for such an application generates immediate benefit for users as soon as they start using the application, even without anybody else contributing. Unfortunately, this kind of feature can't always be found and implemented. As a (partial) replacement for such a feature, one can follow best practices. After analyzing numerous

popular online communities, Kollock (1999) came to the conclusion that there are basically two sources of motivation: self-interest (what seems to be the most common motivation) and altruism. Self-interest as a motivator is linked to expectations of reciprocity: people are willing to help or cooperate with others if they can expect a future quid pro quo. Altruistic behavior, in contrast, denotes people's motivation to increase another's welfare without expecting anything in return (Baumeister & Bushman, 2008).

A widely discussed issue in the context of community building is the so-called public goods dilemma: if people can access public goods without restriction, they tend to benefit from these goods and, therefore, from others' contributions without contributing reciprocally. If the majority of community members are tempted to behave that way, the public good will vanish (Kollock & Smith, 1996). The main problem is to keep the balance between the individual and common interest: An individually favorable and reasonable behavior turns out to be harmful for the others, and in the long run, disastrous for the community (Axelrod, 1984; Ostrom, 1990).

Owing to these circumstances, it is not surprising that a great deal of all online community building projects have failed, even though much effort has been put into these projects due to the high profit opportunities within the field as, for instance, Hagel and Armstrong (1997) predicted.

ONLINE COMMUNITY BUILDING

Recipe-based fabrication of online communities is, at least, a bold venture if not an illusionary enterprise. Social relationships and group momentum are particularly hard to predict. As Rheingold (2000) explicated, online communities grow organically and tend to follow their own rules. Therefore, controlling efforts always have to be readjusted to the current group context and dynamics. Nevertheless, some well-approved principles could be derived from the findings that were discussed in the last chapter.

Kim (2000) presents a membership lifecycle which describes five successive stages and levels of participation:

1. Visitors (people not involved in the community processes);
2. Novices (new community members who are still trying to find their way);
3. Regulars (community members who are consistently involved in the community life);
4. Leaders (community members who keep the community running and bear responsibility as well as acquired rights); and
5. Elders (long-time community members who share their knowledge and communicate the community culture).

We have already stressed the importance of findings of "off-line" groups for online communities. In this respect, Kraut (2003) suggested applying social psychology theory to some of the well-known problems existing in online groups. In particular, Kraut addresses the problem of under-contribution in groups. This issue refers to a common characteristic of online groups, namely their highly uneven distribution of contributions with a small number of members contributing most of the content, and the majority of members acting as so-called lurkers or read-only subscribers. Typically, however, lurkers do not doubt the significance and usefulness of the online group they partake in; they simply do not contribute actively.

To overcome the problem of under-contribution, Kraut (2003) borrows from current social psychology theories like, for example, Karau and William's (1993) theory of social loafing. In particular, he suggests design guidelines to increase participation rates in this group. Kraut's guidelines include the identifiability of members, task attractiveness, group attractiveness, the group's overall size, and the recognition of the uniqueness and high significance of one's own contribution (compared to other members' contributions) as key variables to collective effort in online communities.

With respect to these key variables, Kraut (2003) suggests various design implications or strategies for optimization. For instance, identifiability is known to be an indispensable prerequisite to the success of online communities: Only if anonymity is not allowed, any change or progress being made will be displayed and connected to individual group members (see also Janneck et al., 2005). Individual behavior will thus become accountable.

In addition, to increase the attractiveness of contributing, the underlying software should provide interactive elements. Elements like, for example, a chat function supports mutual communication, which is more attractive and requires less effort than asynchronous communication.

Taken together, identifiability and providing interactive elements address, and eventually reduce, a broad range of group problems like social loafing or production blocking, because they act as a motivating effect on perceiving one's own performance.

Kollock (1999) also focuses on personal identifiability, which he links to the memory functions of a community supporting technological system. More precisely, he argues that cooperation within an online community can only be successful if individuals:

1. Can recognize each other, that is, they are not operating anonymously within the community;
2. Have access to each others interaction history; and
3. Share the presumption of a high likelihood of a future encounter within the online community.

This leads to the conclusion that online communities have to offer possibilities of creating and managing relationships by supporting continuous interaction between their members. Therefore, it is advantageous if the system has a memory, in the sense that every community member and every item stored in the system holds a personal history.

People tend to act from self-interest if they are aware that their actions have effects on their reputations: high-quality contributions, impressive knowledge, and the perception of being willing to help others enhance the prestige of the community member. Although altruism as a motivational state for taking part in an online community is less common in comparison with self-interest, it is still frequent enough to be addressed if one thinks about community building. People with altruistic motivation try to meet the needs of the group or certain group members. This motivational state can be satisfied by establishing a public space where these needs can be stated, communicated, and discussed.

Considering the public goods dilemma, it is essential to introduce a role concept to clearly communicate the borderline between being in a group and being out of a group. To get full access to all group resources, one has to join the group. Several functionalities are only accessible for registered and authorized users. The commitment that is required to join the group leads to establishing a comprehensible boundary between members and nonmembers. This, in turn, facilitates the togetherness of the group and the identification of the members within the group. The membership itself constitutes a strong coupling feature.

Three further selective measures address the public goods dilemma: personal presence, personal responsibility, and personal history. Anonymity and lack of continuity among the members promotes egoistic behavior. Therefore, modifying actions should be tagged with users' login names, which, in turn, should be associated with records of personal data. Tagging entries and actions with user login names makes it easy to recognize people and enhances the development of personal relationships and online cooperation among the community members. Seeing all modifying actions supports the participator's personal responsibility. If the system has a memory of every action, this gives a personal history to every community member, as well as to the community's artifacts. Information about past interactions of the members again increases personal responsibility. Whereas, information about interaction with the artifacts allows members to get up-to-date, or introduce members to new areas of interest, as well as familiarize new members with the online community's etiquette and Who's Who.

"Content is king" is commonplace for virtually all Web-based efforts. This is notably true for online communities operating on a user-as-editors base. To implement a reasonable quality assurance system, it is crucial to apply technical, as well, as social devices. On a technical level, this can be done by employing a content rating system. Employing an "A team" of highly motivated volunteers can, on the other hand, help the online community to start up by delivering good content. For all content producers, it has to be as easy as possible to feed new content into the system. The best way of avoiding barriers is through continuous usability testing.

Introducing dedicated and active moderators seems to be the most important step to nourish motivation of the community members. Moderators can enhance group activities and increase the efficiency of the group. They are responsible for communicating the group codex (etiquette), acting as role models for new community members, and helping in preserving continuity. Rojo and Ragsdale (1997) show that an active moderator can, to some extent, compensate for the lack of active members in an online community.

In face-to-face communities only members can start a conversation. In online communities on the other hand, the technical systems can initiate communication as well. This opportunity should be brought into play by implementing awareness functions as software agents that collect relevant information for users and present it in e-mails, RSS feeds or personalized portal pages. These agents generally base their information gathering and presenting strategies on keywords or categories stored in configuration files (profiles). It is crucial to keep these profiles up-to-date. Experience shows however, that the members' interests continuously change over time. Profile setting dialogues are often accessed once and then forgotten. Thus, there is risk for personalized services to decrease in quality over time. Hence, it is important to monitor user behavior and let the agents ask from time to time if their interpretations of observations of, for example, changing interests, are correct. Furthermore, people may change their general attitude toward the community. This can be connected to an altered degree of involvement and must be considered during the design phase (i.e., modifiable feature sets).

The open-source movement has become very successful in recruiting new developers who start their own projects or join existing software development efforts. Today, most, if not all, open-source software development communities use online services for collaboration. In the remainder of this section, the application of the requirements for software that supports online community building is demonstrated by the following examples of open-source software development communities:

- **"Killer feature":** Open-source projects are often founded to solve an existing problem, that is, the killer feature is the product of the online community. When others join the project, the work becomes even more effective.
- **Recruitment:** Open-source communities produce software systems that are not only intended for use by original members but also for external clients. These

external users, that is, users not actively involved in the open-source online community, can be made active developers that modify the source and give it back to the project. To foster this process of developer recruitment, online communities should provide transparent rules for becoming actively involved. The projects that do not seem to be hermetic have better chances of growing their developer base.

- **Transparency:** The most important possibility of gaining transparency is through a public archive of the project's mailing lists. Because it is often not easy to scan large e-mail archives, open-source communities should provide text documenting guidelines and standards.
- **Policy:** The Debian community, for example, maintains an open-source Linux distribution and is a good example of a growing community that has given itself a substantial set of roles, rules, and guidelines. They achieve transparency of their standards by publication of documents on their Web server: Other projects, such as UserLinux, use a Wiki for that, which makes such standards more vivid and activates community members' attendance.
- **Trust:** Debian has a twofold quality assurance system. There are no anonymous additions to the system, and approved maintainers electronically sign all modifications. Software bugs are reported by all users. The bug lists are available to the public.
- **Cooperation and usability:** CVS and Subversion are systems for configuration management for source code trees for distributed development teams. They are both good examples of cooperation software with a high usability that are efficient to use for everyday tasks in software development.
- **Awareness:** Workflows can provide awareness. Examples include automated e-mail distribution of users' software bug reports and e-mail notifications or RSS feeds of CVS or Subversion commits.

This exploration into open-source projects and their online coordination and cooperation tools reveals that a voluntary community approach works, and the infrastructures and supporting tools of these projects can be taken as a best practice reference case.

FUTURE TRENDS

Recently, the term "Socialware" was proposed for software systems dedicated to enhance social relations. According to Hattori, Ohguro, Yokoo, Matsubara, and Yoshida (1999), Socialware denotes systems which aim to support "various social activities on network communities." Supports include linking people with others, smooth communication in a community and information integration for a community. The Socialware approach was initially intended for CSCW systems that are used by stable communities. This approach seems suitable for implementing software for online communities as well.

It uses rules of interpersonal communication and transfers these structures into software. The technical concept associated with Socialware is a multiagent system architecture. The CSCW functionality is achieved through coordination and cooperation of a distributed set of software entities (agents). Users of a community system have personal agents for gathering and exchanging information, visualizing context information, and supporting decisions. Personal agents and the users they belong to are seen as personal units. Personal units interact with community agents that have the function of providing shared information and mediating communication between other personal units. This approach also makes it possible to link different partially-overlapping online communities.

A current development in online communities is the transformation of the virtuality of computer networks into the real world. There are different enabling technologies for mobile and ad hoc communities. An important factor is the ability to locate in cellular phone networks or with global positioning systems (GPSs). Using the positioning information as part of the application environment allows for mobile communities. They are often based on asynchronous communication, like Internet online communities. An example for such a mobile community is the petrol station price comparison community. In 2000, the German Research Center for Information Technology offered car drivers a location awareness service which gave a comparison price list of the varying petrol rates of all the petrol stations.

The availability of new short-range radio networking technologies, such as Bluetooth, WiFi or WiMAX, enables new synchronous mobile communities. This gives users the ability to connect devices ad hoc (i.e., without a server infrastructure), permitting mobility and interaction. As with other Internet online communities, game playing is an important technology driver, for example, pervasive group games are being developed (Pennanen & Keinänen, 2004) that could build up social structures in some ways comparable to online communities.

Finally, most characteristics that are prototypical to online communities can be found in so-called guilds in Massively Multiplayer Online Role-Playing Games (MMORPG). The gamers follow strict rules according to behavior and tasks for ensuring personal and common progress. Oral and written communication within and outside the game is essential for coordination and team play. Collaboration always has a short-term as well as a long-term perspective. Associated goals vary from coping with short but stressful in-game situations (e.g., fighting the "final enemy") to preparing and organizing activities months in advance (e.g., acquir-

ing needed resources). In spite of the "role-playing" label, serious and reliable relationships can be established within the MMORPG community (Yee, 2006).

CONCLUSION

Advanced software solutions like the aforementioned Socialware approach can help to build and maintain stable online communities. In the long run, though, it is not the technology; it is the people that make an online community work. Using the most advanced technology is neither sufficient nor, as early BBS/MUD approaches show, necessary to assure the building of a stable online community. People will always make creative use of technology by using it in other ways than were originally intended by the designers. This will, once in a while, generate possibilities for new online communities.

Nevertheless, the most important factor for successful building and maintaining an active online community is providing awareness about changes in the communities' databases to members. Awareness functions provide an understanding of the others members' activities and the communities' goals and progress; the user can thus relate and evaluate their own activities accordingly.

KEY TERMS

Community Building: All activities related to building and maintaining online communities.

CSCW (Computer-Supported Cooperative Work): Software tools and technology as well as organizational structures that support groups of people (typically from different sites) working together on a joint project.

MMORPG (Massively Multiplayer Online Role-playing Games): Role-playing games played online by a large number of players at the same time. Participants are represented by customized avatars and solve different tasks (quests) on their own or in coordinated groups.

Online Community: An online community is a voluntary group of active users that partake actively in a certain computer-mediated service.

Socialware: Socialware aims to support various social activities on a network. Rules of interpersonal communication are used and transferred into community software.

UaE (User-as-Editors) Approach: The community members are responsible for supplying new content and assuring the quality of existing content, as well as for creating and maintaining the etiquette of the community.

Virtual Community: This is a featureless and, therefore, often misleading term usually regarded as synonymous to online community. The term "online community" is preferable, as it denotes the character of the community more accurately.

Wiki: Internet service based on HTTP and HTML providing "open editing" of Web pages with a Web browser. Hyperlinks between documents are supported with simple textual references. By default, everybody is allowed to edit all available pages.

Online Learning as a Form of Accommodation

Terence Cavanaugh
University of North Florida, USA

INTRODUCTION

An estimated three billion people, representing approximately half of the planet's population, are in some way affected by disabilities, which includes an estimated 150 million from the United States of America (Half the Planet, 2001). According to the *Twenty-Third Annual Report to Congress on the Implementation of the Individuals with Disabilities Education Act* (U.S. Department of Education, 2002a), concerning students with special needs between the ages of three and 21, the U.S. and its outlying areas are currently serving educationally more than 6,272,000 students classified as having a disability. The inclusion model, in which a special needs student participates in the "regular" classroom, has become the current classroom education standard. Today's special needs students have increasing impacts on the general education teacher as, during the past 10 years, the percentage of students with disabilities served in schools and classes with their non-disabled peers has gradually grown to over 90% in 1998 (U.S. Department of Education, 2000b). Because of the large and increasing number of special needs students, assistive educational technology is growing in importance. The population of postsecondary students with disabilities has increased over the past two decades, and currently there are approximately one million persons in postsecondary institutions who are classified as having some form of disability (U.S. Department of Education, 2000b). In 1994, approximately 45% of the adult population who reported having a disability had either attended some college or had completed a bachelor's degree or higher, as compared to only 29% in 1986 (National Center for Educational Statistics, 1999a).

BACKGROUND

Changes in the Population of Schools

While the makeup of the student population (K-20) has changed, because more students have been classified as having a disability and are now included in the general educational population, so too have the possibilities of the educational setting changed. For the 1999-2000 school year, the number of U.S. students with disabilities served was 588,300 preschool children and 5,683,707 students ages 6 through 21, representing an increase of 2.6% over the previous year (U.S. Department of Education, 2002a). Instructors now have on hand instructional tools that include forms of interactive telecommunication, such as the Internet and two-way video communication, as options for the delivery of instruction. While schools may not have been planning, designing, and creating distance learning courses and programs to meet the needs of students with disabilities, many students' needs were met through such a delivery system nonetheless. Electronic learning in and of itself is a form of instructional accommodation. Additionally, a range of assistive technology can support the student in the distance learning environment. The online class can be an assistive technology tool that students can use who would otherwise not be able to participate in a classroom for physical, health, or other reasons.

The number of students with disabilities is growing in the online education environment. A 1999 Canadian study of students with disabilities attending community colleges and universities found that an overwhelming majority of respondents (95%) indicated that they used a computer in their education situation, to the most noted reason for using the Internet was for doing research (Fichten, Asuncion, Barile, Fossey & De Simone, 2000). Thompson's (1998) summarizing report states that approximately 5% of the undergraduates at Open University of the United Kingdom have disabilities, with their population increasing at a rate of approximately 10% per year. The growth is ascribed to the convenience of home study and the ability of technology to overcome barriers to learning for students with disabilities. According to the U.S. Department of Education's (2002a) National Postsecondary Student Aid Study of 1999-2000, more than 8% of all undergraduates took at least one distance learning course, and 9.9% of those students identified themselves as having some form of disability.

Accommodations or Modifications Needed for Disabled Access

There is a difference between accommodations and modifications for students with special needs. Accommodations are considered to be provisions made in how a student accesses and/or demonstrates learning. The term accommodations focuses on changes in the instruction, or how students are expected to learn, along with changes in methods of assessment that demonstrate or document what has been learned. The use of an accommodation does not change the educational goals, standards, or objectives, the instructional level,

or the content, and provides the student with equal access and equal opportunity to demonstrate his or her skills and knowledge (State of Florida, Department of State, 2000). Accommodations assist students in working around the limitations that are related to their disabilities and allow a student with a disability to participate with other students in the general curriculum program. Accommodations can be provided for: instructional methods and materials; assignments and assessments; learning environment; time demands and scheduling; and special communication systems. By comparison a modification is a change in what a student is expected to learn and demonstrate. The use of a modification for a student changes the standard, the instructional level, or the content to be learned by the student (Beech, 2000).

According to the Assistive Technology Education Network (ATEN) of Florida (2000), instructors of any classes that have students with disabilities should provide students with:

- opportunities to interact with others,
- varied models of print use,
- choices—and then wait for the student to respond,
- opportunities to communicate, and
- expectations that students will communicate, this may require the use of an alternate or augmentative form of communication.

Online instruction, especially through asynchronous Internet presentation, provides all of ATEN's requested opportunities for students. In a "traditional" course, a teacher or professor would be in a classroom, with the students sitting at tables or desks, and there would be lectures, demonstrations, possibly videos and slideshows, handouts, and readings. In an online course in an asynchronous course model, these interactions could still take place, but without the limitations of specific time and location (Picciano, 2001). In such a distance learning course, the main interactions between the student and the instructor take place using course Web pages, streaming audio and video, forums, e-mail, and online books. Assistive tools that a student with special needs may require could be more easily applied in the online environment; such assistive tools may include speech-to-text programs, environmental control devices, or assistive hearing devices. Additionally the asynchronous course design allows the students to access the information at the course Web site and learn at a time convenient to them (Barron, 1999). Within online course sections there could be forums or discussions in which students can participate, allowing each and every student the opportunity and appropriate time to develop and share responses, again without the time restrictions of the standard class period.

The Law, the IEP, and Education

Federal laws and their directives charge that each student classified as having any form of disability have an individual education plan (IEP) developed specifically for that student, that assistive technology devices and services must be considered, and that the student must be taught in the least restrictive environment (Individuals with Disabilities Education Act, 1992). The IEP will be developed by a team of people including teachers, administrators, counselors, parents, outside experts (as needed), and often the student. Distance learning can be considered an adapted form of instruction that through the use of telecommunication technology (usually the Internet) allows a student to participate in a class, meeting the classification of assistive technology. While some students with special needs may choose distance learning courses because these courses provide the necessary accommodations or educational modifications that they need in order to function in that form of "classroom," that in and of itself is not enough. It is up to educators to make sure that the accommodations and educational modifications necessary for these students to function in our classrooms exist or can be made available to these students as they need them. The educational charge extends to ensuring that distance learning classes are also accessible. These distance learning courses or situations must be designed, accommodated, or modified to allow students with special needs to be able to effectively participate.

Distance Learning and Students with Disabilities

A recent survey of seven open enrollment distance learning schools (state, public or private, or college/university) that offered Internet-based instruction may indicate trends in the current status of distance learning programs and special needs students. The distance learning population of the responding schools ran from 300 to 5,000 full- or part-time students, with an average of approximately 1,000 students. Most schools indicated that they did not have records or tracking methods for identifying students with disabilities. Schools that did identify these students indicated that special needs populations ran between 2% and 10%. With the exception of the responding university school, all the K12 distance learning schools indicated that their teachers have participated in IEPs for students. Half of the respondent schools indicated that they currently had students taking courses as part of the student's IEP, as recommended or required by the student's home school IEP team. The schools also indicated that they did not participate as IEP team members, but that the school or distance learning environment was written in as a service in the student's IEP. A consistent thread in the responses was that the distance education schools were

sure that they had special needs students, but that they were not identified. When identifying their accommodations for students with special needs, all of the schools responded that they were willing to make accommodations, and the most common accommodation occurring in their programs was extending required time on tests and assignments. When questioned about the virtual school's faculty, only half of the respondents indicated that they had both counselors and exceptional education teachers on staff. Others indicated that they depended on counselors or other support personal to work with the student's home school. Interestingly, all responding virtual schools did indicate that distance learning instructors have already had, or currently have access to, training concerning accommodations for educating special needs students. Only two of the responding distance learning schools indicated that their Web-based instructional pages were compliant with either national or international accessibility guidelines, with one indicating that it was in the process of becoming so.

Hospital/Homebound Students

According to U.S. government statistics, there are more than 26,000 students classified as hospital/homebound students across the nation (U.S. Department of Education, 2002a). How these students are being served at a distance from their "home" school is a distance learning strategy question. The classic hospital/homebound program has a visiting teacher who acts as intermediary between a student's regular teacher and the student. The hospital/homebound teacher contacts the student's classroom teacher or teachers to collect assignments and directions to deliver to the hospital/homebound student, and visits the student to provide instruction and assistance. The more common approaches for hospital/homebound education are the "teleclass" phone model for secondary students and hospital/home visitation for the elementary level. In phone-based or teleclass instruction, all students taking a course dial into a common number, and a teacher provides oral instruction. Students have the opportunity to ask questions and interact through voice (G.A. Ball, personal phone communication, October 2, 2002). This instruction by phone service qualifies as a true distance learning program, as education is provided to the students through a telecommunication system. Other school systems also use online instruction, audio/videotaped instruction, and CD-ROMs, where the districts provide the needed hardware and software; some district school systems have even placed fax machines in students' homes for students to use to receive and submit assignments (C. Bishop, personal e-mail communication, January 2003).

FUTURE TRENDS

Online Education

Distance learning is a growing educational option. The numbers of both public and private distance learning intuitions are on the rise, along with the numbers of students attending. An instructional example would be the Florida Virtual School, going from 227 students in 1998 to 8,200 in 2002, an increase of 3,612% in just five years. School systems and students need flexible options to increase educational success, and using distance learning as an alternative can do that. We are already seeing experiments with asynchronous distance learning being used as an alternative for the hospital/homebound, but research still needs to be done. Virtual schools need to track the special needs students and identify effective methods that are working with them. Hospital/homebound programs need to investigate options for students who must be out of school for extended periods of time and determine the effectiveness of online skill-building education versus asynchronous module instruction of courses. Also, can distance learning assist such programs by allowing small or rural districts to band together and use common certified teachers, who are in short supply and are needed for No Child Left Behind requirements, to be shared between districts? In addition to human concerns, the future brings hardware and software issues, since most of the course management systems (CMSs) are not "disabled" accessible according to US 508 or W3C accessibility guidelines. Schools need to either create their own accessible course systems or apply pressure so that the currently available systems become compliant with access guidelines.

CONCLUSION

Distance Learning as an Accommodation

Electronic learning in and of itself is a form of accommodation, and there is also a range of assistive technology that can support the student in the distance learning environment. The online class can be an effective assistive technology tool that students can use who would otherwise not be able to participate in a classroom for physical, health, or other reasons. While distance learning may not be appropriate for every course or accommodating to every form of disability, it does provide a viable instructional option for many. As the inclusive education of all students occurs more frequently within the standard K12 classroom and through the electronic environment at the college level, it is reasonable to expect that more students with disabilities will participate in online education. While many accommodations are already avail-

able online, instructors need to insure that online courses should adhere to accessibility guidelines as proposed by state, national, or international organizations to allow all students access. These educational environments should be designed for all students, even those students who may need modifications, accommodations, and assistive technology.

KEY TERMS

Accommodations: Provisions made in how a student accesses and/or demonstrates learning. The term focuses on changes in the instruction, or how students are expected to learn, along with changes in methods of assessment that demonstrate or document what has been learned. The use of an accommodation does not change the educational goals, standards, or objectives, the instructional level, or the content, and provides the student with equal access and equal opportunity to demonstrate his or her skills and knowledge.

Assistive Technology: "…any item, piece of equipment, or product system, whether acquired commercially off the shelf, modified, or customized, that is used to increase, maintain, or improve functional capabilities of individuals with disabilities…." (20 U.S.C. 1401 (33)(250))

Asynchronous: Communications between the student and teacher which do not take place simultaneously.

Disabled Student: From the *U.S. Federal Register*: child/student has been evaluated as having mental retardation, a hearing impairment including deafness, a speech or language impairment, a visual impairment including blindness, serious emotional disturbance (hereafter referred to as emotional disturbance), an orthopedic impairment, autism, traumatic brain injury, an other health impairment, a specific learning disability, deaf-blindness, or multiple disabilities, and who, by reason thereof, needs special education and related services (IEP or 504).

Inclusion: A classroom design where all students should take part and attend "regular" classes. Generally, an ESE and regular education teacher work together with the same group of students, including students with disabilities and

general education students. Both of the teachers share the responsibility for all of the students.

Individualized Education Program (IEP): A written statement for each child with a disability that is developed, reviewed, and revised in accordance with this section. (20 U.S.C. 1414 (d)(1)(A)) (Individuals with Disabilities Education Act, 1997)

Modification: A change in what a student is expected to learn and demonstrate. The use of a modification for a student changes the standard, the instructional level, or the content to be learned by the student.

Specific Learning Disability: Term meaning a disorder in one or more of the basic psychological processes involved in understanding or in using language, spoken or written, that may manifest itself in an imperfect ability to listen, think, speak, read, write, spell, or to do mathematical calculations, including conditions such as perceptual disabilities, brain injury, minimal brain dysfunction, dyslexia, and developmental aphasia.

Teleclass: Voice-only communications linking two or more sites. A standard method used is to connect multiple telephone lines for an audio conference through a phone bridge. A telephone bridge where the conference is established by having all of the distant sites call in to a common bridge telephone number.

Online Student and Instructor Characteristics

Michelle Kilburn
Southeast Missouri State University, USA

Martha Henckell
Southeast Missouri State University, USA

David Starrett
Southeast Missouri State University, USA

INTRODUCTION

As technological advances become mainstream in higher education, many universities have begun delving into online learning as an effective means of course delivery. Transitioning from the Industrial Age to the Digital Age of learning has forced some evaluators to rethink standards of success and the idea of productivity and learning (Leonard, 1999).

Understanding the positive attributes of students and instructors in the online environment will contribute to the understanding of how we can enhance the learning experience for the student and the teaching experience for the instructor. This article will also assist students and instructors in understanding the differences that may be experienced in the online environment vs. the face-to-face environment and provide the opportunity to consider whether online learning or teaching is a "good fit" for them. Understanding why students or instructors might choose the online environment will also assist administrators in developing successful, quality online programs that enrich the experiences for both students and instructors.

BACKGROUND

In 1981, the first online classes were developed at the School of Management and Strategic Studies at Western Behavior Sciences Institute in La Jolla, California. An evaluation of the program, and the discussions that took place, revealed that the quality of the online course was higher than the information collected in the traditional classroom setting (Feenberg, 1999). Jung, Choi, Lim, and Leem (2002) also found that online instruction showed significantly better results on examinations, complicated problems, or student's perception of learning outcomes.

With the popularity of the Internet, and the continuing demand for online courses, many college and university administrators might find it challenging to incorporate online technology. Many may feel pressured to jump on the "online bandwagon" in order to keep up with the student demand for these types of courses.

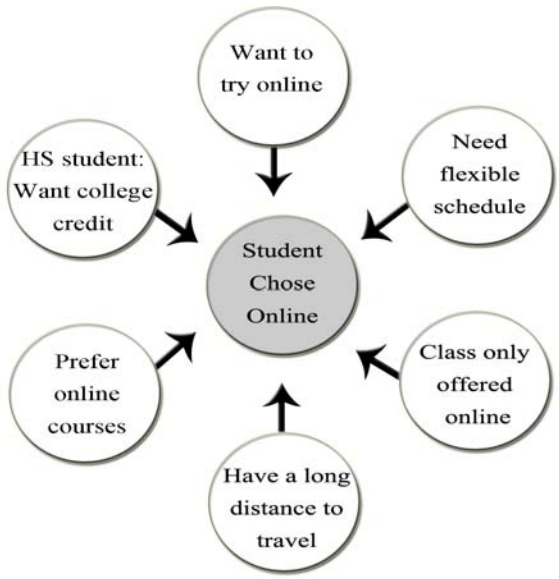
Kilburn (2005) developed the following conceptual map (see Figure 1) regarding student motivations to take an online course at a particular university in the Midwest:

In the upcoming section, an examination of student and instructor characteristics and how each of those different roles contributes to the quality of an online course will help provide insight into the foundational underpinnings of Web-based learning.

STUDENT CHARACTERISTICS

It is estimated that five out of six students taking an online course are employed and would not be able to attend tradi-

Figure 1. Student motivations to take an online course at a Midwest university



tional classes (Thomas, 2001). Moore and Kearsley (1996) and Hardy and Boaz (1997) found that most distance learners are working adults, primarily female. Literature suggests that the growth in online courses is based on attracting new students rather than "stealing" from students enrolled in current on-campus programs (Mangan, 2001; Thomas, 2001).

Some researchers have attempted to identify student abilities that will suggest whether a student will complete an online course, or be less satisfied with an online course, in comparison to the traditional classroom setting. Kilburn (2005) found that positive characteristics identified in studies stress the importance of an active vs. passive student role in an online course and include: self-motivation and the ability to organize thought (Hardy & Boaz, 1997), prior experience with technology (Richards & Ridley, 1997), positive attitude regarding the subject matter (Coussment, 1995), learning and personality styles (Saunders, Malm, Malone, Nay, Oliver, & Thompson, 1998), self-selection of online courses vs. forced-choice (Thomerson & Smith, 1996), intrinsic motivation, and self-reported explorative behavior (Martens, Bastiaens, & Kirschner, 2007).

One attraction to online learning is the presumed capacity to increase access and equity to learners by removing some of the barriers to participation (Harasim, 1990). Sullivan (2001) found that the online classroom is often more welcoming for quiet or shy students than the traditional classroom. Online learning has also been advanced as a powerful, yet neutral, tool for enhancing the potential of distance education (Weisband, 1992).

Sullivan (2001) asserts that nontraditional students, particularly female with children or other familial responsibilities, value online courses. Research has suggested that the asynchronous nature of the online environment might encourage a more reflective type of interaction that changes the dynamics of classroom discussion in a way that female students find rewarding (Selfe, 1999). Another aspect of online learning that female students appear to find appealing is the relative anonymity online affords and changes to the social dynamics inherent in a traditional course (Sullivan, 1999).

Most students may initially select distance education as a result of perceived convenience (Klesius, Homan, & Thompson, 1997). These conveniences may include travel, compatibility with personal schedules, and opportunity for self-paced work. Online courses can accommodate all of these conveniences.

Busy work schedules and the expense of completing a higher education degree have often been the typical roadblocks encountered by students in traditional educational arenas (Holt, 1993). Online education has helped to remove some of these hurdles by saving commuting costs, equalizing classroom participation, and offering convenient scheduling for working students.

The age of a student generally is related to the course completion rate and the type of study in a distance education course. On average, students over 30 and under 50 years old are more likely to finish a distance course than traditional students age 18 to 29 (Willis, 1993). Technical skills also appear to play a role in the success of students taking online courses (Kerka, 1996). Students should possess the ability to navigate the Internet and deal effectively with computer software and hardware difficulties.

In the online environment, successful students shift from a more passive role in the exchange of knowledge to a more active role. Several studies purport that the following are the most influential factors affecting a student's active participation in online learning: (1) prior knowledge of online learning, (2) knowledge of a given subject area, (2) information overload, (3) personality traits, (4) instructor facilitation, and (5) appropriate feedback (Lim, 1999; Vonderwell & Zachariah, 2005).

INSTRUCTOR CHARACTERISTICS

The relationship between student-teacher interactions and learning outcomes has been well documented in the traditional classroom (Powers & Rossman, 1985). Of particular importance in traditional classrooms is teacher "immediacy tendencies." Immediacy alludes to the psychological distance between student and instructor (Weiner & Mehrabian, 1968). Research suggests that a teacher's verbal and nonverbal immediacy behaviors can help diminish the apparent distance between themselves and their students. By lessening the perception of disconnect between the instructor and student in a course, instructors can help facilitate (directly or indirectly) effective learning.

With the importance of interactions established as a crucial component of learning, one might assume it would be equally important online. Certain researchers have suggested that asynchronous media are less capable of representing the social presence of participants (Short, Williams, & Christie, 1976). Researchers with experience teaching online contest this view, arguing that rather than being impersonal, computer-mediated communication often seems to be hyperpersonal (Walther, 1994). According to Kilburn (2005), research indicates that participants in online courses communicate, argue, and create social presence by projecting immediacy behaviors (LaRose & Whitten, 2000; Rourke, Anderson, Garrison, & Archer, 2001).

Previous studies (Thompson & Chute, 1998) suggest that in order to enhance learning motivation, small group activities are important in online courses. One might argue that learning motivation is more important in distance education courses because distance learners with low motivation have more of a tendency to drop out or fail when

compared to traditional on-campus courses (Keller, 1999). Interactions among students seem to clearly matter in online discussions. The development of social presence and the perceived interaction with others is one of the cornerstones for the development of online communities (Rourke et al., 2001). Lu and Jeng (2006) discovered that instructors who strived to serve as both facilitator and co-participant were helpful in "enhancing knowledge construction," particularly in discussion forums (p. 196).

Eastmond (1995) points out that online communication should not be assumed to be intrinsically interactive but it depends on the nature, frequency and timeliness of discussions. Hawisher and Pemberton (1997) found there was a potential correlation with the success of an online course and the value the instructor placed on discussions. Picciano (1998) found that students' perceptions of learning were related to the amount of discussion that took place in online course. Likewise, Jiang and Ting (2000) report correlations between perceived learning in online courses and the specificity of the instructors' discussion, instructions and the percent of course grades based on discussion responses. These studies exemplify the magnitude of importance that is placed on the instructor to assure the quality of an online course.

Researchers have begun to look at the changing roles of teachers in online classrooms. Coppola, Hiltz, and Rotter (2001) assert that in any delivery medium teachers have three roles: cognitive, affective, and managerial. They found with online courses the cognitive role often becomes more complex and paramount. The affective role requires instructors to find new tools to express emotion and the managerial role requires greater attention to detail, more structure, and additional student monitoring. Easton (2003) reported that prior to the start of class, the instructor role was more like an instructional designer and subject matter expert; however, once the class began, the instructor's activities took on more of an interactive, facilitator role. Darabi, Sikorski, and Harvey (2006) describe the various instructors' roles as managerial, social and technical.

Janicki and Liegle (2001) evaluated the work of a wide range of instructional design professionals and developed a list of 10 concepts believed to support effective design of Web-based instruction. The findings included: (1) instructors acting as facilitators, (2) usage of a variety of presentation styles, (3) multiple exercises, (4) hands-on problems, (5) learner control of pacing, (6) frequent testing, (7) clear feedback, (8) consistent layout, (9) clear navigation, and (10) available help screens.

Interaction has been acknowledged as an important component of learning in conventional and distance education (Moore, 1993). Studies have argued for the importance of instructors' social or interpersonal feedback when attempting to improve learning achievement in online courses (Jung, 2000: Leem, 1999). Dennen, Darabie, and Smith (2007) have suggested effective online instructors adopt the following practices: Maintaining frequency of contact, having a presence in class discussion, and making expectations clear to learners.

Instructors must balance academic interaction related to the subject matter with more personal student interaction that will cultivate a sense of relationship and community (Moller, 1998). Immediate and frequent feedback must be sufficient enough to communicate a sense of co-presence and a willingness to be responsive to student needs (Boettcher, 1999). Dennen (2007) purports that "instructors establish a persona via both presence (amount of instructor posts) and position (interaction relative to those in the student role)" (p. 95). Some online learners find it challenging to stay on task. Consequently, they fail to complete coursework. Prompt e-mail responses may help students remain on task and on schedule (Klesius et al., 1997).

FUTURE TRENDS

As online learning continues to grow in the higher education arena, more research needs to be done on the changing roles of students and instructors in the online environment. Time is no longer spent in the classroom passively listening to a lecture; students are required to play a more active role in their learning. Instructors often struggle to adapt their teaching approaches to develop active interaction and engagement in their online courses.

Rethinking quality assurance, how to measure student success and what constitutes quality interaction will be a crucial step in moving instructors and administrators from the traditional teaching and classroom management frame of reference to the "virtual campus." Encouraging instructors and students to "think outside the box" and experiment with ways to enhance interaction will help shape the future of online learning.

CONCLUSION

Students will need to adjust to a more self-directed, student-centered approach to learning, while instructors will need to move toward a facilitating model of instruction. Understanding how to assist both students and instructors to adjust to more nontraditional roles in academe is critical. Instructional designers in higher education have the critical role of helping outstanding face-to-face instructors translate their expertise, knowledge and personality into outstanding online courses. This discussion has reinforced the argument that developing an online course is not a matter of simply putting lecture notes and presentations online. Instructors must assume both an affective and managerial role. The instructional designer must help them stock a new "tool box" to effectively transfer knowledge, communicate with their students and develop a

sense of community in the online environment. Administrators may also need to rethink how to evaluate instructors in the promotion and tenure process in order to acknowledge instructors who excel in the online environment and make that critical connection with their students.

Understanding the premises and concepts in this discussion will not only assist administrators and instructors in developing quality online courses and programs, but also provide an understanding of how online learning has resulted in an evolution of student and instructor roles. Successful students take on a more active and participative role and successful instructors take on a more facilitative and supportive role.

KEY TERMS

Academic Interaction: Occurs when learners study materials and get task-oriented feedback from the instructor (Moller, 1998; Moore, 1993).

Asynchronous Learning: Electronic communication in which the student and teacher interact via e-mail and listservs, but do not do so by being on the Internet at the same time (Berge, Collins, & Day, 1995).

Distance Education: "Any formal approach to learning in which a majority of the instruction occurs while educator and learner are at a distance from one another" (Clark, 1983, p. 8).

Distance Learning: Learning that occurs when the instructor and students are separated by physical distance and technology is used to bridge the instructional gap (Boaz, Elliott, Foshee, Hardy, Jarmon, & Olcott, 1999).

Online Learning/Course: A context for learning in which students interact using technology and do not meet in a physical classroom with the instructor.

Synchronous Learning: Adjective used to describe an operation performed at the same time as another event (Boaz et al., 1999).

Web-Based Instruction: A media-rich online environment allowing people to interact with others asynchronously or synchronously in collaborative and distributed environments (Harasim, 1995), to gain access to remote multimedia databases for active and resource-based learning (Jung & Leem, 1999), and to manage self-paced individual learning in a flexible way (Reeves & Reeves, 1997).

Organization of Home Video

Yu-Jin Zhang
Tsinghua University, Beijing, China

INTRODUCTION

With the progress of electronic equipments and computer technology for taking motion pictures and processing huge data, an increasing number of people now own and use camcorders to make home videos that capture their experiences and document their lives. Home video has no time limits and no restriction in content (Lienhart, 2000), so these videos easily add up to many hours of material. However, the organization and edition of the large amount of information contained in home videos present technical challenges due to the lack of efficient tools. Though a number of prototype systems for content-based video analysis and retrieval have been constructed, for example, as shown in (Wactlar, 1996; Chang, 1998), the development of tools and systems specialized for addressing home video, that is for extracting, representing, organizing, browsing, querying and retrieving video, is just on a preliminary stage (Huang, 2005; Wu, 2005).

Several tasks are needed to confront to make the organization of home video possible and feasible. Home video has certain particular characteristics. The organization of home video should be based on the understanding of video structures, and by taking advantages of this structure. Home video are completed and stored straight in compressed domain. In order to save both time and space, techniques that manipulate home videos directly in compressed domain should be considered (Wang, 2003). Some typical techniques working on compressed domain could be found in (Taskiran, 2004). Home video are made by shot after shot without storyline, these shots may or may not have immediate relationship. To group shots, the visual features should be extracted from every shot (Gatica-Perez, 2003)

Facing these tasks and difficulties, a novel technique is described in this article. It is based on the analysis of characteristics of home video, on the detection of motion attention regions in compressed domain, on the time weighting based on camera motion, and on a novel two-layer shot clustering approach and organization strategy. Experiments made on two home videos from MPEG-7 data set provide encouraging results.

BACKGROUND

Video analysis is an important branch of content-based video retrieval (CBVR). Compared to other types of video programs, home video has some particularities according to the persons in shoot and objects to be screened [Lienhart 1997]. The study on home video analysis may benefit from its unique characteristics.

In general, a typical home video has certain structure characteristics: it contains a set of scenes, each composed of ordered and temporally adjacent shots that can be organized in clusters conveying semantic meaning. The fact is that home video recording imposes temporal continuity. Unlike other video programs, home video just records the life but not composes story, so every shot (clip of video captured in one place without interruption) may have the equal importance. In addition, filming home video with a temporal back-and-forth structure is rare. For example, on a vacation trip, people do not usually visit the same site twice. In other words, the content tends to be localized in time. Consequently, discovering the scene structure above shot level plays a key role in home video analysis. Video content organization based on shot clustering provides an efficient way of semantic video accessing and fast video editing.

Home video is not prepared for very large audience (like broadcasting TV), but for relatives, guests and friends. To analyze home video, the purpose and filming tact should be considered. For example, the subjective feeling transferred by video information can be decomposed into two parts: one from motion region that attract the attention of viewers, another from the general impression of environment. In the same time, different types of camera motions should also be considered. Different camera motions may signify different changes of attentions. For example, zoom in makes the attention of viewers more on motion regions, while pan and tilt make the notice of viewers more on environments.

Home video may be made by different persons in different circumstances. How to reflect the viewers' visual perception during the filming needs to be considered. In fact, different viewer's attention will never stay equal all through the watching of home video. The importance of certain frames or clips should be weighted reasonably by their relative importance according to subjective perception. Sometimes, users are required to assign these weights to express their real preference (Chang, 1998; Babu, 2002). Other approaches include temporally making weights in key frame selection procedure by assuming that the greater number of skipped frames, the more weight is assigned to the current frame (Tan, 1999), or building up a generic user attention model by integrating a set of audio-visual attention model features extracted from video sequence (Ho, 2003).

MAIN FOCUS OF THE CHAPTER

Detection of Attention Regions

Structuring video needs the detection of motion attention regions. This is not equal to the detection of video objects. The detection of video objects requires accurately determination of the boundary of objects and quickly following of the change of objects. For example, an object-based approach first imposes spatial-temporal segmentation to get individual regions (Achanta, 2002). The video structuring stresses more on the subjective feeling of human beings in viewing video. In this regard, the influence of region detection on subjective feeling is more important than just accurate segmentation (Zhai, 2005).

It is know that most object detection methods would fail if there were no specific clear-shaped object in the background. In order to circumvent the problem of actual object segmentation, a different concept: "attention region" could be employed. An attention region does not necessarily correspond to a real object, but denotes the region with irregular movement compared to camera motion. Based on the assumption that different movement from the global motion attracts more attention (supported by the common sense that irregular motion tends to be easily caught by human eyes in a static or regular moving background), these regions are regarded as somewhat important areas in contrast to the background image. The detection of attention region requires less precision in general, since more emphasis has been placed on the degree of human attention than on the accurate object outline. This task could be simply completed by detecting the outliers in frame. In addition, the tracking process for attention region is easier, too.

The first step of attention region detection is to segment a "dominant region" from a single frame, which is illustrated in Figure 1. Figure 1(a) is a typical home video frame. This frame can be decomposed into two parts: the running boy on grassplot, as shown in Figure 1(b); and the background grasses and trees, as shown in Figure 1(c). The latter represents the environment and the former corresponds to the attention region.

The detection of attention regions does not require at very high precision. Therefore, the detection of attention regions can be performed directly in MPEG compressed domain. Two types of information in compressed domain can be used (Jiang, 2005):

DCT Coefficients of Macro Block

Among DCT coefficients, DC coefficient is easy to get. It is the directly obtainable component of image block, and its value equals to eight time of the average value in block. It roughly reflects the brightness and color information.

Motion Vectors of Macro Block

Motion vectors correspond to sparse and coarse motion field. They reflect approximately the general motion information in the block.

With the motion vectors, a simple but effective four-parameter global motion model can be used to estimate simplified camera motions (zoom, rotate, pan and tilt):

$$\begin{cases} u = h_1 x + h_2 y + h_3 \\ v = h_2 x + h_1 y + h_4 \end{cases} \quad (1)$$

A common least-square fitting algorithm is imposed to optimize the model parameters h_1, h_2, h_3, and h_4. This algorithm recursively examines the error produced by the current estimate of the camera parameters and generates an outlier mask, consisting of macro-blocks with motion vectors not following the camera motion model. Then, the camera parameters are re-computed and new outlier mask are formed. This process iterates until the parameters are stabilized. As it operates directly on MPEG video, motion

Figure 1. Illustration of attention region and environment

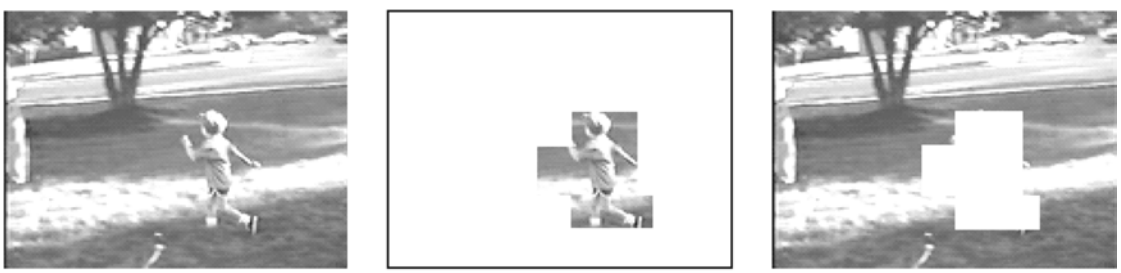

Figure 2. Detected attention regions

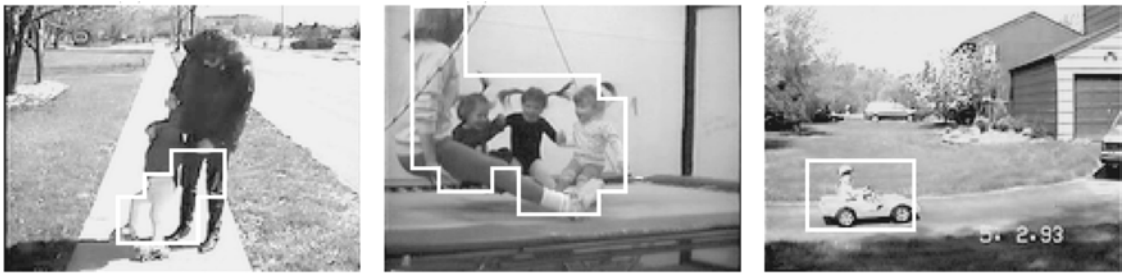


(a) (b) (c)

vector pre-processing has to be taken to get a dense motion vector field.

Some examples of attention regions detected are shown in Figure 2. All of them are macro-blocks characterized by different movement from global motion. Note that these regions are quite different from real objects. They could be a part of real object (kid's legs in Figure 2(a)) or several objects as a whole (woman and kids jumping on trampoline in Figure 2(b), kid and little car on the road in Figure 2(c)). Reasonably, one region drawing for viewer's attention is not necessary to be a complete accurate semantic object.

Time Weighted Model Based on Camera Motion

The detection of attention regions splits video content into two parts both spatially and temporally: attention regions and remnant regions. Two types of features can be used to represent the content of shot: one is the feature in attention regions, which emphasize the part attracting the audience; another is the features for other regions, which stress the global impression for the environment.

Color is often considered as the most salient visual feature that attracts viewer's attention, since the color appearance, rather than the duration, trajectory or area of region, is counted more in mind. Thus, an effective and inexpensive color representation in compressed domain - DC color histogram - is used to characterize each shot of video. In contrast to calculating an overall average color histogram, DC histograms of macro-blocks constituting both the attention regions and background are computed, respectively. The two types of histograms form a feature vector for each shot, which holds more information than a single histogram describing the global color distribution.

As each attention region and the background appears in several frames, the histograms along time can be accumulated to form a single histogram. Instead of the common average procedure, a camera motion based weighting strategy is used, giving different importance to histograms at different time. It is known that camera motion are always utilized to emphasize or neglect a certain objects or a segment of video, that is, to guide viewers' attentions. Actually, it can imagine a camera as a narrative eye. For example, a camera panning imitating an eye movement either to track an object or to examine a wider view of a scene, while a close-up of camera indicates the intensity of an impression. In order to reflect the different impression of viewers affected by camera movement, a camera attention model can be defined.

Camera movement controlled by photographer is useful for formulating viewer attention model. However, the parameters in the four-parameter global motion model do not represent the true camera move, scale and rotation angles. Thus, these parameters have to be first converted to real camera motion for attention modeling (Tan, 2000):

$$\begin{cases} S = h_1 + 1 \\ r = h_2 / (h_1 + 1) \\ L = \sqrt{p^2 + t^2} = \sqrt{h_3^2 + h_4^2} \,/ (h_1 + 1) \\ \theta = \arctan[t/p)] = -\arctan(h_4 / h_3) \end{cases} \quad (2)$$

where S indicates the inter frame camera zoom factor ($S > 1$, zoom in; $S < 1$, zoom out), r is the rotation factor about the lens axis, p and t are the camera pan and tilt factors, L is the magnitude of camera panning (horizontal and vertical) and θ is the angle.

The next step is mapping camera parameters to the effect they have on viewer's attention. Camera attention can be modeled with the help of the following assumptions (Ma, 2002):

(1) Zooming is always used to emphasize something. Zoom-in is used to emphasize the details, while zoom-out is used to emphasize an overview. The faster the zooming speed is, the more important the content focused is.

(2) Situations of camera panning and tilting should be divided into two types: Region-tracking (with attention region) and Surroundings-examining (without attention region). The former corresponds to the situation of a camera tracking a moving object, thus much attention is given to the attention region and little to the background. Camera motion of the latter situation tends to attract less attention since horizontal panning is often applied to neglect something (e.g. change for another view), if no attention region exists. The faster the panning speed is, the less important the content is. Additionally, unless a video producer wants to emphasize something, vertical panning is not used since it brings viewer's unstable feeling.

(3) If the camera pans / tilts too frequently or too slightly, it is considered as random or unstable motion. In this case, the attention is determined only by zoom factor.

In frames with attention region, viewer's attention is supposed to be split into two parts, represented by weight of background W_{BG} and weight of attention region W_{AR}.

$$W_{BG} = 1 / W_{AR} \tag{3}$$

$$W_{AR} = \begin{cases} S & L < L_0 \\ S(1 + L / R_L) & L \geq L_0 \end{cases} \tag{4}$$

where W_{AR} is proportional to S and enhanced by panning, L_0 is the minimal camera pan (panning magnitude less than L_0 is regarded as random), R_L is a factor controlling the panning power to affect attention degree. In this model, a value that is bigger than 1 means emphasis and a value that is smaller than 1 means neglect.

In frames without attention region, only background attention weight W_{BG} is computed.

$$W_{BG} = \begin{cases} S & L < L_0 \\ S /(1 + f(\theta) L / R_L) & L \geq L_0, \quad \theta < \pi/4 \\ S(1 + f(\theta) L / R_L) & L \geq L_0, \quad \theta \geq \pi/4 \end{cases} \tag{5}$$

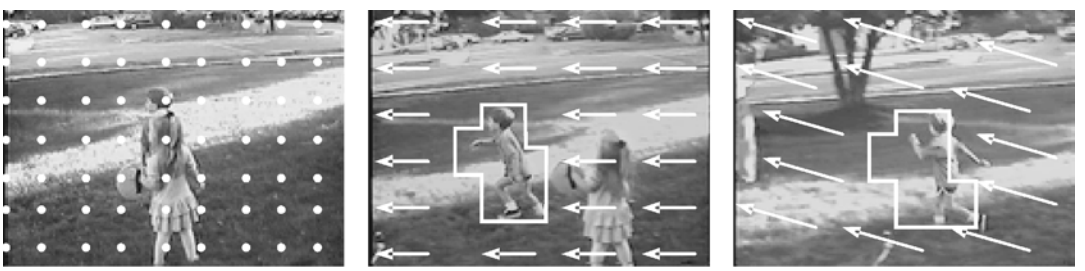
The attention degree decreases in situation of horizontal panning ($\theta < \pi/4$) and increases in situation of vertical panning ($\theta \geq \pi/4$). Function $f(\theta)$ is a function representing the effect of panning angle on decrease or increase rate. It becomes smaller while the panning angle gets nearer to $\pi/4$ because panning in this diagonal direction tends to have little effect on attention.

Figure 3 shows some examples of time-weighted modeling based on camera motion. Figures 3 (a), (b), and(c) are three frames extracted from the same shot of kids playing on lawn. Although they share a similar background, the background attention weight W_{BG} differs in the attention model according to different camera motions of the three frames. Figure 3(a) is almost stationary (without attention region), with attention just determined by zoom factor. Figure 3(b) is panning left tracking a running kid (with an attention region), thus it has less weight on background than on the attention region. Figure 3(c) shows also the region tracking but has a higher panning speed than that of Figure 3(b), thus it has an even smaller background weight. It is observed in Figure 3 that visual contents are spatially split into two attention parts, while temporally weighted by camera motion parameters.

Strategy for Shot Organization

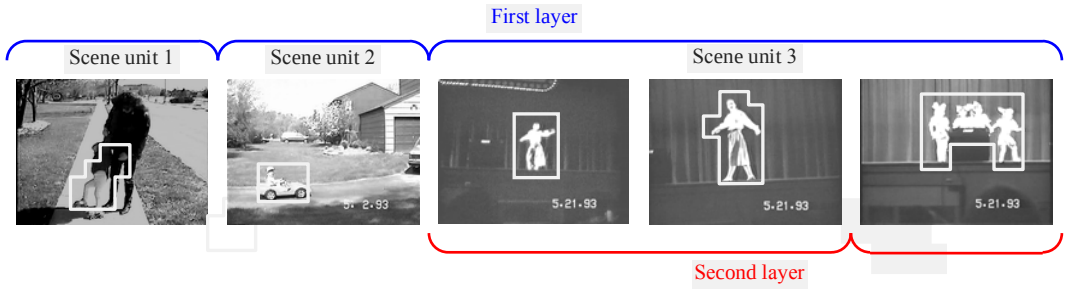
Using shot features and weights obtained above, a feature vector for each shot is composed. The visual similarity between two shots is then computed. In particular, similarities of background and of attention regions are computed separately, for example, by using the normalized histogram

Figure 3. Time weighted modeling based on camera motion



(a) (b) (c)

Figure 4. Two layer clustering of shots



intersection. Based on the similarity among shots, similar shots can be grouped. A two-layer shot organization strategy can be used. In the first layer, scene transition is detected. The place where both attention region and environment change gradually indicates the change of location and scenario. In the second layer, either attention regions or environment is changed (not both). This change can be the change of focus (different moving object in same environment) or the change of object position (same moving object in different environment). The change in the second layer is also called change of sub-scene.

One example of two-layer shot organization is shown in Figure 4. Five frames are extracted from five consecutive shots. White sashes mark detected attention regions. The first layer of organization clusters the five shots into three scene units, which are different both in attention regions and in environments. The last three shots in scene unit 3 of first layer can be further analyzed. The third and fourth shots in Figure 4 can be clustered together, which have similar background and similar attention regions; while the fifth shot has different attention region from the third and fourth shots. In short, the first layer clusters shots with the semantic event, while the second layer distinguishes different moving objects.

FUTURE TRENDS

Further researches are needed in organization of home videos as it is still in a preliminary stage

(1) To make the moving-object detection more robust (Pan, 2007).
(2) To extract visual features in multiple attention regions.
(3) To also make use of other media information, especially audio ones.

CONCLUSION

In this chapter, the organization of home video is discussed. Some concluding points are:

(1) Discovering the scene structure above shot level plays a key role in home video analysis.
(2) Assuming that viewer's attention is spatially divided into two parts: one for a dominant region in the frame that attracts most attention, the other for the rest background that expresses an overall impression, two metrics of shot similarity are developed for grouping shots.
(3) The detection of motion attention regions and the treating of attention regions and other remaining regions separately are important.
(4) The process taken directly in the compressed domain reduced the computational complexity.
(5) Considering a scene as a collection of semantically related and temporally adjacent shots, a high-level concept or story can be depicted and conveyed.

KEY TERMS

Content-Based Image Retrieval (CBIR): A process framework for efficiently retrieving images from a collection by similarity. The retrieval relies on extracting the appropriate characteristic quantities describing the desired contents of images. In addition, suitable querying, matching, indexing and searching techniques are required.

Content-Based Video Retrieval (CBVR): A process framework for efficiently retrieving required clip from video. The retrieval relies on the organization of video and non-linear search techniques.

Content-Based Visual Information Retrieval (CBVIR): A combination of CBIR and CBVR.

Image Engineering: An integrated discipline/subject comprising the study of all the different branches of image and video techniques.

MPEG-7: An international standard named "Multimedia content description interface" (ISO/IEC 15938). It provides a set of audiovisual description tools, descriptors and description schemes for effective and efficient access (search, filtering and browsing) to multimedia content.

Object Segmentation: A process of image analysis. Its purpose is to extract the interesting region from image (corresponding to the interesting objects in scene).

Pan: One type of camera motion forms in capturing the scene image. It consists of the movement of camera around the vertical axis in the imaging plan.

Scene: In video analysis, it is composed of a series of consecutive shots that are coherent from the narrative point of view.

Tilt: One type of camera motion forms in capturing the scene image. It consists of the movement of camera around the horizontal axis in the imaging plan.

Organizational Aspects of Cyberloafing

Elisa Bortolani

Giuseppe Favretto
University of Verona, Italy

INTRODUCTION

The introduction of new technologies at workplaces causes the emergence of new organizational productivity threats. These threats are both inside and outside the organizations themselves. More often, organizations regret[1] programming and administrative errors; system and technical failures; sabotages; unauthorized accesses; disruption, manipulation, or loss of data and programs, not due to cyber-criminality (intrusions, employees' disloyalty, etc.); widespread virus; and issues caused by wireless devices. External threats, on the other hand, are more related to natural catastrophes (flooding, earthquakes, etc.), fires, industrial espionage, cyber-criminality, viruses, unfair competition, and physical damages to structures.

It is necessary for organizations to protect themselves from both intrusion attempts and employees' technology misuse. A United States survey[2] revealed that 35% of companies interviewed about suffered attacks in 2004 said that the prevalence was from insiders; on the other hand, only 26% revealed a prevalence of outsider attacks. Compared to the previous year, the trend was inverted. In 2003, in fact, insider attacks were around 14% and outsider attacks were about 23%. This, it is possible to think that insider threats will become more and more frequent and dangerous.

According to Radcliff (2004), internal data thefts are estimated to be 75% of total data thefts. An employee, for example, can copy and misappropriate a customer's database before passing it to the competitors. Another possible scenario is referred to as waste of efficiency caused by business e-mail abuse or Internet access misuse.

The FBI's Computer Crime Squad affirms that it is not necessary to blame corrupt or vindictive employees for all intrusion issues. Many problems, in fact, can be traced back to an improper use of IT business resources. Actually, for example, many companies that had put up with employees surfing the Internet for non-work-related activities for years now regretted Internet misuse, characterized by pornography, mp3, and illegal software downloading.

More than this, illicit software downloading and surfing insecure sites allow virus and malware introduction. This software, if installed on strategic machines, can make the company vulnerable. And so, costs are not limited to loss of business resources (e.g., working time), but are also related to damages caused by illicit and careless online employees' activities.

If, on one hand, the opportunity to work online helps in increasing several organizations' productivity (Anandarajan, Simmers, & Igbaria, 2000), on the other hand it causes an addition in number and level of risks. So, a lot of Internet access issues are related to information download (copyrighted software, offensive material, infected files, etc.), but the loss of productivity related to this habit does not seem secondary. In other words, without leaving their desks and without social control risk, the employees may, more easily than in the past, give themselves up to surfing the Net for non-work-related purposes.

Some years ago, a U.S. survey affirmed that 30-40% of daily business Internet traffic was attributed to surfing the Net for personal purposes.[3] In another research, carried out in 2001,[4] 51% of Italian employees affirmed access to non-work-related sites — more than English (44%), German (41%), and French (29%). And finally, another U.S. survey[5] shows that the average time spent online by respondents who admitted to using the Internet for personal purposes (58%) is about three-and-a-half hours per week.

Despite many people already having Internet access at home, about half of all online shopping and 70% of the global pornographic traffic[6] are registered during working time.[7] The favorite activities for surfing the Net are: holiday booking (52%), culture (42%), hobbies (41%), shopping (28%), sports (30%), and job searching.

The average user spends about two hours per day online, and 31% is for non-work-related surfing.[8] Seventy percent of employees admit either visiting "for adult" sites or sending personal e-mails during work time, 64% also send offensive or politically incorrect messages, and 57% admit surfing online decreases their own productivity.

A survey conducted in 2004[9] reports that of 3,245 respondents belonging to 750 employers, 40% answered to spending 40% of his or her working time cyberloafing, with an increase of one hour per day in the last year.

Organizational expenses in loss of productivity are estimated at billions of dollars per year (Greengard, 2000; Gordon, Loeb, Lucyshyn, & Richardson, 2005). After all, as evidenced by IDC Research (2000), U.S. and European Internet users seem to spend more time online when they are at work than when they are at home. This is probably due

to two characteristics of the workplace: perceived privacy and higher speed to link.

This new form of productive deviance, defined by Lim (2002) as *cyberloafing*, consists of business Net access during working time to surf for personal ends and/or to manage personal e-mails.

Siau, Nah, and Teng (2002) identify 11 categories of Internet abuses: general e-mail abuses, unauthorized usage and access, copyright infringement/plagiarism, newsgroup postings, transmission of confidential data, pornography, hacking, non-work-related download/upload, leisure use of the Internet, usage of external ISPs, and e-moonlighting (side jobs).

Especially, focusing on e-mails, Whitty and Carr (2006) affirm that cyberloafing is not always an intentional choice but sometimes is induced by other people. Ninety percent of their respondents, in fact, perceive chain e-mail, sent by friends or known people in any case, as more unpleasant than e-mail spam, and 17% perceive joke e-mails as objectionable. The modality to manage e-mails is increasingly an emerging issue and requires new and socially shared rules.

BACKGROUND

Lim (2002) categorizes cyberloafing as productive deviance (see Robinson & Bennett, 1995) but, for its consequences, it may also be included in:

- Property deviance (Hollinger & Clark, 1983);
- personal aggression (psychological harassment, e.g., sexual or racist e-mails); and
- political deviance, defined as the use of incorrect means to put someone at a political disadvantage in comparison with someone else (see Robinson & Bennett, 1995).

Mastrangelo (2002) suggests three dimensions below a counterproductive computer use. Each of them corresponds to the necessity of:

a. Social linking (personal e-mail, instant messaging, chat);
b. doing an errand; or
c. indecent behavior.

Lim (2002) proposes a cyberloafing explanation model starting from considerations about treatment equity (see Adams, 1965; Foa & Foa, 1976) and distributive justice (Deutsch, 1985; Skarlicki & Folger, 1997) in the organizations. She identifies in neutralization (Sykes & Matza, 1957) the theory construct to explain cyberloafing. Neutralization, in her opinion, is the individual attempt to rationalize a situation to convince himself and the others to be right and that deviant behavior is understandable. This mechanism of rationalization aims at building and preserving one's image.

Through neutralization, deviant behavior does not appear as a revenge to the employee. This feeling, in fact not acceptable for the person, is mediated from a rational explanation. After all, cyberloafing becomes a way to reestablish a trade-off in the person-organization relationship. Loss of equity (in terms of economic, relational, or symbolic treatment) is restored through a cyberloafing behaviour, so the individual feels rewarded for the time and energy he or she spent for the company that was not recognized.

Anandarajan et al. (2000), instead, describe both organizational and personal factors involved in Internet misused at work. They applied Fishbein and Ajzen's (1975) Theory of Reasoned Action (TRA) to Internet use at work. The authors affirm that the use of the Net is influenced by perceptions, personal attitudes, and social influences. TRA is extended by authors to the Technology Acceptance Model (TAM), which focuses on information technologies' perceived usefulness. In TAM, the factors that motivate a person to use a computer could be categorized into two groups: extrinsic motivators (perceived advantages, social pressure, etc.) and intrinsic motivators (playfulness, distraction, etc.). The proposed model shows four kinds of multidimensional variables. Research outcomes refer a more frequent, easier access and more time spent online by men than by women. Moreover, the ability to use the Internet and the Web are related to improvement in job characteristic perception (significance, autonomy, heterogeneity, job control, etc.). Playfulness can lead to perception of job characteristics improvement, more job satisfaction, and more global productivity. Actually playfulness, is a double-edged weapon; in fact, it can lead easily to Internet misuse with negative consequences in terms of increasing loss of time, necessity of redoing work because of a loss of accuracy, and a longer period of time in order to complete a task. These factors contribute to ineffectiveness and loss of productivity. On the other hand, social pressure and organizational support are associated to a kind of intimidation, which implies a lower use of the Internet. It suggests that management's commitment and support in the use of the Net can reduce the abuse. In addition, employees with high-structured tasks are less involved in improper use of the Internet at their workplace. The same result has emerged for people who have a low task variability. These considerations imply that employees with less structured tasks have a higher use of the Internet for personal scopes.

Henle and Blanchard (2005) suppose that, at first, employee cyberloafing is a modality of stress coping and that they do it only if the perception of sanctions by the organization is low. In fact, cyberloafing increases when there are no sanctions, but contrary to their initial expectations, it increases when workload is low.

It is interesting to quote the research of Lara, Tacoronte, and Din (2006). Their study shows that the variable leader

physical proximity (LPP) is an antecedent positively associated to fear of formal punishment (FFP) and perceived organizational control (POC). This last factor decreases cyberloafing, whereas Fear of Formal Punishment increases it. Fear of Formal Punishment and Perceived Organizational Control moreover mediate the relationship between Leader Physical Proximity and cyberloafing.

So, is employee monitoring a solution? Nowadays, solutions to cyberloafing are mainly based on monitoring of employee surfing and on filtering Web sites considered to be inappropriate. Chalykoff and Kochan (1989) showed that satisfaction of employees with computer-aided monitoring has a strong impact on job satisfaction. Recently, moreover, research revealed that employees perceive monitoring software as invasive, and this decreases their job satisfaction (Stanton & Weiss, 2000). With regard to this, Urbaczewski and Jessup (2000) affirm that subjective motivation has an important role both in productivity and in performance quality, and in monitoring satisfaction. Employees, in fact, accepted monitoring when it was used to give a feedback about their job quality; when, on the contrary, monitoring was used as a way of control, as in Web monitoring, the impact on organizational climate was negative.

Davis, Flett, and Besser (2002) affirm that an alternative way to cope with cyberloafing is to prevent the phenomenon, not to apply sanctions. So, authors suggest that attention be paid to some individual characteristics during the selection process.[10] For example, Wyatt and Phillips (2005), contrarily to expectations and previous literature, found that extraverted[11] people used and abused the Internet in the workplace as a means of socializing and developing relationships, and moreover that disagreeable people spent more time on the Internet than agreeable[12] people.

Contextually many companies are attempting to solve the problem by internal policies that clarify in detail permitted, tolerated, forbidden, and sanctioned behaviors. Often, in fact, the employee does not perceive the real risks to which he or she exposes his or her company by surfing the Web.

The flexibility favored by the new communication and information technologies imposes to give strong responsibilities to human resources in terms of autonomy and control on their own job, and this is possible only if appropriate employee training is provided. Although there are many discordant opinions about policies' preventive usefulness (Young & Case, 2004),[13] we think it is necessary to make employees responsible for an awareness use of technologies. These policies, if they include clear behavioral rules, may be a good first step to helping employees build a cognitive map to make head of their company. The lack of clearness about the existence of a specific managerial way to administer Web surfing and e-mail, in fact, can become a large organizational cost both in terms of dissatisfaction and distress (with the subsequent turnover, absenteeism, etc.; see Favretto, 1994).

It is interesting to report an important result of Whitty's (2004) study: 19% of her sample (N=524) ignored if their company had a policy, and 17% did not know if the Web sites were filtered. Other relevant data is that 19% of the respondents state that they do not have a policy, according to 17% of Greenfield and Davis's (2002) research. In reality, our research (Bortolani, 2005), conducted in Italy (N=190), shows that 25% of the respondents affirm that their companies do not have any forms of monitoring, and 31% state that they do not know if any type of monitoring exists. So, a good policy, shared with all employees (and if possible, different according to the various professional families), can give at least the awareness about this issue and, contextually, give the right to the company to contest the debit to the defaulting employee.

FUTURE TRENDS

In the future, it would be interesting to study in depth personality characteristics as well as organizational factors that favor cyberloafing. Moreover it could be interesting to investigate what kind of professional figures, what kind of workplaces, and what moments of the working day are more exposed to this activity. If cyberloafing, as shown in Henle and Blanchard (2005) and Bortolani (2006) surveys, reveals itself as an expression of employment unease (boredom and monotony, distress and social and physic isolation), it would be useful to remove favoring conditions through *job redesign* techniques. This process allows the change of tasks perceived as poor, boring, and deprived of meaning by employees. In addition, we report another consideration: in Bortolani's (2006) study the variable *loneliness/physic and social isolation* and the variable *mistrust organization and perception of unfair treatment* are more often chosen by public sector employees than by private sector employees.

CONCLUSION

The article analyzes cyberloafing (also known as cyberslacking or cyberbludging), a new kind of productive deviance in organizations. The phenomenon concerns Internet misuse at work, surfing the Net, sending personal e-mails, and other non-work-related activities during work time. Loss of productivity, damage to the organization's image, and lawsuit problems are some of the cyberloafing-related issues.

Managerial actions are necessary in order to lead human resources to the phenomenon containment. Potentially, all employees that have a computer linked to the Internet can easily engage themselves in cyberloafing activities. Research, carried out in a manufacturing industry (LaPlante, 1997) with 400 employees, pointed out that in a typical workday (eight hours), more than 250,000 Web sites are visited, 90%

of which are non-work-related. If, on one hand, it is very difficult to estimate the real entity of the phenomenon, on the other it is interesting to understand the meaning that employees assign to this activity.

Bortolani (2006), for example, found that younger employees spend more time cyberloafing (more than five hours per week) than older employees (less than one hour per week), and they affirm to do it when they are distressed and frustrated for personal reasons (not due to the work environment). Moreover, younger employees (less than 30 years old) state that cyberloafing increases perceptions of both job productivity and job satisfaction (this last data according to Anandarajan et al., 2000; Mastrangelo, 2002). Despite that we are talking about perceptions, we think this is useful information to plan actions more aimed at this definite target (e.g., during work socialization).

KEY TERMS

Cyberloafing: The activity of surfing the Net, sending and reading e-mails in the workplace for personal ends during working time. Also called *cyberslacking* or *cyberbludging.*

Job Satisfaction: The pleasure feeling derived from one's own job and from the fact that the job meets some personal needs.

Job Redesign: Process that aims to reorganize the elements of work to enrich the job and to allow an employee to best match with the job.

Monitoring Software: Software used by employers to record computer activities of their employees; examples include e-mail, chat, instant messaging, and visited Web sites.

Netiquette: A set of non-written behavioral rules developed by the Internet community to facilitate social interactions and avoid reproaches.

Policy: A set of behavioral and procedural written rules that a company drafts as guidelines for its employees.

Social Control: Mechanism, present in all societies, that regulates individual behavior to lead to conformity with social rules. This mechanism — including the influence of family, moral values, beliefs, and so forth — aims to guarantee social order.

Theory of Reasoned Action (TRA): Model theorized by Fishbein and Ajzen (1975) that says human behavior springs from intensions and that these intensions are shaped by positive or negative attitudes towards something. This theory focuses on three components: individual attitude, reference group influence, and subjective propensity to allow that external influences may affect one's own choices.

10 Online Cognitive Scale (OCS), for example, is a questionnaire that aims at surveying a possible problematic relationship with technology, studying the most used Internet applications. Young (1998), in fact, affirms that Internet Addiction Disorder reveals in the preference for interactive applications that provide synchronous communication (e.g., chat lines, instant messaging), rather than applications that provide asynchronous communication (e.g., e-mail, newsgroups).

11 Extraversion concerns traits of warmth, gregariousness, assertiveness, activity, excitement-seeking, and positive emotions (Anastasi & Urbina, 1997).

12 Agreeableness concerns trust, altruism, compliance, and modesty (Anastasi & Urbina, 1997).

[13] Young and Case (2004) realized that only 40% of human resources managers respondent to an online survey believed that their policies were effective.

Organizational Assimilation Capacity and IT Business Value

Vincenzo Morabito
Bocconi University, Italy

Gianluigi Viscusi
University of Milano, Italy

INTRODUCTION

IT business value represents important outcomes in firms (Banker & Kauffman, 2004; Gable, Darshana, & Chan, 2003; Ravichandran & Chalermsak Lertwongsatien, 2005) whereas information systems (IS) integration represents a relevant amount of the IT spending. Notwithstanding, while most firms are making major investments in information technology, particularly in information systems integration (e.g., ERP and data warehouse solutions), not all of them apply IT effectively in their business activities (Brynjolfsson, McAfee, Zhu, & Sorell, 2006; Dehning & Stratopoulos, 2003; Jason, Vijay, & Kenneth, 2003) obtaining IT business value and organizational competitive advantage.

This research is based on an integrative model of IT business value, aiming to evaluate the mediating effect of an "IT organizational assimilation capacity" between IS integration and organization competitive advantage. Taking into account the theoretical premises that IT business value is generated by the exploitation of both IT and organizational resources, we develop a research model and propose two research hypotheses.

The model and the related hypotheses are based on a large-scale sample survey (Francalanci & Morabito, 2006). The responses were obtained from 466 CIOs and senior business executives, who were members of the firms' top management teams in Italian companies.

BACKGROUND

The term IT business value is commonly used to refer to the organizational performance impacts of IT resources at both the intermediate process level and the organization-wide level, comprising both efficiency and competitive impacts (Melville & Kraemer, 2004). In fact, IT resources generate business value when they are "assimilated" as a routinized element of firms' value-chain activities and business strategies (Aral, Brynjolfsson, & Wu, 2006).

Researchers have employed several theoretical paradigms in examining the organizational performance impacts of IT, including microeconomics (Brynjolfsson & Hitt, 2003; Tanriverdi, 2005; Wade & Hulland, 2004), industrial organization theory (Belleflamme, 2001; Mahnke, Overby, & Vang, 2005), sociology and socio-political paradigms (Chatfield & Yetton, 2000; Devaraj & Kohli, 2003; Hatami, Galliers, & Huang, 2003) and, finally, strategic perspective (Bharadwaj, 2000; Caldeira & Ward, 2003).

Analyzing this stream of studies by focusing on the "focal firm", we can summarize that if the right IT is applied and assimilated within the right business process, the IT application improves processes and organizational performance/competitiveness, conditional upon appropriate investments in complementary organizational resources. In particular, the competitive environment, including industry characteristics and trading partners, as well as the macro environment are relevant to IT business value generation (Melville et al., 2004). Our research is focused at firm level, where IT business value is generated by the deployment of IT resources (including both technology IT resources and human IT resources) through a process that involves the deployment of complementary organizational resources within business processes. Referring to technological IT resources, there are studies that aggregate diverse technological IT resources into a single measure, and studies that examine specific information systems and types of IT.

In the first case, scholars use large-sample data sets, finding support for a positive association between aggregate measures of the technological IT resource and organizational performance (Bharadwaj, 2000; Kohli & Devaraj, 2003). The idea that the technological IT resource confers economic value is preserved when considering alternative econometric specifications, assumptions, data sets, and time frames (Aral et al., 2006). Early evidence indicates both a positive impact (Brown et al., 2000) and no association between technological information resources (TIR) and sustainable performance advantages (Powell & DentMicallef, 1997). Whereas others point out the relevance of managerial IT

skills and culture in order to confer a competitive advantage (Hafeez, Zhang, & Malak, 2002; Mata, Fuerst, & Barney, 1995; Zahra, Hayton, & Salvato, 2004).

Considering the second research approach introduced earlier, scholars have examined specific information systems and types of IT. Several studies find a positive impact on cost reduction, for example, in the context of a production data management system in the clothing industry (Tatsiopoulos, Ponis, Hadzillias, & Panayiotou, 2002), and supply chain management in the food industry (Hill & Scudder, 2002). Enterprise resource planning systems are associated with higher financial market valuation, although short-term effectiveness is reduced after implementation (Hitt & Wu, 2002).

Focusing on organizational performance, the firm's absorptive capacity (Cohen et al., 1990) plays a strategic role, exploiting IT business value by transforming into performance the IT-driven change of the organization, and mediating the assimilation of new external knowledge (Malhotra, Gosain, & El Sawy, 2005; Zahra & George, 2002). In this context, there are studies that assess the degree to which complementary organizational resources mediate organizational performance/competitive advantage impacts, and studies that analyze the highly contextual value generation process.

In the first category, mainly by using quantitative empirical methods applied to large samples of firms, the findings confirm that firms must not only customize technological systems and deploy and maintain them, but also must manage teams of IT and non-IT resources, together generating greater value than they do alone (Brynjolfsson & Hitt, 2000). Non-IT resources include organizational practices and structures that complement the functions of information systems. Empirical analyses discover decentralization of decision authority in firms with higher levels of IT, these firms having disproportionately higher market valuations (Brynjolfsson, Hitt, & Yang, 2002). Another set of organizational resources that may be complementary to IT are firm characteristics, such as worker composition, size, financial condition, and culture. Francalanci and Galal (1998) find that IT business value, as measured by productivity, differs according to employee category: firms with higher IT investment that have also decreased their clerical and professional ranks have higher productivity.

Focusing on the second category of studies introduced previously, the well known example from Clemons and Row (1988) documents IT-enabled efficiencies at McKesson, where customers benefit from rationalizing operations in preparation for the new order entry and distribution system adopted by McKesson. Other case and field studies examine, for example, package delivery (Williams & Frolick, 2001). The co-introduction of IT and complementary organizational changes may not result in immediate success, due to adjustment costs, learning, and other factors (Melville et al., 2004).

In summary, empirical evidence supports the claim that the technological IT resource (TIR) has economic value (Kohli et al., 2003), and that complementary organizational resources interact with IT in the processes of IT assimilation value generation.

Taking these findings into account, *we propose that competitive advantage can result from a specific information systems characteristic* (also realized by mixing different technological IT resources, i.e., ERP and EAI as in our case) *that is, in our case, the "information systems integration"*. But how "IS integration" improves organizational performance? In line with this question, we propose that "IS integration" effect is mediated by a specific complementary organizational resource: the "IT organizational assimilation capacity".

ORGANIZATIONAL ASSIMILATION CAPACITY AND IT BUSINESS VALUE

Based on theoretical proposition that IT business value is generated by the deployment of IT and complementary organizational resources, we develop a research model and propose two hypotheses. In particular, taking into account the role of firm's absorptive capacity (Cohen et al., 1990; Malhotra et al., 2005; Zahra et al., 2002), we propose that the IS integration business value is generated by the mediating effect of the IT organizational assimilation capacity. Although it is possible to apply IT for improved organizational performance with few organizational changes (McAfee, 2002), the IT business value is often generated by the deployment of IT and complementary organizational resources within business processes (Melville et al., 2004). In addition, firm-specific organizational resources tend to be tacit and deeply embedded in the organization's social fabric and history; what is not understood is what specific resources qualify the complementary effect, under what conditions, and how are the attributes of complementary resources related to business process and organizational performance impacts. Due to these issues, we propose a multi-variables concept defined "IT organizational assimilation capacity". We introduce four distinct groups of constructs that represent the elements of an IT organizational assimilation capacity: *training* (or *knowledge*) *orientation*, *change orientation*, *flexibility orientation* and *process orientation*. Further, we point out that the presence of IT organizational assimilation capacity largely influences how well the organization assimilates the business potential of IT, that is, in our case, the "information system integration". This "assimilation capacity" includes devising new IT-ways in which knowledge is distributed and accessed throughout the organization, tasks are accomplished, and so forth. As a result, IT organizational assimilation capacity may amplify or enhance the organizational effects of IT in general and information system integration in particular. Indeed, we propose that:

Hypothesis 1: *Stronger IT organizational assimilation capacity leads to a higher level of firm competitiveness.*

In particular, we argue that IT organizational assimilation capacity mediates the effect of information system integration on firm competitive advantage. Information systems integration implies that all functional information systems exchange data each others and that functional activities are interrelated and should be handled together. This "system integration" should be coupled with an "organizational integration". In particular, the achievement of an information system integration needs to be "assimilated" by the organization. In order to realize an effective information system integration, firms should work by process, be open to changes required by the integration, have skilled workers, and be flexible in its operations. Thus, we propose that:

Hypothesis 2: *Stronger information systems integration leads to a higher level IT organizational assimilation capacity.*

To fully account for the differences among organizations, we include *organization size* as control variable. We use the number of employees as measure of organization size. Organization size is an important control variable for another reason. IT/IS vendors and systems integrator could have to define different implementation programs in larger client or SME ones. IT organizational assimilation capacity (ITACP) refers to the firm's ability to identify, assimilate, and exploit the business potential from IT/IS solutions or IT/IS characteristics, in our case, the information system integration. The IT organizational assimilation capacity is a strategically valuable capability because it is path dependent, firm-specific, and socially embedded. It lowers the transaction costs of adopting and using IT/IS solutions, and its focus is on the individual firms' internal capabilities.

To capture the readiness of the organization towards assimilating IT/IS solutions or characteristics, we have identified four distinct groups of dimensions that represent the elements of the IT organizational assimilation capacity*: training (or knowledge) orientation*, *change orientation*, *flexibility orientation,* and *process orientation*. These dimensions should serve as the bases upon which organizations can be differentiated in their ability to identify (training orientation), assimilate (change orientation and process orientation), and exploit (flexibility, process and change orientation) IS integration.

Focusing on sustainable competitive advantage (SCA), the actual term emerged in 1985, when Porter discussed the basic types of competitive strategies firms can possess (low-cost or differentiation) to achieve SCA. However, no formal conceptual definition was presented by Porter in his discussion. Further, Barney (1991) offers the following definition: "A firm is said to have a sustained competitive advantage when it is implementing a value creating strategy not simultaneously being implemented by any current or potential competitors and when these other firms are unable to duplicate the benefits of this strategy". Taking these definitions into account, we define SCA as the prolonged benefit of implementing some unique value-creating strategy not simultaneously being implemented by any current or potential competitors along with the inability to duplicate the benefits of this strategy (in our case, implementing an information system integration). Concentrating on "prolonged benefit" we refer to superior organizational performances that, in our study, are designed as four items scale. Three items are referred to as a subjective measure of financial and economic performance over the previous 3-year period; one item is referred to as subjective perception of future sustainability of organization superior performances themselves.

In using subjective performance measures, given the senior executives involved (Francalanci et al., 2006), we assumed that respondents had sufficient perspective and information to assess their firms' performances relative to competitors. Subjective measures have been widely used in organizational research (Dess, 1987; Powell et al., 1997), and are often preferred to economic and financial statement data, since firms may adopt varying accounting conventions in areas such as inventory valuation, depreciation, and officers' salaries.

FUTURE TRENDS

Future research should test alternative measures of assimilation capacity by focusing on key business processes or units. We also acknowledge that the relationship between IS Integration, assimilation capacity, and competitive advantage may unfold through cyclical causal relationships. For example, a high competitive advantage may facilitate further developments of assimilation capacity and IS integration. Future trends must address these cycles of causal relationships.

CONCLUSION

Our thesis is that IS integration generates an organizational competitive advantage through the mediation effect the "IT organizational assimilation capacity". This capacity encompasses four distinct groups of dimensions: training (or knowledge) orientation, change orientation, flexibility orientation, and process orientation. These dimensions should serve as the basis upon which organizations can be differentiated in their ability to obtain a competitive advantage from investing in IS integration. Further, our data suggest that information system integration investments do not merge themselves automatically with others' organization resources, but they require what we define as "IT organizational assimilation capacity". From a theoretical point of view, this study contributes theory-based conceptual synthesis and empirical evidence to an IT literature still dominated by anecdotes and consultants' IT implementation models. Finally, we can sustain that "organization matters" in generating IT business value from IT/IS investments

KEY TERMS

Absorptive Capacity: Absorptive capacity is defined as the firm's ability to identify, assimilate, and exploit external knowledge to commercial ends (Cohen & Levinthal, 1990); upon a resource-based view perspective, absorptive capacity represents the ability of a company to translate a change in a combination of input resources into organizational performance (Malhotra et al., 2005; Zahra et al., 2002).

Business Process: A business process is the specific ordering of work activities across time and space, with a beginning, an end, and clearly identified inputs and outputs (Davenport, 1993).

IS Integration: IS integration is defined as the outcome of initiatives leading to greater technical standardization and broader user access to a common set of technical resources, infrastructure, data, or software applications (Hasselbring, 2000; Jhingran, Mattos, & Pirahesh, 2002).

IT Business Value: IT business value is the organizational performance impacts of information technology at both the intermediate process level and the organization wide level, and comprising both efficiency impacts and competitive impacts (Melville et al., 2004).

Organizational Performance: Organizational performance denotes IT-enabled overall firm performance, including productivity, efficiency, profitability, market value, and competitive advantage (Melville et al., 2004).

Sustainable Competitive Advantage: A firm is said to have a sustained competitive advantage when it is implementing a value creating strategy not simultaneously being implemented by any current or potential competitors and when these other firms are unable to duplicate the benefits of this strategy (Barney, 1991).

Technological IT Resource (TIR): TIR can include both hardware and software, and can be categorized into IT infrastructure, and business applications using the infrastructure (Melville et al., 2004)

Organizational Hypermedia Document Management Through Metadata

Woojong Suh
Inha University, Korea

Garp Choong Kim
Inha University, Korea

INTRODUCTION

Web business systems, the most popular application of hypermedia, typically include a lot of hypermedia documents (hyperdocuments), which are also called Web pages. These systems have been conceived as an essential instrument in obtaining various beneficial opportunities for CRM (customer relationship management), SCM (supply chain management), e-banking or e-stock trading, and so forth (Turban et al., 2004). Most companies have made a continuous effort to build such systems. As a result, today the hyperdocuments in the organizations are growing explosively.

The hyperdocuments employed for business tasks in the Web business systems may be referred to as organizational hyperdocuments (OHDs). The OHDs typically play a critical role in business, including the forms of invoices, checks, orders, and so forth. The organization's ability to adapt the OHDs rapidly to ever-changing business requirements may impact on business performance. However, the maintenance of the OHDs increasing continuously is becoming a burdensome task to many organizations; managing them is as important to economic success as is software maintenance (Brereton et al., 1998).

An approach to solve the challenge of managing OHDs is to use metadata. Metadata are generally known as data about data (or information about information). Concerning this approach, this article first reviews the previous studies and discusses perspectives desirable to manage the OHSs and then provides metadata classification and elements. Finally, this article discusses future trends and makes a conclusion.

BACKGROUND

The hyperdocument is a special type of digital document based on the interlinking of nodes such as multimedia components and sets of data elements derived from databases. For digital document, metadata have typically been employed for the access to media- and application-specific documents, such as for information discovery (Anderson & Stonebraker, 1994; Glavitsch et al., 1994; Hunter & Armstrong, 1999). Also, most of the previous studies on metadata for hyperdocuments have also been interested in information discovery from a content-oriented perspective (Lang & Burnett, 2000; Li et al., 1999; Karvounarakis & Kapidakis, 2000). Especially, a set of hyperdocument metadata, the Dublin Core (Dublin Metadata Core Element Set) (Weibel et al., 1995; Weibel & Koch, 2000), has been paid attention to as a standard for Web information resources and also focuses on the information discovery. However, besides this perspective, for the OHDs metadata, the organizational perspectives also need to be considered to satisfy various managerial needs of organizations.

First, a process-oriented perspective needs to be considered. It is also pointed out that the perspective needs to be reflected on defining metadata of corporate digital documents (Murphy, 1998). OHDs as corporate digital documents are closely related to business tasks and information for them in an organization. Generally, corporate documents are produced in undertaking an organizational process (Uijlenbroek & Sol, 1997); furthermore, most businesses are based on, or driven by, document flow (Sprague, 1995). Thus, documents and business processes may be considered simultaneously in the analysis of a corporate information system (Frank, 1997). In this context, the OHDs may affect the speed of communications to perform business process. Accordingly, the OHDs should be designed to support collaboration among workers in business processes. Also, the OHDs can be rapidly improved to fit ever-changing business requirements.

Second, the metadata for OHDs are to be considered from a technical perspective. The system resources linked to the OHDs, such as program files and data components dynamically cooperated, are a considerable part of the organizational assets. The links between such resources and OHDs are very complex. Accordingly, managing the resources and the links through metadata can result in the efficient use of the organizational asset; the metadata related to the technical components can help developers change and improve the OHDs more efficiently.

Third, in the long term, the metadata role of OHDs should be extended toward organizational memory (OM), because organizational digital documents are a major source of OM (Murphy, 1998; Sprague, 1995). The OM techniques concentrate on managing an organization's information or knowledge of the past (Stein & Zwass, 1995; Wijnhoven, 1998). The metadata for OHDs need to play a critical role in managing a variety of histories in terms of business functions, communication mechanisms, technical artifacts, and contents. The memory may provide knowledge to support various decisions for controlling communication mechanisms in a business process, linking to the previous responsible workers, or maintaining the hypermedia applications.

Considering all the perspectives discussed previously, metadata roles for OHDs can be summarized in three levels--operation, system, and organization--as shown in Table 1. In fact, we believe that these roles can also be applied to other kinds of corporate digital documents.

METADATA CLASSIFICATION AND ELEMENTS FOR OHDS

Metadata classification can be perceived as a fundamental framework for providing metadata elements. According to the our perspective on the metadata for OHDs described in the previous section, the following categories of metadata need to be considered:

- *Content-dependent Metadata*: These metadata are used to enable understanding of the content of documents. The metadata include information that depends on (i) the content directly, and (ii) semantic meanings based on the content of the document indirectly.
- *Workflow-dependent Metadata*: These metadata provide information about workflow related to an organizational hyperdocument. These metadata are concerned with process-related factors such as workers, tasks, or business rules.
- *Format-dependent Metadata*: These metadata describe information on formats related to organizational hyperdocuments as well as hypermedia components such as nodes, anchors, interface sources, and database attributes.
- *System-dependent Metadata*: These metadata provide information concerned with storage- and software-related information on system resources such as hyperdocuments, interface sources, and databases.
- *Log-dependent Metadata*: These metadata describe information on the history and the status of organizational hyperdocuments.

Content-dependent metadata are essential for discovering information in OHDs. Workflow-dependent metadata can contribute to increasing the ability to control business processes through the efficient adaptation of OHDs to ever-changing organizational requirements. Format-dependent metadata can provide an understanding of the hypermedia features in terms of structures and operational mechanisms, so that they can be useful in the technical maintenance of OHDs. System-dependent metadata can also play a critical role in technical maintenance by providing information on hardware and location, and software technologies applied to the hyperdocuments. This meta-information is essential for sharing and reusing system resources. Finally, log-dependent metadata may contribute to organizational memories. Thus, the metadata in this category should be specified in order to capture the history of OHDs. According to this classification, detailed metadata elements may be specified under the classification suggested in this article, as shown in Table 2.

Content-dependent classification consists of elements that enable users to understand the content of the hyperdocuments. The document domain may be in terms of content and

Table 1. Metadata roles for OHDs

Level	Metadata Roles
Operation	● Easy and fast access ● Increased accuracy
System	● Interoperability under heterogeneous environment ● Document maintenance ● Document distribution
Organization	● Increased reusability of information and knowledge resources ● Increased capacity of business management ● Increased organizational memory

Table 2. Metadata elements of OHDs

Classifications	Elements
Content-dependent	[Document] Title, Description, Document Domain Name, Conceptual Attribute Name [Anchor] Name [Data Node] Title [Interface-Source] Name
Workflow-dependent	Task Domain Name, Task, Agent Domain Name, Agent Object Name, Business Rule
Format-dependent	[Document] Type [Anchor] Type [Node] Type, [Data Node] Property [Interface-Source] Property [DB] Physical Attribute Type
System-dependent	[Document] File Name, H/W Name, Location Path, S/W Technology [Data Node] File Name, H/W Name, Location Path [Interface-Source] File Name, Storage, Location Path [Database] Name, H/W Name, Location Path, Table Name, Table Type, Physical Attribute Name, DBMS Name
Log-dependent	Document Number, Version Number, Loading Date, Withdrawal Date, Update Date, Update Description, Director, Operator

roles. The conceptual attributes, as data items represented on a hyperdocument, are connected to a corporate database. Interface sources are primarily multimedia components such as image or animation that are represented on interfaces.

A node, an essential factor of hypermedia, has been defined as the fundamental unit of hypertext (Nielsen, 1993), fragments of information (Fluckiger, 1995), or basic information containers (Schwabe & Rossi, 1994). This article defines a node as any navigational object with hyperlinks. An object may a type of media, such as image, sound, animation, or a hyperdocument itself. Nodes may be categorized into two types from the perspective of their properties: document nodes and data nodes. Nodes are also of two types from the perspective of link directions: source and destination. The fundamental definitions for nodes are summarized in Table 3.

An interface may consist of one or more hyperdocuments. Accordingly, a document node, a hyperdocument, can be either only a part of an interface or an interface itself. From these definitions, the element of node type in format-dependent metadata may take a document node or data node as its value.

The information of a hyperdocument in terms of a process can be obtained effectively by the use of a document-based workflow concept. The workflow concept typically includes common essential factors in terms of a unit of a work, a tool of a work, and a person for a work (Lee & Suh, 2001). In the document-based workflow approach, an OHD is regarded as a tool of a work. A task, as a work unit consisting of a workflow, may be described as operations or descriptions of human actions with a hyperdocument. An agent refers to a person who performs the task, and is expressed by hierarchical status in an organization. An agent domain can be defined as a group of agent objects having common tasks or organizational objectives. The agent domain can be typically conceived as a department of an organization. The task

Table 3. Types of nodes

Perspectives	Types	Descriptions
Properties	Document Node	A unit of an HTML document, which may be a whole interface or a part of it.
	Data Node	A unit of multimedia data that may be accessed from a document node.
Link Direction	Source Node	Nodes that can access a current node.
	Destination Node	Nodes that a current node can access.

domain is a set of tasks corresponding to an agent domain.

The format-dependent metadata are concerned with type or properties of hyperdocuments, anchors, nodes, interface sources, and databases. The types of anchors can be static or dynamic depending their value. The definitions of these types are as follows:

- *Static anchor:* One fixed in a hyperdocument.
- *Dynamic anchor:* One generated by data stored in a database; that is, it refers to data transformed into and represented as an anchor when the data are accessed by a hyperdocument according to any event that occurs as a function or another anchor.

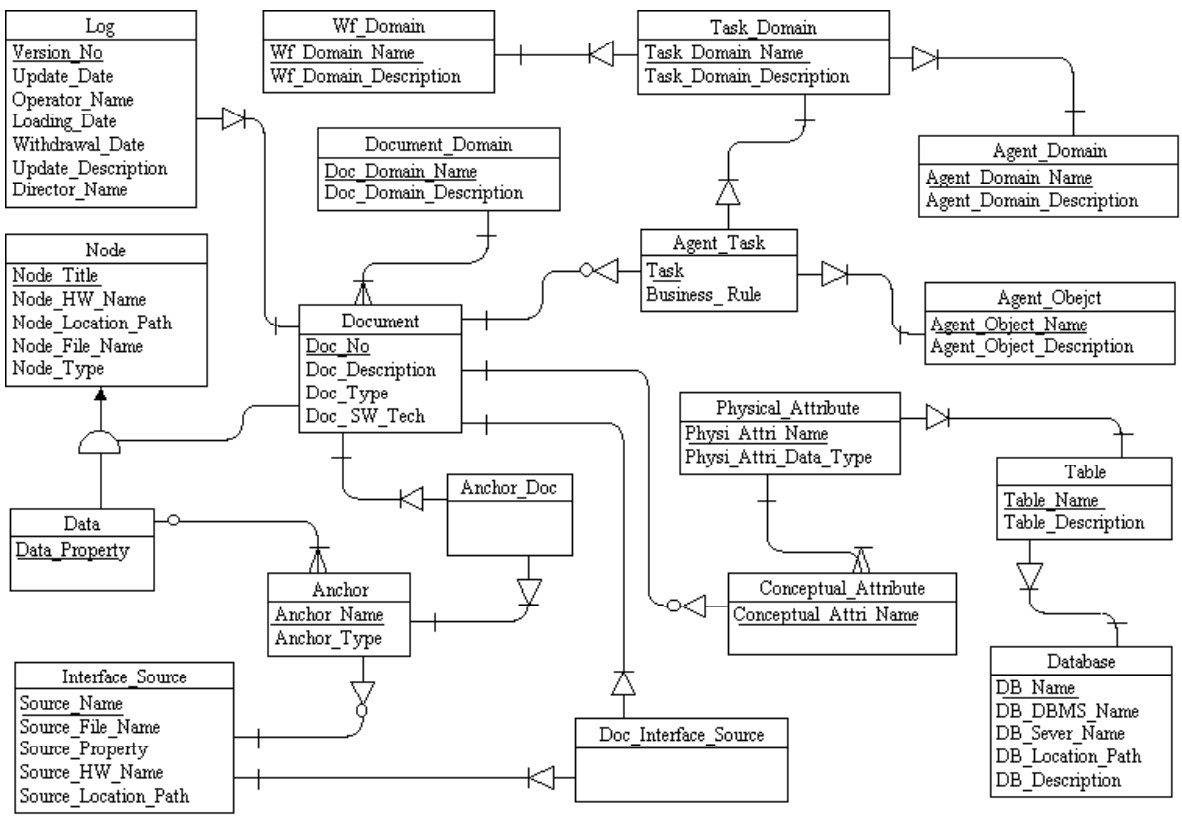
The types of OHDs can be categorized into three: control, processing, and referential, according to their roles in a hypermedia application. These types are defined as follows:

- *Control Type:* Hyperdocuments that typically guide users to other hyperdocuments of processing or referential types. Homepages or index pages are examples of this type.
- *Processing Type:* Hyperdocuments that typically contain data attributes connected with a database in the style of a form.
- *Referential Type:* Hyperdocuments that provide supplementary information about work instructions, business rules, news, or products.

Properties of interface sources are multimedia properties such as images or animation. The properties of data nodes are the same as those of interface sources. The physical attribute type of a database implies the data properties of the attribute.

System-dependent metadata focus on storage-related information. The storage-related information can be found in various applications, but they are not integrated, so it is difficult to create a synergetic effect. However, if metadata of all the components of hypermedia systems, such as hyperdocuments, data nodes, interface sources, and databases, are integrated into a repository, it is possible to manage a hypermedia system effectively. Software technology is a major factor in determining the capacity and characteristics of a system. Recently, for example, a variety of emerging

Figure 1. Metadata DB schema of OHDs



software technologies, such as ASP (Active Server Page), Java scripts, Visual Basic scripts, or Perl, have had a considerable impact on the improvement of hypermedia systems. Accordingly, the information on software technologies applied to a hyperdocument may contribute to the maintenance of a hypermedia application.

Log-dependent metadata are used for tracing the history of hyperdocuments for the maintenance of their system. Although there may be log information captured automatically by an operating system or an application program, it is typically separated, so it is difficult to obtain a synergetic effect in maintenance. Furthermore, it is insufficient to maintain a hypermedia system effectively. Therefore it is necessary to capture the information about changes of hyperdocuments synthetically. Some hyperdocuments may be operated temporally, depending on their purposes. Accordingly, version- or time-related information should be managed. The loading date is a date pushing a hyperdocument into its system. The withdrawal date is a date removing a hyperdocument from the system for the expiration of its periodic role or for updating. Information on responsible operators and directors for a hyperdocument may be required for responsible management, or questions by new staff members.

The metadata elements in Table 2 can be designed as shown in Figure 1. The schema was implemented in a meta-information system for the maintenance of OHDs (Suh & Lee, 2002). The system consists of two main modules: metadata management and a supporting module. The metadata management module is responsible for metadata handling such as creating, editing, or deleting. The supporting module serves two types of functions: searching an OHD and reporting its meta-information.

FUTURE TRENDS

Concerning the challenge to cope with a flood of OHDs, today content management system (CMS) is drawing great attention; the market size of content management solutions are forecasted to grow explosively (WinterGreen Research, Inc., 2003). CMSs help organizations develop Web applications, and support content lifecycle including the following phases: creation, approval, publishing, deployment, delivery and removal. Now, CMSs are conceived as an essential infrastructure for not only developing but also maintaining Web applications; most Web projects include implementing CMSs along with Web applications. Furthermore, CMSs are often incorporated into the existing infrastructures of Web applications to support the maintenance of the applications.

The lifecycle of content is supported primarily by the engines of workflow and personalization on the basis of a repository that includes the metadata as well as actual content. The metadata are a critical component required to operate those engines and other functions of CMSs, so their importance has been addressed (Perry, 2001). In fact, current CMS solutions originate from some different backgrounds, so that the functional features and metadata schema are also different from each other. Accordingly, in the near future, the metadata standard may be required in the CMS solution industry as it has been in other application domains of information technologies so far.

CONCLUSION

Recently, many organizations have expanded their business workplaces through Web business systems. Organizational hyperdocuments (OHD), critical information resources, are growing explosively in such organizations. Accordingly, the maintenance of these documents is becoming a burdensome task. For this challenge, this article offers an approach based on metadata required from the managerial perspectives as well as content-oriented. The managerial perspectives address the adaptability of Web business systems to the ever-changing business requirements and the efficiency of developers' works. The presented metadata are expected to help manage organizational memory in the long term through implementation into a metadata-based system.

KEY TERMS

Guided Tours: A navigation type that leads users to a predefined trail of nodes without freely explorative navigation, using, for example, previous and next anchors.

HTML: HyperText Markup Language. It is markup language using tags in pairs of angle brackets, for identifying and representing the Web structure and layout through Web browsers; it is not a procedural programming language like C, Fortran, or Visual Basic.

Hyperspace: Information spaces interlinked together with hypermedia structures. Concerning World Wide Web, cyberspace is sometimes used instead of hyperspace.

META Tag: A type of HTML tags with a word, "META". Web "spiders" read the information contained within META tags to index Web pages. The information consists of keywords and a description of its Web site.

Open Hypermedia: As a more generalized concept addressing interoperability among hypermedia services, it has the following characteristics: it should be platform independent and distributed across platforms, and users should be able to find, update, make links to, and exchange the information, unlike hypermedia titles on CD-ROM.

SGML: Standard Markup Language. Document standard from ISO (reference ISO 8897). It is a meta-language that can define document logical structure by using Document Type Definition (DTD) component. An example of document types defined using the DTD of SGML is HTML.

XML: eXtensible Markup Language. It is quite different from HTML in that XML gives document authors the ability

to create their own markup. XML is flexible in creating data formats and sharing both the format and the data with other applications or trading partners, compared with HTML.

Organizational Project Management Models

Marly Monteiro de Carvalho

Marcelo Schneck de Paula Pessôa
University of São Paulo, Brazil

INTRODUCTION

Project management plays an important role in the competitive scenario, and achieved in the 1990s the status of methodology (Carvalho & Rabechini, Jr., 2005). Nowadays, there are more than 100,000 practitioners that earned the Project Management Professional (PMP®) certification from the Project Management Institute (PMI). This indicator highlights the increasing interest in project management area, especially in the IT companies, which are one of the top five industries in PMI's membership numbers (PMI, 2005).

The widely spread framework proposed by PMI called Project Management Body of Knowledge (PMBoK), now in the third edition (PMBoK, 1996, 2000, 2004), has been adopted by several kinds of project-driven organization (PMI, 2004). PMBoK clusters the main project management best practices in nine key areas.

Nevertheless, a research carried out by Standish Group (2003) showed high failure level in IT project in North America. The research involved about 13.522 projects, of which only 34% can be considered a success. The main causes for IT projects failure were related to user's commitment, manager support and requirement definition. It is important to emphasize that, regarding the project success measure in historical perspective, the success rate improved if compared to the first similar research carried out in 1999, which was just 16%.

Based on this scenario, this chapter presents the main organizational project management models in order to help companies to upgrade project performance.

BACKGROUND

Several project management models had been discussed in the academic literature concerning its effectiveness and efficiency. The models focus on project efficiency, balancing scope expectations and the available resources (Carvalho & Rabechini, Jr., 2005). However, the project management efficiency models, such as PMBoK framework, cannot provide a standard benchmark for project management competences and maturity enhancing. Thus, in order to extend the efficiency models to an effectiveness perspective, several PM organizational models have been proposed.

Nevertheless, project management efficiency models focus on the project and not on organizational issues. As Engwall (2003, p. 789) states "no project is an island" and to achieve success in this area it is important to fit project management best practices to organizational environment.

On the other hand, the effectiveness issue encompasses the organizational project management models, which promotes the strategic alignment between this area and the organizational vision. It means providing an appropriate strategic alignment and portfolio analysis, project management organizational structure, methodology and project manager carrier (Carvalho & Rabechini, Jr., 2005; Carvalho, Laurindo, & Pessoa, 2003, 2005; Rabechini, Jr., Gelamo, & Carvalho, 2005; Shimizu, Carvalho, & Laurindo, 2006).

The implementation of formal efficiency and effectiveness procedures is quite new in IT projects and organizations. There are different approaches and this article focuses on the organizational project management models. The theoretical models selected to discuss this issue are the Capability Maturity Model (CMM) (Humphrey, 1989; Paulk, Weber, Curtis, & Chrissis, 1995), Project Management Maturity Model (PMMM) (Kerzner, 2000, 2001); the Quality Systems to software ISO9000-3 (2001) and ISO 12207 (1995); and the Organizational Project Management Maturity Model (OPM3) (PMI, 2003).

CAPABILITY MATURITY MODEL (CMM)

Humphrey (1989) identifies maturity levels in the IT project development process, based on the managerial behavior found in companies. The fundamental concepts of the process maturity derive from the belief that the development management process is evolutionary. Paulk et al. (1995) identify the distinguishing characteristics between immature and mature organizations, as shown in Table 1.

Table 1. Immature organization x mature organization (Paulk et al., 1995)

IMMATURE ORGANIZATION	MATURE ORGANIZATION
• *Ad hoc*: improvised process by practitioners and managers • Not rigorously followed and not controlled • Highly dependent on personal knowledge • Little understanding of progress and quality • Compromising product functionality and quality to meet schedule • High risk when new technology is applied • High maintenance costs and unpredictable quality	• Coherent with action plans: the work is effectively achieved • Processes are documented and continuously improved • Perceptible top and middle management commitment • Well controlled assessment of the process • Product and process measures are used • Disciplined use of technology

The CMM (Humphrey, 1989; Paulk et al., 1995; Pessôa & Spinola, 1997) was developed by SEI (the Software Engineering Institute of Carnegie Mellon University) and presents five maturity levels, each corresponding to a set of structural requirements for key process areas (Figure 1).

Although each project is unique, it could be organized in a process to be applied in other projects. IT projects managers used to apply a "methodology," that is, they established the steps to be followed in order to develop a system. Another singular characteristic is the dynamic technologies breakthrough that demands continuous improvements in the development methods and management of changing process, as described in the CMM model at level 5, the highest level of maturity.

The CMM second level has a consistent project management structure and the goal of this level is to deliver projects on time. To perform this, the model has several points that must be achieved, like effort and size estimation, strong process control (such as periodic meetings between technical people and managers), and several measures to show project status more clearly.

CMM is not an adequate reference for the assessment of internal methodologies, because it was not conceived to perform this kind of analysis. ISO 15504 (1998) proposed the standard project SPICE as a more appropriated model to evaluate maturity level of specific processes. While CMM level of maturity specifies a set of processes that have to be performed, ISO 15504 establishes maturity levels for each individual process: level 0-incomplete; level 1-performed; level 2-managed; level 3-established; level 4-predictable; and level 5-optimizing. This is a different approach of CMM, because an organization does not perform a maturity level, but has a maturity profile: A maturity level is measured for each specific process. This new approach is very useful to the organization perspective because one can easily measure strong and weak points of their process and plan improvement activities. Furthermore, from the companies' point of view, it is easier to understand staged levels, as the performed processes are already predefined.

The SPICE approach defined in standard ISO 15504 (1998) had firstly influenced *CMM for Systems Engineering*, published in 1995, and more recently influenced CMM I (CMM-I1; CMM-I2), just published in 2002. CMM-I, the integration model, was enhanced in two dimensions: *scope dimension* and *evaluation dimension*.

In the scope dimension, this new model incorporated other published models and covered all project activities, not only software, as the original software CMM did, but also other engineering fields. In the evaluation dimension, CMM-Il incorporated both approaches: the traditional (called staged CMM) and the maturity profile (called continuous CMM). Figure 2 shows the continuous CMM-I representation to be compatible with the ISO/IEC 15504 standard.

Figure 1. Maturity levels (Paulk et al., 1995)

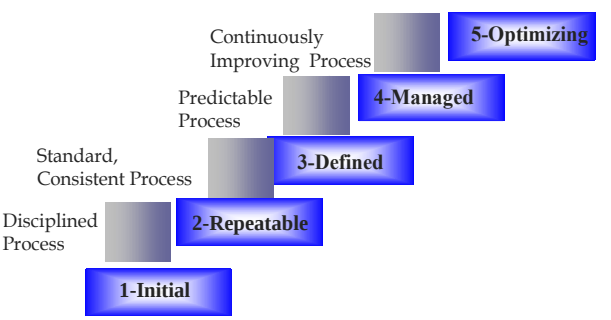

Figure 2. Continuous maturity process representation in CMM-I (CMM-I1, 2002)

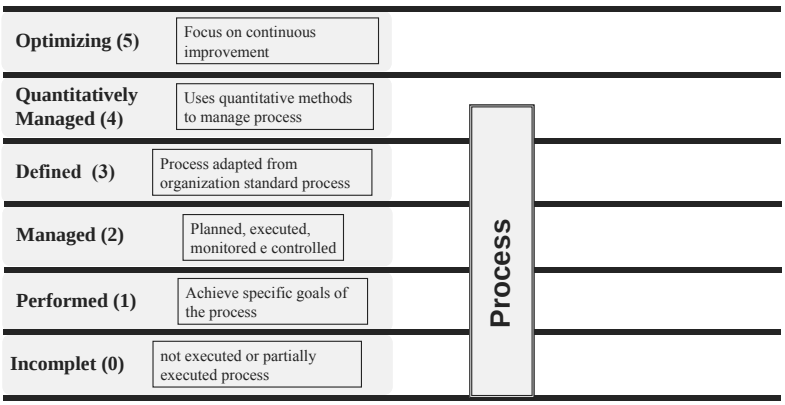

CMM-I (and software CMM) considers that maturity level is an organizational characteristic and it is independent of the professionals involved. Nowadays, there is a strong tendency toward the adoption of CMM-I models which were sponsored by the Department of Defense (DoD); meanwhile, ISO standards are less used.

PROJECT MANAGEMENT MATURITY MODEL

In order to extend the capability maturity model (CMM) to project management, Kerzner (2000) and (2001) proposes a Project Management Maturity Model (PMMM).

The PMMM differs in many aspects from the CMM, but this framework also introduces benchmarking instruments for measuring an organization's progress along the maturity model, detailing five levels of development for achieving maturity (Carvalho et al., 2003). Figure 3 shows PMMM's levels.

It is important to highlight the differences in terminology between the CMM and PMMM (compare Figures 2 and 3), which could lead to misunderstanding when both models are being implemented in the IT domain of the same organization.

PMMM addresses the key knowledge areas across the project management process, in compliance with PMBoK, and integrates them with the Project Management Office (PMO) in the strategic level.

Kerzner (2000) identifies a life cycle in PMMM level 2, common processes, which could be broken into five phases, as shown in Figure 4. It is important to note that some simultaneity among the phases can occur.

Figure 3. Project Management Maturity Model (Adapted from Kerzner, 2001)

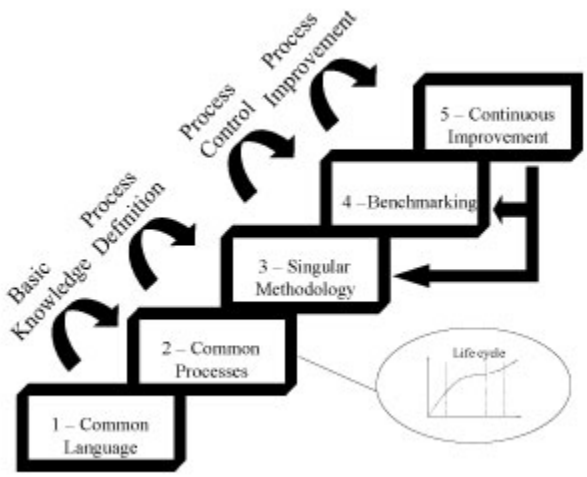

Table 2. Life cycle phases characteristics (Kezner, 2001)

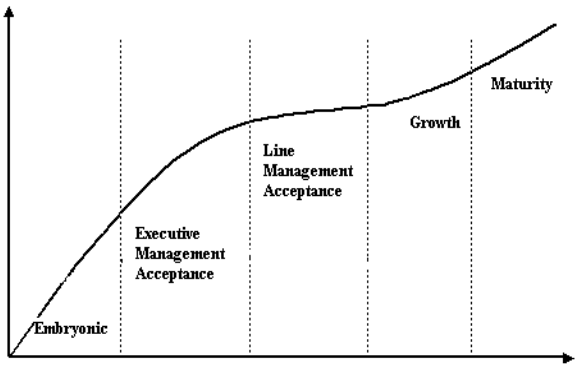
Phase	Characteristics
embryonic	• recognizing the need for PM • recognizing PM's potential benefits • applications of PM to the business • recognizing the changes necessary to implement PM
executive management acceptance	• visible executive support • executive understanding of PM • project sponsorship • willingness to change the way the company does business
line management acceptance	• visible line management support • line management commitment to PM • line management education • release of functional employees for PM training programs
growth	• development of company PM life cycles • development of a PM methodology • a commitment to effective planning • minimization of scope • selection of PM software to support methodology
maturity	• development of a management cost/schedule control system • integration of schedule and cost control • development of an educational curriculum to support PM

Figure 4. Life cycle phases (Kerzner, 2000)



The embryonic phase means that the organization starts to recognize the benefits of project management (PM), usually by lower and middle levels of management. The two next phases are achieved when the PM concepts are accepted and have visible support and commitment by executive and line management.

Kerzner (2001) emphasizes the growth phase as the most critical, because it is the beginning of the creation of the PM process, and warns that different methodologies for each project should be avoided.

The last life cycle phase—maturity—is difficult to achieve due to several factors such as organizational resistance to project cost control and horizontal accounting.

The main characteristics of these life cycle phases emphasized by Kerzner (2001) are described in Table 2.

QUALITY SYSTEMS

It is important to note that the adoption of systems models, such as ISO 9000, focuses on the creation and maintenance of a quality system, applied to any process. The ISO 9001:2000 new version, published in the year 2000, was fully restructured to have a more clear process-focused approach. Other ISO standards offer an overview of these standards to the software field and contribute to deploying this approach to specific processes, such as software products (ISO 9126-NBR 13596), quality requirements for software packages (ISO 12119), and the software life cycle process (ISO 12207).

ISO 9000-3 (2001) is a guide to help with ISO 9001 interpretation for the software field (Pessôa & Spinola, 1997). The previous versions of this guide were developed by the ISO/TC/SC2 committee, the quality branch of ISO. Nowadays, this ISO 9000-3 guide is being revised by ISO/IEC JTC1/SC7, the information technology branch. The ISO9001:2000 new structure made this task easier than previous versions and it is incorporating a map of the relationship between IT standards (ISO/IEC JTC1/SC7) and its respective quality systems described in ISO 9001 to this standard. For example, ISO 9001 specifies that the organizations have to identify their processes and ISO 12207 (ISO12207) proposes a set of processes involving software

development, supply, acquisition and maintenance. In addition to ISO 12207, other standards are referenced, such as ISO 9126 for software products, ISO 12119 for quality requirements for software packages and ISO 15504 for software evaluation. This was considered an improvement of the standards structure that matches quality system standards with technical and specific standards.

ISO 9001:2000 standards have the purpose of certifying organizations, in which Quality Systems comply with the standards and provide a structure to manage quality independent of the organizational activity. This is not enough for specific fields of application and, for this reason there are complementary sets of standards in some areas, like QS-9000 for the automobile industry and TL-9000 for the telecommunications industry.

The standards from ISO/IEC/ JTC1/SC7 have the purpose of complementing the quality system for the IT specific area, not focusing on applications as with the automobile or telecommunications industry, but considering the specificities of software and systems development.

In general, ISO 9000 can be a good starting point for implementing a quality system. This system allows the organizations to disseminate quality culture and create the initial structure to implement more specific quality systems.

ORGANIZATIONAL PROJECT MANAGEMANT MATURITY MODEL

In 2003, the *Project Management Institute* (PMI) concluded the *Organizational Project Management Maturity Model* (OPM3) development, started in 1998 (PMI, 2003). According to PMI (2003), the meaning of the OPM3 can be defined as follows. *Organizational* increases the work domain, leaving the context of the project itself, which is a matter for PMBoK to the organizational perspective. The meaning of the word *maturity* implies that the capacities should grow during the project management implementation period but also demonstrates how success occurs and ways of correcting or preventing common problems. The model implies change and progression in 4 stages: *standardize measure, control* and *continuously improv*e.

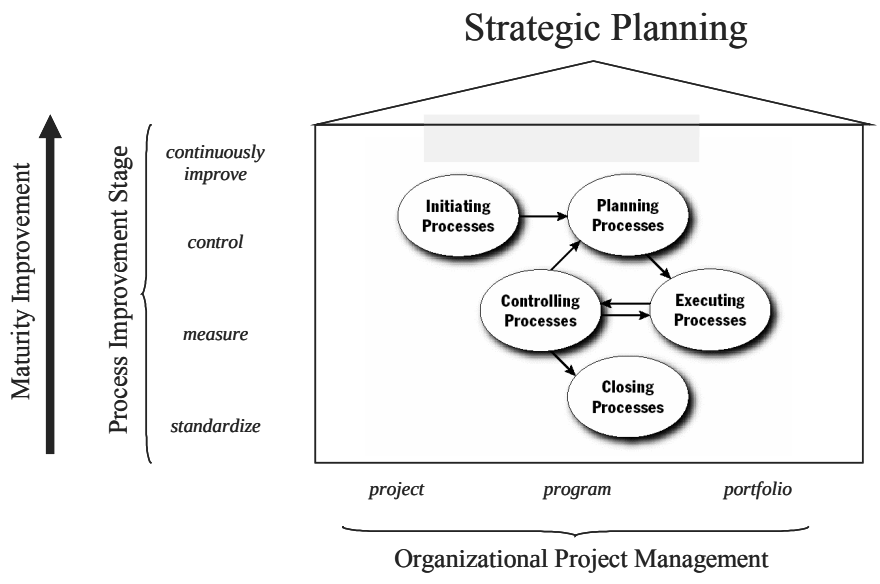
The OPM3 model is organized into the five groups of processes, proposed in PMBoK, as following: *initiating, planning, executing, controlling* and *closing* processes. Besides, the model classifies improvement stages: *standardize, measure, control* and *continuously improve.* Finally, this maturity model considers three constructs: *project, program* and *portfolio.* Figure 5 shows the relation among life cycle processes, improvement stages and constructs.

The OPM3 seems to be more detailed than the others and has specific recommendations concerning portfolio and programs.

FUTURE TRENDS

All the organizational models analyzed propose a step by step guide in order to drive organizations to achieve project management maturity. However, competences and organizational structure issues should be incorporated in order to achieve project success.

Figure 5. The OPM3 (Adapted from PMI, 2003)



The competences in professional, teams and organizations levels should be designed and developed. In each of these levels further research is necessary.

The appropriate organizational structure to support maturity progress in all constructs also demands more research. This important issue encompasses several factors in order to design the most appropriate organizational structure to organize project activity such as: projects typology (size, complexity, and uncertainty), organizational culture and philosophy, flexibility demanded and responsiveness.

Thus, the integration of competences build and the design of organizational structure in the maturity models should be considered in futures research.

Finally, companies are spending significant quantities of resources in the implementation of organizational project management models, keeping the discussion about the results controversial, when considering the return over the investments. Thus, the impact of the adoption of organizational models in the results of organization should be measured in further research.

CONCLUSION

In spite of different approaches regarding the organizational project management, there is a general consensus about the importance of the following widely used models: the CMM (Humphrey, 1989; Paulk et al., 1995), the Project Management Maturity Model (PMMM) (Kerzner, 2000, 2001), Quality Systems for software ISO9000-3 (2001) and ISO 12207 (1995), and the Organizational Project Management Maturity Model (OPM3) (PMI, 2003). All of them are empirical and were developed based on methodologies and best practices adopted in organizations.

Although they have different approaches in their conception, they are rather more complementary than conflictive. These models consider that project management maturity level is an organizational characteristic and it should not depend on individual professional expertise and skills but in organizational procedures, methodologies and culture.

In general, the Quality System (ISO 9000) and the maturity models (CMM, PMMM and OPM3) models have the possibility of mutual and complementary synergy, maintaining consistency with their fundamental points. On the other hand, there are important differences among these models, especially concerning the degree of abstraction (Carvalho et al., 2003, 2005; Pessôa, Spinola, & Volpe, 1997; Shimizu et al., 2006; Tingey, 1997).

It is important to highlight the differences in terminology between these models which could lead to misunderstanding when these models are being implemented in the IT domain of the same organization.

KEY TERMS

CMM I (CMM-I1, CMM-I2): A model, which has been enhanced in two dimensions: *scope dimension* and *evaluation dimension*. The CMM-Il incorporated both approaches, the traditional (called staged CMM) and the maturity profile (called continuous CMM).

CMM: The *Capability Maturity Model* is a framework to achieve maturity in project activities in the software field, which presents five maturity levels, each corresponding to a set of structural requirements for key process areas.

ISO 15504: An international standard that proposes the standard project SPICE, which establishes maturity levels for each individual process: level 0-incomplete; level 1-performed; level 2-managed; level 3-established; level 4-predictable; and level 5-optimizing.

ISO 9000-3: A guide to help ISO 9001 interpretation for the software field, that is, the development, supply, acquisition and maintenance of software.
