PMBoK: The *Project Management Body of Knowledge* provides a framework to manage project efficiency, balancing scope expectations and the available resources. This model proposes the following nine key areas: (i) integration; (ii) scope; (iii) time; (iv) cost; (v) quality; (vi) human resource; (vii) communication; (viii) risk; and (ix) procurement.

PMMM: The Project Management Maturity Model is a framework that introduces benchmarking instruments for measuring an organization's progress along the maturity model, detailing five levels of development for achieving maturity: level 1 - common language; level 2 - common processes; level 3 - singular methodology; level 4 – benchmarking; and level 5 - continuous improvement, as shown in Figure 3.

Project Life Cycle: Common processes identify in PMMM, level 2, which could be broken into five phases: embryonic; executive management acceptance; line management acceptance; growth; and maturity.

OPM3: The Organizational Project Management Maturity Model is an organizational model, proposed by PMI in 2003, that encompasses five groups of processes, four improvement stages, and three constructs in order to drive organizations to achieve maturity in project management.

An Overview of Asynchronous Online Learning

G. R. Bud West

INTRODUCTION

Distance education typically refers to a process where students complete their coursework at a location other than a primary campus. Effectively, this method first developed in the mid-19th century in the form of correspondence courses in the United Kingdom. The correspondence course design includes the instructor and the student mailing assignments back and forth between the university and the student's location. In many cases, the use of the Internet has replaced the correspondence-by-mail method of instructional delivery.

With the advent of television and the further development of radio, some colleges and universities saw an opportunity to present classes via these media. By these methods, various instructors present lectures during set broadcast times while students continue to conduct assignments via correspondence. Additionally, some primary and secondary schools also began at the same time to provide information via television, mainly to supplement and reinforce standard pedagogical instruction in the classroom. Similar to correspondence courses, television and radio instruction generally decreased after the introduction of the Internet as an educational delivery vehicle. However, a notable exception currently exists in some university programs where instructors broadcast live satellite feeds to and from their classroom with classrooms located in regional community colleges, military installations, and other locations. In Virginia, Old Dominion University's TELETECHNET initiative represents an example of one such effort where students both regionally and around the world sit in local centralized meeting places and access instructors while they teach classes at the home campus in real time through two-way television broadcasts.

Once described as the wave of the future, some educators, researchers, and educational administrators suggest that online Internet instruction represents one educational process that has truly come of age. The use of the Internet as an instructional delivery system is exploding in the new millennium. With that explosion comes recognition of the existence of both opportunities and challenges for its effective use as a conduit for meaningful and structured education. In that regard, several researchers describe distinct time and location advantages in the use of Internet instruction, as well as its usefulness in developing knowledge about knowledge (Blair, 2002; Hung, Tan, & Chen, 2005). However, upon review of some examples of online coursework, one may witness a broad range of approaches and quality in online educational programs. In fact, experts specifically note that some online courses lack pedagogical emphasis and design and that universal promises of limitless Internet instruction fail the rationality test (Hung et al.; Wojnar, 2002). This suggests the importance of the Internet as a conduit of learning, but it also suggests a significant and, in some cases, unmet responsibility for those who would help mold and shape lives by instructing and helping to educate people through Internet and intranet mediums. In that regard, dialogue or online discussion has proven valuable in enhancing the online educational process (Blair; Dennen, 2005). Although many university programs use several methods of online discussion with varying degrees of success, some benchmarks have emerged and proven their effectiveness.

BACKGROUND

Different experts consider dialogue differently, but most would describe it in either or all of three primary categories: (a) one-on-one synchronous discussion, (b) group synchronous discussion, and (c) asynchronous discussion. As with most differing methodologies, each of these processes has its own distinct advantages and disadvantages.

One-on-one synchronous discussion refers to what many people call a chat. Popular delivery vehicles for one-on-one chat include programs like Yahoo! Messenger and Microsoft's Instant Messenger, among others. To use this technology, one need only start the application that resides on their local computer, select the name or pseudonym of the targeted individual, and begin typing when the window on the computer's screen opens. Real-time, one-on-one discussions provide some of the same benefits in application that phone or face-to-face conversations allow. Advantages of one-on-one chat include the ability to conduct real-time question-and-answer sessions that provide for a more personal approach than group discussions or those found in typical classroom settings.

Group synchronous discussion refers to what many people call chat rooms. Yahoo!, Microsoft, Google, AOL, and a host

of other service providers offer chat-room delivery platforms for both social and professional purposes. Most chat rooms require users to subscribe to their respective services. Some charge a nominal fee and others charge no fee to use their services. When starting up a particular service, a program downloads to the random-access memory of the user's computer. The user then selects and logs into the room of choice using his or her name or pseudonym. This method allows several people to join a discussion at the same time as information appears in a real time, bulletin-board manner. One of the main advantages of group chat includes the provision for people to brainstorm ideas and receive feedback across vast distances in real time. Additionally, clear documentation exists after the fact, regarding who says what and how much. Depending on hardware, software, bandwidth, and other infrastructure limitations, either form of synchronous discussion might additionally offer two-way voice and streaming video communications directly over the Internet or intranet. Downsides of either form of synchronous discussion include the logistical coordination of events and the need to enter the discussion well prepared.

Asynchronous discussion refers to both e-mail and to the classic bulletin-board approach where members of particular board groups post sequential comments and responses on given topics. Although instructors and students usually use e-mail on ongoing bases, researchers have conducted few studies that identify any relevant theoretical constructs concerning e-mail as it pertains to enhancing online education. However, researchers have conducted a substantial number of investigations on asynchronous bulletin-board discussions as an educational method. Some advantages of this method include allowing members of the group to read and respond to the information on the board at their leisure, lower demand for activity coordination among members, the time allowed for responders to develop deeper and more thoughtful responses to existing posts, and the likelihood that more people will actually participate in the event. Some researchers suggest that it also offers better opportunities for critical thinking and deep learning, resulting in metacognition (Havard, Du, & Olinzock, 2005; Weigel, 2001).

THE ASYNCHRONOUS METHOD

Several of the current leaders in distance education, including Cappella University, The University of Phoenix, and Regent University, along with scores of other colleges and universities, employ the asynchronous method of instruction as their central delivery systems with Blackboard and WebCT providing popular instructional delivery system packages that include bulletin-board conduits. These institutions usually require students to complete some formal training on the methods of delivery and response early in their programs. Then, before each course, instructors and administrators provide students with course requirements, syllabi, and other pertinent information through e-mail, bulletin boards, or both. Typically, during grading periods, students submit and instructors or other graders provide feedback on both major and minor projects via e-mail. Concurrently, instructors or other designated moderators periodically post topics for discussion. They also solicit participation from and provide feedback for students concerning those given topics. Additionally, through many software products, students have access to communication and course tools that provide for announcements, collaboration with other students on group projects, the development of group and individual Web pages, grade checking, and course materials beyond those initially provided (Johnson & Rupert, 2002; Hutchins, 2001).

The stated purpose of much asynchronous dialogue includes helping students to understand the relevance of concepts. Students demonstrate their mastery by contextualizing these concepts through discussion and application. Moderators can run asynchronous discussion boards using several different styles. Some styles that have demonstrated significant value include (a) point-counterpoint-response, (b) open forum, (c) two-sided debate, and (d) multiple posts of specific word counts. Point-counterpoint-response offers the opportunity for an initiator to post an initial point and justification, a respondent to counter the initial point, and the initial poster to rebut the counter. An open forum provides opportunities for students to develop relevant, theoretical conceptualizations and to post concise, significant contributions to the topic. Two-sided debate requires students to divide into two groups and to debate the strengths and weaknesses of given positions germane to the given topic. Multiple posts of specific word counts challenge students to move more deeply into forum concepts as they seek clarification and challenge other students' positions on the given topic. In each of these processes and in many other asynchronous bulletin-board learning environments, student participants use the process of threaded dialogue or discussion to enhance the information exchange process. In a threaded dialogue, the software package groups contributed messages together to form an easily traced thread of information. When using an asynchronous bulletin board, threading discussion entries allows respondents the opportunity to consider thoughtfully their responses before posting, thus potentially aiding in the quality and depth of the respondent's contribution to the forum. Researchers offer that threading might actually result in improved student contributions to discussions, critical thinking, and ease of communicating (Blair, 2002; Dennen, 2005; Smith, Ferguson, & Caris, 2002).

Preparation

To ensure success, both instructors and students have several items to consider in using a given asynchronous discussion method. Instructors first prepare by mastering the particular

delivery vehicle deployed by the educational institution. This may include software packages like those already mentioned or it may include some other software solution outside of the mainstream. However, once the instructor masters the appropriate package, preparation of the structure and content of the pedagogy begins and continues for as long as the institution offers educational programs online. In that regard, several researchers find that online instructing requires a different approach from classroom instructing. In fact, some experts imply a requirement for a paradigm shift for instructors. Some suggest that with asynchronous, online learning, instructors now have to focus on facilitating learning in new ways and with different approaches for online class discussion, including initiation, conclusion, and feedback, and that they might possibly provide very little in the way of content (Dennen, 2005; Smith et al., 2002). Finally, other scholars suggest that instructors preparing to enter into the world of online instruction, especially for the first time, should best experience it by fully immersing themselves in the process. They recommend that instructors should learn to teach online by first participating in training classes actually conducted online (Cook, 2007; Hewett & Ehmann, 2004).

Likewise, students must prepare for online dialogue or discussion by learning the requirements of the delivery vehicle, as well as the expectations, procedures, rules, and standards developed and enforced by their particular institution. Moreover, structure or the lack of structure directly affects students' eagerness and aptness to participate in asynchronous discussions. Other considerations for effective preparation include the following: (a) Students participate more in relevant and goal-based activities, (b) students participate more when they understand an activity's associated learning objective, (c) moderate instructor presence contributes to the learning process, especially if it includes well-designed, conversational contributions, and (d) appropriate feedback designed to meet students' needs contributes to the learning process (Dennen, 2005).

Performance

Many instructors cite the central challenge of online instruction as the time commitment involved. Some experts say that online courses require much more of a time investment than traditional, in-class educational courses. However, others suggest that online instruction requires no more time, but that it seems like it does because the timing now spreads across a 24-hour day (Dennen, 2005; Young, 2002). Other identified issues in performance include the inability of instructors to observe students and their reactions, and the inability of instructors to use classroom theatrics prevent on-the-spot, as-needed adjustments that in classroom settings could otherwise enhance learning processes (Blair, 2002; Dennen). Conversely, researchers have shown that for any limitations one may find regarding Internet education, the Internet finally provides an avenue to enable students to realize the educational dialogues that educators and researchers consider fundamental to situated cognition and social constructivism (Hung et al., 2005).

In the Internet age, students often demonstrate outstanding skills in computer and Internet usage. However, comparing performance success on a computer or on the Internet to that of using dialogue or a discussion board might correspond to the similarities and differences between communication and rhetoric. One construct might prepare an individual to accomplish the other, but the foundation might not provide an accurate indicator for the outcome. Researchers have identified significant differences in students' approaches and involvement in Net-based educational opportunities and have further identified some factors for consideration. These include the following.

1. Not all students appreciate the possibilities for learning through collaboration and some students lack the ability to cooperate.
2. A student's self-confidence (self-efficacy) concerning success in studying contributes to his or her involvement and success in completing dialogue work on the Internet.
3. Students with nonacademic backgrounds demonstrate higher levels of success than those with traditional academic backgrounds, as measured by test scores.
4. Students who participate more in quantity to the dialogue process generally contributed higher quality submissions (Dennen, 2005; Jakobsson, 2006).

In any educational endeavor, grades are at least as important for some people as the learning itself. Testing has consistently concerned distance educators, primarily because of the lack of direct educator supervision. Some institutions address these issues by requiring proctored examinations on campus or at some acceptable testing center. However, experts suggest that one can easily assess the quality and quantity of threaded discussions and that it thereby provides a relatively objective method for graders to assign grades based on participation. They further suggest that when students write all of their communication, most graders could easily assess whether or not the student submitting the examination actually wrote it based on writing style alone (Smith et al., 2002).

FUTURE TRENDS

It is clear that the volumes of distance education generally and learning by asynchronous discussion in particular will only increase as the future unfolds. On an almost daily basis, the number of institutions offering greater numbers of courses in online formats seems to increase. This means that in the

not-so-distant future, the competition will also increase between institutions for instructors who have mastered the processes associated with asynchronous learning. Moreover, as the Internet provides a truly global marketplace, educational institutions will continue to expand into cities, towns, and villages around the world, presenting opportunities to groups and individuals who might never have otherwise been able to experience the quality of instruction provided online. Some universities already offer students opportunities to participate in asynchronous discussions that cover core competencies, which all students in the curriculum must master. However, those students in places all around the globe must also meet together in pockets close to home where they experience learning events that help them integrate what they have learned online into knowledge that applies in local applications. These programs and others like them are sure to provide continued opportunities to form a global educational neighborhood.

Technologically, the future appears to hold further integration of classroom and asynchronous learning support services as instructors produce Web-based assignments for local classrooms in addition to distance programs. Education providers also will continue to integrate databases and systems to provide broader ranges of services in both real-time and asynchronous environments, for both unique and routine interactions. The concerns that some experts express regard the fact that the culture of education has not kept pace with the technological explosion. Consequently, administrative and regulatory barriers will likely have a neutering effect on the full utilization of technology. Conversely, some theorists project that rather than broadening and deepening existing programs, the technological boom will enable educators and institutions to offer highly customized curriculums designed to meet specific needs of individuals and small groups of learners. To these ends, the technology will continue to offer greater levels of student-to-instructor and student-to-student interactions, learning activities, design flexibility, and cost effectiveness (Garrison & Anderson, 1999; Saba, 2005).

CONCLUSION

This article provided a topical review of correspondence courses, television and radio, and online distance education delivery systems. It specifically discussed synchronous and asynchronous processes of online dialogue, including preparation by instructors or curriculum developers and students. It also provided a review of the best practices and potential drawbacks generally associated with educational dialogue and particularly associated with asynchronous dialogue as used in educational processes. It specifically covers the capabilities, advantages, and disadvantages of the three primary categories of online educational dialogue. It also defined threaded dialogue and provided an overview of suggested methodologies and other structural components, which if used by the educator and students, could enhance the overall online educational process. It further discussed the ongoing requirement that exists for pedagogical development after instructors master the techniques associated with the particular delivery systems employed by their institutions. Understanding the advantages and limitations of these processes, as well as mastery of the techniques listed herein, can provide both teachers and students with an overall better learning environment and enhanced online educational experiences.

KEY TERMS

Asynchronous: In distance education, asynchronous refers to communication in a learning process that is not necessarily immediate. This includes methods like Web logs (blogs), bulletin boards, e-mail, and correspondence.

Distance Education: It refers to the processes of teaching and learning in environments other than those associated with traditional, on-campus classrooms. These processes include correspondence, usually through the postal service, Internet, or intranet via synchronous learning like Webcasts and real-time messaging; via asynchronous methods like e-mail and bulletin boards; and through two-way audio and video feeds.

Self-Efficacy: It is the belief one possesses about his- or herself that suggests he or she has the wherewithal to achieve a given outcome.

Situated Cognition: Stemming from pragmatism, theories regarding situated cognition suggest that one learns better in contextual circumstances than in classroom or laboratory settings.

Social Constructionism: This refers to a theory of knowledge that suggests people collectively develop their methods of interacting with each other. Members of a given society or culture might assume or otherwise perceive one of the particular methods they employ as a natural way to think or feel. However, upon deconstruction, one might discover that the method originated through a number of decision-making processes.

Synchronous: In distance education, synchronous refers to real-time communication in a learning process. This includes methods like individual and group chat and parallel audio and video streaming.

TELETECHNET: This refers to a distance education tool pioneered by Old Dominion University (ODU) in Norfolk, Virginia. TELETECHNET consists of an integrated system of computers and two-way audio and video feeds whereby ODU links with other institutions to provide live classroom instruction, at both the undergraduate and graduate level, to place-bound students throughout the world.

Thread: The topic thread refers to hierarchical, asynchronous postings that focus on a particular topic. Threading generally promotes reflection and considered responses, and therefore overall deeper learning than that found in similar, synchronous methods.

Overview of Electronic Auctions

Patricia Anthony
Universiti Malaysia Sabah, Malaysia

INTRODUCTION

Online auctions are one of the most popular and effective ways of trading goods over the Internet (Bapna, Goes, & Gupta, 2001). Thousands of items are sold on online auctions everyday including books, toys, computers, antiques, and even services. As an example, eBay (http://www.ebay.com), the largest online auction house, has more than 241 million registered users today, and in the year 2006 alone, eBay recorded consolidated net revenue of $6 billion (eBay, 2007). On any given day, there are more than 78 million items listed on eBay, and approximately 6 million listings are added per day. It has also spread its wings to other countries outside the USA, and to date it is present in 24 countries. In addition to eBay, there are more than 2,600 auction houses that conduct online auctions (common sites include Amazon.com, http://www.amazon.com; Yahoo! Auctions, http://auctions.shopping.yahoo.com; priceline.com, http://www.priceline.com; and uBid, http://www.ubid.com). These auction houses conduct many different types of auctions according to a variety of rules and protocols.

BACKGROUND

An auction is defined as a bidding mechanism described by a set of auction rules that specify how the winner is determined and how much he or she has to pay (Wolfstetter 2002). Auctions are widely used in many transactions including the sale of arts, wine, fresh products, diamonds, and real estate. In fact, auctions are not new. They were used to allocate scarce resources in Babylon from about 500 B.C. (Shubik, 1983). During those times, an annual Babylon marriage market was conducted where men had to bid for their prospective wives. The richest Babylonians who wished to wed had to bid against each other for the loveliest maiden, while the poorer ones had to settle for the less beautiful ones. Moreover, in ancient Rome, auctions were used in commercial trade to liquidate property and to sell surplus spoils of war on the battlefield (including plundered booty). Since then, auctions have flourished in many other civilizations, but they became more prominent in the 17th century where they were used to liquidate goods and to sell unsalable goods (such as domestic animals, tobaccos, natural resources, horses, and slaves) at the end of the season.

The practice of auctioning goods has been popular throughout the years because auctions are an extremely effective way of allocating resources to the individuals who value them most highly (Reynolds, 1996). This effectiveness means that very many variants have been produced (Wurman, Wellman, & Walsh, 2001); however, there are four main types of single-sided auctions that are commonly and traditionally held (Klemperer, 1999):

- the ascending-bid auction (also called the open, oral, or English auction),
- the descending-bid auction (also called Dutch auction),
- the first-price sealed-bid auction, and
- the second-price sealed bid auction (also called Vickrey auction).

In more detail, in an English auction, the auctioneer starts the auction with a low price that is then successively raised until one bidder remains. That remaining bidder wins the object and pays a value equivalent to his or her bid value. This type of auction is commonly used when selling antiques, artwork, and houses. The descending auction is the opposite of the ascending-bid auction. The auctioneer starts at a very high price and this price is then progressively lowered until there is a call from any bidder to claim the item. The first bidder who calls out wins the object at the current price. This auction is also called the Dutch auction because it is used in the sale of flowers in the Netherlands (van Heck & Ribbers, 1997). Fish and tobaccos are also sold in a similar way in Spain, Israel, and Canada (Klemperer, 1999).

The last two auctions are sealed-bid auctions. In the first-price sealed-bid auction, each bidder submits a single bid independently without knowing what the others bid. When the auction closes, the bids are opened and the winner is the bidder with the highest bid; he or she gets the item at a price equivalent to the bid value. First-price sealed-bid auctions are used in auctioning mineral rights in government-owned land and are also sometimes used in the sales of artworks and real estate (Klemperer, 1999). Finally, the second-price sealed-bid auction works in the same way as the first-price sealed-bid auction, but the price paid by the winner is equivalent to the second-highest bid. This type of auction is widely used for auctioning stamps, autographs, and Civil War memorabilia by mail (Lucking-Reiley, 2000b; Rothkopf, Teisberg, & Kahn, 1990).

Against this background, an online auction can be defined as an Internet-based version of a traditional auction (Jansen, 2003). The major difference between the two types is the additional degree of flexibility in the way the online variety is conducted. Specifically, in a traditional auction setting, the auctioneer and the bidders gather in one room at a given time to decide who gets the item and at what price. Such auctions generally last only for a few minutes or even seconds for each item sold. This rapid process gives very little time to the auction participants to make decisions, so they may decide not to bid in the auction. As a consequence, the sellers may not get the highest possible price for their goods (Turban, Lee, King, & Chung, 2000). Apart from that, bidders are usually required to come to the auctions, and this practice leaves out many potential bidders that may not be able to attend the auction sessions. It may also be very difficult for the sellers in traditional auctions to move their goods to the auction site (especially when the items are bulky), and there may be a large cost associated with operating the auction since the sellers have to rent the auction site, auctioneers and other employees need to be hired, and the auction needs to be advertised in advance.

Things are somewhat different in the online case. In particular, many of the geographical and temporal limitations of the traditional auctions are removed (Lucking-Reiley, 2000a). Specifically, the consumers can be sitting in the comfort of their homes while participating in an online auction that may be located many thousands of miles away. Moreover, online auctions generally last for days and weeks, giving the bidders more flexibility about when to submit bids. Online auctions also allow sellers to sell their goods efficiently and with little action or effort required. Apart from that, sellers have fewer problems of getting a large group of bidders together on short notice because of the availability of a large number of online bidders distributed across the globe. This creates a larger market for the goods on sale.

In summary, online auctions provide a selection of goods that Internet communities can buy or sell, allowing the consumers a greater chance of getting their goods and the sellers a greater chance of selling their goods. Since online auctions offer a wide array of items, generally speaking, there are likely to be many online auctions that sell similar items. For example, a search for the term *digital camera* using the auction search engine AuctionSeek (http://www.auctionseek.net) yields 49,768 results. The current bid prices range between $1.00 and $18,000, and the duration of these auctions range between less than a minute and a week. This means it is quite possible for buyers to get a bargain based on the fact that there is a wide selection of choices with a variety of prices. Online auctions have also been used by sellers to dispose of aging items, unwanted items, and excess items to the community of buyers who may require them. This is the reason why online auctions are an ideal place to search for collectors' items and for hard-to-find items (Turban, 1997). From the sellers' perspective, online auctions are the perfect place to trade goods due to the presence of a huge number of bidders that are distributed globally (Lucking-Reiley, 2000a). There are of course some disadvantages of online auctions such as the bidder's inability to physically view the item being auctioned off, or the possibility of fraud. However, generally speaking, the benefits outweigh the risks.

ONLINE AUCTION ISSUES AND CHALLENGES

Online auctions have been the focus of attention of many academic researchers because of its complexities and its dynamics. Historical data from eBay are downloaded and analyzed to investigate the bidder behaviors and the bid arrivals, and to predict the closing price of a given auction. However, in order to study these, one has to understand the auction settings, the bidding and selling processes, as well as the different types of auctions that may be employed by the auction houses.

The most common format of online auctions that are used by most auctions houses is the ascending-bid auctions constrained by time. Each auction is given a start time and an end time, and bidders are free to post bids anytime while the auction is on going. The winner is the one that posts the highest bid. However, this type of auction can be further classified into a variety of options. For example, eBay offers five options: reserve-price auction, private auction, multiple-item auction, "buy it now," and best offer. The reserve-price auction allows the seller to fix a reserve price, which is the minimum price that the seller is willing to accept for the item being sold. The seller is not obligated to sell the item if the reserve price is not met.

The seller can also choose to create a private auction in which the buyer's user ID does not appear in the listing or in the listing's bid history. Only the seller is authorized to view the buyer user IDs associated with the listing. This kind of auction is usually used to sell high-priced items or approved pharmaceutical products. The multiple-item auction, also known as the Dutch auction (this is not the same as the traditional Dutch described earlier), allows the seller to offer multiple identical items for sale. Each bidder is required to enter the quantity required and the bid amount for each item. The winning bidders are determined in order of bid price per item and will pay a price equal to the lowest winning bid. A variation of this auction style is the Yankee auction in which the successful bidders pay what they bid.

The buy-it-now option enables the bidder to purchase an item when he or she wants it at a known set price without having to wait for the online auction to end. During the bidding period, the buy-it-now option is only available for a limited time. The best-offer feature allows sellers to receive price-based offers from buyers that can be accepted at the

discretion of the seller. This feature is available for listings in fixed-price auctions and classified ads. Once a buyer's best offer is accepted by the seller, the listing ends.

Another auction format that is commonly used is the reverse auction. In this auction, the bidder is the seller and not the buyer. It is a fixed-duration bidding event hosted by a single buyer, in which multiple suppliers compete for business. The bid reflects how much the buyer is being asked to pay and not how much the good or service is being sold for. These kind of Web-based reverse auctions have become extremely popular for purchasing everything from accounting services to securing raw materials.

Bidding in online auctions is time consuming. Bidders are always looking to simplify the bidding process as well as to ensure that they get good deals. On the other hand, sellers are always looking for ways to dispose of their items with profits. Hence, most auction sites provide a tool for the bidders that can automate the bidding process. This tool, referred to as the proxy bidder, only requires the bidders to key in the maximum bid for a given item and will place bids on the bidder's behalf starting with the next bid increment for the auction. It will only bid as much as necessary to make sure that the bidder remains the highest bidder and will keep bidding until the bidding reaches the maximum amount or until the auction is closed. Despite the convenience, this tool does not give the freedom to bidders to specify the time they wish to place their bids (Bapna, 2003). Moreover, the auction host may try to offer a price very close to the bidder's maximum amount to guarantee that he or she obtains as much profit as possible.

Another popular method employed by bidders is sniping (or also known as late bidding). Sniping refers to the practice of bidding at the last opportunity in online auctions with fixed closing times. Some bidders snipe manually during the last seconds before the auction closes while others use software (known as snipers) to perform the auction sniping. Placing bids at the end of the auction ensures that no other bidders are able to place another bid and almost always guarantee a win in the auction. This practice is not favored by the bidding communities, resulting in some auction houses like Amazon.com and uBid to extend the auction if there are any bids within 10 minutes of the auction close time; there is no limit to the number of times an auction can be extended. This practice of sniping also converts the auction into a single-shot sealed-bid auction.

Those sellers looking for more profit in online auctions resort to all sort of tricks and tactics. One such tactic is shill bidding. Shilling occurs when a seller bids on his or her own auction in an effort to increase the price other bidders need to pay to win the auction (Kauffman & Wood, 2005). It usually occurs in the form of competitive shilling, where the seller starts bidding so that the final bidder is forced to bid higher than would otherwise be necessary to win the auction item. Shilling is considered a criminal fraud in the United States and elsewhere, and the offence is punishable by a jail term or heavy fines. Unfortunately, shilling is one of the online auction frauds that are the hardest to detect.

As discussed, bidding in an online auction is complicated since the bid changes from time to time and the closing price of a given auction is only known when the auction is concluded. First, the bidder needs to decide what item to buy and in which auction to participate. To do this, he or she will need to monitor several auctions to analyze the progression of the auctions. In any given auction, the bidder can access information about the auction such as the current bid value, the bids history, the bidding duration, and the seller's rating. So, using this information, the bidder needs to decide when to bid and at what price to bid. Bidders usually have their own reservation price, which is the maximum price they are willing to bid for a given item. Even if the bidder is able to determine these parameters, this does not guarantee a win in the auction (some other bidder may bid at the last second with a higher bid value). This process needs to be repeated several times until the bidder succeeds in obtaining the item.

Even if the item is obtained, the bidder may end up paying more than the intrinsic value of the item. This is called the winner's-curse phenomenon. This is one of the reasons why prices determined by auctions deviate from standard purchases: Auctions tend to favor those bidders who have most overestimated the value of the item for sale (since the winning bidder is always the one with the highest bid). The winner, therefore, may have overpaid relative to the true value of the item.

To maximize the chances of winning in an auction, bidders can always place bids simultaneously in multiple auctions. While this may reduce the likelihood of not winning an auction, this will also increase the risk of the bidders in that they may end up getting more than a single item. It would be desirable to have software to monitor bids, deciding on which auction to bid as well as determining how much to bid.

On the other hand, sellers want to auction off their items at a reasonable price with a reasonable profit. The timing and the placement of the item on certain auction sites also need to be considered to ensure that the item is sold in a manner consistent with the seller's requirement. A seller may get a higher profit in an auction that has many bidders and when the bidding time is longer.

In view of the auction complexities, many researchers have embarked on a variety of research-related online auctions with varying objectives in order to address the issues highlighted in the previous section. Some notable work includes exploring factors that affect final prices as well as predicting the closing price for a given auction (Ghani, 2005; Jank & Shmueli, 2005; Lucking-Reiley, Bryan, Prasad, & Reeves, 2007), modeling the bidder arrival process (Akula & Menasce, 2005; Shmueli, Russo, & Jank, 2007), studying reputation and trust in online auctions (Dewan & Hsu, 2001; Houser & Wooders, 2006), finding empirical evidence

for late bidding (sniping; Bapna, 2003; Roth & Ockenfels, 2002), analyzing and detecting shill bidding, investigating bidding strategies (Anthony & Jennings, 2003; Jiang & Leyton-Brown, 2007; Shah, Joshi, Sureka, & Wurman, 2003), studying bidders' behavior (Dewally & Ederington 2004; Walley & Fortin, 2005), and developing strategies for sellers (Anthony, 2006; Kim, 2007).

FUTURE TRENDS

Due to the popularity of online auctions, in the future we expect that an emerging technological force, in the form of smarter ubiquitous open-source bidding agents, is likely to have a significant influence on their future practice (Bapna, 2003). Online auctions will be populated by software agents that will bid and sell on behalf of the users. More research on online auctions will be undertaken that will address issues such as online auction closing-price prediction, bidder behavior prediction, the development of bidding strategies that can be utilized by bidders, and the development of seller strategies. More complicated auction protocols are expected to emerge to counter shill bidding and sniping activities.

CONCLUSION

The online auction is still the major contributor to the Net economy and is still growing. Millions of people are hooked on eBay with similar objectives: to look for bargains and to sell goods. We foresee that online auction sites will be populated by software agents that will bid and sell on the customer's behalf. Hence, the economic impact of having software agents in the online auction environment should be further analyzed and investigated.

KEY TERMS

Auction: It is a mechanism described by a set of auction rules that specify how the winner is determined and how much he or she has to pay.

Bid: It is the price offered by a given buyer in an auction at a given time while the auction is on going.

Bid Sniping: This occurs when bids are placed just a few minutes or seconds before an auction ends. This type of bidding is applicable in English auctions that have fixed deadlines (such as the ones conducted in eBay).

Dutch Auction: It is an auction in which the auctioneer starts at a very high price that is then progressively lowered until there is a call from any bidder to claim the item.

English Auction: It is an auction in which the auctioneer starts the auction with a low price that is then successively raised until one bidder remains.

Online Auction: it is an Internet-based version of a traditional auction in which there is no time and location constraints.

Reservation Price: This is the maximum price the bidder is willing to pay for the item being auctioned.

Reverse Auction: It is an auction where the bidder is the seller and not the buyer. The buyer will indicate the requirements and sellers will submit bids.

Sealed-Bid Auction: This is an auction in which each bidder submits a single bid independently without knowing what the others bid.

Shill Bidding: This occurs when a seller bids in his or her own auction in an effort to increase the price other bidders need to pay to win the auction.

Software Agents: These are software capable of making decisions on behalf of the user and are usually endowed with some level of autonomy and intelligence.

An Overview of Enterprise Resource Planning for Intelligent Enterprises

Jose M. Framinan
University of Seville, Spain

Jose M. Molina
University of Seville, Spain

INTRODUCTION

Enterprise resource planning systems can be defined as customizable, standard application software which includes integrated business solutions for the core processes and administrative functions (Chan & Rosemann, 2001). From an operative perspective, ERP systems provide a common technological platform unique for the entire corporation allowing the replacement of mainframes and legacy systems. This common platform serves to process automation as well as to simplify current process either by an explicit reengineering process or by the implicit adoption of the system "best practices" (Markus & Tanis, 2000). Finally, the common centralized platform allows the access to data that previously were physically or logically dispersed. The automation of the processes and the access to data allows the reduction of operating times (thus reducing operating costs) while the latter serves to a better support of business decisions (see e.g., Umble, Haft & Umble, 2003 for a detailed review of ERP benefits). ERP is considered to provide businesses with new opportunities to acquire knowledge (Srivardhana & Pawlowski, 2007), being the sources of knowledge the aforementioned best practices from the ERP, and the ERP software company's staff during the implementation phase.

At present, ERP systems are either used or implemented in a large number of enterprises. According to Genoulaz and Millet (2006), up to 74% of manufacturing companies and up to 59% of service companies use an ERP system. In addition, more than 70% of Fortune 1000 companies have implemented core ERP applications (Bingi, Sharma, Godla, 1999; Yen, Chou & Chang, 2002). The objectives for implementing an ERP system can be classified as operational, strategic, dual (operational plus strategic), or without objective (Law & Ngai, 2007). The adoption of an ERP system with operational objectives is aimed at improvement operating efficiency together with the reduction of costs, while companies implementing ERP with a strategic objective would experience a change in business processes, improving sales and market expansion.

A widespread critique to ERP systems is their high total cost of ownership (Al-Mashari, Al-Mudimigh & Zairi, 2003) and hidden costs in implementation (Kwon & Lee, 2001). Besides, ERP systems impose their own logic on an organization's strategy and culture (Davenport, 1998), so ERP adopters must adapt their business processes and organization to these models and rules. Consequently, organizations may face difficulties through this adaptation process which is usually carried out without widespread employee involvement. This may cause sore employees, sterile results due to the lack of critical information usually provided by the employees; and also late delivery, with reduced functionality, and/or with higher costs that expected (Kraemmeraard, Moeller & Boer, 2003). Additionally, some analysts have speculated that widespread adoption of the same ERP package in the same industry might lead to loss of competitive advantage due to the elimination of process innovation-based competitive advantage (Davenport, 1998). This has been observed, for instance, in the semiconductor manufacturers sector (Markus & Tanis, 2000).

The early stage of ERP was carried out through Materials Requirement Planning (MRP) systems (Umble, Haft & Umble, 2003). The next generation of these systems, MRP II (Manufacturing Resources Planning), crossed the boundaries of the production functionality and started supporting not only manufacturing, but also finance and marketing decisions (Ptak & Schragenheim, 2000). Current ERP systems appeared in the beginning of the 1990's as evolved MRP II, incorporating aspects from CIM (Computer Integrated Manufacturing) as well as from EDP (Electronic Data Processing). Therefore, ERP systems become enterprise-wide, multilevel decision support systems. ERP systems continue evolving, incorporating Manufacturing Execution Systems (MES), Supply Chain Management (SCM), Product Data Management (PDM), or Geographic Information Systems (GIS), among others (Kwon & Lee, 2001).

BACKGROUND

Most enterprise resource planning systems share a number of common characteristics, both from a technological as well as a business perspective. These include:

- **Client/server, open systems architecture**. Most ERP packages adopt an open systems architecture that separates data (database server), application (ERP server), and presentation (user interface/ERP client) layers, guaranteeing cross-platform availability and systems integration (Basoglu, Daim & Kerimoglu, 2007). In order to interoperate with existing business applications or information systems, most ERP adhere to the majority of common standards for data exchange or distributing processing.
- **Enterprise-wide database**. One of the most distinguishable characteristics of ERP is the strong centralization of all relevant data for the company (Al-Mashari, Al-Mudimigh & Zairi, 2003). When physical centralization is not possible, communication and/or replication protocols among the different databases should be implemented in order to ensure data consistency and accessibility throughout the entire enterprise.
- **Kernel architecture**. Some ERP systems support more than 1,000 different business functionalities (Bancroft, Seip & Sprengel, 1998), covering nearly all-relevant business aspects for most of the enterprises. As all these functionalities cannot be loaded in the ERP server at the same time, the majority of ERP systems employ a so-called "kernel architecture". In this architecture, most functionalities are stored in the ERP database, usually in the form of source code of a proprietary, fourth generation, programming language. When certain functionality is required by an ERP client, the ERP server loads it from the database and compiles the corresponding code so the functionality is made available for the clients. Once it is not required, the functionality is removed from the ERP server. Note that this mechanism also allows for an easy enhancement/updating of existing functionalities as well as for the construction of new ones.
- **Process-oriented, business reference model**. ERP is process-oriented software that has been developed starting from an implicit or explicit business reference model in order to appropriately describe the relevant business functions covered by the ERP system. For most ERP vendors, this model is explicit and takes the form of the best practices extracted form the ERP vendor experience (Markus & Tanis, 2000). This can be used to analyze and evaluate current business processes in the enterprise prior to the implementation of the ERP package, serving thus as benchmark processes for business process reengineering (BPR).
- **Adaptation to the enterprise**. In order to meet the specific requirements of different enterprises, ERP systems are highly configurable. This potential for customization is considered to be one of the main differences between ERP and other standard software packages (Kraemmeraard, Moeller & Boer, 2003). The customization process may take several months, or even years, depending on the enterprise.
- **Modularity**. Although the term "ERP system" is usually employed to design a system covering all corporate functions (Slater, 1998), generally an ERP system is composed of a set of ERP modules. An ERP module is a group of function-oriented, tightly integrated, functionalities which in many cases can be separately purchased and installed. Typical ERP modules are the financial-accounting module, production-manufacturing module, sales-distribution module, or human resources module. This allows enterprises to purchase only these modules strictly required as well as the possibility of integrating them with existing information systems.

An intelligent enterprise is an organization which acts effectively in the present and is capable to deal effectively with the challenges of the future (Wiig, 1999). Since most enterprises operate today in a complex and dynamic environment characterized by increasing competition and continuous changes in products, technology and market forces, an intelligent enterprise should be proactive, adaptable, knowledgeable, and well-resourced (Kadayam, 2002). In order to achieve this behavior, it is expected that all employees in the intelligent enterprises not only deliver the work products that are directly associated with their functions, but that they also innovate to improve customer relationships, enterprise capabilities, and envision opportunities for new products and services (Wiig, 1999). Therefore, it is clear that an intelligent organization should have timely access to all critical information in order to gain insight into its performance and should be able to provide effective decision support systems. Hence, one of the requisites for the intelligent enterprise is the availability of all relevant data in the organization. Indeed, access to the right information is considered to be one of the key characteristics of intelligent enterprises (Smirnov, Pashkin, Chilov & Levashova, 2003).

FUTURE TRENDS

One of the main problems presented by ERP systems is the large amount of time needed to carry out their implementation. The length of these periods tends to be reduced even to a period of weeks and 2-3 months at most (Jacobs & Weston, 2007), as the majority of companies have realized the benefits gained from short implementation cycles. This reduction of the implementation period is also achieved by means of the so-called "pre-customized" packages, which essentially include tailored modules with default values usually depending on the different sectors of activity.

Up to date, ERP systems lack or have very little "intelligence". Data mining and intelligence tools would lead to an increase in the use of these systems in the decision-making business, thanks to the expert systems and advanced planning (optimization) (Jacobs & Weston, 2007). If we adopt the generic intelligent enterprise architecture by Delic and Dayal (2002), ERP addresses issues of supply chain efficiency and back-office optimization, and provide the basis for Enterprise Knowledge Management (EKM). At the same time, the evolution of enterprises to the form of intelligent organizations requires the cooperation of independent companies into a virtual multitier enterprise (Olin, Greis & Kasarda, 1999), the Internet providing the glue for their heterogeneous information systems (Delic & Dayal, 2002). In order to achieve this, one of the main trends followed by most ERP systems vendors is the introduction of Internet (Chan & Rosemann, 2001; Kwon & Lee, 2001). The use of Web services within the scope of these systems is believed to provide two major advantages: firstly, the ease of integration, and the cost reduction through the hosted application model (Tarantilis, Kiranoudis & Theodorakopoulos, 2006). The adoption of the Internet can be seen from two viewpoints, i.e. the user interface viewpoint, and the internal/external communication viewpoint. With respect to the user interface, ERP systems are transaction-oriented. However, the connectionless nature of the Internet protocols (i.e., the connection between the Web server and the browser is not maintained after the former has sent the requested data to the later) makes it not well suited for transactions. Therefore, it is intrinsically difficult to adapt the ERP internal structure to the Internet. As a consequence, most of the ERP vendor's effort is on creating reliable gateways between the ERP system and an Internet server.

Regarding the internal or external communication of the ERP system, the emphasis is done in the adoption of the Internet standards for data exchange. This is done with respect to both the exchange of data among the different ERP modules and to the exchange of data among the ERP system and external applications. Hopefully, this effort will result in the adoption of a common communication standard that will allow the integration of the information systems of customers and/or providers in a supply chain. Additionally, it will make feasible the so-called "component ERP": that is, the acquisition of the "best-of-breed" modules from every ERP vendor (Fan, Stallaert & Whinston, 2000). Since communications among ERP modules has been driven by proprietary protocols, the ERP market has been forcing the enterprises to purchase all modules of the ERP system from the same vendor or face huge costs in developing interfaces for modules from different ERP systems. This may be greatly simplified by the adoption of a public, common, protocol standard such as those in the Internet. Even in the most likely case that interfaces between modules from different vendors are still required; the decrease in the cost of their development may render it affordable for the enterprises (Appleton, 1997; Kwon & Lee, 2001).

Another trend is caused by the high cost of acquisition and maintenance of ERP packages, which makes them too expensive for SMEs. To solve this, there are several open source ERPs. The implementation of these open source packages has the same complexity than those of proprietary ERP systems, but with lower costs of licenses, reduces dependency on a limited group of suppliers, and increased adaptability of the software. At present, the open source ERP packages include Compiere, ERP5, Openbravo ERP, Fisterra, OFBiz, among others (Serrano & Sarriegi, 2006).

THE ERP MARKET: VENDORS AND MARKET TRENDS

The world ERP market has been growing at a rate between 3%-13% per year in the period between 2000 and 2004 (AMR research reported in 2005 that the market grew by 14% in 2004 and became a $23.6 billion business, see Basoglu, Daim & Kerimoglu, 2007). AMR research expects that the annual growth of the market between the years 2006 and 2009 will be in the range of 6%-7%. Nowadayas, the ERP market is the largest segment of company's application budget (34%), and it is expected to remain so (Aloini, Dulmin & Mininno, 2007; Basoglu, Daim & Kerimoglu, 2007; Scott & Shepherd, 2002; Somers & Nelson, 2004). This growth has been boosted by a number of reasons, such as globalization, market maturity in developed countries, and advances in information and communication technologies, among others.

Market analysis shows the enormous fragmentation of the ERP market, where more than 100 products are targeted as ERP (see APICS, 2000). With respect to the main market players, by 2002 it was composed by the following companies: SAP, Oracle, PeopleSoft, and JD Edwards, as some former major players such as Baan had disappeared (Jacobs & Weston, 2007). At the end of 2002, JD Edwards (whose products were strong in manufacturing, accounting, and finance) and PeopleSoft (expert on human resources) contemplated the possibility of merging, resulting in a company larger than Oracle, its main competitor along with SAP. The merger was announced in June 2003. A few days later, Oracle spears hostile to a takeover PeopleSoft, causing the breakdown of the agreement that came with JD Edwards. After a period of hesitation, because the takeover offer by Oracle had raised antitrust issues, the takeover was consummated in 2005. Currently, the market is composed of two large companies such as SAP and Oracle, but with the abilities of the five initial companies. It is not easy to offer precise information about market shares, since the comparative analysis of the published results show a great dispersion depending on the sources. However, there is consensus that SAP AG is the world market leader with the product SAP

R/3, being its market share around 40%, while the market share of Oracle is approximately 22% (Basoglu, Daim & Kerimoglu, 2007).

THE ERP IMPLEMENTATION PROJECT: RISKS AND KEY SUCCESS FACTORS

The ERP acquisition and implementation constitutes a risky project that may result, in a high number of cases, in unsatisfactory, if not failed, system implementations. It has been reported that nearly three-fourths of ERP implementation projects are judged unsuccessful by the ERP implementing form (Griffith, Zammuto & Aiman-Smith, 1999). ERP implementation involves a significant commitment of time and money (King & Burgess, 2006), ranging from $300,000 to several million dollars depending on the size of the enterprise (Heizer & Render, 2003). Cases of failures in well-known organizations such as Boeing (Stein, 1997) or Siemens (Seidel & Stedman, 1998) have been described. Furthermore, these cases involve software of all primary ERP vendors (Motwani, Mirchandani, Madan & Gunasekran, 2002). More detailed reports (see in Cunningham, 1999 a study of 7,400 IT projects) confirm that nearly 35% of ERP implementation projects are late or over budget, 31% are abandoned, scaled or modified, and only 24% are completed on time and in budget. For this reason, studies that seek to identify factors that are critical (so-called Critical Success Factors or CSFs) for achieving a successful implementation have been carried out (see e.g., Akkermans & van Helden, 2002; Finney & Corbett, 2007; Holland & Light, 1999; Hong & Kim, 2002; Remus, 2007; Somers & Nelson, 2001). In this line, Finney and Corbett raised a methodology to identify CSFs, and they found 26 types of CSFs that may be classified according to the classification by Holland and Light (1999) into strategic and tactical. Strategic CSFs include top management commitment and support, visioning and planning, build a business case, project champion, implementation strategy and timeframe, vanilla ERP, project management, change management, and managing cultural change. Tactical CSFs include balanced team, project team: the best and brightest, communication plan, empowered decision makers, team morale and motivation, project cost planning and management, BPR and software configuration, legacy system consideration, IT infrastructure, client consultation, selection of ERP, consultant selection and relationship, training and job redesign, troubleshooting/crises management, data conversion and integrity, system testing, post-implementation evaluation. In addition, it is possible to organize CSFs into organizational and technological (see Esteves & Pastor, 2000).

According to Tarantilis, Kiranoudis, and Theodorakopoulos (2006); Genoulaz and Millet (2006), and Amoako-Gyampah (2007), the implementation of an ERP system is associated with a range of benefits for the company. Some of these include the following:

- Through streamlining, improving, and controlling business processes more meaningful, there is an increase in the operation of the company.
- Cost reduction and execution times of the most important business processes.
- Support for the management of the supply chain through the integration and synchronization of all activities within it.
- Using the module management, the enterprise has the ability to handle matters related to personnel and costs.
- Improving the use of the system of quality management of the company, allowing it to avoid paperwork, reduce staff tasks related to quality, among others.
- By complementing the management module, it gets a production scheduling more flexible and efficient.
- Design of an integrated information system that would eliminate multiple data sources, facilitating proper information flows and communication among different departments of the company in real time.
- Exploiting abilities to control sales and promotional activities, receiving data on each technique promotional to increase the efficiency of the sales department

CONCLUSION

ERP systems have been considered one of the most noteworthy developments in information systems in the past decade. ERP systems are present in most big companies that operate in the new millennium. Their advantages in terms of access to information or the integration of business functions has been outlined. However, ERP implementation projects are not risk-free: rates of ERP implementation failures are rather high. Although the failure figures may be partly explained by the intrinsic complexity of the ERP implementation project, some others may be minimized by the consideration of the ERP implementation as a strategic decision in the enterprise, and thus a principal, long-term project rather than a single information system change.

ERP systems will play a central role in the intelligent enterprise of the future. ERP vendors are continuously adding new features and providing an easy integration with other information systems as well as among modules from different vendors. Success in the latter issue is claimed to be

crucial for maintaining the now outstanding ERP position in the new enterprise.

KEY TERMS

Best Practices: Process procedures of recognized excellence, usually obtained from companies' experience and or process optimization analysis.

Big-Bang ERP Implementation: ERP implementation strategy consisting in implementing all required modules and features at once.

BPR: Business Process Reengineering (BPR) radically rethinks key enterprise process in order to achieve substantial process improvement.

Client/Server Architecture: Computer network model separating computers providing services (servers) from computers using these services (clients).

EKM: Enterprise Knowledge Management (EKM) is aimed to inject knowledge into business processes and to enable reuse of human expertise through the creation of common data objects and definitions that can be used with equal ease and success by all employees in the enterprise.

ERP: Enterprise Resource Planning (ERP) denotes packaged software to support corporate functions such as finance, human resources, material management, or sales and distribution.

Intelligent Enterprise: Organization capable to act effectively in the present and to deal effectively with the challenges of the future by being proactive, adaptable, knowledgeable, and well-resourced.

Modularity: Most ERP packages decompose their functionality in modules grouping typical business functions such as finance, sales, manufacturing, among others.

Process Orientation: Recognition of series of functions that carry out an overriding task by providing the customer with a meaningful result.

An Overview of Executive Information Systems (EIS) Research in South Africa

Udo Richard Averweg
eThekwini Municipality and University of KwaZulu-Natal, South Africa

INTRODUCTION

Executive information systems (EIS) are designed to serve the needs of executive users in strategic planning and decision-making. Sometimes the terms "executive information systems" and "executive support systems" are used interchangeably (Turban, McLean, & Wetherber, 1999). Definitions of EIS are varied but all identify the need for information that support decisions about the organization. EIS can be defined as "a computerized system that provides executives with easy access to internal and external information that is relevant to their critical success factors" (Watson, Houdeshel, & Rainer, 1997).

This article is organized as follows: The background to EIS implementation is given. EIS research studies undertaken in South Africa are then described. Some future EIS trends are then suggested.

BACKGROUND TO EIS IMPLEMENTATION

A number of possible indicators for a successful information system (IS) have been suggested in various implementation studies (see, for example, Laudon & Laudon,1998). The definition of implementation includes the concept of success or failure. Implementation is a vital step in ensuring the success of new systems.

The EIS implementation process is defined as the process used to construct an EIS in an effective manner (Srivihok, 1998). Different factors have been suggested by various researchers as influencing successful EIS implementation (see, for example, Rainer & Watson, 1995). However, there is no agreement on which factors play key roles in EIS implementation. A large number of success factors have been repeatedly suggested by practitioners and researchers, even though empirical studies on the success factors are rare.

EIS are high-risk application systems that are expensive to build and maintain (Strydom, 1994). For example, in October, 1997, the largest water utility in South Africa, Rand Water, took a decision to build an EIS (based on Oracle® products) and invested ZAR4.5m in revamping its IT infrastructure to support that deployment. In the case of Rand Water, the organization's EIS eventually played a major role in providing its executives with benchmarking information helping them track Rand Water's overall performance against a set of objective criteria.

EIS RESEARCH UNDERTAKEN IN SOUTH AFRICA

A review of previously conducted EIS research at universities in South Africa is undertaken. From this collection, the nature of EIS research for each study is discussed. South African databases were searched for research literature (essays, technical reports, thesis, dissertations, etc) with the keywords "Executive Information Systems" in the title. Nine successful "hits" were found. Those research articles are reflected in chronological publication sequence in Table 1.

The nature of each of the nine EIS studies in South Africa is now briefly discussed:

- **Researcher No 1: Design and Implementation of Executive Information System (EISs):** DeWitt (1992) discusses critical success factors (CSFs) for EIS development and states that the type of EIS for an organization will depend on the information requirements of the organization. It should be driven by the CSFs that are unique to a particular business. From previous studies, DeWitt (1992) identifies nine CSFs for an EIS (see Table 2) and notes that there "are differences of opinion in the literature regarding the selection of the right technology" as a CSF.
  This study was undertaken with sixteen large Cape Town companies from various industry sectors. The findings from Watson's international survey (Watson, Rainer, & Koh, 1991) were compared against the local (South Africa) survey findings. The findings indicate (1) congruences between the literature search and survey

Table 1. Research literature (essays, thesis or dissertations) with the keywords "executive information systems"

No	Researcher(s)	Publication Date	Research title	Report Type	Qualification and Institution

findings; (2) major conflicting results between the local survey, the international survey and literature search; and (3) major problems encountered in developing EIS.

- **Researchers No 2: An Assessment of the Penetration of Executive Information Systems:** Twemlow et al. (1992) carried out an exploratory study that showed the extent of EIS penetration in South Africa. The sample (61 companies) was selected from the 1992 Financial Mail survey (a reputable weekly financial publication) of "top" companies in South Africa. The research instrument was designed to evaluate EIS as a significant business trend, the extent of penetration of this trend in the organization and perceived impact on the business. From these researchers' findings, the problems experienced by companies during the implementation and use of their EIS is reflected in Table 3.
  Twemlow et al. (1992) suggest that even though studies have been performed to determine the nature of executive work and their information requirements, there is still uncertainty in this area. Twemlow et al. (1992) note that "it is not surprising" that the first two out of the top four problems associated with EIS implementation were concerned with the complex and changing executive information needs.
- **Researcher No 3: Executive Information Systems: A Fundamental Approach:** Strydom's (1994) research investigated the problems concerning EIS "from a fundamental research perspective." Based on the results of the research an augmented EIS was proposed and referred to as a computer supported executive system (CSES). Strydom (1994) discussed the role of training in successful implementation of IS and focuses on computer supported learning for EIS.
- **Researcher No 4: Critical Success Factors for Executive Information Systems Implementation:** Steer's (1995) study used the findings of research undertaken by Harris (1993) and others. The basis of Steer's research "was to identify the critical success factors for the successful implementation of an Executive Information System ..... where an EIS had been implemented." Seventeen well-established organizations in Gauteng (a province in South Africa) that have EIS experience were targeted and surveyed. The analysis of Steer's findings indicate 21 major concepts that were raised by interviewed respondents in relation to the CSFs for implementing EIS. The top 10 CSFs (in descending order) that were identified in this study for the successful implementation of EIS are reflected in Table 4.
  Steer indicates that although "the remaining 11 concepts of the 21 discussed during the research are not the most important critical success factors of implementing an EIS, they are still important, and should therefore be considered when implementing an EIS." Steer (1995) labels these CSFs as "secondary" CSFs for the successful implementation of EIS. These secondary CSFs are reflected in Table 5.

- **Researcher No 5: The Impact of Executive Information System on the User:** The focus of Faure's (1995) research was to highlight "the key features of an EIS, the benefits that can be achieved from implementing an EIS and the development methodologies that can be adopted to achieve success in the implementation of an EIS."
- **Researcher No 6: Critical Success Factors for the Management of Executive Information Systems in Manufacturing:** The aim of Chilwane's (1995) research was "to identify those critical issues, which when managed properly, will ensure that the system remains providing and meeting the needs of the executives. Ten interviews were conducted from business organizations in order (*sic*) identify these factors." Table 6 reflects the CSFs for managing an operating EIS "as seen by respondents who organizations have implemented EIS" (Chilwane, 1995). Chilwane (1995) states that ensuring "that these factors are monitored will contribute to sustaining the investment an organization has made in this technology."
- **Researcher No 7: The Benefits and Capabilities of Executive Information Systems:** The objective of Khan's (1996) research was to identify and evaluate the organizational benefits derived from EIS and to establish which of its capabilities contribute to the realization of the benefits. Khan (1996) notes that a major problem when implementing an EIS is determining the information requirements for the system (Watson & Frolick, 1993). For these researchers a major developmental problem is determining the information to include in the system.

  Khan (1996) notes that practitioners find it difficult to get executives to specify what they want and to keep abreast of executives' changing information desires and needs. Khan's (1996) findings identify six major benefits of EIS and five major capabilities of EIS.
- **Researcher No 8: Experiences Gained from Executive Information Systems:** Baillache's (1997) research investigated the experiences gained by South African users of EIS. The results are seen as important in identifying problem areas that negatively affected the evolution of EIS in South Africa. Some 30 companies participated in this survey. Four users from each company surveyed were requested to complete a questionnaire.

  The findings indicate that (1) some important capabilities had been omitted in systems; (2) users expectations of benefits were far greater than benefits delivered; (3) key CSFs did not occur during the implementation of the project; and (4) the growth of the system by new users was not strongly correlated to the CSFs. Baillache's (1997) summary of results of CSFs implemented is reflected in Table 7.

Table 2. DeWitt's (1992) nine CSFs for an EIS

A committed and informed executive sponsor
An EIS driver
A clear link to business objectives
Carefully defined system requirements
Ensure feasibility of data availability
An active team approach to ensure spread to additional users
An evolutionary development approach
Quick response and user friendliness
Managing organisational resistance

Table 3. Problems with Implementation and Use of EIS (Source: Adapted from Twemlow et al., 1992)

Complex information needs of EIS users
Changing needs of EIS users
Insufficient management support
Lack of clarity of EIS purpose
Data availability
Failure to incorporate EIS into management processes
Hardware compatibility
Software compatibility
Unexpected increase in costs
Failure to meet the user's expectations

Table 4 . The top ten CSFs for the successful implementation of EIS (Source: Adapted from Steer, 1995)

Concept
An EIS needs a project champion
An EIS must support the cross-functional integration of information
An EIS has to link to the organisation's business strategy
An EIS should be implemented using a phased approach
An EIS project champion should be a steering committee rather than one person
Resistance from the information users must be managed
An EIS must have the capability to access external information
Resistance from the information providers must be managed
The project champion should change during the project
An EIS must support "drill down" facilities

Table 5. Secondary CSFs for the successful implementation of EIS (Source: Adapted from Steer, 1995)

Concept
An EIS should be made available to everyone
An EIS must have "what if" and simulation facilities
Resistance from IT people must be managed
An EIS must support trend analysis
The user must be able to interact with and manipulate the information
An EIS must support exception reporting
It must be possible to track actuals against plans
An organisation must develop a formalized business strategy before it embarks on an EIS project
An EIS must have a good graphical user interface
An EIS should be for executives only
An EIS must be able to access financial information

Table 6. CSFs for the management of an operating EIS (Source: Adapted from Chilwane. 1995)

Executives or users should provide regular feedback on the EIS either formally or informally
Continued alignment of EIS ensures that the system remains useful to the users
Continued executive involvement ensures success of the system
An EIS should be flexible to accommodate the dynamic business environment
As EIS spreads new requirements should be reflected in the system
ISD should provide somebody who knows the business to look after the users
An EIS should help individual managers to monitor their individual CSFs
EIS data should always be consistent with the operational data it summarizes
There should be prompt attention to user queries and requirements
An EIS should be portable that is loaded on a notebook and accessed offline

- **Researcher No 9: Executive Information Systems Usage: The Impact of Web-based Technologies:** The objective of Averweg's (2002) study was *inter alia* to identify and rank Web-based technologies in order of their perceived future impact on EIS.
  Only 6.4 percent of organizations surveyed reported that it is unlikely that the intranet will impact future EIS implementations. Almost half of organizations surveyed reported that it is unlikely that e-commerce (business-to-consumer) will impact future EIS implementations. WAP and other mobile technologies have similar unlikely future impact levels. It is striking to note that 67.7 percent of respondents indicated that it is *extremely unlikely* that other technologies (such as portal) will impact future EIS implementations. There was a positive impact level trend for all Web-based technologies on future EIS implementations. The largest trend increase was the Intranet rising from 32.2 percent to 87.1 percent. Averweg (2002) suggests that this "should occur as the use of Web-based technologies in the distribution of information becomes more widespread."

DISCUSSION OF PREVIOUS EIS RESEARCH UNDERTAKEN IN SOUTH AFRICA

From Table 1, four EIS researchers (Nos 1, 4, 6 and 8) dealt with CSFs for EIS implementation. A synopsis of the results and findings indicates that there is no consistent "shopping basket" of CSFs for EIS implementation for use by South African practitioners.

Like other systems, EIS are constantly changing. Khan (1996) suggests an investigation into new technologies being employed in the IT area and "to what extent advances in technology have influenced ... EIS." Khan's (1996) EIS research "identified the employment of new technologies as the most important future trend of EIS." The EIS research undertaken by Averweg (2002) serves to fill that gap.

The Web serves as the foundation for new kinds of IS (Laudon & Laudon, 1998). As the Web grows in direct usage by executives, existing EIS implementation models may need to be revisited. While there is no single listing of key variables for EIS success factors (Rainer & Watson, 1995), strong human factors are nevertheless associated with EIS research. These are influenced by cultural, political and other "soft" human factors. It is therefore neither possible nor valid to generalize experiences on other continents to South Africa's conditions. This makes relevant local studies (in South Africa) of EIS implementation and usage.

FUTURE EIS TRENDS

Information Technology (IT) is more than just computer systems and it is rapidly changing and developing, especially due to the Web, altering the way in which an IS is built. With the Internet, information is no longer a scarce resource. It has changed the way in which organizations are doing business and the way in which they compete.

Table 7. Summary of results of CSFs implemented

CSFs supported by the research	CSFs Implemented
	Having an executive sponsor on the project
	System reliability was ensured
	Quality data
	The skills of the system designers
CSFs not supported by the research	Having an operating sponsor on the project
	Local representation of software companies for support
New CSFs which emerged from the research	There was a clear link between the EIS and business objectives
	Appropriate resources were used from the information systems function
	Appropriate technology was used
	Users specified their own information requirements
	The first deliverable by the ITD was information that was highly valuable
	The EIS contained information of much value to me
	The EIS was implemented as quickly as possible
	The hardware used was reliable
	Pilot sites were used in the implementation

The environment for EIS is undergoing upheaval based on the emergence of Web-based technologies. The following trends for EIS implementation are envisaged:

- Data warehouses store data that have been extracted from the various operational databases of an organization over some years. The intrinsic design of the Web resembles that of a data warehouse bringing access to data collected and provided by a host of users outside a specific organization. The immediacy of the Web is *not* seen as a factor for improved decision-making since EIS are rarely used by executives in emergency or critical time-modes;
- With the increasing amount of IT investment and substantial evidence of failures (Remenyi & Lubbe, 1998), many managers and researchers feel that IS justification and evaluation has become a key management issue. It is contended that wise judgement is needed when deciding on the selective use of IT and feel that this is particularly relevant to EIS in South Africa;
- There will be a significant degree of EIS diffusion to lower organizational hierarchical levels and use by these lower levels. EIS in organizations will spread to managers at various levels such as functional areas and other levels of management (Singh et al., 2002). This will be in keeping with international trends where EIS are being diffused in organizations as EIS is becoming less strictly defined to support professional decision-makers throughout the organization;
- Web-based technologies have enabled EIS to become available to more management levels in the organization. The Web browser has become the common interface to end-user access. While applications can now be accessed by browsers, the capabilities long associated with decision support software are still found (Averweg & Erwin, 2000). Nowadays vendors of decision support software are making their products Web-enabled;
- Xu et al. (2003) suggest that the internal information orientation is the main reason for dissatisfaction with EIS. In order to overcome this dissatisfaction, it is felt that greater use will be made from data from *external* sources (for an organization's CSFs); and
- Special care will be needed when implementing EIS because of its major potential importance to an organization's performance. Failure can lead to long delays in further attempts to use such technology effectively.

This information is particularly useful for IT practitioners in the planning of future EIS implementations in South Africa. An understanding of Web-based technology taxonomies is important to EIS researchers and practitioners.

CONCLUSION

Organizations must "start simple, grow fast" (McKenna Group, 1999) using technologies that will enable it to build on what it has, link to legacy systems, rather than throwing away what has been achieved and developed through each new enhancement iteration. EIS will be impacted by these

change catalysts as EIS become integrated with Web-based technologies not specifically designed for EIS usage.

EIS is going through a major change to take advantage of Web-based technologies in order to satisfy information needs of an increasing group of users (Averweg & Roldán, 2006). Web technologies are often not just a single technical solution, rather a host of an industry specific with inter-connective capabilities that pull together people, processes and technology infrastructure. EIS is being catalyzed through a major change as technical barriers disappear.

KEY TERMS

Critical Success Factors (CSF): Those key areas of activity in which favorable results are *absolutely necessary* for a particular manager to reach his or her goals.

Data Cube: In a multidimensional database, data can be viewed and analyzed from different views or perspectives, known as business decisions. These dimensions form a cube.

Data Warehouse: A repository of subject-oriented historical data that is organized to be accessible in a form readily acceptable for analytical processing activities.

Executives: Corporate knowledge workers responsible for corporate strategic management activities.

Executive Information System: A computerized system that provides executives with easy access to internal and external information that is relevant to their critical success factors.

Information Systems (IS): A combination of technology, people and processes to capture, transmit, store, retrieve, manipulate and display information.

Web-Based Technology: A technology that did not exist prior to the World Wide Web ("the Web") and utilizes core Internet and Web technologies as the platform on which the solution operates.

World Wide Web ("the Web"): An information space consisting of hyperlinked documents published on the Internet.

INTRODUCTION

Knowledge translation (KT) was traditionally framed as a problem of moving research results into policy and practice. The impetus for the flow of knowledge originated with researchers constructing new knowledge and seeing its utility, or with policymakers and administrators seeing problems in practice and looking to researchers for solutions.

In the 1970s, a shift in focus away from knowledge use was exemplified by Caplan's (1979) two-communities theory, which posits that researchers and policymakers comprise two different communities with two different languages (Jacobson, Butterill, & Goering, 2003). A shift back to knowledge use with a new focus on user-centered design is evident in more recent KT models that provide frameworks for researcher and user interaction in order to build better understanding between diverse groups.

The flow of knowledge from its construction in one context to its use in another context has been variously termed knowledge translation, knowledge exchange, knowledge transfer, research transfer, technology transfer, knowledge transformation, knowledge dissemination, knowledge mobilization, knowledge utilization, and research utilization. The terms are often used synonymously, but a specific term is sometimes used because it highlights a particular component of the knowledge flow process. For example, *knowledge exchange* implies a sharing of information between partners of equal value and focuses on the movement of knowledge between them, whereas *research utilization* implies the transformation of research results into usable knowledge and focuses on embedding the usable knowledge in practice.

Information technologies have the potential to support knowledge translation in powerful ways. Key processes in the translation of knowledge include: (1) knowledge creation, management, and dissemination; (2) recognition of links between existing knowledge and its potential application to problems or practice; (3) translation into usable knowledge in practice; and (4) change in practice.

Information technologies are a natural solution for these knowledge translation processes. For example, group and social software such as blogs and wikis support collaborative construction and sharing of knowledge; knowledge management systems support capture, storage, accessibility, and maintenance of constructed knowledge; and most Internet-based technologies support dissemination of information. Well-designed virtual communities provide online environments for the kinds of human interaction that enable collaborative exploration of ideas, that foster recognition of potential links between existing knowledge and its application to solve problems or change practice, and that inspire people to transform their practice. Data mining and artificial intelligence techniques can be used to enhance identification of potential links between knowledge in one context and problems in another context.

BACKGROUND

A variety of approaches to knowledge translation have been developed, most focusing on the interaction of researchers, practitioners, and policymakers to move research results into practice. KT is not inherently unidirectional (research to practice), and Lavis et al. (2001) have argued that researcher-user interaction should become standard practice in research contexts, not simply an add-on. This practice has the potential to open new communication channels from knowledge constructed in practice to new research questions and hypotheses. The five models described below demonstrate a variety of KT approaches in use, from a national initiative to a framework for individual researchers.

The Canadian Institutes of Health Research

The Canadian Institutes of Health Research (CIHR) were created in June 2000 by the government of Canada with a mandate that included health research and knowledge translation defined as:

the exchange, synthesis and ethically-sound application of knowledge—within a complex system of interactions among researchers and users—to accelerate the capture of the benefits of research for Canadians through improved health, more effective services and products, and a strengthened health care system. (http://www.cihr-irsc.gc.ca/e/29418.html)

This definition acknowledges the importance of interaction between researchers and users in order to develop a sound

translation. CIHR (2004) also recognizes that "knowledge translation strategies and activities vary according to the type of research to be translated…and the intended user audience…."

The Knowledge Translation Strategic Plan 2004–2009 (CIHR, 2004) identifies four strategic directions to promote knowledge translation at a national level:

1. Support KT research, i.e., research on KT concepts and processes;
2. contribute to building KT networks, i.e., networks of researchers and research users;
3. strengthen and expand KT at CIHR, i.e., improve capability to support KT research and, with partners, KT itself; and
4. support and recognize KT excellence, i.e., build and celebrate a culture of KT.

The Ottawa Model of Research Use

Logan and Graham (1998) developed the Ottawa Model of Research Use (OMRU), a holistic, interactive approach to knowledge translation intended for use by policymakers to increase utilization of health research results and by researchers interested in the integration of research results into practice. The six key elements include the practice environment, potential adopters of the evidence, evidence-based innovation, research transfer strategies, the use of the evidence, and health-related and other outcomes.

These elements are continuously evaluated in order:

(1) to identify potential barriers and supports to research use related to the practice environment, potential adopters, and the evidence-based innovation; (2) to provide direction for selecting and tailoring transfer strategies to overcome the identified barriers and enhance the supports; (3) to track the progress of the transfer effort; and (4) to evaluate the actual use of the evidence-based innovation and its impact on outcomes of interest. (Logan & Graham, 1998, p. 230)

Research Implementation Approach

Grol and Jones (2000), the National Cancer Institute (2002), and Caburnay, Kreuter, and Donlin (2001) have developed research implementation approaches. Grol and Jones (2000) describe an iterative process of research implementation and evaluation consisting of "Research evidence → Develop concrete proposal for change → Analysis of target social and organizational context, obstacles to change → Link interventions to obstacles → Develop plan → Carry out plan and evaluate progress" (p. S33).

Based on KT implementation research results, four factors that influence the uptake and continued use of clinical guidelines were identified (Grol & Jones, 2000). These factors include:

1. Features of the guidelines (such as the underlying research evidence and the language of the guidelines),
2. features of the target group,
3. features of the social context/setting, and
4. features of the organizational context.

Lavis, et al.'s Framework

Lavis, Roberston, Woodside, McLeod, and Abelson (2003, p. 222) developed a framework for knowledge transfer based on five questions:

1. What should be transferred to decision makers (the message)?
2. To whom should research knowledge be transferred (the target audience)?
3. By whom should research knowledge be transferred (the messenger)?
4. How should research knowledge be transferred (the knowledge-transfer processes and supporting communications infrastructure)?
5. With what effect should research knowledge be transferred (evaluation)

The framework was derived from a review of the research literature across the five questions, four target audiences (general public/service recipients, service providers, managerial decision makers, and policy decision makers at federal, state/provincial, and local levels) and a range of disciplinary perspectives and methodological approaches (Lavis et al., 2003). For example, with regard to question 1 (What should be transferred to decision makers?), they concluded that action should be taken to transfer knowledge based on a body of research results as opposed to a single published paper to assure validity.

Jacobson, Butterill, and Goering's Framework

Jacobson et al. (2003) developed a framework for knowledge translation focused on building understanding between researchers and user groups. The framework was derived from a review of the literature and the authors' experiences. Articles related to user groups and the knowledge translation process were coded into conceptual categories that emerged from the data. The synthesis of this analysis resulted in a framework containing five domains: user group, issue, research, researcher-user relationship, and dissemination strategies. Each domain consists of a series of questions to guide researchers toward increased understanding of the

intended user context. The framework also provides the research results from which the questions were derived.

KNOWLEDGE TRANSLATION CHARACTERISTICS

KT involves the interaction of elements in a complex knowledge ecosystem of people, contexts, bodies of knowledge, ideologies, methodologies, organizational structures, cultures, and languages. Five key components underlie each of the KT models described above:

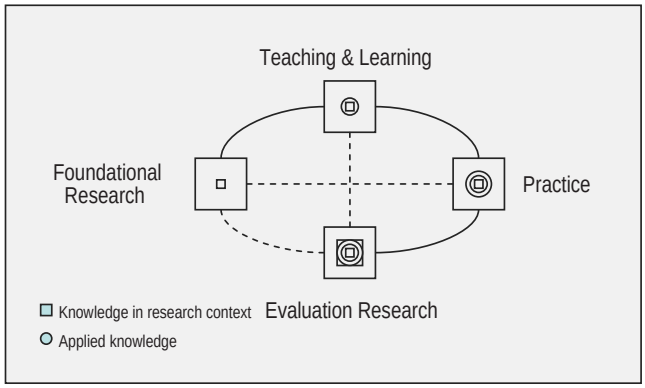
1. Knowledge construction;
2. knowledge contexts;
3. knowledge movement, or flow;
4. knowledge adaptation, or transformation; and
5. evaluation of the translation.

Knowledge construction refers to the building of knowledge using paradigms from a community of practice within a particular context. In order to interpret its meaning for a target context, a translator needs to understand how the knowledge was constructed in the source context. The translator also needs to understand how the problem was framed and constructed in the target context.

Four broad categories of knowledge contexts include:

- Foundational research typically conducted in universities and industry labs,
- education and training typically conducted in universities and other organizations,
- practice in the real world including policymaking, and
- evaluation research assessing the translation.

Figure 1. Knowledge contexts and flow (Groeneboer, 2006)



Knowledge constructed in one context may be applied in another context as shown in Figure 1. The solid links demonstrate typical knowledge flow from research to education to practice, whereas the dashed links indicate connections that need to be strengthened. One difficulty in creating channels between contexts is that they are often ideologically and geographically divided.

To summarize knowledge flow, suppose that knowledge K_R was constructed in research context R, and that problem Q_P was identified in real-world context P. First, someone must know about K_R and Q_P, and recognize that K_R is a potential solution for Q_P. Once that connection is made, knowledge K_R needs to be translated into a localized form of knowledge K_{RP} that can be utilized by the intended user group in their context P. The translation is necessary but not sufficient in that the user group needs to adopt practical knowledge K_{RP} and change their individual practice. Finally, the translation

Table 1. General questions to orient knowledge flow activities

#	Knowledge Flow Activity	Questions
1.	Construct source knowledge K_A in context A	How was the knowledge K_A constructed in context A? For example, is it generalizable? Does K_A describe a correlational or causal relationship?
2.	Construct target problem Q_B in context B	How was the problem Q_B framed in context B? What does it mean in context B?
3.	Make connection between $K_A \leftrightarrow Q_B$	What does K_A mean? Does it have meaning in context B? Does it address Q_B effectively and affordably?
4.	Plan the translation $K_A \rightarrow K_{AB}$	What was the context in which K_A was constructed? What are the characteristics of context B and the user community that are relevant to the design of K_{AB}? How do we get from A to B?
5.	Translate $K_A \rightarrow K_{AB}$	Given contexts A and B, how should K_A be interpreted and localized for context B? What action in context B does K_A imply?
6.	Support adoption of K_{AB} in target context B	How can individuals and organizations be supported in changing their practice to adopt K_{AB}? What incentives or rewards are there? Are there existing policies that might dissuade adoption of the new practice?
7.	Evaluate the process	Does K_{AB} effectively solve Q_B? What worked and what did not work in designing and implementing the translation plan? What would you do differently next time?

process needs to be evaluated to determine whether the translation successfully solved problem Q_P.

General questions need to be addressed at each activity in the knowledge translation flow as shown in Table 1.

A major barrier to #3 (making connections between $K_A \leftrightarrow Q_B$) is that there are very few communication channels bridging contexts. For example, foundational researchers rarely hear the experiences of practitioners in the field, yet this type of interaction early in a cycle can lead to construction of knowledge more readily adapted to a new context. Examples of established environments supporting interaction are teaching hospitals where research, education, training, and practice contexts have been integrated. Cross-disciplinary channels are also important for KT because real-world problems experienced in practice do not usually fall squarely in one discipline, and results obtained in one discipline may have useful applications in other fields.

KNOWLEDGE TRANSLATION STRATEGIES

The goal of the knowledge translation process is to enhance the multi-directional, cross-disciplinary flow of knowledge between contexts so that knowledge constructed in one context can be utilized in others. Conceptually, a space is needed that fosters dialogue regarding research, education and training, policy and practice, and evaluation. This space is referred to as the *nexus*.

The nexus forms a means of connection between different contexts as shown in Figure 2. Here researchers, educators, practitioners, policymakers, and others 'meet' to share information and gain a better understanding of the cultures and contexts in which each operates. Virtual spaces provide a natural solution for a nexus of this type because:

1. Technologies are available to enable key processes of knowledge translation such as online environments for human interaction and tools for collaborative creation and sharing of knowledge,
2. virtual space overcomes geographical and time-based barriers, and
3. there are precedents of successful virtual communities from which lessons can be learned.

Well-designed virtual environments also offer flexibility so that participants shape the structure of the space to fit their needs over time. For example, subgroups may form around shared interests and subspaces may be developed for special activities and events.

KT requires a new kind of professional, what Cernada (1982) called *linkers*—people who can facilitate the translation of research results into practice. He argued that linkers are necessary but not sufficient for research utilization, and suggests researchers and practitioners themselves need to come together. Professional development of linkers is a key strategy for KT, as linkers need to understand both source and target contexts and the construction and use of knowledge in each context.

The nexus becomes a point of convergence for a *metacommunity* of researchers, educators, practitioners and policymakers, evaluators, and linkers. The nexus also serves as a point where hierarchical roles are put aside, and the ultimate goal of knowledge acquisition and application is of primary importance. Table 2 summarizes some of the strategies that could be used at the nexus and linker levels to overcome potential barriers and support the knowledge flow activities of Table 1.

Figure 2. The nexus of research, teaching and learning, practice, and evaluation (Groeneboer, 2006)

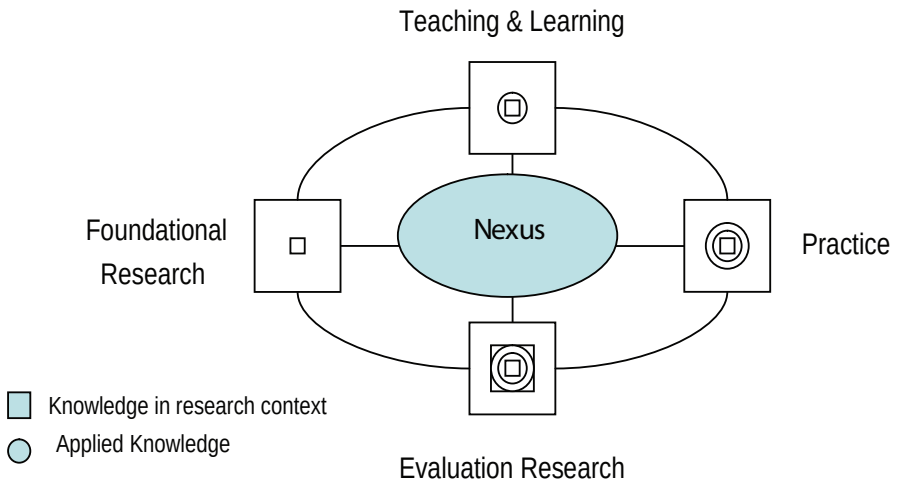


Table 2. Summary of knowledge translation strategies

Level	#	Strategy
Responsibilities/ Roles of the Nexus	1.	Create collections of knowledge constructed in different contexts for sharing (e.g., a nexus knowledge base)
	2.	Create virtual spaces and events to bridge people and knowledge from different communities
	3.	Professionally develop linkers who can translate and support the interaction of diverse communities in the nexus
Responsibilities/ Roles of the Linker	1.	Scan published results in target and related fields
	2.	Conduct meta-analysis of potential applicable research
	3.	Interpret research for use—what do the results really mean? — create a resource for general use in target contexts
	4.	Create a framework/template learning design for teaching the interpreted knowledge
	5.	Localize knowledge for a particular identified context
	6.	Create case studies of translated knowledge embedded in practice
	7.	Share evaluation results through the nexus
	8.	Support community building, events, awareness-raising activities, etc.
	9.	Scaffold researchers, educators, and practitioners in becoming linkers themselves
	10.	Create future scenarios to inspire others and articulate a vision of the ways in which good KT practice can help

FUTURE TRENDS

Future trends in KT include:

1. Given the current climate of user-centered design and interaction, more systems-theoretic approaches will emerge to deal with the growing complexity of a dynamic knowledge ecosystem (see Wingens, 1990, for an early example).
2. Given the current general consensus that KT flow should be multi-directional and cross-disciplinary, more strategies will need to be developed to support flow and overcome barriers in non-traditional directions.
3. If Lavis et al.'s (2001) argument that researcher-user interaction should become standard practice—not simply an add-on— in research contexts is realized, this could open new communication channels from knowledge constructed in practice to new research questions and hypotheses.
4. New techniques and strategies in knowledge management will be required to handle knowledge bases of knowledge objects and associated metadata to enhance knowledge translation.

CONCLUSION

Knowledge translation is the movement and transformation of knowledge constructed in one context for the purpose of utilization in another context. It is generally agreed that interaction between researchers and intended user groups is essential to the success of translation and adoption into practice, and that knowledge flow should be multi-directional and cross-disciplinary. However, most of the work to date has focused on translation from knowledge constructed in a research context to usable knowledge embedded in practice.

The KT process consists of: (1) construction of source knowledge K_A in context A, (2) construction of target problem Q_B in context B, (3) recognition of potential connection between $K_A \leftrightarrow Q_B$, (4) planning of the translation $K_A \rightarrow K_{AB}$, (5) translation of $K_A \rightarrow K_{AB}$, (6) support for the adoption of K_{AB} in target context B, and (7) evaluation of the process. Strategies are required at multiple levels to increase the success of each of these activities, and information technologies can provide powerful support for the implementation of these strategies.

KEY TERMS

Adoption: The process by which practitioners accept new knowledge translated from research results and transform their personal practice to incorporate the translated knowledge.

Applied Knowledge: Knowledge constructed in one context, often a research context, and translated to another context to solve a problem or improve practice. Applied knowledge is distinguished from theoretical or abstract knowledge and implies practical use.

Blog: Short form of *Web log*, a chronology-based Web application for sharing information and commenting on the shared information. It is usually organized around a particular topic with most-recent entries displayed at the top. It is sometimes used as an online personal diary in which the owner posts entries and invites others to comment.

Implementation Research: Research designed to reduce disparity or space between any and all steps from research to practice.

Knowledge Construction: The creation of knowledge, typically using the paradigm(s) of the community in which the knowledge builder is situated.

Knowledge Context: The contexts in which knowledge is constructed, exchanged, utilized, and between which knowledge flows, including broad categories such as research, education and training, practice and policy, and evaluation.

Knowledge Flow: The process that transforms knowledge from constructed knowledge in the source context to translated knowledge embedded in practice in the target context.

Knowledge Transformation: The process of changing the form of the knowledge constructed in the source context to a form that is usable in the target context.

Knowledge Translation: The movement and transformation of knowledge constructed in one context for the purpose of utilization in another context. This broad definition attempts to maintain direction-neutrality. In contrast, the CIHR (2004) defines KT within the context of health care:

Knowledge translation is the exchange, synthesis and ethically-sound application of knowledge — within a complex system of interactions among researchers and users — to accelerate the capture of the benefits of research for Canadians through improved health, more effective services and products, and a strengthened health care system. (http://www.cihr-irsc.gc.ca/e/29418.html)

Synonyms include: knowledge exchange, knowledge transfer, research transfer, technology transfer, knowledge transformation, knowledge dissemination, knowledge mobilization, knowledge utilization, and research utilization.

KT Model: A framework designed to facilitate knowledge translation. Criteria for a good model (adapted from Dasgupta, 1989) include: (1) a structural form that describes the components of the process and their interrelationships, (2) an explanation of the process so that design decisions can be inferred, (3) predictive power so that impacts of certain changes in the system can be anticipated, (4) the model should serve as a basis for analysis and criticism of the process, and (5) the model should serve as a basis for exploration and testing of design options.

Linker: A person who facilitates the translation of knowledge from one context to another by bridging ideas and people in different domains. A key role is in recognizing a link between knowledge constructed in one context and its potential translation into usable knowledge in another context.

Nexus: The *Oxford English Dictionary* (n.d.) defines nexus as a means of connection between things, a connected group, a central point of convergence; a focus; a meeting place. Used conceptually to describe the *space* needed to support knowledge translation.

Wiki: A resource-based Web application that supports collaborative creation of content.

An Overview of Semantic-Based Visual Information Retrieval

Yu-Jin Zhang
Tsinghua University, Beijing, China

INTRODUCTION

Content-based image retrieval (CBIR) could be described as a process framework for efficiently retrieving images from a collection by similarity. The retrieval relies on extracting the appropriate characteristic quantities describing the desired contents of images. Content-based video retrieval (CBVR) made its appearance in treating video in the similar means as CBIR treating images. Content-based visual information retrieval (CBVIR) combines CBIR and CBVR together (Zhang, 2003).

With the progress of electronic equipments and computer techniques for visual information capturing and processing, a huge number of image and video records have been collected. Visual information becomes a well-known information format and a popular element in all aspects of our society. The large visual data make the dynamic research to be focused on the problem of how to efficiently capture, store, access, process, represent, describe, query, search, and retrieve their contents. In the last years, CBVIR has experienced significant growth and progress, resulting in a virtual explosion of published information. It has attracted many interests from image engineering, computer vision and the database community.

The current focus of CBVIR is around capturing high-level semantics, that is, the so-called Semantic-based Visual Information Retrieval (SBVIR). This article will first show some statistics about the research publications on SBVIR in recent years to give an idea about its developments statue. It then gives an overview on several current centers of attention, by summarizing results on subjects such as image and video annotation, human-computer interaction, models and tools for semantic retrieval, and miscellaneous techniques in applications. Finally, some future research directions, the domain knowledge and learning, relevance feedback and association feedback, as well as research at even high levels, such as cognitive level and affective level, are pointed out.

BACKGROUND

To get a general idea about the scale and progress of research on CBVIR and SBVIR for the past years, several searches in EI Compendex database (http://www.ei.org) for papers published in English from 1995 through 2005 have been made. In Table 1, the results of two searches in the title field for the numbers of English published papers (records) are listed: One term used is "image retrieval (IR)" and other term is "semantic image retrieval (SIR)." The papers found out by the second term should be a subset of the papers found out by the first term. Both numbers are increasing in that period, as seen from Table 1.

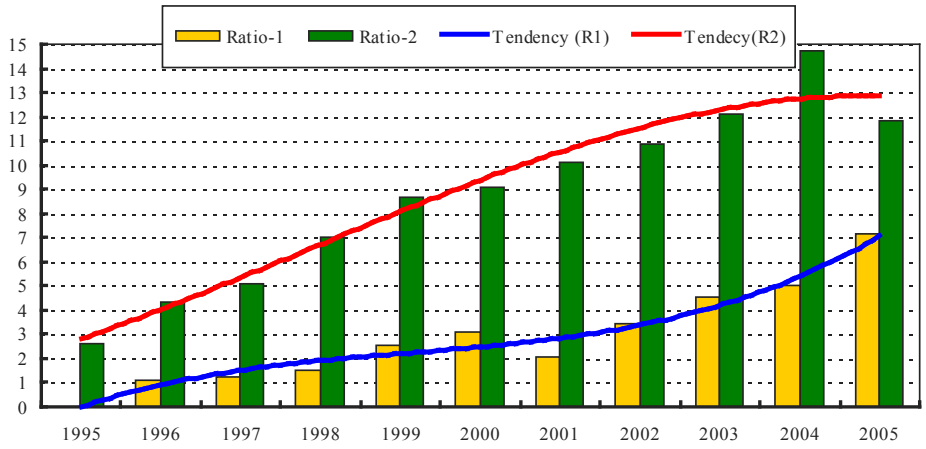
Table 1. List of English records found in the title field of EI Compendex

Searching Terms	1995	1996	1997	1998	1999	2000	2001	2002	2003	2004	2005	Total
(1) Image Retrieval	70	89	80	131	155	161	191	233	241	358	417	2126
(2) Semantic Image Retrieval	0	1	1	2	4	5	4	8	11	18	30	84
Ratio of (2) over (1)	0	1.12	1.25	1.53	2.58	3.11	2.09	3.43	4.56	5.03	7.19	3.95

Table 2. List of English records found in the subject/title/abstract field of EI Compendex

Searching Terms	1995	1996	1997	1998	1999	2000	2001	2002	2003	2004	2005	Total
(1) Image retrieval	421	580	531	640	718	871	1080	1203	1267	2196	2174	11681
(2) Semantic image retrieval	11	25	27	45	62	79	109	131	153	324	257	1223
Ratio of (2) over (1)	2.61	4.31	5.08	7.03	8.64	9.07	10.09	10.89	12.08	14.75	11.82	10.47

Figure 1. Comparison of two groups of ratios



Other searches take the same terms as used for Table 1, but are performed in the field of title/abstract/subject. The results are shown in Table 2.

The numbers of records in Table 2 for both terms are increasing in that period, too.

Comparing the ratios of SIR over IR in two tables, these ratios in Table 2 are much higher than those ratios in Table 1. This difference indicates that the research for SIR is still in an early stage (many papers have not put the word "semantic" in the title of papers) but this concept has started to get numerous considerations and attracts much attention ("semantic" appeared already in the abstract or subject parts of these papers).

To have a closer comparison, these ratios in Table 1 and Table 2 are plotted together in Figure 1. In Figure 1, light bars represent ratios from Table 1 and dark bars represent ratios from Table 2. In addition, the tendencies of ratio developments are approximated by a third order polynomial. It is clear that many papers have the "semantic" concept in mind although they do not always use the word "semantic" in the title.

MAIN FOCUS OF THE CHAPTER

Recently, a book specially contributing to SBVIR has been published (Zhang, 2007) from which, the current advancements on SBVIR on various topics can be perceived.

From Feature to Semantics

It is recognized that high-level research often relies on low-level investigation, so the development of feature-based techniques would considerably help semantic-based techniques.

A suitable start for going into the complex problem of content representation and description can be found in Konstantinidis, Gasteratos, and Andreadis (2007). Considering IR as a collection of techniques for retrieving images based on features (in its general sense), both low-level feature and high-level feature, and especially their relations, are discussed. An efficient way to present these features is by means of a statistical tool capable of bearing concrete information, such as the histogram. A number of IR systems using histograms is presented in a thorough manner and some experimental results are discussed. The steps in order to develop a custom IR system, along with modern techniques in image feature extraction, are also presented.

Among the existing CBIR techniques based on different perceptual features, shape-based ones are particularly challenging due to the intrinsic difficulties in dealing with shape localization and recognition problems. Nevertheless, there is no doubt that shape is one of the most important perceptual features, and successful shape-based techniques would significantly improve the spreading of general-purpose systems. A shape-based image retrieval approach, which is able to efficiently deal with domain independent images with

possible cluttered backgrounds and partially occluded objects, is proposed in Sangineto (2007). It is based on an alignment approach proven robust in rigid object recognition, which has been modified in order to deal with inexact matching between the stylized shape input by the user as query and the real shapes represented in the system's database.

Video has a large data volume and complex structure. Automatic video segmentation into semantic units is important in effectively organizing long videos. A statistical video scene segmentation approach, which detects scenes boundaries in one pass by fusing multimodal audio-visual features in a symmetrical and scalable manner, is derived (Parshin & Chen, 2007). The approach deals properly with the variability of real-valued features and models their conditional dependence on the context. It also integrates prior information concerning the duration of scenes. Two kinds of features, video coherence and audio dissimilarity, extracted both from visual and audio domains, are used in the process of scene segmentation. This approach effectively fuses multiple modalities with higher performance as compared with an alternative rule-based fusion technique.

Image and Video Annotation

Currently, the topic of image and video annotation gets a lot of attention from the SBVIR research community. Text could be considered as a compact medium that expresses more abstract sense than image and video do. By annotating image and video with characteristic textural entities, their semantic contents would be efficiently represented and be used in retrieval.

A novel framework for image categorization and automatic annotation has been proposed in Xu and Zhang (2007). Image classification and automatic annotation could be treated as effective solutions to enable keyword-based SIR. To choose representative features for obtaining information from images, a feature selection strategy is proposed and visual keywords are constructed, by using both discrete and continuous methods. Based on the selected features, the Integrated Patch (IP) **model** is proposed to describe the properties of different image categories. As a generative model, the IP model describes the appearance of the mixture of visual keywords, in considering the diversity of the object composition. The parameters of IP model are then estimated by EM algorithm. Some experimental results on Corel image dataset and Getty Image Archive demonstrate that the proposed feature selection and image description model are effective in image categorization and automatic image annotation, respectively.

Automatic and semi-automatic techniques for image annotation have also been investigated in Shah, Benton, Wu, and Raghavan (2007). When retrieving images, users may find that it is easier to express the desired semantic content with keywords than with visual features. Current methods for automatically extracting semantic information from images can be classified into two classes. One is text-based methods, which use metadata such as ontological descriptions or texts associated with images, to assign or refine annotations. Although highly specialized in domain (context) specific image annotations, the text-based methods are usually semi-automatic. Another is image-based methods, which focus on extracting semantic information directly and automatically from image content, though they are domain independent and could deliver arbitrarily poor annotation performance for certain applications. By identifying some currently unsolved problems in these two classes, several suggestions for future research directions are pointed.

To provide a methodology allowing the integration of the results of content analysis of visual information, the adaptive metadata generation is proposed in Sasaki and Kiyoki (2007). It consists of the content descriptors and their text-based representation to attain the semantically precise results of keyword-based image retrieval operations. The main visual objects under discussion are images, which do not have any semantic representations therein. Those images demand textual annotation of precise semantics that is to be based on the results of automatic content analysis but not on the results of time-consuming manual annotation processes. The technical background and literature review on a variety of annotation techniques for visual information retrieval has been outlined. The proposed method and its implemented system for generating metadata or textual indexes to visual objects by using content analysis techniques are then described.

Human-Computer Interaction

Human beings play an important role in semantic level procedures. By putting humans into the loop of computer routine, it is quite convenient to introduce the domain knowledge into description module and to improve the performance of retrieval system greatly.

A typical form of human-computer interaction is that of relevance feedback whereby users supply relevance information on the retrieved images. This information can subsequently be used to optimize retrieval parameters and to enhance retrieval performance. A comprehensive review of existing relevance feedback techniques and a number of limitations for browsing is discussed in Heesch and Rueger (2007). Browsing models where the merit of hierarchical structures and networks for interactive image search are also evaluated. This exposition provides many details to enable the practitioner to implement many of the techniques.

A method of semi-automatic ground truth annotation for benchmarking of face detection in video is proposed in Tsishkou, Chen, and Bovbel (2007). It aims to illustrate the solution where an image processing and pattern recognition expert is able to label and annotate facial patterns in video

sequences at the rate of 7500 frames per hour. These ideas are extended to the semi-automatic face annotation methodology, where all object patterns are categorized into four classes in order to increase flexibility of evaluation results analysis. A guide to speed up manual annotation process by 30 times is presented.

To overcome the limitations of keyword- and content-based visual information access, an ontology-driven framework is developed in Dasiopoulou, Doulaverakis, Mezaris, Kompatslaris, and Strintzis (2007). Under the proposed framework, an appropriately defined ontology infrastructure is used to drive the generation of manual and automatic image annotations and to enable semantic retrieval by exploiting the formal semantics of ontology. In this way, the descriptions considered in the tedious task of manual annotation are constrained to named entities, because the ontology-driven analysis module can automatically generate annotations concerning common domain objects of interest.

Models and Tools for Semantic Retrieval

New models and tools for semantic retrieval have continuously been incorporated in recent years. As for other disciplines or subjects, the progresses of research on SBVIR should also get support from a variety of mathematic models and technique tools. Several models and tools utilized in SBVIR are thus introduced and some pleasing results are obtained.

A machine learning based model for constructing index of retrieval system is proposed (Hacid & Zighed, 2007). A suitable index makes it possible to group data according to similarity criteria. An effective method for locally updating neighborhood graphs, which constitute the structure of required index, is first introduced. This structure is then exploited in order to make the retrieval process using queries in an image form more easy and effective. In addition, the indexing structure is used to annotate images in order to describe their semantics. The proposed approach is based on an intelligent manner for locating points in a multidimensional space.

A critical literature review of the use of neural networks for CBIR systems is presented in Verma and Kukkarni (2007). It shows how neural networks and fuzzy logic can be used in various retrieval tasks, such as interpretation of queries, feature extraction and classification of features by describing a detailed research methodology. It investigates a neural network-based technique in conjunction with fuzzy logic to improve the overall performance of the CBIR systems. The results of the investigation on a benchmark database with a comparative analysis are presented. The methodologies and results presented will allow researchers to improve and compare their methods and will allow system developers to understand and implement the neural network and fuzzy logic-based techniques for CBIR.

A new emotion-based video scene retrieval method is proposed in Yoo (2007). Five features extracted from a video are represented in a genetic chromosome and target videos that users have in mind are retrieved by the interactive genetic algorithm through the feedback iteration. After selecting the videos that contain the corresponding emotion from the initial population of videos by the proposed algorithm, the feature vectors extracted from them are regarded as chromosomes, and a genetic crossover is applied to those feature vectors. Next, new chromosomes after crossover and feature vectors in the database videos are compared based on a similarity function to obtain the most similar videos as solutions of the next generation. By iterating this process, a new population of videos that users have in mind are retrieved.

Miscellaneous Techniques in Applications

Research on SBVIR is still in its infancy, and a large number of special ideas and exceptional techniques have been applied. These works provide new sights and fresh views from various sides, and enrich the technique pool for treating the process on semantics.

The functionalities of multimedia databases that are not present in traditional databases are discussed in Picariello and Sapino (2007). Multimedia data are inherently subjective. For retrieval purposes, such subjective information needs to be combined with objective information obtained through (generally imprecise) data analysis processes. Therefore, the inherently fuzzy nature of multimedia data, both at subjective and at objective sides, may lead to multiple, possibly inconsistent, interpretations of data. A fuzzy nonfirst normal form (FNF^2) data model that is an extension of the relational models is presented. It takes into account subjectivity and fuzziness. It enables user-friendly information access and manipulation mechanisms.

A new approach with multiple steps for improving image retrieval accuracy by integrating semantic concepts is presented in Kherfi and Ziou (2007). First, images are represented according to different abstraction levels. At the lowest level, they are represented with visual features. At the middle level, they are represented with a set of very specific keywords. At the highest level, they are represented with keywords that are more general. Second, visual content together with keywords are used to create a hierarchical index. A probabilistic classification approach is proposed, which allows to group similar images into the same class. Finally, this index is exploited to define three retrieval mechanisms: text-based, content-based, and a combination of both.

Finally, a comprehensive review of analysis algorithms to extract semantic information from multimedia content is presented in Magalhães and Rueger (2007). It considered SBVIR as a combination of multimedia understanding, information extraction, information retrieval and digital

libraries. Some statistical approaches to analyses image and video contents are described and discussed.

FUTURE TRENDS

With the recent advancements, some future research work can still be conducted.

(1) Domain Knowledge and Learning: Domain knowledge is critical in the SBVIR system to make the system more competent to handle the semantics of the query. The knowledge, which can be in the form of rules, heuristics or constraints, could be acquired by using various learning techniques, such as active learning, or multiple instance learning. An active role of statistical learning will bridge the gap between the user's desire and the system's reply.
(2) Relevance Feedback and Association Feedback: Feedback has been used for refining the retrieval results. The use of relevance feedback based on high-level content description in the object level could further improve the performance. In addition, association feedback tries to find out the associated parts between the existing interest (user intent) and new target (related to the current retrieval results), which bridges to the new retrieval (Xu & Zhang, 2003).
(3) Higher Level Exploration: Semantic level is higher than feature level, while affective level is higher than semantic level (Hanjalic, 2001). Affection is associated with some abstract attributes, which are quite subjective.

CONCLUSION

An introduction to SBVIR, some statistics about its publications, and several practical approaches, such as multi-level model, classification and annotation, machine-learning techniques, human-computer interaction, as well as various models and tools have been discussed. Few potential research directions, such as the domain knowledge and learning, relevance feedback and association feedback, as well as research at even high level, are discussed.

KEY TERMS

Content-Based Image Retrieval (CBIR): A process framework for efficiently retrieving images from a collection by similarity. The retrieval relies on extracting the appropriate characteristic quantities describing the desired contents of images. In addition, suitable querying, matching, indexing and searching techniques are required.

Content-Based Video Retrieval (CBVR): A process framework for efficiently retrieving required clip from video. The retrieval relies on the organization of video and nonlinear search techniques.

Content-Based Visual Information Retrieval (CBVIR): A combination of CBIR and CBVR.

Feature-Based Image Retrieval: A branch of CBIR, which is based on specific visual characteristics called features, such as color, texture, shape, and so forth, and is considered at a low abstraction level.

Image Engineering: An integrated discipline/subject comprising the study of all the different branches of image and video techniques.

MPEG-7: An international standard named "Multimedia content description interface" (ISO/IEC 15938). It provides a set of audiovisual description tools, descriptors and description schemes for effective and efficient access (search, filtering and browsing) to multimedia content.

Semantic Gap (SG): The discrepancy between the perceptual property and semantic meaning of images in the context of CBVIR. The semantic gap is also considered as a gap between current techniques and human requirements.

An Overview of Software Engineering Process and Its Improvement

Alain April
École de Technologie Supérieure, Montréal, Canada

Claude Laporte
École de Technologie Supérieure, Montréal, Canada

INTRODUCTION

The software engineering process is concerned with the definition, implementation, measurement, change, and improvement of software processes.

This short article presents software engineering process knowledge along the lines of the software engineering body of knowledge (International Organization for Standardization & International Electrotechnical Commission [ISO/IEC], 2005b). The objective of the software engineering process is to implement new or better processes in current software engineering practice.

BACKGROUND

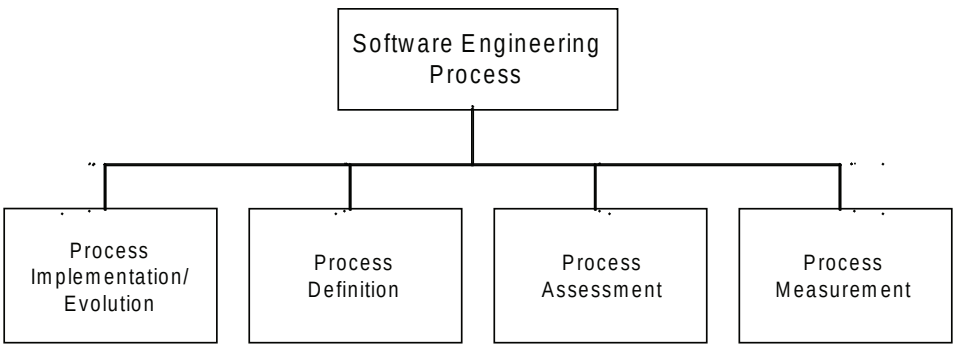
Software engineering is a young discipline, and many authors maintain that process engineering is crucial to its success, as well as being key to software quality assurance activities. This article presents generally accepted knowledge about the software engineering process. This knowledge has been adapted from industrial engineering, the management sciences, and human resources management. We have witnessed the emergence of software engineering process literature during the past 20 years and watched as some process topics have appeared while others have disappeared. This article presents four key topics (see Figure 1) that represent the fundamental concepts that must be acquired by all software engineers.

PROCESS IMPLEMENTATION AND EVOLUTION

Process implementation and change concern the initial deployment of processes and ongoing changes designed to improve and develop a supporting infrastructure (software process assets). Software engineering process activities typically follow a life cycle in which some process models are used as a reference, and certain practical considerations must be considered to ensure their success.

The first section of this article introduces concepts relating to the initial deployment of processes and to the improvement of current processes. In both cases, existing software engineering practices have to evolve. If the evolution process is extensive, then the possibility of cultural changes within

Figure 1. Key topics in the software engineering process and its improvement



the organization may need to be addressed to lower the risk of resistance and failure.

Software process improvement typically follows an improvement life cycle composed of four activities: (a) Establish the process infrastructure and assets, (b) plan the implementation (or improvement), (c) implement and evolve the process, and (d) evaluate the process. Improvement is often a project in and of itself, requiring appropriate planning, resources, monitoring, and review. Completing these life cycle activities permits continuous feedback and improvement of the software process. The first activity, establishing the process infrastructure and assets, involves establishing commitment to the process implementation and change, and acquiring the appropriate resources and personnel. The objective of the second activity, planning the implementation (or improvement), is to describe and communicate the improvement project's objectives and process needs following an assessment of the strengths and weaknesses of the current processes. The third activity, implementing and evolving the process, involves executing the planning step and deploying new processes or evolving existing processes, or both. This activity will often require piloting the new or enhanced processes. The last activity, evaluating the process, is concerned with measuring the resulting process and assessing how well it has achieved the initial objectives. This information is then used as input for subsequent improvement cycles.

The need for an appropriate software engineering infrastructure should always be considered in process improvement. This includes having the resources as well as a clear assignment of process ownership. Management commitment is essential to the success of the process improvement effort. Having an individual or an isolated group develop and evolve the software engineering processes in isolation, sometimes using proven practice handbooks, may not be the best approach as it often creates the impression that the process has been imposed by an individual or a specific organization (like quality assurance). It would be better to establish mixed-group committees that are involved in the software engineering process definition and evolution as this will ensure better representation and involvement of all software engineering staff. Two examples of such committees are the Software Engineering Process Group (Fowler & Rifkin, 1990) and the Experience Factory (Basili, Caldiera, McGarry, Pajerski, Page, & Waligora, 1992).

Moitra (1998) presents guidelines for process implementation and evolution within software engineering organizations. Hutton (1994) debates the importance of change agents in the case of major process evolution. Organizational change can also be viewed from the perspective of technology transfer (Rogers, 1983). Krasner (1999) presents examples of software definition and evolution initiatives.

PROCESS DEFINITION

The defining of processes can be represented in models, as well as in the automated process infrastructure. In an organization, a process is often composed as a procedure, a policy, or a standard, and software engineering processes are defined to harmonize software engineering activities and communication, as well as to support process improvement and its automation. In the software engineering body of knowledge, a process is defined in terms of four perspectives: life-cycle models, software life-cycle processes, notations, and automation.

Life-cycle models serve as high-level definitions of the phases that occur during development, maintenance, and operations. They are not aimed at providing detailed definitions, but rather at highlighting the key activities and their interdependencies. Examples of life-cycle models in practice are the waterfall model, the prototyping model, the evolutionary model, incremental or iterative development, the spiral model, and the reusable software model, among others (Comer, 1997).

Definitions of life-cycle processes tend to be more detailed than framework models, and unlike the standards associated with the latter, life-cycle process standards do not attempt to order their processes in time. Therefore, in principle, life-cycle processes can be arranged to fit any of the life-cycle models. The main reference in this area is ISO/IEC (1995).

Other important standards providing process definitions include the following.

- Institute of Electrical and Electronics Engineers (IEEE) Standard 1074: developing software life cycle processes (IEEE, 1991)
- ISO/IEC Standard 14764: software maintenance (ISO/IEC, 2006)
- ISO/IEC Standard 19759: software measurement process (ISO/IEC, 2005b)

To meet some certification criteria, like ISO9001 (ISO, 2000), the CMMi (capability maturity model integration; Software Engineering Institute [SEI], 2006), or the Sarbanes-Oxley Act (SOX; Securities and Exchange Commission [SEC], 2002), the definition of software processes must be compliant with quality management standards and other reference guides. ISO9001 provides requirements for quality management processes. Specifically, for the software industry, ISO/IEC 90003 (ISO, 2004) interprets each ISO9001 clause, and ISO/IEC 20000-1 (ISO/IEC, 2005a) has recently been released to address the IT service quality management system.

Processes can be defined at different levels of abstraction (Pfleeger, 2001). Various elements of a process can be

defined, for example, as roles and responsibilities, activities, controls, artifacts, and resources. Madhavji et al. made a proposal in 1994 that sets out the types of information required to define software engineering processes. In addition to the type of information, processes are always presented using a particular representation.

A number of representations are used to define processes (Software Productivity Consortium [SPC], 1992) and, more recently, the software domain ontology (Kitchenham et al., 1999). They vary as to the type of process structure and the components, symbols, and information they define, capture, and use. While these notations are gradually being normalized (Object Management Group [OMG], 2006), current approaches a software engineer should be aware of are data flow diagrams (Yourdon & DeMarco), state charts (Harel & Politi, 1998), and ETVX (Radice, Roth, O'Hara, & Ciarfella, 1985), and for representing business processes, DFD (Gane & Sarson, 1979), office support system analysis and design (OSSAD; Commission des Communautées Européennes, 1992), and more recently, BPMN (OMG).

Process automation supports human activities by means of a set of services describing the environment's capabilities. The software engineering environment (SEE) is defined as "a set of tools providing full or partial automated support to software engineering activities." Software process automation is a new technology with significant promise (Christie, Levine, Morris, & Zubrow, 1996)

Automated tools either support the execution of the process definitions, or they provide guidance to humans performing the defined processes. There exist tools that support each notation, and these tools can execute the process definitions to provide automated support to the actual processes or to fully automate them in some instances. An overview of process modeling tools is presented by Finkelstein, Kramer, and Nuseibeh (1994), and one of process-centered environments is given by Garg (Garg & Jazayeri, 1996).

PROCESS ASSESSMENT

ISO/IEC 15504 (ISO/IEC, 2004) defines an exemplar assessment model and conformance requirements on other assessment models. Popular process assessment models available are the following.

- SW-CMMi for software development processes (SEI, 2006)
- S3M for small software maintenance processes (April & Bran, 2008)
- Information Technology Infrastructure Library (ITIL, 2007) and CMMi (SEI, 2007) for IT services (data center processes)

Many more capability maturity models have been developed over the years. Process assessment using a capability maturity model is often referred to as process maturity assessment. In order to perform a maturity assessment, a specific assessment method needs to be followed to produce a quantitative score that characterizes the capability of the process (also referred to as the maturity of the organization). For example, SCAMPI (standard CMMi appraisal method for process improvement; SEI, 2000) focuses on assessments for the purpose of process improvement using the CMMi. The activities performed during an assessment, the distribution of effort on these activities, and the atmosphere during an assessment are different if the purpose is improvement and not a contract award.

ISO9001 is another process model that has been applied by software organizations. ISO9001 conformity is assessment using an audit process rather than an assessment method per se. There are five key differences between the maturity assessment and the ISO9001 audit.

a. Level of involvement: The organization's level of involvement is greater with the maturity assessment.
b. Review method: Maturity assessment reviews are performed in small groups, which facilitates and stimulates communication. These reviews do not focus as much on quality documentation.
c. Results reporting: Maturity assessment results are presented in their initial and final form in a presentation to all employees of the organizational group that was evaluated. The ISO9001 audit report is presented to the management representative only.
d. Assessment: Maturity assessment requires a chief evaluator and an assessment team (five to nine people), whereas the ISO9001 audit requires one auditor.
e. Certification of the evaluators: Who evaluates the evaluators to ensure the quality of their evaluations? ISO/IEC prescribes four evaluator insurance levels: (a) ISO9001 auditor courses, (b) evaluation of auditor performance by the registrar, (c) evaluation of the registrars through accreditation, and (d) evaluation of the accreditation by the International Accreditation Forum. Maturity assessment, by contrast, has only three levels: (a) courses, (b) certification, and (c) registration of the chief evaluators once they have been supervised for a few evaluations.

PROCESS MEASUREMENT

Software engineering process measurement can be performed to support the initiation of process implementation and change, or to evaluate the consequences of process imple-

mentation and change. Key terms on software measures and measurement methods have been defined in ISO/IEC 15939 (ISO/IEC, 2007).

Process measurement, as used here, means that quantitative information about the process is collected, analyzed, and interpreted. It can be used for process conformance assessment, process improvement, evaluation of suppliers' process capability, and benchmarking with other organizations. Measurement is used to identify the strengths and weaknesses of processes, to assess conformance, and to evaluate processes after they have been implemented and/or changed. The steps for deploying a software engineering measurement program are described in ISO/IEC 15939 (ISO/IEC, 2007). Software engineering process measures can be aimed at many different outcomes: quality, progress, productivity, and reliability. Therefore, measurement programs tend to measure multiple process outcomes that are important to the organization's business and to customer satisfaction.

Software process quality measures focus on error removal and its effectiveness. Progress measures report on the completion of milestones. Productivity measures represent the amount of work performed (in lines of code or function points) per person-month. A comparison of productivity can be achieved in a benchmarking exercise (International Software Benchmarking Standards Group [ISBSG], 2003).

In general, we are most concerned about process outcomes. However, in order to achieve the process outcomes that we desire (e.g., better quality, better maintainability, greater customer satisfaction), we have to measure the particular process.

Of course, it is not only the process that has an impact on outcomes. Other factors, such as the capability of the staff and the tools used, play an important role. Furthermore, the extent to which the process is institutionalized or implemented (i.e., process fidelity) is also important as it may explain why good processes do not necessarily lead to the desired outcomes.

FUTURE TRENDS

We have presented here an overview of current knowledge on software engineering process. Future trends are developing in five main directions: first, the ongoing debate regarding the use of lightweight and open-source life cycles (Agile, Open UP); second, the need for greater conformity of IT to rules and regulations (SOX, CobiT); third, the challenge of applying quality paradigms to software engineering processes (i.e., Six Sygma); fourth, the introduction of new international standards that will recommend the process support services for SEEs; and finally, we predict that there will be a consolidation of reference models for IT processes in the near future, and that simplicity and ease of use will prevail.

CONCLUSION

This short article has presented the software engineering process body of knowledge (ISO/IEC, 2005b).

KEY TERMS

Audit: It is an independent examination of a work product or set of work products to assess compliance with specifications, standards, contractual agreements, or other criteria.

Capability Maturity Model: The model is a description of the stages through which organizations evolve as they define, implement, measure, control, and improve their processes.

Maturity Level: It is a well-defined evolutionary plateau toward achieving a mature software acquisition process. The typical five maturity levels are initial, repeatable, defined, quantitative, and optimizing.

Measurement Process: This is a set of interrelated resources, activities, and influences related to a measurement.

Measurement Program: A measurement program is the set of related elements for addressing an organization's measurement needs. It includes the definition of organization-wide measurements, methods, and practices for collecting organizational measurements and analyzing data, and measurement goals for the organization.

Process Assessment: It is a disciplined evaluation of an organization's software processes against a model compatible with the reference model.

Process Assets: They are a collection of items, maintained by an organization, for use by programs in developing, tailoring, maintaining, and implementing their processes.

Software Process Assets: They are a collection of entities, maintained by an organization, for use by projects in developing, tailoring, maintaining, and implementing their software processes.

An Overview of Threats to Information Security

R. Kelly Rainer, Jr.
Auburn University, USA

INTRODUCTION

Organizations and individuals have many information assets, which are subject to an increasing number of threats. The purpose of this article is to provide (1) an overview of the factors that are increasing the threats to information security and (2) an overview of the threats to information security.

BACKGROUND

Several factors are contributing to today's dangerous threat environment. The first factor is the evolution of the information technology resource from mainframe-only to today's highly complex, interconnected, interdependent, wirelessly networked business environment. This environment exposes organizations and individuals to a world of untrusted networks and potential attackers.

The second factor results from the fact that modern computers and storage devices (e.g., thumb drives) continue to become smaller, faster, cheaper, and more portable, with greater storage capacity. These characteristics make it much easier to steal or lose a computer or storage device that contains huge amounts of sensitive information. Also, far more people are able to afford powerful computers and connect inexpensively to the Internet, thus raising the potential of an attack on information assets.

The third factor is that the computing skills necessary to be a hacker are *decreasing*. The reason is that the Internet contains information and computer programs (called scripts) that users with few skills can download and use to attack any information system connected to the Internet.

The fourth factor is that international organized crime is turning its attention to cybercrime, which are illegal activities taking place over computer networks, particularly the Internet. These crimes can be committed from anywhere in the world, at any time, effectively providing an international safe haven for cybercriminals. Computer-based crimes cause billions of dollars in damages to businesses each year, including the costs to repair information systems, the costs of lost business, and the loss of customer confidence.

The fifth factor is downstream liability. Downstream liability occurs in this manner. If company A's information systems were compromised by a perpetrator and used to attack company B's systems, then company A could be liable for damages to company B. Note that company B is "downstream" from company A in this attack scenario. A downstream liability lawsuit would put company A's security policies and operations on trial. Under tort law, the plaintiff (injured party or company B) would have to prove that the offending company (company A) had a duty to keep its computers secure and failed to do so, as measured against generally accepted standards and practices.

At some point, all companies will have some minimal set of standards that they have to meet when operating information systems that connect to the Internet. The models already exist in the form of regulations and laws (e.g., Gramm-Leach-Bliley Act and the Health Insurance Portability and Accountability Act). Contractual security obligations, particularly *service level agreements* (SLAs), which spell out very specific requirements, might also help establish a security standard. Courts or legislatures could cite typical SLA terms, such as maintaining up-to-date antivirus software, software patches, and firewalls, in crafting minimum security responsibilities.

A company being sued for downstream liability will have to convince a judge or jury that its security measures were reasonable. That is, the company must demonstrate that it had practiced due diligence in information security. Due diligence can be defined in part by what your competitors are doing, which defines best practices.

The sixth factor is increased employee use of unmanaged devices, which are devices outside the control of an organization's IT department. These devices include customer computers, business partners' mobile devices, computers in the business centers of hotels, computers in Starbucks and Paneras, and many others.

The final factor is lack of management support. For the entire organization to take security policies and procedures seriously, senior managers must set the tone and provide necessary resources. Ultimately however, lower-level managers may be even more important. These managers are in close contact with employees every day and thus are in a better position to determine whether employees are following security procedures.

THE THREAT ENVIRONMENT

Whitman and Mattord (2003) classified threats into five general categories to enable us to better understand the complexity of the threat problem. Their categories are natural disasters, technical failures, management failures, unintentional acts, and deliberate acts.

Natural disasters include floods, earthquakes, hurricanes, tornados, lightning, and in some cases, fires. In many cases, natural disasters can cause catastrophic loss of systems and data. Technical failures include problems with hardware and software. The most common hardware problem is a crash of a hard disk drive. The most common software problem is errors, called bugs, in computer programs. We discussed management failures in the Introduction.

Unintentional Acts

Unintentional acts are those with no malicious intent and consist of human errors, deviations in the quality of service by service providers, and environmental hazards. Of these three, human errors are by far the most serious threats to information security.

Before we discuss the various types of human error, we categorize organizational employees. The first category consists of regular employees. There are two important points to be made about regular employees. First, the higher the level of employee, the greater the threat the employee might pose to information security. Higher-level employees may have greater access to corporate data and enjoy greater privileges on organizational information systems. Second, employees in two areas of the organization pose significant threats to information security. Human resources employees generally have access to sensitive personal information about all employees. Likewise, information systems employees not only have access to sensitive organizational data, but they often control the means to create, store, transmit, and modify that data.

The second category of employee includes contract labor, consultants, and janitors and guards. Contract labor, such as temporary hires, may be overlooked in information security. However, these employees often have access to the company's network, information systems, and information assets. Consultants, while technically not employees, do work for the company. Depending on the nature of their

Table 1. Human mistakes

Human Mistake	**Description and Examples**
Tailgating	A technique designed to allow the perpetrator to enter restricted areas that are controlled with locks or card entry. The perpetrator follows closely behind a legitimate employee and, when the employee gains entry, asks them to "hold the door."
Shoulder surfing	The perpetrator watches the employee's computer screen over that person's shoulder. This technique is particularly successful in public areas such as airports, commuter trains, and on airplanes.
Carelessness with laptops and portable computing and storage devices	Losing or misplacing them, or using them carelessly, so that malware can be introduced into an organization's network.
Opening questionable e-mails	Opening e-mails from someone unknown, or clicking on links embedded in e-mails (see phishing attacks below).
Careless Internet surfing	Accessing questionable Websites; can result in malware and/or alien software being introduced into the organization's network.
Poor password selection and use	Choosing and using weak passwords (see strong passwords).
Carelessness with one's office	Unlocked desks and filing cabinets when employees go home at night; not logging off the company network when gone from the office for extended period of time.
Carelessness with discarded equipment	Discarding old computer hardware and devices without completely wiping the memory; includes computers, cell phones, Blackberries, and digital copiers and printers.

work, these people may also have access to the company's network, information systems, and information assets.

Finally, janitors and guards are the most frequently ignored people in information security. They are usually present when most – if not all – other employees have gone home. They typically have keys to every office, and nobody questions their presence in even the most sensitive parts of the building. In fact, an article from the Winter 1994 edition of *2600: The Hacker Quarterly* described how to get a job as a janitor for the purpose of gaining physical access to an organization.

Human errors or mistakes by employees pose a large problem as the result of laziness, carelessness, or a lack of information security awareness. This lack of awareness comes from poor education and training efforts by the organization. Human mistakes manifest themselves in many different ways, as we see in Table 1.

Deviations in the quality of service by service providers consist of situations in which a product or service is not delivered to the organization as expected. For example, heavy equipment at a construction site cuts a fiber optic line to your building or your Internet Service Provider has availability problems. Organizations may also experience service disruptions from various providers, such as communications, electricity, telephone, water, wastewater, trash pickup, cable, and natural gas.

Environmental hazards include dirt, dust, humidity, and static electricity, which are harmful to the safe operation of computing equipment.

Deliberate Acts

Deliberate acts include espionage or trespass; information extortion; sabotage and vandalism; theft of equipment and information; social engineering and reverse social engineering; identity theft; compromises to intellectual property; software attacks; and supervisory control and data acquisition attacks.

Espionage or trespass occurs when an unauthorized individual attempts to gain illegal access to organizational information. When we discuss trespass, it is important that we distinguish between competitive intelligence and industrial espionage. Competitive intelligence consists of legal information-gathering techniques, such as studying a company's Website and press releases, attending trade shows, and so on. In contrast, industrial espionage crosses the legal boundary.

Information extortion occurs when an attacker either threatens to steal, or actually steals, information from a company. The perpetrator demands payment for not stealing the information, for returning stolen information, or for agreeing not to disclose the information.

Sabotage and vandalism are deliberate acts that involve defacing an organization's Website, possibly causing the organization to lose its image and experience a loss of confidence by its customers. One form of online vandalism is a hacktivist or cyberactivist operation. These are cases of high-tech civil disobedience to protest the operations, policies, or actions of an organization or government agency.

Theft of equipment and information result from computers and storage devices becoming smaller yet more powerful with vastly increased storage (e.g., laptops, Blackberries, smart phones, digital cameras, thumb drives, and iPods). As a result, these devices are becoming easier to steal and easier for attackers to use to steal information.

The uncontrolled proliferation of portable devices in companies has led to a type of attack called pod slurping. In *pod slurping*, perpetrators plug portable devices, such as an iPod, into a USB port on a computer and download huge amounts of information very quickly and easily.

Another form of theft, known as *dumpster diving*, involves the practice of rummaging through commercial or residential trash to find information that has been discarded. Files, letters, memos, photographs, IDs, passwords, credit cards, and other forms of information can be found in dumpsters. Unfortunately, many people never consider that the sensitive items they throw in the trash may be recovered and used for fraudulent purposes.

Social engineering is an attack where the perpetrator uses social skills to trick or manipulate a legitimate employee into providing confidential company information (e.g., passwords). The most common example of social engineering occurs when the attacker impersonates someone else on the telephone, such as a company manager or information systems employee. The attacker says he forgot his password and asks the legitimate employee to give him a password to use. Other common exploits include posing as an exterminator, air conditioning technician, or fire marshal.

In one example of social engineering, a perpetrator entered a company building wearing a company ID card that looked legitimate, and put up signs on bulletin boards saying, "The help desk telephone number has been changed. The new number is 555-1234." He then exited the building and began receiving calls from legitimate employees thinking they were calling the company help desk. Naturally, the first thing the perpetrator asked for was user name and password. He now had the information necessary to access the company's information systems.

In social engineering, the attacker approaches legitimate employees. In reverse social engineering, the employees approach the attacker. For example, the attacker gains employment at a company and, in conversations, lets it be known that he is "good with computers." As is often the case, they ask him for help with their computer problems. While he is helping them, he loads Trojan horses on their computers that e-mail him with their passwords and information about their machines.

Table 2. Types of software attacks

	Description
Virus	Segment of computer code that performs malicious actions by attaching to another computer program.
Worm	Segment of computer code that performs malicious actions and will replicate, or spread, by itself (without requiring another computer program).
Trojan Horse	Software programs that hide in other computer programs and reveal their designed behavior only when they are activated.
Back Door	Typically a password, known only to the attacker, that allows the attacker to access a computer system at will, without having to go through any security procedures (also called trap door).
Logic Bomb	Segment of computer code that is embedded with an organization's existing computer programs and is designed to activate and perform a destructive action at a certain time or date.
Dictionary Attack	Attacks that try combinations of letters and numbers that are most likely to succeed, such as all words from a dictionary.
Brute Force Attack	Attacks that use massive computing resources to try every possible combination of password options to uncover a password.
Denial of Service Attack	Attacker sends so many information requests to a target computer system that the target cannot handle them successfully and typically crashes (ceases to function).
Distributed Denial of Service Attack	An attacker first takes over many computers, typically by using malicious software. These computers are called *zombies*, or *bots*. The attacker uses these bots (which form a *botnet*) to deliver a coordinated stream of information requests to a target computer, causing it to crash.
Phishing Attack	Phishing attacks use deception to acquire sensitive personal information by masquerading as official-looking e-mails or instant messages.
Zero-day Attack	A zero-day attack takes advantage of a newly discovered, previously unknown vulnerability in a software product. Perpetrators attack the vulnerability before the software vendor can prepare a patch for the vulnerability.
Rootkit	Software that enables an attacker to have administrator-level access (meaning complete control) to a computer or computer network.
Blended Threats	Combine the characteristics of viruses, worms, Trojan horses, and rootkits to initiate, transmit, and spread an attack.
Alien Software	Clandestine software that is installed on your computer through duplicitous methods. Uses valuable system resources and can capture your Web surfing habits and personal information. Includes spyware,
Keystroke Logger	Software and/or hardware that records your keystrokes. Purposes range from criminal (e.g., theft of passwords) to annoying (e.g., recording your Internet browsing history for targeted advertising).
Screen Scrapers	Software that records a continuous "movie" of a screen's Contents rather than simply recording keystrokes.

Identity theft is the deliberate assumption of another person's identity, usually to gain access to another person's financial information or to frame another person for a crime. Techniques for obtaining information include stealing mail, dumpster diving, stealing personal information in computer databases, infiltrating organizations that store large amounts of personal information (e.g., data aggregators), and impersonating a trusted organization in an electronic communication (e.g., phishing).

Recovering from identity theft is costly, time-consuming, and difficult. Victims report difficulties in obtaining credit and obtaining or holding a job, as well as adverse effects on insurance or credit rates. Victims also note that is is difficult to remove negative information from their records, such as their credit reports.

Compromises to intellectual property is a vital issue for people who make their livelihood in knowledge fields. I**ntellectual property** is the property created by individuals or corporations that is protected under trade secret, patent, and copyright laws.

The most common intellectual property related to IT deals with software. Copying a software program without making payment to the owner—including giving a disc to a friend to install on the owner's computer—is a copyright violation. Not surprisingly, this practice, called **piracy,** is a major problem for software vendors. The global trade in pirated software amounts to hundreds of billions of dollars.

Software attacks have evolved from the outbreak era, where malicious software tried to infect as many computers worldwide as possible, to the profit-driven, Web-based attacks of today. Cybercriminals are heavily involved with malware attacks to make money, and they use sophisticated, blended attacks typically via the Web. Table 2, although not inclusive, shows a variety of well-known software attacks.

A Supervisory Control and Data Acquisition (SCADA) system uses sensors to monitor and control chemical, physical, or transport processes in oil refineries, water and sewage treatment plants, electrical generators, and nuclear power plants. The sensors connect to physical equipment. They read status data such as the open/closed status of a switch or a valve, as well as measurements such as pressure, flow, voltage, and current. By sending signals to equipment, sensors control equipment, such as opening or closing a switch or valve or setting the speed of a pump.

The sensors are networked, and each sensor typically has an Internet Protocol (IP) address. In a SCADA attack, the attacker tries to gain access to the network in order to, for example, disrupt the power grid over a large area or disrupt the operations of a large chemical plant. Such actions could have catastrophic results.

FUTURE TRENDS

Unfortunately, the threat environment continues to be bleak. Attackers are moving from mass malware attacks to stealthy, blended, targeted attacks, where the attacker tries to control as many computers for as long as possible without the users being aware of it. In fact, botnets have become today's biggest threat.

CONCLUSION

The contributions of this chapter are threefold. First, it addresses the factors increasing today's level of threats. Second, it provides a brief overview of the numerous threats to information security. Third, it addresses the lengthy topic of information security threats in a concise, readable manner.

KEY TERMS

Downstream Liability: A potential liability incurred by a company whose computer systems are compromised by an attacker and used to attack another company's systems.

Distributed Denial of Service Attack: An attacker takes over many computers (called *zombies* or *bots*), typically by using malicious software. The attacker uses these bots (which form a *botnet*) to deliver a coordinated stream of information requests to a target computer, causing it to crash.

Phishing Attack: Attacks that use deception to acquire sensitive personal information by masquerading as official-looking e-mails or instant messages.

Rootkit: Software that enables an attacker to have administrator-level access (meaning complete control) to a computer or computer network.

Social Engineering: An attack where the perpetrator uses social skills to trick or manipulate a legitimate employee into providing confidential company information.

Tailgating: The perpetrator follows closely behind a legitimate employee and, when the employee gains entry, asks them to "hold the door" so the perpetrator can enter restricted areas that are controlled with locks or card entry.

Trojan Horse: Software programs that hide in other computer programs and reveal their designed behavior only when they are activated.

Virus: Computer code that performs malicious actions by attaching to another computer program.

Worm: Computer code that performs malicious actions and will replicate, or spread, by itself (without requiring another computer program).

Zero-Day Attack: An attack that takes advantage of a newly discovered, previously unknown vulnerability in a software product. Perpetrators attack the vulnerability before the software vendor can prepare a patch for the vulnerability.

An Overview of Trust Evaluation Models within E-Commerce Domain

Omer Mahmood
University of Sydney, Australia
Charles Darwin University, Australia

INTRODUCTION

This chapter outlines various models which can be used to predict users' trust on online shopping, to enhance user's trust on online vendor, and to estimate the risk in an online transaction. The discussed models are selected to provide an overview of different aspects which can be used by the service providers and developers to identify the factors which impact user's online trust. The factors that have been identified can be further used as a guide to enhance user's trust levels. The rest of the article is organized as follows. In the next section, four models are discusses starting from Cheung and Lee (2000) conceptual model of trust in electronic environment to the model presented by Mahmood (2006a) that relies on mathematical equations to assist user to compare and evaluate online retailers. After discussing the presented models, the impact and effect of Web 2.0 technologies are discussed in future directions. The potential use of FOAF and RDF to create completely decentralized repository of users' trust evaluations which can be tapped into any application that uses Web 2.0 is also discussed in future directions. Concluding remarks and model comparison are presented the conclusion.

BACKGROUND

In electronic commerce the gap between payment and delivery of service or product is substantial as compared to physical transactions. These gaps impact the users' estimated trust on the service provider as well as on user's decision to commit or abort a transaction. Although the estimation of trust is based on personal, subjective properties, recently, several models have been proposed to translate trust into quantifiable terms. Such models target to assist the user's to establish the degree of trust so that the user can make an informed decision while committing a transaction in electronic environment. The right degree of trust has been defined as the risk that the user accepts in case of failure is estimated to be less than the expected subjective utility in case of success (Castelfranchi & Falcone, 2000).

AN OVERVIEW OF TRUST MODELS

Trust in Internet Shopping: Model and Measurement

Cheung and Lee (2000) showed that consumer trust in online shopping can be predicted by following two sets of experiences: factors which contribute to the sense of merchant's trustworthiness, and external factors which are linked to the external environment. The merchant's associated sense of trustworthiness is linked to its perceived integrity, competence, security and privacy controls in place. The external environment contributing factors include third party recognition (e.g., trusted party seals of approval) and legal framework. The model showed that the combined effect of both sets of factors on consumer's overall trust belief is mediated by the consumer's tendency to trust. The model also acknowledges the relationship between perceived risk and online consumer's trust response.

A Model of Internet Trust from the Customer's Point of View

Ang, Dubelaar, and Lee (2001) proposed a model of trust which focuses on consumer's perception on online retailer's trustworthiness. The authors used the following equation to describe the process by which a consumer makes a decision to commit a transaction or not:

$$G_b = p_b L_b,$$

where

G_b = Gain to the user from the transaction
p_b = Subjective probability that the online merchant will be untrustworthy
L_b = The loss the consumer will suffer in case of fraud

Ang et al., in their study, argued that in order to further capture the market share the online retailer will either have to increase the LHS or reduce the RHS. For example, the

Figure 1. A conceptual model of trust in Internet shopping (Cheung & Lee, 2000)

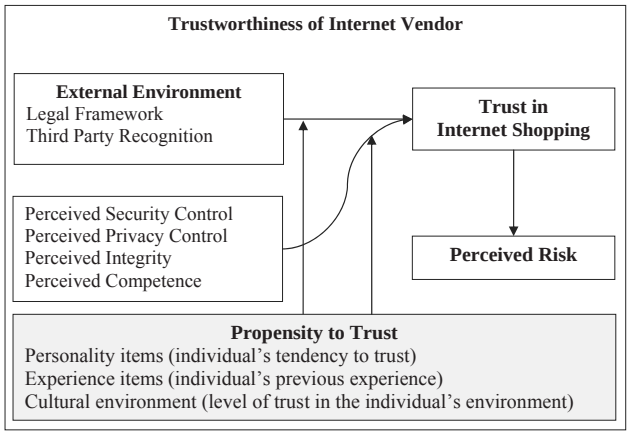

Table 1. Trust variables and corresponding levels

	Trust Variables		
Levels	**Ability to deliver**	**Willingness to rectify**	**Personal privacy**
	Known Brand	30-days guarantee	Has privacy policy statement
	Unknown Brand	No guarantee	No Privacy policy statement

LHS can be increased by giving more discounts to the customer. This will also reduce the computer value of RHS as the value of Lb will decrease. RHS can also be reduced by portraying a sense of trustworthiness. In the study following three aspects of trustworthiness in an online transaction were identified:

1. Ability of the merchant to deliver the product or service. This aspect could be highlighted with the help of previous customer's comments, access to detailed information regarding the product and availability of widely known respected brands
2. The willingness of the merchant to rectify the problem and honor its commitments for example, money-back guarantee, access to physical customer service centre or phone support system, and so forth
3. Clear statement from the merchant on the use of user's personal information that is, whether the information will be shared with third parties or not

The following table summarizes the identified trust variables and their corresponding levels used in the study

A Model of Trust for E-Commerce System Design

Egger (2000) states that "Traditional HCI analysis and design methods can be employed effectively to address usability aspects of ecommerce interfaces, but they may fail to deliver when it comes to designing trust-inducing features susceptible to convert users into customers. Indeed, the discipline of HCI currently lacks substantive knowledge about how trust is formed, maintained and lost in B2C e-commerce" (pp. 101). The author identified six factors which were later grouped into three following categories:

1. **Purchase knowledge:** Knowledge acquired before the user interacts with the system, this could be the reputation of the system, referral or user's previous experience
2. **Interface properties:** Interface properties consist of two sub properties, namely familiarity and attitude. Familiarity refers to both experience in terms of both navigation and online technology while attitude is the first impression the system makes on the user with respect to information presentation
3. **Information content:** Information content consists of risk, transparency and cooperation components. The risk component outlines the financial risks and security measures for example, insurance, and so forth. Transparency component refers to openness of the merchant in terms of privacy policy and business policies, while the cooperation content of information focuses on assisting effect of merchant and user.

Trust Evaluation in Electronic Environment

Mahmood (2006a) based his trust evaluation model on the notion that in business to consumer e-commerce trust consists of two non-separable aspects. First, it involves the trust in other party and second, trust in the transaction medium. The view of trust, adopted by Mahmood, is also consistent with the generic model of trust presented by Tan and Theon (2001). In the same study Mahmood (ibid), suggested that while committing an online transaction the user mainly considers functional and financial risk factors. The risk factors are evaluated on the basis of user's subjective initial trust assessment of functional and financial aspects of a transaction. Functional risk factors primarily relate to the business, that is, trust in party, rather than the actual

Figure 2. Revised MoTEC model (Egger, 2000)

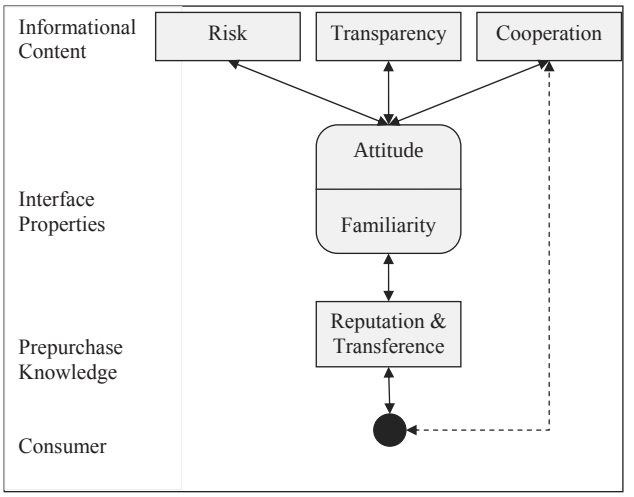

Figure 3. Dynamics of initial trust in electronic transactions (Mahmood, 2006a)

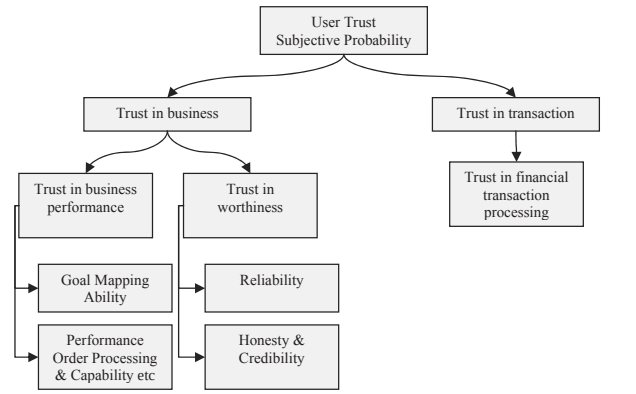

exchange of funds. The study outlined following aspects which impact user's functional trust evaluation:

- Business's capability and ability to deliver the desired good or service
- Business's ability to deliver the service and goods within desired time frame
- The business can be relied in fulfilling the desired goals
- The business will use and maintain the user's personal information with honesty
- The business is professional in conducting business

Besides functional evaluation the financial initial trust evaluation of the transaction includes risk of losing funds, either the whole or part of the transaction amount. The financial risks can be significantly reduced by providing alternate dispute resolution, transaction insurance and appropriate use of online security technologies that increase user's perceived trust on transaction medium.

From this, Mahmood concluded that trust in the e-environment consists of two main parts, firstly, trust in transaction where the transaction includes exchange of funds and second, trust in the party or business. The model further divided the user's perceived trust in online business and online transactions into subjective trust levels on the business's performance and honesty and trust in financial transaction processing respectively. The following figure outlines the involved dynamics of trust in an electronic transaction:

The study proposed following variables which represent different dynamics of trust in e-business. Each proposed variable represents the subjective probability that is, user's level of trust on each dynamic (i.e., aspect) of the transaction. The probabilities are appropriately aggregated in order to assist the user to judge and evaluate the factors involved and their determinants.

Initial Trust in Business:

p_b: Subjective probability (trust) based on business performance in terms of business ability (i.e., capability) to deliver and order processing (does not include dispute resolution as that comes after the transaction). This is dependant on online reputation, trusted referral(s) and structure and verbal communication of the Web site.

p_h: Subjective probability (trust) based on business honesty in terms of reliability and credibility. This is based on trusted referral(s), presence of third party privacy seals and Web interface.

Initial Trust in Transaction:

p_t: Subjective probability (trust) in financial transaction processing in terms of whether the transaction is insured by the bank, credit card service provider or by some third party trusted party, for example, PayPal. This is based on alternate dispute resolution, presence of third party security seals and transaction insurance from trusted credit card service provider.

Since the user may assign high value to business performance in the case of some transactions and/or may trust few e-businesses over others in the case of certain types of transactions each of these probabilities will have varied levels of impact on the user's final decision. For example, Albert may trust a business to buy small household items but may feel a higher level of risk when buying a car or while ordering certain types of services from the same e-business. Therefore weights have to be assigned to each subjective probability in order to represent the importance of each initial trust dynamic in an online transaction. Previous studies support that the user may feel more confident to buy a known brand from an

e-business than an unknown brand (Ang et al., 2001). The model defined following subjective weights:

Business related weights:

w_b: Subjective weight of business performance
w_h: Subjective weight of business honesty and credibility

Transaction related weight:

w_t: Subjective weight of financial transaction processing

Each of these subjective weights value will range from zero to 10, where the value zero represents that the user's final decision is not effected by user's level of trust on a particular aspect of the transaction and the value ten reflects that the user's decision is very sensitive to a particular subjective probability. The defined range between zero to 10 is to make it easy for the user to evaluate and to assign subjective value. Higher weight value range would result in same final computed result as the weights are fractioned in the final equation, discussed later. By using subjective weights and probabilities the weighted subjective probabilities or user's weighted trust values are calculated as follows:

Weighted Trust in business:

Weighted trust in business performance (w_{bp}) = $p_b * w_p$

Weighted trust in business honesty (w_{bh}) = $p_h * w_h$

Other than the trust levels (subjective probability of each trust evaluation component) and weights in a transaction, the total uninsured part of investment (u_i) that is, the maximum dollar amount a user may lose in case of online fraud (financial loss) will have to be incorporated in order to logically estimate the user's possibility to commit a transaction. In order to balance out the absolute amount of investment the fraction of uninsured investment is used.

t_i = Total Investment
i_i = Insured Investment
u_i = Uninsured Investment (the maximum amount a user can lose) where $u_i = t_i - i_i$

Equation 1: Fraction of uninsured investment.

$$f_{ui} = \frac{u_i}{t_i}$$

Where f_{ui} is the fraction of uninsured investment.

The user's subjective probability on financial transaction processing 'p_t' and user's subjective weight of financial transaction processing 'w_t' only affects the uninsured portion of transaction i.e. 'f_{ui}'. Therefore the user's weighted subjective probability of losing uninsured investment has to be incorporated in order to evaluate user's total trust level in an online transaction. The following equation is composed in order to calculate ratio of weighted probability of losing uninsured investment:

Equation 2: Ratio of weighted probability of losing uninsured investment

$$rw_{ui} = \frac{(1 - p_t) * f_{ui} * w_t}{m_{wt}}$$

Where:
'$1 - p_t$' represents the user's subjective probability of losing the uninsured portion of investment
'm_{wt}' represents the maximum weight which can be assigned to financial transaction processing. 'm_{wt}' will always be 10

The weighted probabilities have to be grouped as they correspond to two different aspects of an electronic transaction, that is, user's trust in business and user's trust in transaction. Moreover weighted trust in business performance (w_{bp}) and weighted trust in business honesty (w_{bh}) have a positive affect on the user's decision while rw_{ui} has a negative impact on user's decision to commit an online transaction. The following equation is composed in order to calculate Worthy of Investment '*WoI*' value:

Equation 3: Worthy of this Investment.

$$WoI = \left(\left(\frac{w_{bp} + w_{bh}}{w_p + w_h} \right) - rw_{ui} \right) * 100$$

The computed value of *WoI* can be used by the user to get an indication of whether they should commit to a certain online transaction or not, on the basis of weights and subjective probabilities assigned by the user for each dynamic (aspect) of the transaction. Moreover, *WoI* can also be used to compare two or more e-businesses or online available options.

FUTURE TRENDS

Since a certain level of uncertainty or risk is prerequisite for trust to exist (Koller, 1988), this notion of trust suggests that when consumers willingly become vulnerable to a Web retailer, they consider both the characteristics of the Web retailer and the characteristics of the related technological infrastructure. Although the user's perceived risk of technological infrastructure can be significantly reduced by employing appropriate security technologies but effective

techniques to develop and enhance user's trust in Web retailer are yet to be developed.

In future, the use of Web 2.0 (O'Reilly, 2006) technologies and social networking applications, for example, use of friend of a friend (FOAF) (Brickley & Miller, 2005) network to connect the online users who are interested in contributing to and sharing online trust evaluations, will emerge. Such applications will enable the users to add friends and families information to the network on the basis of their personal trust and relationship. The users will use FOAF network to exchange contact information, views and trust evaluations of companies, businesses and parties with whom they have already completed transactions. Such information will be exchanged openly and freely within and across networks. Such applications will use FOAF, Atom (Nottingham & Sayre, 2005), RDF (W3C, 2004a) and RDF Schema—RDFS (W3C, 2004b). This will eventually result in an open and decentralised repository of users' trust evaluations, which will be used by potential customers as assistive guide before they commit e-transaction.

CONCLUSION

The chapter outlines the proposed models which can be used to predict user's trust in online shopping, enhance user's trust in online vendor and estimate the risk in an online transaction. The Cheung and Lee (2000) model proposes the external factors, user's propensity to trust and user's perceived trust worthiness in determining overall user's trust in online merchant. Ang et al. model focuses on merchant's ability to deliver; bands offered by the merchant, dispute resolution process and privacy statements as the determining factors of user's trust. The model proposed by Egger (2000) uses user's previous purchase knowledge, interface of the Web site and the contents of the Web site as the foremost factors which impact users' online trust. All these models suggest different aspects of online transaction which contribute to user's level of trust in a transaction. The proposed factors can be used by online businesses to concentrate on the aspects of online businesses which contribute most to user's online trust.

The model proposed by Mahmood (2006b) recommends that the user's trust in an electronic business can be further enhanced if the e-business portrays professionalism, credibility and honesty in its practices and portrays capability and performance to deliver the desired service or product. Mahmood presented the proposed trust evaluation model into a mathematical form. The model can be used by the e-business to recognize the areas which can be improved in order to increase users' level of online trust, to recognize and resolve the users' online trust reducing factors and also to map the user's desired outputs from the transaction to impacting factors.

The discussed models highlight excellent opportunities for improvements to the service providers. By focusing on areas which impact user's online trust the service and product providers can really make the online shopping experience easy and more practical for the users. In future, it is expected that online users' will use social networking to exchange and gather information on e-merchants in a decentralized open manner.

KEY TERMS

Collective Trust Transfer: Collective trust transferring techniques rely on combined effort of several users, service providers and communities. Such techniques have much wider impact on potential customers, as they involve large number of contributing parties and are widely available.

Online Reputation: The online information regarding an e-business from the past direct or indirect experiences of a large body of users. It is the general opinion of the users toward a person, a group of people, or an organization in the cyberspace.

Privacy Statement: a statement posted on the company's or individual's Web site that explains the personal information being collected with or without a visitor's consent, the reasons it is being collected, and how the collected information will be used or shared. The privacy statement also states that how the information provided by someone else is used and shared.

Trust: The subjective estimation by which an individual, A, estimates about how likely another individual, B, performs a given task on which its welfare (interests) depends. It also consists of the elements of dependence, competence, disposition and fulfillment.

Trusted Referral: The information regarding a product or physical or online business, service or individual acquired from either the user's physical or online trusted network. It impacts the user's initial and subsequent levels of trust in an online business. The impact is directly related to the user's level of trust on the source in terms of source's credibility, honesty and ability.

Web 2.0: A network platform, enabling the utilization of distributed services such as social networking and communication tools. It is also referred as the architecture of participation.

An Overview of Wireless Network Concepts

Biju Issac
Swinburne University of Technology, Sarawak Campus, Malaysia

Wireless networks and the subsequent mobile communication are growing by leaps and bounds in the past years and the demand for connection without cables is certainly high. Nowadays, wireless networks are quite common and can be found on university campuses, corporate offices and in public places like hotels, airports, coffee shops and so forth. Not only are mobile devices getting smaller and cheaper, they are also becoming more efficient and powerful, capable of running applications and network services. This is causing the uncontrollable growth of mobile computing as we are witnessing today. Among the many number of applications and services that are executed by mobile devices, network and data services are in high demand. Brief descriptions of some selective wireless technologies that help mobile computing, like IEEE 802.11 networks (with infrastructure mode and ad-hoc mode), Bluetooth, HomeRF, WiMAX and cellular technologies are given below.

IEEE 802.11 INFRASTRUCTURE NETWORK

Wireless local area network (WLAN) which is also known as Wi-Fi (Wireless Fidelity) networks, requires an infrastructure network that could provide the services of accessing other networks, along with forwarding functions and medium access control. The Institute of Electrical and Electronics Engineers (IEEE) in 1997 initiated the first WLAN standard and they called it 802.11. But, 802.11 only supported a maximum bandwidth of 2 Mbps, which is quite slow for most applications. The IEEE 802.11 family consists of different standards. The initial standard was approved in 1997 and it backed wireless LAN Medium Access Control (MAC) and Physical layer (PHY) specifications that supported 1 Mbps and 2 Mbps data rate over the 2.4 GHz ISM band.

In a wireless infrastructure setup, there are two basic components, access points and wireless stations. An access point or base station functions as a bridge by connecting to a wired LAN (Local Area Network) through Ethernet cables. It receives data, buffers and transmits data between the wireless and the wired network infrastructure. A single access point supports on average 20 users and has a coverage varying from 20 meters in areas with obstacles like walls, stairways, elevators, and so forth, and up to 100 meters in areas where there is clear line of sight. The design of infrastructure-based wireless network is rather simpler as most of the network functionality lies within the access point. Transmission and reception of wireless communication can happen in different channels.

A building may require several access points to provide complete coverage and allow users to roam seamlessly between access points. A wireless network adapter connects users via an access point to the rest of the LAN. A wireless station can be using a PC card in a laptop, an ISA or PCI adapter in a desktop computer, or can be fully integrated within a handheld device. Security of a WLAN is of great concern with WEP (Wired Equivalent Privacy) encryption as static WEP keys could be easily recovered because of a design flaw (Stubblefield, Ionnidis, & Rubin, 2002). RADIUS Server authentication which uses EAP protocol (Extensible Authentication Protocol) with TKIP (Temporal Key Integrity Protocol) encryption is proposed as interim solution in WPA (Wi-Fi protected Access) standard, with AES encryption option being looked into as long term solution (Gast, 2002). Figure 1 shows a simple wireless network that uses RADIUS server authentication.

There are different wireless LAN technologies that the IEEE 802.11 standard supports in the unlicensed bands of 2.4 and 5 GHz. They share the same MAC (Medium Access Control) over two PHY layer specifications: Direct-Sequence

Figure 1. The wireless network in an organization showing mobile laptops

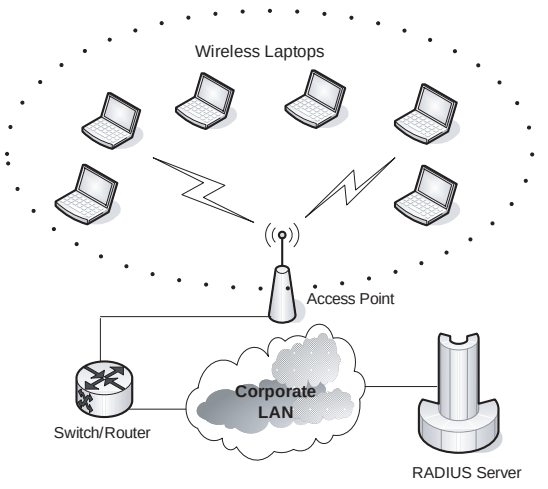

Table 1. Popular IEEE 802.11 comparisons

IEEE Standard	Maximum Speed	Frequency band	No. of nonoverlapping channels	Notes
802.11 (legacy)	1 Mbps to 2 Mbps	2.4 GHz	n/a	First standard (ratified in 1997). Uses FHSS and DSSS.
802.11a	54 Mbps	5 GHz	8 to 14 (or more in future)	Second standard (ratified in 1999). Uses OFDM.
802.11b	11 Mbps	2.4 GHz	3 (Channel 1,6 and 11)	Third and the most common standard (ratified in 1999). Uses DSSS.
802.11g	54 Mbps	2.4 GHz	3 (Channel 1,6 and 11)	Popular standard (ratified in 2003). Uses OFDM.

Spread Spectrum (DSSS) and Frequency-Hopping Spread Spectrum (FHSS) technologies. Infrared technology though supported, is not accepted by any manufacturer. Data rates of up to 2 Mbps were achieved initially by IEEE 802.11 systems operating at the 2.4 GHz band. Their wide acceptance initiated new versions and enhancements of the specification. The different extensions to the 802.11 standard use the radio frequency band differently. Popular 802.11 standards like 802.11a, 802.11b and 802.11g are listed in table 1.

As a strong and robust standard, 802.11i deals with the limitations of WEP encryption that was used with 802.11b and enhances the overall wireless security. The architecture uses 802.1x for authentication (with the use of EAP and an authentication server that uses 4-way handshake), includes improvements in key management and the Advanced Encryption Standard (AES) for encryption. Other 802.11 extensions include 802.11c that focuses on MAC bridges, 802.11d that focuses on worldwide use of WLAN with operation at different power levels, 802.11e that focuses on Quality of Service, 802.11f that focuses on access point interoperability and 802.11h that focuses on addressing interference problems when used with other communication equipments. Table 1 shows the comparison of the popular 802.11 standards (Held, 2003; Issac, Hamid, & Tan, 2006).

IEEE 802.11 AD HOC NETWORK

A wireless ad-hoc network is a network that uses wireless links where each node is willing to forward data to the other neighbouring nodes dynamically, based on the network connectivity. Types of wireless ad-hoc networks include Mobile ad-hoc networks (MANET), Wireless Sensor Networks (WSN) and Wireless Mesh Networks (WMN). A mobile ad-hoc network can be defined as a network of computer nodes that happens to be in proximity with each other, having no fixed infrastructure. A wireless sensor network (WSN) is a wireless network that makes use of distributed autonomous devices that uses sensors to measure or monitor environmental conditions like temperature, motion, sound, vibration, pressure and so forth, in a cooperative fashion. Wireless mesh networking (WMN) is mesh networking that is implemented on top of a wireless LAN in a decentralized (with no central server) way or centralized way (with a central server). Mesh networks are also extremely reliable with its redundant links, as each node is connected to several other nodes. If one node shuts down due to hardware errors or due to some other reason, its neighbours can easily find another route. Mesh networks can involve either fixed or mobile nodes.

Generally, in any ad-hoc network, each node can directly communicate with other nodes and so no access point or controlling station is needed. It is a self configuring network of routers along with associated hosts connected by wireless links. This union of network nodes or devices forms an arbitrary topology. This type of network provides great flexibility as it can be used for unplanned meetings, fast replacements of communication scenes far away from any infrastructure. Nodes or devices may look or rather search for target nodes that are out of vicinity by flooding the network with broadcasts packets that would be forwarded by each node. Wireless connections are even possible through multiple nodes forming a multihop ad-hoc network. Routing protocols then provide reliable connections even if nodes are moving around.

The routers are free to move randomly and organize themselves arbitrarily, making unpredictable changes in network's wireless topology. There is no need for access point and if one station working in ad-hoc mode is connected to wired network, stations forming ad-hoc network have a wireless access to Internet. IEEE 802.11 technology can be used to implement single-hop ad-hoc networks where the stations need to be in the same transmission radius to be able to communicate. But in multihop ad-hoc networking,

routing mechanisms can be enabled to extend the range of the ad-hoc network beyond the transmission radius of the single source station. Routing solutions for wired network doesn't apply to ad-hoc networks, because of its dynamic topology.

Some common problems that affect ad-hoc network performance are as follows: (1) stations cannot receive network frames outside the fuzzy wireless boundaries, (2) interference from other signals and (3) the channel has time varying and asymmetric propagation properties.

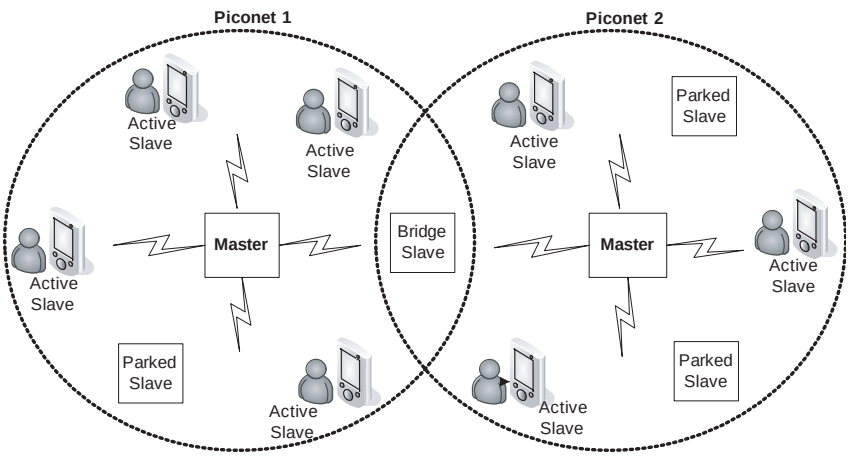
Ad-hoc routing protocols are getting popular with the increase in mobile computing. Ad-hoc networks include resource-starving devices, low bandwidth, high error rates and a topology that is continuously changing. Some of the design goals with ad-hoc routing protocols are minimal control overhead, minimal processing overhead, multihop routing capability, dynamic topology maintenance and loop prevention. The protocols should operate in a distributed manner. The nodes should operate either in proactive or reactive mode. Proactive protocols are table-based and maintain routes for the entire network within each node. The nodes must be fully aware of the changing topology. For topologies that are overtly dynamic, this approach can introduce a considerable overhead. Reactive or on-demand protocols trade off this overhead with increased delay. A route to destination is established when it is needed based on an initial discovery between the source and destination. Security of ad-hoc networks are a great concern with WEP (128 bits) encryption and 802.1x authentication offers some temporary solution (Basangi, Conti, Giordano, & Stojmenovic, 2004).

BLUETOOTH NETWORK

Bluetooth standard for wireless personal area networks is defined by the Bluetooth Special Interest Group (SIG) founded in 1998 by five companies; namely, Ericsson, Intel, IBM, Nokia and Toshiba. Currently, the SIG includes hundreds of other member companies. Bluetooth is a radio standard that is primarily designed for short range communication and for low power consumption, based on low-cost transceiver chips embedded in portable devices. It is named after Denmark's first king Harald Blaatand (or Bluetooth in English). Bluetooth provides a convenient way to connect and exchange information between devices such as personal digital assistants (PDAs), mobile phones, laptops, printers, digital cameras and so forth, via a secure, low cost, globally available short range radio frequency. The range of radio is from 10 meters to 100m (through optional amplifier). It aims to be a cable replacement technology and it defines three topologies: point-to-point, single cell (piconet) and multicell (scatternet). The basic unit of networking in Bluetooth is a piconet.

A device can be either a slave or master in piconet and can thus be part of more than one piconet. This network overlapping is called scatternet, as shown in Figure 2. As one of the devices in the piconet can act as a master and the other as slaves, the master decides the hopping pattern and the slaves have to synchronize to this pattern. Each piconet has a unique hopping pattern. Two other devices can also exist in the piconet, namely parked devices and standby devices. Parked devices which can be around 200 numbers maximum, cannot actively participate in the piconet, but can be reactivated within some milliseconds delay. Standby devices do not participate in the piconet. Each piconet has

Figure 2. Two piconets connected to form a scatternet



exactly one master and up to seven slaves. The frequency hopping (FH) used in Bluetooth provides resistance to interference and multiple path effects and provides multiple accesses from colocated devices in different piconets. The first step in forming a piconet involves the master sending its clock and device ID, which is a 48-bit unique identifier. After synchronizing its internal clock with the master's clock, a device may join a piconet whereby it is assigned a 3-bit active member address (AMA). The parked devices use an 8-bit parked member address (PMA). Devices on standby do not use any address (Schiller, 2003).

The Bluetooth version 2.1 specification includes the following features: *extended inquiry respons*e that provides more information during the inquiry process that would allow better filtering of devices before connection, *sniff subrating* that reduces the power consumption when devices are in the sniff low-power mode, *encryption pause resume* that enables an encryption key to be refreshed, enabling much stronger encryption and *secure simple pairing* that radically improves the pairing process securely for Bluetooth devices. Bluetooth provides support for three general wireless application areas like data and voice communication, cable replacement and ad-hoc networking.

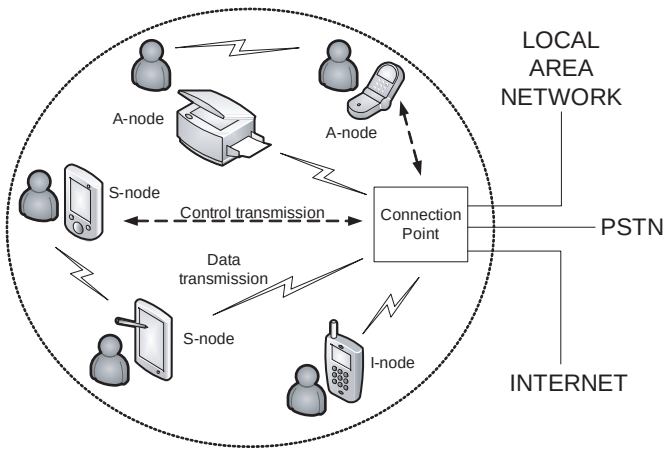
The security mechanism in Bluetooth uses a 48-bit address defined by IEEE, a 128-bit authentication key, a 128-bit symmetric encryption key and a generated random number. In order to add more value to this prospective radio technology, two potential aspects should be looked into to strengthen the Bluetooth platform for future applications; they are Bluetooth-enabled secure access to wide area networks and the interference issues with other devices operating within the same frequency band. In recent years, the research communities have been looking into the possibility to expand the coverage of Bluetooth networks for greater coverage and applications.

HomeRF NETWORK

HomeRF 2.0 specification defines a common interface that supports wireless voice and data networking within a home. It was developed by the HomeRF Working Group, a consortium of mobile wireless companies that included Siemens, Proxim, National Semiconductor, Motorola and more than 100 other companies. It supports three types of data services: asynchronous data service (that provides best effort service), priority asynchronous data service (that provides priority service) and isochronous data service (that provides support for applications with strict QoS requirements). HomeRF created a new class of mobile consumer devices using personal computers and the Internet. It is also referred to as the last 50 meters access. The availability of high speed last mile access technologies such as xDSL, cable modem and ISDN has also created a high speed demand on home networking. The Shared Wireless Access Protocol (SWAP) that has been developed by the Home Radio Frequency Working Group (HomeRF WG) was launched in March 1998 as a single specification for consumer devices interoperability (HomeRF, n.d.; Issac, Chee, & Mohammed, 2005).

HomeRF 2.0 delivers Ethernet equivalent bandwidth to support wider wireless voice and data networking applications at home. It allows 800 kbps for isochronous voice and a maximum of 10 Mbps for asynchronous data transfer. The standard categorizes the HomeRF devices into 3 types: Asynchronous data device (also called A-node), Streaming data device (S-node) and Isochronous data device (I-node).

Figure 3. Managed HomeRF network



The Connection Point (CP) provides service management for the A-node, S-node and I-node. CP supports A-nodes with power savings and data access to Internet or other network computers, S-nodes with session setup and priority channel access to other S-nodes and finally I-nodes with connection setup, resource allocation and connectivity to PSTN. The HomeRF standard defines two kinds of network topologies: Ad-hoc network and Managed Network. An ad-hoc network is a distributed network in which the devices can make a peer-to-peer communication that includes only A-nodes without any CP. The Managed Network as shown in Figure 3 is a network managed by the CP and the devices can either communicate peer-to-peer (data services) or can establish communication through the CP (voice services) depending on the type of HomeRF devices used. HomeRF 2.0 supports 128 bit encryption so that all the data traveling across the radio waves is encrypted. The major drawback of this implementation is the lack of a centralized key management for the network. But this is not a concern for home users because it is a common assumption that the manual key management needs to be done only for a few devices in a home network. Similar to some of the competing technologies such as Bluetooth and WiFi, HomeRF operates in the license free 2.4GHz frequency band and utilizes frequency hopping spread spectrum technology to achieve a secure and robust communication (Dean, 2004; Ganz, Ganz & Wongthavarawat, 2004).

WiMAX: THE BROAD BAND WIRELESS NETWORK

WiMAX (Worldwide Interoperability for Microwave Access) forms the set of standards developed by IEEE 802.16 working group in 2001 that defines a broad band wireless network. 802.16 networks are geared toward point to multipoint (PMP) communication topology in which a central base station communicates with a number of subscriber stations and all the communication will have to go through the base station, as in Figure 4. As the wavelengths are short in the 10 to 66 GHz frequency bands, the standard requires line of sight between the communicating points. It supports data rates in excess of 120 Mbps (theoretically).

There are two types of WiMAX, namely fixed and mobile, typified by 802.16d and 802.16e. 802.16d provides 2 Mbps or more data rates within a distance of up to 5 miles and its aim is to provide wireless connection between one central base station and a set of fixed networks, like connecting a set of offices to a central office without WAN links. 802.16e is intended to help mobile users. It provides multiple channels with an effective data rate of 5 Mbps with a distance limit of up to 6 miles (Ganz, Ganz, & Wongthavarawat, 2004).

2G/2.5G/3G CELLULAR NETWORKS

Mobile phones that use cellular technologies have traversed three generations with three different technologies: analog voice, digital voice and digital voice with data. The cells are modeled as hexagons (or roughly circular), as in Figure 5, with transceiver towers in them. A mobile device can move from one cell to the other cell, keeping connected. The first generation (1G) mobile phones used analog voice that used AMPS (Advanced Mobile Phone System). The second generation (2G) used digital voice and had used D-AMPS (Digital AMPS), GSM (Global System for Mobile Communication) and CDMA (Code Division Multiple Access) systems. The third generation (3G) uses W-CDMA (Wideband CDMA)

Figure 4. Point to multipoint network topology in WiMAX

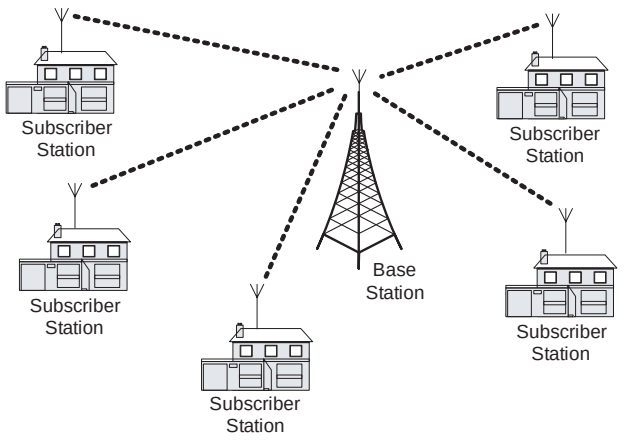


Figure 5. Cell sites with transceiver towers

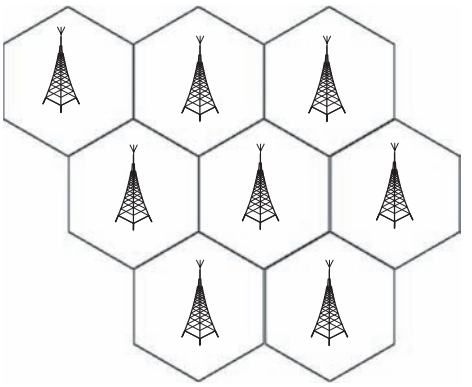

and CDMA2000. GSM is the dominant 2G mobile system worldwide primarily due to its roaming capability, and due to its early standardization and deployment by European countries. GSM uses TDMA (Time Division Multiple Access) technology in three different bands: 900MHz & 1800 MHz in most countries, and 1900MHz in USA. GSM data rate is around 9.6 Kbps. CDMA IS-95a (CDMAone) is also a 2G cellular wireless technology and the first commercial CDMA network was mainly deployed in USA and South Korea and was developed by Qualcomm. IS-95a supports data rates of up to 14.4 Kbps and uses GPS satellites for network system timing.

GPRS (Global Packet Radio Service) is a 2.5G technology based on GSM. 2.5G is a term used for a 2G technology that has been modified to give it the packet data qualities of 3G. It has improved data rates but it is still not near the maximum rate of 2Mbps of a 3G system. GPRS data rate is 20 to 40 Kbps (with 144 Kbps theoretical maximum). CDMA IS-95b is also a 2.5G descendant of IS-95a. It has low deployment costs and theoretically provides data rates up to 115Kbps, but providing less than 64 Kbps in practice.

EDGE (Enhanced Data for Global Evolution) is also a 2.5G technology, but it is an enhanced version of GPRS. It uses enhanced modulation to include more data into the available radio bandwidth. Its data rate is much more comparable to 3G data rates.

Wideband-CDMA network is a 3G system that was proposed by Ericsson and it uses direct sequence spread spectrum modulation. It is designed to interwork with GSM networks and runs in 5 MHz bandwidth. The other 3G technology is CDMA2000 proposed by Qualcomm. It is backward compatible with IS-95, but doesn't work with GSM. CDMA2000 also uses direct sequence spread spectrum and uses 5MHz bandwidth. Work is in progress toward 4G systems that promises much higher bandwidth, ubiquity, seamless integration with wired network and high service quality for multimedia (Tanenbaum, 2004).

COMPARISION OF WIRELESS TECHNOLOGIES

Table 2 compares the features of different wireless technologies like modulation, frequency range, distance range, network type and data rate (Ferro & Potorti, 2004).

CONCLUSION

Brief descriptions of popular wireless technologies were presented through the discussions done. The world is increasingly becoming mobile and wireless networking is getting greater focus in the recent past, especially with hardware technology breakthroughs and price drops. As wireless networks facilitate mobile computing, the future of the above mentioned technologies are being watched with eagerness. Mobility when combined with computing power makes a deadly combination and that's why relentless research is going on to make wireless technologies even better. The convergence of all these wireless technologies to form one single network is the greatest challenge ahead, as they all

Table 2. Wireless technology comparison

Standard / Feature	802.11a/b/g (Wi-Fi)	802.11n (Wi-Fi)	Bluetooth	HomeRF	802.16 (WiMax)	2G/2.5G/3G (Cellular)
Modulation	OFDM or DSSS	DSSS	Adaptive FHSS	FHSS (2 or 4 Level FSK)	QPSK, 16-QAM, 64-QAM	D-AMPS /CDMA/ GSM/
Operating Frequency	2.4 GHz (b/g) and 5 GHz (a)	2.4 GHz or 5 GHz	2.4 GHz	2.4 GHz	10-66 GHz	869-894 MHz
Distance Range	~30 to 110m	~70m to 160m	~10m	~150 feet	~2 km to ~10 km	Cell range of 1 to 5 miles (approx.)
Network Type	IP and peer-to-peer	IP and peer-to-peer	peer-to-peer (point to multi-point)	peer-to-peer	IP (point to multi-point)	IP
Data Rate	2 Mbps to 54 Mbps	200Mbps	721Kbps to 3 Mbps	800kbps to 10Mbps	5 Mbps to 70 Mbps	>128kbps to 2Mbps

use different networking technologies and that could take us to a world where seamless and ubiquitous computing will become a definite reality and not a future dream.

KEY TERMS

Access Point: The central or master device through which an infrastructure wireless node makes a connection to the local area network. It acts more like a bridge between wireless node and LAN.

Bluetooth: It is an industrial specification and standard for wireless personal area networks (W-PANs).

Direct Sequence Spread Spectrum: A form of spread spectrum in which each bit in the original signal is represented by multiple bits in the transmitted signal, using a spreading code.

Encryption: To convert plain text or data into unreadable form by means of a reversible mathematical computation.

Frequency Hopping Spread Spectrum: It is a spread-spectrum method of transmitting radio signals by rapidly switching a carrier among many frequency channels, using a pseudorandom sequence known to both transmitter and receiver.

HomeRF: Short form for "home radio frequency." It is designed specifically for wireless networks in homes, in contrast to 802.11, which was created for use in businesses.

Medium Access Control (MAC): For a communication network, the method of determining which station has access to the transmission medium at any time.

Piconet: A small network of communication devices connected in an ad-hoc fashion using Bluetooth technology.

Scatternet: A scatternet is collection of piconets connected through sharing devices.

WiMax: Short form for Worldwide Interoperability for Microwave Access, to provide wireless data over long distances from point to point links to full mobile cellular type access.

Wireless Transmission: Electromagnetic transmission through air, vacuum or water by means of antenna.

OWL: Web Ontology Language

INTRODUCTION

The World Wide Web (WWW) emerged in 1989, developed by Tim Berners-Lee who proposed to build a system for sharing information among physicists of the CERN (*Conseil Européen pour la Recherche Nucléaire*), the world's largest particle physics laboratory.

Currently, the WWW is primarily composed of documents written in HTML (hyper text markup language), a language that is useful for visual presentation (Cardoso & Sheth, 2005). HTML is a set of "markup" symbols contained in a Web page intended for display on a Web browser. Most of the information on the Web is designed only for human consumption. Humans can read Web pages and understand them, but their inherent meaning is not shown in a way that allows their interpretation by computers (Cardoso & Sheth, 2006).

Since the visual Web does not allow computers to understand the meaning of Web pages (Cardoso, 2007), the W3C (World Wide Web Consortium) started to work on a concept of the Semantic Web with the objective of developing approaches and solutions for data integration and interoperability purpose. The goal was to develop ways to allow computers to understand Web information.

The aim of this chapter is to present the Web ontology language (OWL) which can be used to develop Semantic Web applications that understand information and data on the Web. This language was proposed by the W3C and was designed for publishing, sharing data and automating data understood by computers using ontologies. To fully comprehend OWL we need first to study its origin and the basic blocks of the language. Therefore, we will start by briefly introducing XML (extensible markup language), RDF (resource description framework), and RDF Schema (RDFS). These concepts are important since OWL is written in XML and is an extension of RDF and RDFS.

BACKGROUND

Everyday, the Web becomes more attractive as an information sharing infrastructure. However, the vast quantity of data made available (for example, Google indexes more than 13 billion pages) makes it difficult to find and access the information required by the wide diversity of users. This limitation arises because most documents on the Web are written in HTML (HTML, 2007), a language that is useful for visual presentation but which is semantically limited. As a result, humans can read and understand HTML Web pages, but the contents of Web pages are not defined in a way that computers can understand them. If computers are not able to understand the content of Web pages it becomes impossible to develop sophisticated solutions to enable the interoperability and integration between systems and applications.

The aim of the Semantic Web is to make the information on the Web understandable and useful to computer applications and in addition to humans. *"The Semantic Web is an extension of the current Web in which information is given well-defined meaning, better enabling computers and people to work in cooperation"* (Berners-Lee et al., 2001). The Semantic Web is a vision for the future of the Web, in which information is given explicit meaning, making it easier for machines to automatically process and integrate the information available on the Web.

One of the corner stones of the Semantic Web is the OWL. OWL provides a language that can be used by/on applications that need to understand the meaning of information instead of just parsing data for display purposes. Nowadays, several projects already rely on semantics to implement their applications. Example include semantic wikis (Campanini et al., 2004), social networks (Ding, et al., 2005), semantic blogs (Cayzer & Shabajee, 2003), and Semantic Web services (McIlraith et al., 2001),

THE SEMANTIC WEB STACK

The Semantic Web identifies a set of technologies and standards which form the basic building blocks of an infrastructure

that supports the vision of the Web associated with meaning. Figure 1 illustrates the different parts of the Semantic Web architecture. It starts with the foundation of URI (universal resource identifier) and Unicode. URI is a formatted string that serves as a means of identifying abstract or physical resources. For example, http://dme.uma.pt/jcardoso/index.htm identifies the location from where a Web page can be retrieved and urn:isbn:3-540-24328-3 identifies a book using its ISBN. Unicode provides a unique number for every character, independent of the underlying platform, program, or language.

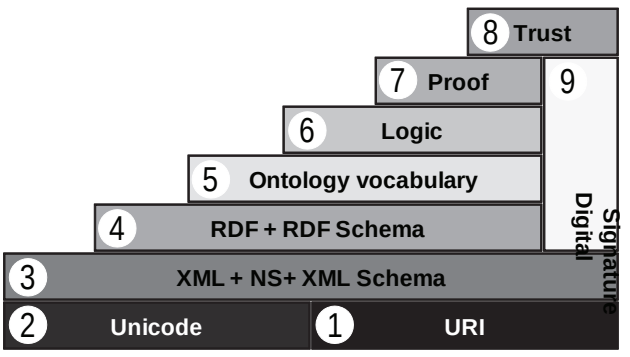
Directly above URI and Unicode we find the syntactic interoperability layer in the form of XML, which in turn underlies RDF and RDFS. Web ontology languages are built on top of RDF and RDFS. The last three layers are logic, proof, and trust, which have not been significantly explored. Some of the layers rely on the digital signature component to ensure security.

In the following sections we briefly describe the most relevant layers (XML, RDF, and RDFS). While the notions presented have been simplified, they give a reasonable conceptualization of the various components of the Semantic Web.

XML

The extensible markup language (XML) (Decker et al., 2000; XML, 2007) was originally pictured as a language for defining new document formats for the WWW. An important feature of this language is the separation of content from presentation, which makes it easier to select and/or reformat the data. SGML (standard generalized markup language) and XML are text-based formats that provide mechanisms for describing document structures using markup tags (words surrounded by '<' and '>'). Both HTML and XML representations use tags such as <h1> or <name>, and information between those tags, referred to as the content of the tag. However, there are significant differences between HTML and XML.

Figure 1. Semantic Web layered architecture (Berners-Lee et al., 2001)



XML is case sensitive while HTML is not. This means that in XML the start tags <Table> and <table> are different, while in HTML they are the same. Another difference is that HTML has predefined elements and attributes whose behavior is well specified, while XML does not. Instead, users can create their own XML vocabularies that are specific to their application or business' needs.

The following structure shows an example of an XML document identifying a 'Contact' resource. The document includes various metadata markup tags, such as <first_name>, <last_name>, and <e-mail>, which provides various details about a contact.

```
<Contact contact_id="1234">
      <first_name> Jorge </first_name>
      <last_name> Cardoso </last_name>
      <organization> University of Madeira </organization>
      <email> cardoso@uma.pt </email>
      <phone> +51 291 705 156 </phone>
</Contact>
```

While XML has gained much of the world's awareness, it is significant to identify that XML is simply a way of standardizing data formats. But from the point of view of semantic interoperability, XML has restrictions. One important characteristic is that there is no way to recognize the semantics of a particular domain because XML aims at a document structure and enforces no common interpretation of the data. Although XML is simply a data-format standard, it is part of a set of technologies that constitute the foundations of the Semantic Web.

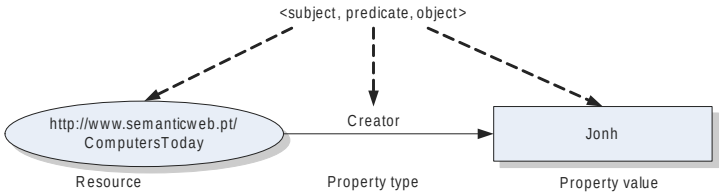
RDF

Resource description framework (RDF) (RDF, 2002), was developed by the W3C to provide a common way to describe information so it could be read and understood by computer applications. RDF was designed using XML as the underlying syntax language. RDF provides a model for describing resources on the Web. A resource is an element (document, Web page, printer, user, etc.) on the Web that is uniquely identifiable by a URI. The RDF model is based upon the idea of making statements about resources in the form of a subject-predicate-object expression, a 'triple' in RDF terminology.

- Subject is the resource, that is, the thing that is being described;
- Predicates are aspects about a resource, and expresses the relationship between the subject and the object;
- Object is the value that is assigned to the predicate.

RDF has a very limited set of syntactic constructs, no other constructs except for triples is allowed. Every RDF

Figure 2. RDF graph



document is equivalent to an unordered set of triples. Let us write a RDF triple that describes the following statement:

"The creator of the page named ComputersToday is John."

In this example, 'http://www.semanticweb.pt/ComputersToday' is a resource, and it has a property, 'Creator,' with the value 'John.' The resulting RDF statement is:

st = (http://www.semanticweb.pt/ComputersToday, Creator, John)

The statement can also be graphically represented as illustrated in Figure 2.

One way to represent the statement in Figure 2 using RDF language is the following:

```
<? xml version="1.0" ?>
<RDF xmlns = "http://w3.org/TR/1999/PR-rdf-syntax-19990105#"
      xmlns:DC = «http://dublincore.org/2003/03/24/dces#»>

      <Description about =
         "http://www.semanticweb.pt/ComputersToday">
      <DC:Creator>John</DC:Creator>
   </Description>
</RDF>
```

The first lines of this example use namespaces to explicitly define the meaning of the notions that are used. The first namespace xmlns:rdf="http://w3.org/TR/1999/PR-rdf-syntax-19990105#" refers to the document describing the syntax of RDF. The second namespace http://dublincore.org/2003/03/24/dces# refers to the description of the Dublin Core (DC) (DC, 2005), a basic ontology about authors and publications.

RDF SCHEMA

RDF schema (RDFS) (XMLSchema, 2005) is technologically more advanced when compared to RDF. RDFS describes the resources with classes, properties, and values. RDFS associates the resources in classes and states the relations between these classes, or declares properties and specifies the domain and range of these properties. RDFS' specification consists of some basic classes and properties that can be extended to any given domain.

Classes in RDFS are much like classes in object oriented programming languages. These allow resources to be defined as instances of classes, and subclasses of classes. Properties can be seen as attributes that are used to describe the resources by assigning values to them. RDF is used to declare a property and RDFS can extend this capability by defining the domain and the range of that property (however, RDFS has some limitations but these have been resolved with the introduction of OWL).

THE WEB ONTOLOGY LANGUAGE

The Web ontology language (OWL) (OWL, 2004) is one of the most important ontology languages. It enables the interoperability of applications and allows computers to understand the Web's content. In this respect it is more expressive than XML, RDF or RDF Schema due to providing additional vocabulary along with formal semantics.

OWL Flavors

There are three OWL sublanguages: OWL Lite, OWL DL, and OWL Full. An important feature of each sublanguage is its expressiveness. OWL Lite is the least expressive and the OWL Full is the most expressive sublanguage. OWL DL is more expressive that OWL Lite but less expressive than OWL Full. In other words, this entails that every legal OWL Lite ontology is a legal OWL DL ontology; every legal OWL DL ontology is a legal OWL Full ontology; every valid OWL Lite conclusion is a valid OWL DL conclusion; and every valid OWL DL conclusion is a valid OWL Full conclusion.

OWL Full is the most expressive of the OWL sublanguages and it uses the entire OWL language primitives. It is intended to be used in situations where very high expressiveness is more important than being able to guarantee the

Figure 3. OWL sublanguages

decidability or computational completeness of the language. This sublanguage is meant for users who want maximum expressiveness and the syntactic freedom of RDF, but with no computational guarantees.

OWL DL is a sublanguage of OWL Full that restricts the application of OWL and RDF constructors. OWL DL (DL stands for description logics) is not compatible with RDF, in the same way that not every RDF document is a legal OWL DL document, although every legal OWL DL document is a legal RDF document. This sublanguage supports those users who want the maximum expressiveness without losing computational completeness and decidability.

OWL Lite is syntactically the simplest sublanguage. It is intended to be used in situations where only a simple class hierarchy and constraints are needed. This sublanguage supports those users primarily needing a simple classification hierarchy and constraint features.

Note that every OWL Lite ontology or conclusion is a legal OWL DL ontology or conclusion, but not the inverse, and so on for OWL DL and OWL Full, as showed in Figure 3:

The choice between OWL Lite and OWL DL may be based upon whether the simple constructs of OWL Lite are sufficient or not. The choice between OWL DL and OWL Full may be based upon whether it is important to be able to carry out automated reasoning on the ontology or whether it is important to be able to use highly expressive and powerful modeling facilities.

OWL Syntax

In this section we describe the syntax of OWL. We illustrate step-by-step how to build an ontology using OWL. We also explain how to define the heather of ontology, its classes, properties and relationships. After reading this section the reader should be able to recognize an ontology written in OWL and identify some of its components.

Header

The first element in an OWL document is an rtf:RDF element which specifies a set of XML namespace's declarations that provide a means to unambiguously interpret identifiers and make the rest of the ontology presentation much more readable. For example,

```
<rdf:RDF
    xmlns="http://apus.uma.pt/~adelia/RUD.owl#"
    xmlns:rdf="http://www.w3.org/1999/02/22-rdf-syntax-ns#"
    xmlns:xsd="http://www.w3.org/2001/XMLSchema#"
    xmlns:rdfs="http://www.w3.org/2000/01/rdf-schema#"
    xmlns:owl="http://www.w3.org/2002/07/owl#"
    xml:base="http://apus.uma.pt/~adelia/RUD.owl">
```

A namespace is composed by: reserved XML attribute xmlns, a prefix that identify the namespace and the value.

Information Version

After the namespace declaration, an OWL document specifies a collection of assertions that are grouped under an owl: ontology element and offers details about the ontology:

- **owl:versionInfo:** Provides information about the current ontology.
- **owl:priorVersion:** Indicates an earlier version of the current one.
- **owl:backwardCompatibleWith:** Contains a reference to an ontology that is a prior version of the containing ontology that is backward compatible with it.
- **owl:incompatibleWith:** Indicates that the containing ontology is not backward compatible with the referenced ontology.
- **owl:imports:** Only this assertion has a formal meaning to the ontology and represents a set of other ontologies that are considered to be part of the current ontology. Note that owl:imports is a transitive property because if ontology A imports ontology B, and ontology B imports ontology C, then ontology A also imports ontology C.

The following is a simple example:

```
<rdf:RDF>
...
<owl:Ontology rdf:about="">
    <rdfs:comment> University Ontology </rdfs:comment>
    <owl:versionInfo> v.1 2006-9-05 </owl:versionInfo>
    <owl:priorVersion>
    <owl:Ontology rdf:about = "http://apus.uma.pt/~adelia/RUD.owl"/>
    </owl:priorVersion>
    <rdfs:label> University Ontology </rdfs:label>
</owl:Ontology>
...
</rdf:RDF>
```

Class Element

Classes are a collection of individuals, a way of describing part of the world. They are defined in an OWL document with the owl:Class element. For example, the class "Teacher" can be define as follows,

```
<owl:Class rdf:ID="Teacher">
    <rdfs:subClassOf rdf:resource="#Person"/>
</owl:Class>
```

Note that the rdf:ID element defines the name of the class. If we want to make reference to a class we use the rdf: resource element. An OWL ontology can represent the hierarchy between classes using the element owl:subClassOf. For example, the class "Teacher" is a subclass of "Person."

Between the two classes it is possible to establish relations using owl:equivalentClass and owl:disjoinWith elements. The assertion owl:equivalentClass when applied to two classes A and B, represents that class A has the same individuals as class B. For example, the class "faculty" is equivalent to the "academicStaffMember" class:

```
<owl:Class rdf:ID="faculty">
  <owl:equivalentClass rdf:resource="#academicStaffMember"/>
</owl:Class>
```

The owl:disjoinWith element applied on two classes A and B suggest that class A and B disjoin, that is, if an instance is member of class A it cannot be an instance of class B. For example, a "Full Professor" cannot be an "Associate Professor" at the same time.

```
<owl:Class rdf:about="#AssociateProfessor">
    <owl:disjoinWith rdf:resource="#FullProfessor"/>
</owl:Class>
```

Complex Class

Another way to create classes in OWL is to combine simple classes using Boolean operators (union, intersection, and complement) and create complex classes. The members of the class are completely specified by the Boolean operators. The owl:unionOf element applied on classes A and B creates a new class that contains all members from class A and B. For example, the combination of the class "staff members" and the class "student" create the new class "peopleAtUni."

```
<owl:Class rdf:ID="peopleAtUni">
    <owl:unionOf rdf:parseType="Collection">
        <owl:Class rdf:about="#staffMember"/>
        <owl:Class rdf:about="#student"/>
    </owl:unionOf>
</owl:Class>
```

The owl:intersectionOf element creates a new class from the two classes A and B which has elements that were both in class A and class B, which follows as,

```
<owl:Class rdf:ID="facultyInDME">
  <owl:intersectionOf rdf:parseType="Collection">
    <owl:Class rdf:about="#faculty"/>
    <owl:Restriction>
      <owl:onProperty rdf:resource="#belongsTo"/>
      <owl:hasValue rdf:resource="#DMEDepartment"/>
    </owl:Restriction>
  </owl:intersectionOf>
</owl:Class>
```

The individuals of the new class created in this example are those individuals that are members of both the classes "faculty" and the anonymous class created by the restriction on the property "belongTo."

The owl:complement element selects all individuals from the domain that do not belong to a certain class,

```
<owl:Class rdf:about="#course">
  <rdfs:subClassOf>
    <owl:Class>
      <owl:complementOf rdf:resource="#staffMember"/>
    </owl:Class>
  </rdfs:subClassOf>
</owl:Class>
```

In this example, the class "course" has as its members all individuals that do not belong to the" staffMember" class.

Property

Properties let us describe a kind of relationship between members of classes. In an OWL document two types of properties are distinguished:

- Object properties which relate objects to other objects, i.e. instances of a class with instances of another class. In the next example the object property "isTaughtBy" relates the class "course" with the class "academicsStaffMember." This means that a "course" "isTaughtBy" an instance of the "academicStaffMember" class.

  ```
  <owl:ObjectProperty rdf:ID="isTaughtBy">
      <owl:domain rdf:resource="#course"/>
      <owl:range rdf:resource="#academicStaffMember"/>
  </owl:ObjectProperty>
  ```

- Datatype property which relates objects to data type values. OWL does not have predefined data types, but it allows one to use the XML Schema data types. In following example, the year in which a tourist was born is specified using the "http://www.w3.org/2001/XLMSchema#nonNegativeInteger" data type from the XML Shema.

```
<owl:DatatypeProperty rdf:ID="ageYear">
    <rdfs:domain rdf:resource="#Person"/>
    <rdfs:range rdf:resource=
http://www.w3.org/2001/XLMSchema#nonNegativeInteger"/>
</owl:DatatypeProperty>
```

Note that both kinds of properties can use the rdfs:domain and rdfs:range element to restrict the relation.

Property Restrictions

More elaborate boundaries can be made by applying restrictions to a property, this results in the subclasses of individuals that satisfy that condition. There are two kinds of restrictions: values constraints and cardinality constraints. Examples of values constraints include owl:allValuesFrom, owl:someValuesFrom, and owl:hasValues.

owl:allValuesFrom: Defines the set of individuals, for which all the values of the restricted property are instance of a certain class:

```
<owl:Class rdf:about="#firstYearCourse">
  <rdfs:subClassOf>
    <owl:Restriction>
      <owl:onProperty rdf:resource="#isTaughtBy"/>
      <owl:allValuesFrom rdf:resource="#professor"/>
    </owl:Restriction>
  </rdfs:subClassOf>
</owl:Class>
```

In this example, the individuals that are members of the class "firstYearCourse" are all the courses that have the property "isTaughtBy" assigned to a "professor"

owl:someValuesFrom: Defines the set of individuals that have at least one relation with an instance of a certain class, for example:

```
<owl:Class rdf:about="#academicStaffMember">
  <rdfs:subClassOf>
    <owl:Restriction>
      <owl:onProperty rdf:resource="#teaches"/>
      <owl:someValuesFrom rdf:resource="#undergraduateCourse"/>
    </owl:Restriction>
  </rdfs:subClassOf>
</owl:Class>
```

owl:hasValues: Defines a set of individuals for which the value of the restricted property is equal to a certain instance. For example the individuals of the class "mathCourse" can be characterized as those that are taught by the professor "949352:"

```
<owl:Class rdf:about="#mathCourse">
    <rdfs:subClassOf>
        <owl:Restriction>
            <owl:onProperty rdf:resource="#isTaughtBy"/>
            <owl:hasValues rdf:resource="#949352"/>
        </owl:Restriction>
    </rdfs:subClassOf>
</owl:Class>
```

Cardinality constraints point out how many times the property can be used on an instance. Examples include owl: maxCardinality, owl:minCardinality, and owl:cardinality.

owl:maxCardinality: Defines the set of individuals that have at the most N distinct values of the property concerned. For example, we can specify that the class "department" has at the most 30 members:

```
<owl:Class rdf:about="#department">
  <rdfs:subClassOf>
    <owl:Restriction>
      <owl:onProperty rdf:resource="#hasMember"/>
        <owl:maxCardinality rdf:datatype="&xsd;nonNegative
        Integer">
        30
      </owl:maxCardinality>
    </owl:Restriction>
  </rdfs:subClassOf>
</owl:Class>
```

owl:minCardinality: Defines the set of individuals that have at least N distinct values of the property concerned. For example, a course must be taught at least by one teacher. In OWL it is defined as follows:

```
<owl:Class rdf:about="#course">
  <rdfs:subClassOf>
    <owl:Restriction>
      <owl:onProperty rdf:resource="#isTaughtBy"/>
        <owl:minCardinality rdf:datatype="&xsd;nonNegative
        Integer">
        1
      </owl:minCardinality>
    </owl:Restriction>
  </rdfs:subClassOf>
</owl:Class>
```

owl:cardinality: Defines the set of individuals that have an exact number of distinct values of the property concerned. This element is used to specify a precise number, that is, to express that a property has a minimum cardinality which is equal to the maximum cardinality.

Properties' Characteristics

Properties' characteristics add more expressivity to the OWL language. owl:equivalentProperty and owl:inverseOf elements are examples of those characteristics. The owl: equivalentProperty element associate properties that have the same range and the same domain. For example, the property "leacturesIn" is equivalent to "teaches" and in OWL this can be represented as:

```
<owl:ObjectProperty rdf:ID="leacturesIn">
    <owl:equivalentProperty rdf:resource="#teaches"/>
</owl:ObjectProperty>
```

The owl:inverseOf element can be used to define inverse relation between properties. If property P' is stated to be the inverse of property P'', then if X'' is related to Y'' by the P'' property, then Y'' is related to X'' by the P' property. For example, "teacher teaches a course" is the inverse of "a course is taught by a teacher." This can be expressed in OWL as:

```
<owl:ObjectProperty rdf:resource="#teaches">
    <owl:inverseOf rdf:resource="#isTaughtBy"/>
</owl:ObjectProperty>
```

The property element has some properties that can be defined directly:

- **Function property:** The function property (owl: FunctionProperty) defines a property that has at the most one value for each instance.
- **InverseFuncionalProperty:** In OWL, by using the InverseFuncionalProperty (owl:InverseFuncional-Property) it is possible to define properties that have different values to different instances, that is, two different instances can not have the same values.
- **Transitive property:** The transitive property is understood as: if the pair (x, y) is an instance of the transitive property P, and the pair (y, z) is an instance of P, we can infer the pair (x, z) is also an instance of P.
- **Symmetric property:** The symmetric property (owl: SymmetricProperty) is interpreted as follows: if the pair (x, y) is an instance of A, then the pair (y, x) is also an instance of A.

The following example illustrate the application of the owl:SymmetricProperty and owl:TransitiveProperty elements.

```
<owl:ObjectProperty rdf:ID="hasSameGradeAs">
    <rdf:type rdf:resource="&owl;TransitiveProperty"/>
    <rdf:type rdf:resource="&owl;SymmetricProperty"/>
    <rdfs:domain rdf:resource="#student"/>
    <rdfs:range rdf:resource="#student"/>
</owl:ObjectProperty>
```

FUTURE TRENDS

Many researchers worldwide have recognized that the Semantic Web (or Web3.0) is the key to develop the new generation of information systems. The number of international conferences organized every year on this topic clearly shows the interest and importance of this new technology. In this context, OWL is the most widespread language to develop a new breed of the Semantic Web-based applications. OWL has been used in many areas; some applications and tools use this conceptual approach to build Semantic Web based systems. According to TopQuadrant (TopQuadrant, 2005), a consulting firm that specializes in Semantic Web technologies, the market for semantic technologies will grow at an annual growth rate of between 60 percent and 70 percent until 2010

In the near future, we will see the use of OWL to implement applications raging from semantic social networking, semantic RSS, semantic podcasts, semantic wikis, semantic blogs to semantic mashups. As you can see, we will be devising a solution that matches most of executives' future product acquisitions strategies. Adding semantics to these types of applications is important since in a survey of 8,300 executives from McKinsey it was found that when asked about their plans to invest in tools in the future, the answers given included those applications.

Enterprise Information Integration (EII) is another area that will benefit from the Semantic Web and OWL. Today, integration is a top priority for many European and worldwide enterprises. Most organizations have already realized that the use of Semantic Web technologies (Berners-Lee et al., 2001) is the best solution to support cross-organizational cooperation for SMEs that operate in dynamically changing work environments. Semantic Web technologies are already viewed as a key technology to resolve the problems of interoperability and integration within the heterogeneous world of ubiquitously interconnected systems with respect to the nature of components, standards, data formats, protocols, etc. Moreover, we also believe that Semantic Web technologies can facilitate not only the discovery of heterogeneous components and data integration, but also the communication, coordination and collaboration behavioral of employees and individuals. semantics can help not only the system, but also human integration and interoperability.

Managing information in enterprises faces three barriers that have to be overcome: the diverse data formats, the disparate nature of content and the need to drive "intelligence" from this content. The Semantic Web helps to surpass these limitations by providing a way to add semantic metadata to documents. Metadata allows software programs to automatically understand the full context and meaning of each document. So, it is accurate to say that semantics will enable information integration and analyses in the following tasks:

- Extracting, organizing and standardizing information from many disparate and heterogeneous content sources and formats.
- Identifying interesting and relevant knowledge from heterogeneous sources and formats.
- Making efficient use of the extracted knowledge and content by providing tools that enables fast and high-quality querying, browsing and analysis of relevant and actionable information.

Finally, programming the Semantic Web with OWL can reduce and eliminate terminological and conceptual confusion by defining a shared understanding, that is, a unifying framework enabling communication and cooperation amongst people in reaching a better inter-enterprise organization. Presently, one of the most important roles ontology plays in communication is that it provides unambiguous definitions for terms used in a software system, but semantics needs to be applied rapidly to human integration to enable communication, coordination, and cooperation. The use of ontologies for improving communication has already been shown to work in practice.

CONCLUSION

The Semantic Web is the future vision of the current Web, where information will have a precise meaning. Currently, the WWW is primarily composed of documents written in a language (HTML) that is useful for visual presentation, but not for computerized understanding. The Semantic Web is not a separate Web, but an extension of the current one, in which information is a given well-defined meaning, enabling computers and people to work better in cooperation. To make possible the creation of the Semantic Web it is important to have a language that: (1) describes the concepts of a given domain, and (2) creates ontologies. One of the most prominent ontology languages to achieve those two tasks is OWL (ontology Web language) which can be used to develop Semantic Web applications. These applications will constitute a new wave of enhanced systems that will understand better the domain in which they are working and with which they interact. OWL defines a common set of terms that are used to describe and represent a specific domain. Thus, standard OWL enables the Web to be a global infrastructure for sharing both documents and data, which makes searching and reusing information easier and more reliable as well. OWL can be used by applications to improve search engines on the Web and tools to manage knowledge. In this chapter we have laid out the foundations of the Semantic Web, its associated languages and standards. These elements are the basic building blocks of any Semantic Web application.

KEY TERMS

Metadata: Data that describe other data. Generally, a set of metadata describes a single set of data, called a resource.

Ontology: Is a description of concepts and relationships that can be used by people or software agents that want to share information within a domain. An ontology document defines the terms used to describe and represent a domain.

OWL: A markup language for publishing and sharing data using ontologies on the Internet. OWL is a vocabulary extension of the RDF and is derived from the DAML+OIL Web Ontology Language.

RDF: Resource description framework is a family of World Wide Web Consortium (W3C) specifications originally designed as a metadata model using XML but which has come to be used as a general method of modeling knowledge, through a variety of syntax formats.

RDFS: RDF schema is an extensible knowledge representation language, providing basic elements for the definition of ontologies, otherwise called RDF vocabularies, intended to structure RDF resources.

Semantic Web: The Semantic Web provides a common framework that allows data to be shared and reused across applications, enterprises, and community boundaries. It is a collaborative effort led by W3C with the participation of a large number of researchers and industrial partners.

XML: The extensible markup language (XML) is a simple, very flexible text format derived from SGML (ISO 8879). XML is accepted as a standard for data interchanged on the Web, allowing for the structuring of data but without meaning.

INTRODUCTION

Visualization is the process of mapping numerical values into perceptual dimensions and conveying insight into visible phenomena. With the visible phenomena, the human visual system can recognize and interpret complex patterns. One can detect meaning and anomalies in scientific data sets. Another role of visualization is to display new data in order to uncover new knowledge. Hence, visualization has emerged as an important tool widely used in science, medicine, and engineering.

As a consequence of our increased ability to model and measure a wide variety of phenomena, data generated for visualization are far beyond the capability of desktop systems. In the near future, we anticipate collecting data at the rate of terabytes per day from numerous classes of applications. These applications can process a huge size of data, which are produced by more sensitive and accurate instruments, for example, telescopes, microscopes, particle accelerators, and satellites (Foster, Insley, Laszewski, Kesselman, & Thiebaux, 1999). Furthermore, the speed of the generation of data is still increasing.

Therefore, to visualize large data sets, visualization systems impose more requirements on a variety of resources. For most users, it becomes more difficult to address all requirements on a single computing platform, or for that matter, in a single location. In a distributed computing environment, various resources are available, for example, large volume data storage, supercomputers, video equipment, and so on. At the same time, high speed networks and the advent of multi-disciplinary science mean that the use of remote resources becomes both necessary and feasible (Foster et al., 1999).

BACKGROUND

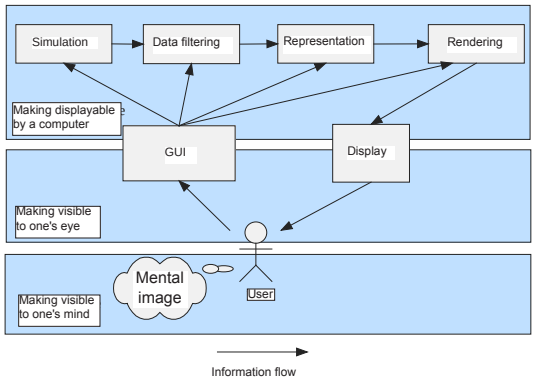
Visualization Process

The process of visualization is decided by the choice of representation. The process of visualization with 3-D, real-time interaction is much more complicated than one with still images. No matter how a specific process behaves, it can be considered in three different but interrelated semantic contexts (see Figure 1). They are *making displayable by a computer*, *making visible to one's eyes* and *making visible to one's mind* (Brodlie et al., 2004). This section provides an overview of the process of creating a 3-D, real-time, interactive visualization.

Interactive means that the system responds quickly enough for users to adjust the controlling inputs in rapid response to the output (Mueller, 2001). *Real time* means that the system must always keep updating outputs within a certain small fixed amount of time (Mueller, 2001). Generally, *real time interactive visualization* is defined as the process of creating images at rates between approximately 1 and 100 frames per second. In particular, if the latency exceeds beyond approximately 1 second, humans would feel that the computer's responses is too slow to interact continuously. However, increasing the frame rate from 100 frames per second to 1000 frames per second is of no use due to perceptual characteristics of the human brain (Igehy, 2000).

Figure 1 shows the visualization flow chart of real-time, interactive visualization. In this diagram, information flow follows the arrows. Firstly, data are generated from some simulation systems such as a mathematically based computational model or a collection of observed values. Data filtering involves a wide range of operations, such as removing noise, replacing missing values, and so on, and makes data readable to visualization software. These operations are also used to refine the data by sifting the most relevant aspects and removing unnecessary values.

Figure 1. Interactive visualization process



After the data are filtered, the representation procedure maps data to some geometric form. At this point, a geometric scene graph will be setup. The scene graph involves the geometric objects, the color value of the objects, the materials, and so on. These parameters can also be driven by computational models within the constraints imposed by visualization software.

The rendering procedure takes the information of scene graph and computes the 2-D image for human eyes to see. These images will be stored in a color buffer temporal for display. The resultant images will be displayed on computer screens or other output devices, such as project wall, Head Mounted Display (HMD).

Using graphical user interfaces (GUI), users can steer visualization systems. One can adjust the visualization system by modifying variables and data in the simulation, data filtering, representation, and rendering stages and get real-time response. It is important for real-time interaction that both simulations and graphics systems should provide real-time performance and allow for user input.

Towards Distributed Visualization

There are trends to increase not only the complexity of the models that are displayed, but also the resolution of the images. However, users still require that the system must always respond with updated output within a certain small fixed amount of time (Mueller, 2001). Then hundreds of megaFLOPS of performance and memory bandwidth of gigabytes per second are demanded. These requirements are far beyond capabilities of a single desktop system (Molnar, Cox, Ellsworth, & Fuchs, 1994). Therefore, research efforts have been made to build high performance architectures for visualization. Several recent developments have demonstrated how graphics hardware of a PC cluster can accelerate a graphics and visualization task (Muraki, Lum, Ma, Ogata, & Liu, 2003). In order to speed up the development of distributed visualization systems, some toolkits are developed for distributed parallel visualization.

WireGL (Humphreys, Buck, Eldridge, & Hanrahan, 2000; Humphreys et al., 2001) is the first sort-first cluster rendering system. It includes an efficient network protocol, a geometry bucketing scheme, and an OpenGL (http://www.opengl.org) state tracking algorithm. It supports heterogeneous hardware platforms. WireGL divides the computational nodes into clients and rendering servers. It replaces the OpenGL driver on client machines, intercepts the OpenGL calls, and sends the calls over a high-speed network to servers, which render the geometry. WireGL classifies each OpenGL call into one of three categories: (1) geometry, (2) state, or (3) special. Each rendering server receives OpenGL commands from remote clients and renders a portion of the screen space. Chromium (Humphreys et al., 2002), the new version of WireGL, is a stream-oriented framework for processing streams of OpenGL commands on parallel architectures, for example, clusters. It can support sort-first, sort-last, and hybrid parallelization strategies by the use of stream processing units. Some researches, such as VTK and OpenRM (Bethel, Humphreys, Paul, & Brederson, 2003), integrated Chromium with visualization software.

Mesa is an open source software implementation of OpenGL without using a hardware accelerator. PMesa (Mitra & Chiueh, 1998) is a parallel version of Mesa. PMesa is built with sort-last architecture. The geometry data are arbitrarily assigned to rendering processors. Mitra and Chiueh developed a general parallel compositing algorithm, which is integrated with both binary swapping composition (Ma, Painter, Hansen, & Krogh, 1994) and parallel pipeline composition (Lee, Raghavendra, & Nicholas, 1996). According to the number of composition processors, it divides the processors into several groups. Inside one group, it performs parallel pipeline composition. Between groups, it runs binary sweeping composition. In this way, it not only keeps all processors at high utilization efficiency, but also cuts down the step number for composition to optimize the performance.

AnyGL (Yang, Shi, Jin, & Zhang, 2002) is a software implementation of a sort-anywhere architecture.

Sort-Both (Zhu, Chan, Wang, & Jegathese, 2004) is a hybrid architecture which includes both sort-first and sort-last stages in the rendering pipeline. Other systems, such as OpenSG (http://www.opensg.org), Aura (Van der Schaaf, Renambot, Germans, Spoelder, & Bal, 2002), and PGL (Crockett & Orloff, 1993), have achieved a set of valuable results in parallel rendering.

TECHNOLOGIES OF PARALLEL AND DISTRIBUTED VISUALIZATION

Design Methods for Parallel Visualization

Parallelism

When scenes are complex, or when high quality images or high frame rates are required, rendering processes become computationally demanding. To provide necessary levels of performance, parallel computing technologies have been applied in the research field. Parallel visualization refers to the exploitation of parallelism in performing the visualization computations. Several different types of parallelism can be applied in visualization processes. These include functional parallelism, data parallelism, and temporal parallelism (Crockett, 1998). Each type is suitable for a set of applications or specific rendering methods.

- **Functional Parallelism:** Different processors perform different functions in the visualization pipeline. It is used in pipelines of processors, where the operations to be performed are distributed among a set of processors. As a processor completes work on one data item, the processor forwards the data item to the next processor, and then it receives a new item from its upstream neighbor. The degree of parallelism achieved is proportional to the number of functional units in the pipeline. Therefore, the available parallelism is limited to the number of stages in the rendering pipeline.
- **Data Parallelism:** The data are split up among processors, and each processor performs operations on a portion of the data. The parallelism that is achievable with this approach is not limited by the number of stages in the rendering pipeline. However the performance is challenged by the network bandwidth and the number of processors which can be incorporated into a single system. Data parallelism can be classified into two categories—object parallelism and image parallelism (Crockett, 1998). Because the data parallelism approach can take advantage of larger numbers of processors, it has been adopted in one form or another by most of the software rendering implementations. Data parallelism has been implemented for general purpose massively parallel systems. Data parallelism also lends itself to scalable implementation. It can allow the number of processing elements to vary with some factors, for example, scene complexity, image resolution, and desired performance levels. Data parallelism is the most suitable for interactive visualization with massive data sets.
- **Temporal Parallelism:** Temporal parallelism is also mentioned as frame parallelism. In animation visualization, the tasks can be decomposed in the time domain. Different processors work on successive frames in an animation sequence or interactive session. The main advantage of frame parallelism is its linear speedup—the usual performance is proportional to the number of processors. However, the performance increase is not accompanied by a reduction in network latency.

Temporal parallelism and function parallelism is naturally load balanced and easy to be implemented. However, they are not suitable for real–time, interactive visualization. The following discussion will focused on data parallelism.

Parallel Visualization Strategy

For data parallelism visualization systems, Molnar et al. (1994) have classified parallel rendering strategies into sort-first, sort-middle, and sort-last. The classification is based on where the data redistribution takes place in the graphics pipeline.

- **Sort-First:** In sort-first architectures, also known as *image space parallel*, the image space is partitioned into nonoverlapping 2-D regions (i.e., tiles) and each processor does just enough geometry processing to determine the region of the raster image which a primitive will belong to. The primitive is then sent to the appropriate processor to perform both the geometry processing and rasterization for that region of the raster image. The main advantage of sort-first is low communication requirements. Another advantage is that the processors implement the entire rendering pipeline for a portion of the screen. These improve the performance of distributed systems. However, it is susceptible to load imbalance with the reason of the random distribution of primitives in the image space. Another significant disadvantage is that it produces extra rendering work. Therefore, the scalability of sort-first systems is limited.
- **Sort-Middle:** Sort-middle architectures are those that perform sorting and data redistribution at the obvious place between geometry processing and rasterization. In a sort-middle strategy, each geometry processor computes screen coordinates for each primitive that has been assigned to it. It then determines the rasterizing processor to which it will send a primitive's scan line information, based on the raster image's partition among processors. One problem with sort-middle strategy is that they are susceptible to load imbalance of rasterizing processors due to nonuniformly distributed primitives. Another problem is high communication

cost if the tessellation ratio is high. Sort-middle is best suited for tightly coupled systems that use a fast, global interconnection to send primitives between geometry and rasterization processors.

- **Sort-Last:** Sort-last architectures, also known as *object space parallel*, defer sorting until the last stage. Primitives are arbitrarily distributed to available processors. Each processor then performs both geometry processing and rasterization of its assigned primitives, regardless of where they fall within the raster image. The final stage is to compose (sort and merge) the raster images from all rendering processors to form the final image with depth information. The advantage of the sort-last strategies is that it is less prone to load imbalance and is scalable. The main disadvantage is that it usually requires an image composition network with very high bandwidth and processing capabilities to support transmission and composition of overlaps (Molnar et al., 1994).

Task Decomposition

Task partitioning is important for parallel and distributed systems. It is particularly critical for distributed memory architectures, for example, Beowulf clusters, where partitioned data are distributed to different processing nodes.

For sort-middle and sort-last strategies, the geometry data can be arbitrarily and evenly partitioned before sending to the graphics pipeline. Sort-first strategy subdivides the screen and the divided regions are assigned to different processors. Because of the arbitrary distribution of geometry data in screen space, it is critical to keep load balancing. The task partitioning methods for sort-first architectures can be broadly categorized as either static or adaptive.

- **Static Data Partitioning:** The general static approach is to divide the screen into more regions than number of processors and assign the regions to the processors in interleaved fashion. Region shapes have been based on scan lines, horizontal strips (Eldridge, 2001; Whelan, 1985), vertical strips (Whelan, 1985), and rectangular areas (Chen, Stoll, Igehy, Proudfoot, & Hanrahan, 1998; Cox, 1997). The key idea is that if the screen is divided finely enough, each processor would have similar portions of both the populated and the sparse areas of the screen, and thus they should have nearly equal loads. The first interleaved partitioning algorithm is proposed by Fuchs and Johnson (1979). Figure 2 shows the processors are assigned regions in an interleaved pattern.

Figure 2. Assignment in interleaved pattern (based on Ellsworth, 1996)

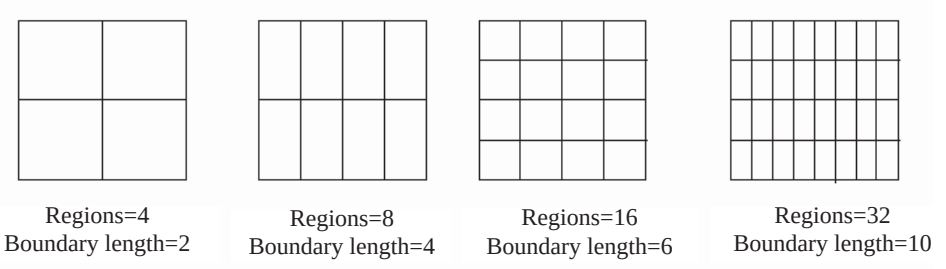
1	2	1	2	1	2	1	2
3	4	3	4	3	4	3	4
1	2	1	2	1	2	1	2
3	4	3	4	3	4	3	4
1	2	1	2	1	2	1	2
3	4	3	4	3	4	3	4

Obviously, in this way, load balance is difficult to guarantee, since it is still possible that most of the primitives are concentrated into one region. Then, the overloaded processor will be the bottleneck of the system. In order to address this problem, some techniques have been utilized, such as level of detail (LOD) (Clark, 1976) control and culling algorithms. Another problem is that a large number of partitions will introduce large redundant rendering. Primitives that overlap region boundaries must be processed in multiple regions. This inefficiency is expressed in terms of the overlap factor—the number of regions covered by a typical primitive. Both the overlap factor and primitive traffic are proportional to the total linear length of the region boundaries. As shown in Figure 3, it is intuitively easy to see that more boundaries will provide more opportunities for primitives to cross them. Therefore, a large number of partitions will dramatically increase computation and communication overhead and do harm to the system scalability. Therefore, the number of data partitions, namely granularity ratio, is important for static sort-first algorithms. For overhead considerations a small granularity ratio is better, whereas a larger granularity ratio would generally improve the load balance.

- **Adaptive Data Partitioning:** Adaptive approaches dynamically partition the screen space. There are a variety of solutions. Adaptive solutions offer the possible benefit of keeping the number of divisions to a minimum, but at the cost of increased overhead and complexity.

Samanta, Zheng, Funkhouser, Li, and Singh (1999) divide adaptive decomposition approaches into three types, top-down, bottom-up, and optimization. Top-down approaches start from the screen space as a whole and divide it recursively into regions based on estimated workloads. Bottom-up approaches start from a large number of predetermined small regions and combine them into larger regions that are then assigned to processors. Optimization approaches begin with some initial decomposition and assignment (e.g., a static one or the one from the previous frame) and adjust it to balance workloads by cutting out and reassigning smaller

Figure 3. Boundary length and number of regions (Muller, 2001)



regions from existing partitions to meet some load balancing criterion.

Whelan's (1985) median-cut method is a typical top-down approach. Median-cut splits the screen into subregions based on the onscreen position of the centroids of each polygon. The algorithm recursively splits the screen (along the longer dimension of the given region) until the number of regions equals the number of processors. Since the algorithm is based only on the centroids of primitives, it cannot accurately take into account the onscreen area overlapped by the primitives. Therefore, it is difficult to achieve good and steady load balance in this way.

Muller's (1995) mesh-based adaptive hierarchical decomposition (MAHD) algorithm is another top-down decomposition approach. Primitives are first tallied up according to how their bounding boxes overlap a fine mesh. For each cell covered by a given primitive's bounding box, an amount proportional to the rendering costs for that primitive is tallied. Once all the primitives have been counted, the cells are added up to form a summed area table. Then, using this data table as a hint, screen space tiles are recursively split along their longest dimensions until the number of regions equals the number of processors.

Samanta, Funkhouser, Li, and Singh (2000) introduced a hybrid sort-first and sort-last task decomposition algorithm. It simultaneously decomposes the 2-D screen into regions and the 3-D polygonal model into groups and assigns them to PCs to balance the load and minimize overheads. However, different regions may overlap each other. The overlapped area will do image composition like sort-last. It may cause large communication overhead when a large partition number is needed.

Image Composition

Image composition transforms parallel streams into a useful output (usually a single image). It is often the bottleneck of algorithms, especially sort-last algorithms, in high performance visualization (Brodlie et al., 2004).

In sort-last approaches, primitives are arbitrarily distributed to available processors. Each processor then performs both geometry processing and rasterization of its assigned primitives, regardless of where they fall within the raster image. The final stage is to compose (sort and merge) raster images from all nodes to form a final image with depth information.

The naive composition approach is to have a designated processor accept the contributions from all of the other processors, performing the appropriate Z-buffering or composing operations for each contribution. Obviously, in this way, the composing processor will become the bottleneck. With a large number of processors, it will be overloaded. Ma et al. (1994) developed the binary-swap composing algorithm to parallelize the image composition among processors. It first distributes primitives arbitrarily among processors. Then, each processor renders its primitives into a whole frame image with Z-buffer. After that, as its name implies each processor exchanges data with another processor and composes the image. Each processor sends half of its remaining color and Z-buffer to the other processor and composites its remaining buffer with the incoming data. The resulting smaller color-buffer and Z-buffer are then used in the next iteration until all the processors have exchanged data with each other. Figure 4 shows an example of the binary-swap composing algorithm using four processors.

Lee et al. (1996) developed a family of image composition algorithms, named *parallel pipeline composition*, for sort-last rendering systems. In this approach, the color-buffer and Z-buffer at each processor is divided into N portions, where N is the number of processors. Processors are organized in a circular ring and the subimages are accumulated in a pipelined fashion along the ring with each processor involved in each stage. At the end, each processor holds a fraction of the final image. Figure 5 shows the procedure of parallel pipeline composition with four processors. In order to improve the performance of the parallel pipeline composition, many optimization methods have been developed, including bounding box optimization, direct pixel

Figure 4. Binary-swap compositing algorithm (based on Ma et al., 1994)

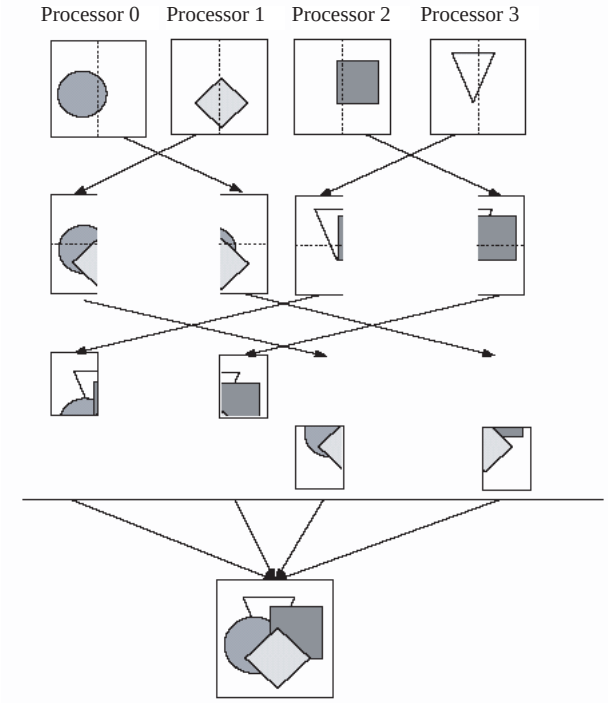


Figure 5. Parallel pipeline composition with four processors (based on Lee et al., 1996)

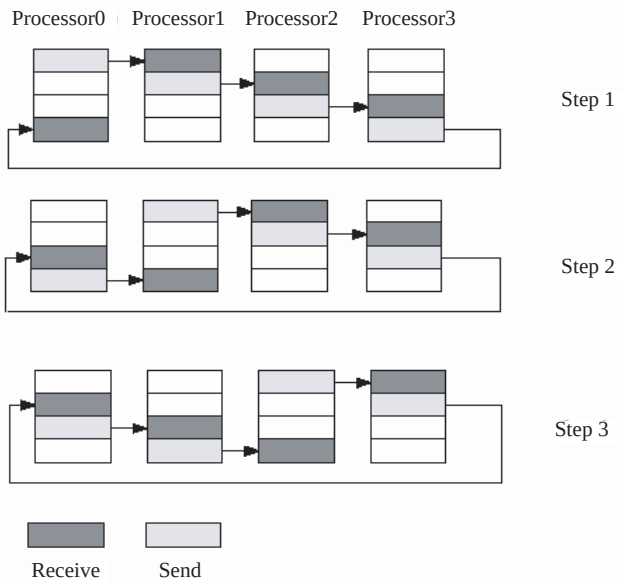

forwarding, interleaved composition region, and adaptive task scheduling.

Nguyen, Peery, and Zahorjan (2001) developed a partition algorithm—Image Layer Decomposition (ILD), which is similar to sort-last in that it uses an object partition. However, unlike sort-last, for each frame, ILD repartitions the scene objects into *P* nonmutually occlusive subsets for a system with *P* nodes and assigns each subset to a node for rendering. Since subsets are nonmutually occlusive, each node generates a coherent image layer; to compose the final image. ILD simply layers these image layers on top of one another according to the visibility order of the subsets (and thus does need the Z-buffer generated at each node).

FUTURE TRENDS

Grid computing (Foster, Kesselman, & Tuecke, 2001) now becomes a new computing paradigm and solution for high performance distributed computing. Computational grids can provide dependable, consistent, pervasive, and inexpensive access to high-end computational capabilities for high performance scientific and engineering applications.

Several research challenges for large scale distributed visualization system, for example, large data set management, network performance improvement, and adaptation to heterogeneous environments are needed to be addressed. State-of-the-art grid technologies provide numbers of solutions for these problems (Karonis et al., 2003).

CONCLUSION

This article firstly introduces the background of visualization systems, with specific regard on distributed visualization technologies and systems. Sort-first, sort-middle, and sort-last algorithms are presented, analyzed, and evaluated. Recent popular parallel and distributed visualization systems are introduced and investigated. Some interesting observations can be found after the study. The strategies used in parallel and distributed visualization are in multiple levels. In the pipeline of visualization, parallelism can be exploited by executing the steps in the pipeline currently in the distributed resources. In the separate steps, parallelism can be exploited by partitioning the task and mapping them to multiple compute elements.

Visualization is a useful approach for computational scientists and engineers to analyze and represent data. As modern computational science evolves, increasing requirements are imposed on visualization systems, for example, large volume data, geographically distributed research environments, more complex computational models, and so forth. On the other hand, development of computing technologies, for example, high speed network, large size data storage, and especially grid technology, propose a promising solution for the research challenges—large scale distributed visualization on computational grids.

KEY TERMS

Computational Grid: Computational grid is a hardware and software infrastructure that provides dependable, consistent, pervasive, and inexpensive access to high-end computational capabilities. (Foster & Kesselman, 1998).

Distributed Memory: Distributed memory means the memory is associated with individual processors and a processor is only able to address its own memory. Some authors refer to this type of system as a *multicomputer*, reflecting the fact that the building blocks in the system are themselves small computer systems complete with processor and memory.

Graphics Pipeline: Graphics pipeline has two major steps. Starting with primitives (polygons) in object space, a geometry processing step transforms the primitives into screen space. This is followed by a rasterization step to convert the primitives into a set of screen pixels. They finish with a set of appropriately colored pixels in the frame buffer. Each step includes several computationally intensive procedures.

Rasterization: Rasterization is the process of converting a vertex representation to a pixel representation; rasterization is also called *scan conversion.*

Rendering: Rendering is the computational process of generating an image from the abstract description of a scene (Crockett, 1994).

Scene Graph: Scene graph is a data structure used to hierarchically organize and manage the contents of spatially oriented scene data.

Z-Buffer: Z-buffer is an area in graphics memory reserved for storing the Z-axis value of each pixel.

Pattern-Oriented Use Case Modeling

Pankaj Kamthan
Concordia University, Canada

INTRODUCTION

The majority of the present software systems, such as those that run on automatic banking machines (ABMs), on mobile devices, and on the Web, are interactive in nature. Therefore, it is critical to precisely understand, identify, and document the services that an interactive software system will provide from the viewpoint of its potential users. A large and important class of models that these services encapsulate is *use cases* (Jacobson, Christerson, Jonsson, & Övergaard, 1992).

In the last few years, use cases have become indispensable as means for behavioral modeling of interactive software systems. They play a crucial role in various software development activities, including estimating development cost (Anda, 2003), eliciting behavioral requirements, and defining test cases.

It is well known that addressing quality *early* is crucial to avoid the propagation of problems to later artifacts (Moody, 2005). With the increasing deployment of use cases as early artifacts in software process environments, the question of *how* these models should be developed so as to attain high quality arises. In response, this article focuses on the use case modeling process (the *act* of constructing use case models) and, based on the notion of patterns (Appleton, 1997), proposes a systematic approach towards the development of use case models.

The rest of the article is organized as follows. The background and related work necessary for the discussion that follows is outlined. This is followed by the presentation of a pattern-oriented use case modeling process for systematically addressing the semiotic quality of use case models in a feasible manner. Next, challenges and directions for future research are outlined, and finally, concluding remarks are given.

BACKGROUND

In this section, the terminology necessary for the discussion that follows is presented and the significance of quality in the development of use case models is briefly reviewed.

A Primer on Use Case Models

A *use case* models the behavior of a software system, which yields an observable result of value to an actor of the system (Jacobson et al., 1992). In doing so, a use case intends to capture typical interactions between the actors and the software system being built. There can be multiple use cases of a system and they can be related. The use cases can be classified into analysis use cases (those addressing the problem domain) and synthesis use cases (those addressing the solution domain). There are three possible types of (binary and non-reflexive) relationships among use cases: "include," "extend," and "generalization."

An *actor* is an external entity that interacts with each instance of a use case. An actor could be a (human) user or another program. Each actor plays a unique *role* with respect to a use case from the viewpoint of the system. There can be multiple actors of a system, and they can also be related. The actors can be classified into primary actors (those initiating a use case) and secondary actors (those supporting the goal of a primary actor). There is one possible type of (binary and non-reflexive) relationship among actors: "generalization."

A use case is an abstraction of the real-world use of a system. A *scenario* is a concrete realization or instance of a use case; it can be classified as either normal or non-normal (including alternates and exceptions).

The s*ystem boundary* is a means to illustrate the separation of actors and use cases. The set of all actors and use cases describing the complete usage of a system is known as the system's *use case model.*

There are two common means of representing use cases: as structured text and as a graphic. Each means of representation has its own advantages and limitations (Jacobson, 2003); a detailed discussion of this issue is beyond the scope of this article.

The Unified Modeling Language (UML) (Booch, Jacobson, & Rumbaugh, 2005) is a standard language for modeling the structure and behavior of object-oriented software systems. UML provides explicit support for use case models (Bittner & Spence, 2003): the Use Case Diagram is a commonly used UML diagram type to graphically represent use case models, the Activity Diagram is used to represent the sequential order in which use cases are executed, and the Sequence Diagram is used to represent scenarios.

A View of the Quality of a Use Case Model

Using ISO/IEC 9126-1:2001 Standard, the quality of a use case model could be formally but broadly defined as the totality of characteristics of a use case model that bear on its ability to satisfy stated and implied needs.

There are different views of quality (Wong, 2006) of which an intersection of the product, user-based, manufacturing, and value-based views are applicable in our case. That is because a use case model must satisfy certain quality attributes, be communicable to the user, must conform to the language specification it is expressed in, and its development must be feasible.

Related Work on Quality-Centered Use Case Modeling

There are various reasons why quality of a use case model can be compromised, including lack of understanding of the underlying domain, lack of knowledge or skills in the modeling language, or limitations imposed by modeling tools. There have been a few initiatives addressing the quality of textual and graphical use case models (Rosenberg & Scott, 1999; Fantechi, Gnesi, Lami, & Maccari, 2003; El-Attar & Miller, 2006; Törner, Ivarsson, Pettersson, & Öhman, 2006). However, these efforts focus on the product, not on the process.

It was previously suggested that the development of use case models needs to be carried out iteratively (Rosenberg & Scott, 1999; Bittner & Spence, 2003; Leffingwell & Widrig, 2003). However, details are sketchy, and the emphasis on the improvement of quality of use case models is lacking. In particular, there is no use of patterns. A model-driven requirements engineering process that integrates certain metrics for the improvement of quality of use case models has been proposed (Berenbach & Borotto, 2006). However, the rationale for the selection of quality attributes is unclear.

A SYSTEMATIC APPROACH FOR THE DEVELOPMENT OF USE CASE MODELS OF HIGH SEMIOTIC QUALITY

In this section, a use case modeling process for systematically addressing the semiotic quality of use case models is proposed.

A Pattern-Oriented Use Case Modeling Process

The motivation for a use case modeling process (henceforth labeled as UCMP for brevity) is based on the assumption that a "good" process will lead to a "good" outcome of the process (Nelson & Monarchi, 2007), namely the use case model.

Characteristics of a Use Case Modeling Process

UCMP is expected to have the following characteristics:

1. UCMP must be cost-effective. The advantages of adopting UCMP must substantially outweigh the costs.
2. UCMP is a *sub-process* of a user-sensitive software development process. Examples of these include Crystal Methodologies (Cockburn, 2005) and the Unified Process (UP) (Jacobson, Booch, & Rumbaugh, 1999). The processes for domain modeling and requirements elicitation can impact the "velocity" of UCMP.
3. UCMP must be *both* iterative and incremental. They are complementary: being iterative enables re-visitation of a use case model, and being incremental facilitates the progress of a model.
4. UCMP must have *explicit* support for model quality assurance and model evaluation. This is necessary for construction of use case models to attain desirable quality.
5. UCMP should have a quantifiable and feasible stopping criterion.

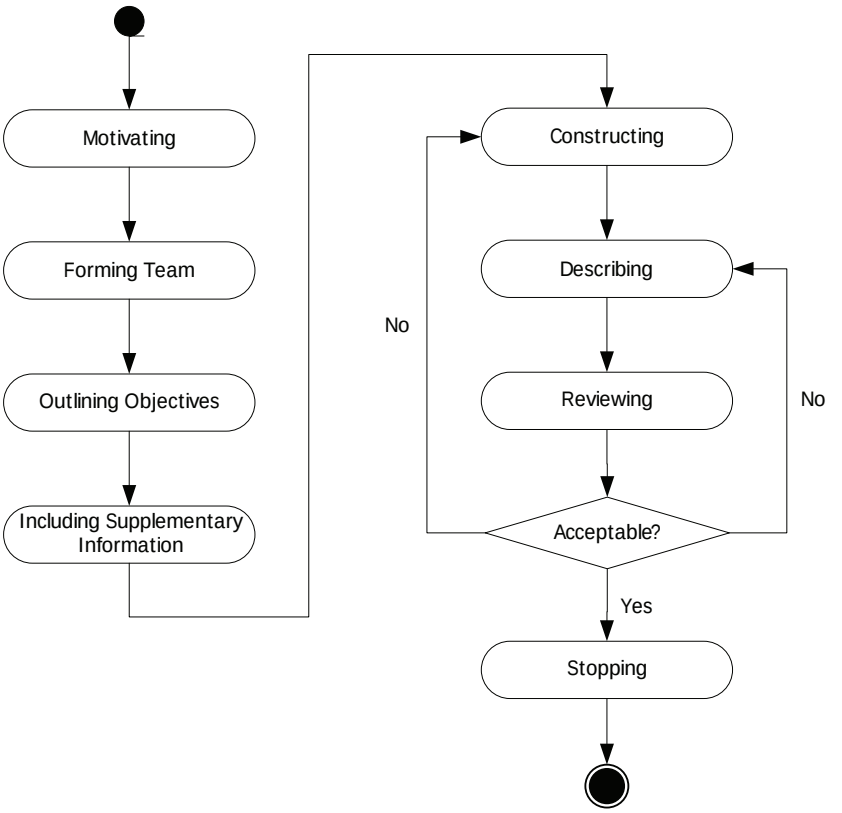
Use Case Modeling Process, Quality, and Patterns

The reliance on past experience and expertise is critical to any development. A pattern is a proven solution to a recurring problem in a given context (Appleton, 1997). A unique aspect of a pattern is that it not just describes how but *why* a certain solution works, the scope within which it works,

Table 1. A framework for addressing the semiotic quality of use case models using patterns

Product	Semiotic Level	Means for Quality Assurance	Decision Support
Use Case Model	• **Pragmatic:** Maintainability (Modifiability, Portability, Reusability), Usability (Comprehensibility, Readability) • **Semantic:** Completeness, Validity • **Syntactic:** Correctness	Patterns	Feasibility

Figure 1. The steps of a pattern-oriented use case modeling process



and it is preventative rather than curative (Dromey, 2003) in its approach towards quality improvement.

A general framework for the semiotic quality of use case models (FSQUCM) was presented by Kamthan (2008). As shown in Table 1, FSQUCM suggests the use of patterns as one means for improving the semiotic quality of use case models.

In the rest of the section, a pattern-oriented use case modeling process (POUCMP) that complies with UCMP characteristics 1-5 is proposed. Indeed, POUCMP is carried out with FSQUCM in consideration.

Steps of POUCMP

As illustrated in Figure 1, POUCMP consists of a nonlinear sequence of steps. At each step, POUCMP utilizes (process and product) patterns available from different collections (Adolph, Bramble, Cockburn, & Pols, 2003; Björnvig, 2003; Övergaard & Palmkvist, 2005).

The following assumes that the prerequisites to POUCMP have been satisfied: the team responsible for use case analysis has carried out feasibility study including domain understanding, and resource allocation (selection of a modeling language, selection of a modeling tool, and so on) has taken place. The names of patterns are expressed in *italics* to distinguish them from the surrounding text.

Step 1. Motivating: The prospective team may need motivation to get started. The *Know-HowKickoff* pattern suggests that identifying the market and making a business case to the team may help.

Step 2. Forming Team: The modeling starts with a *SmallWritingTeam* for small projects or a *BalancedTeam* for large projects. This pattern could be realized in practice using Pair Modeling (Kamthan, 2005), a practice that involves two people such that one person works on the model, while the other provides input and critical feedback on all aspects of the model as it evolves. Using the *ParticipatingAudience* pattern, one can involve the stakeholders and solicit their feedback. A systematic approach for identifying and classifying stakeholders is available (Sharp, Galal, & Finkelstein, 1999).

Step 3. Outlining Objectives: It has long been recognized that requirements elicitation is a social process (Macaulay, 1993). Thus, the team needs to have a *SharedClearVision* with respect to objectives and scope of the system.

Step 4. Including Supplementary Information: The *Adornments* pattern allows the association of information that is not central to the definition of the use case model but important nevertheless. This supplementary information, for example, could include details of non-functional requirements. It could also include metadata information such as project title, author name (using the *WritersLicense* pattern), date/time, version, copyright (Perry & Kaminski, 2005), and so on.

The process of use case modeling can lead to contentious issues (for example, due to the involvement of multiple people or otherwise) that may not be resolved instantly. These issues could also be documented separately (to be visited later in step 5) using the *ReadinessReflectionsList* pattern.

Step 5. Constructing: The actual contents of a use case model are derived as follows:

Step 5.1: The system boundary is set as a *VisibleBoundary* to have a clear separation between what is and what is not part of the system.

Step 5.2. The actors are identified using the *ClearCastOfCharacters* pattern. In the first iteration of the use case model, the primary actors can be elicited. The *MultipleActors:DistinctRoles* pattern can be used if two or more actors play different roles toward a single use case. If two or more actors play the same role toward a use case, then this role is represented by a single actor inherited by the actors sharing the role using the *MultipleActors:CommonRole* pattern.

Step 5.3: The team considers the *BreadthBeforeDepth* pattern during development to get an overview of the possible use cases before delving into details.

Step 5.4: Each use case models a complete usage of the system and corresponds to an atomic goal using the *CompleteSingleGoal* pattern. The *GoalsDefineNumber* pattern can be used to manage the number of goals and therefore the number of use cases.

Step 5.5. The pre-conditions (including triggers) of a use case are determined by *DetectableConditions.*

Step 5.6. Each use case is defined using the *UserValuedTransactions* and labeled using the *VerbPhraseName.*

Step 5.7. The (normal, alternate, or exceptional) flows are determined by the following steps.

Step 5.7.1. According to the *ScenarioPlusFragments* pattern, each flow is given the following structure: the normal behavior is described first, followed by the description of the possible alternates and exceptions (including failures).

Step 5.7.2. Using the *ExhaustiveAlternatives* pattern, it is made sure that alternates take into account all possibilities and therefore are indeed exhaustive.

Step 5.7.3. It is made sure that each (normal, alternate, or exceptional) flow ranges from 3-9 steps and all the steps in a single flow are roughly at the same level of abstraction using the *LeveledSteps* pattern, and that each step shows clearly which actor is performing the action and what the actor gets accomplished using the *ActorIntentAccomplished* pattern.

Step 5.8. Any relationships across use cases are captured using *CommonSubBehavior* (for the "include" relationship), *InterruptsAsExtensions* (for the "extend" relationship), and *CapturedAbstraction* (for the "generalization" relationship) patterns.

Step 6. Describing: The team adopts one of the many *MultipleForms* to describe the use case model, using text or using UML. This description takes the format of an *EverUnfoldingStory* so that details are revealed on a need-to-know basis. It is assured during the documentation that each use case in the use case model is *PreciseAndReadable* and *TechnologyNeutral.*

Step 7. Reviewing: The team performs a *TwoTierReview* of the use case model and revisits the previous steps 5 and/or 6 as necessary. The reason for revisiting a use case model is evaluation and the reason for subsequent refinement is the discovery of model "smells" or an unacceptable degree of one or more semiotic quality attributes. This is reminiscent of the use of patterns as "targets" for refactoring.

For example, during a review one could focus on reducing the details of each step of a flow to a minimum so as not to hinder the progress of an actor interacting with the system using the *ForwardProgress* pattern, restructuring (rather large use cases are decomposed into smaller use cases via the *RedistributeTheWealth* pattern and very small use cases may need to be merged into another use case using the *MergeDroplets* pattern), focus on the removal of redundant use cases as described by the *CleanHouse* pattern, and so on.

Step 8. Stopping: Any refinement of the use case model can take place via the *SpiralDevelopment* pattern until the stopping criterion such as that set by the *QuittingTime* pattern has been reached. Indeed, the *QuittingTime* pattern assists in making POUCMP feasible.

Note that not all steps of POUCMP are mandatory. For example, step 1 could be skipped if deemed unnecessary. Furthermore, not all steps will require the same time for completion; it is likely that steps 5-7 are the most time consuming.

Use of Anti-Patterns in POUCMP

An anti-pattern is a frequently faced "negative" solution to a recurring problem (Appleton, 1997). Indeed, if a pattern reflects a "best practice," then an anti-pattern reflects a "lesson learned." There are some anti-patterns available for use cases (Övergaard & Palmkvist, 2005; El-Attar & Miller, 2006). An anti-pattern will not explicitly improve

any of the quality attributes of a use case model; instead avoiding the anti-pattern will simply allow some quality attribute not to get worse.

For example, the anti-pattern of having *a single use case that does everything for a software system* is an impediment to comprehensibility. To mitigate this, one can for example use the *LargeUseCase:MultiplePaths* pattern (Övergaard & Palmkvist, 2005), where each of the longer flows can be modeled as a separate use case.

Scope and Limitations of POUCMP

There are inevitable constraints associated with respect to allocation of resources (i.e., time, effort, budget, or personnel) in any initiative towards quality improvement, and the same applies to use case models. In this section, the scope and certain limitations of POUCMP are highlighted.

Steps 4 and 6 of POUCMP are oriented towards textual use case models, and a graphical counterpart requires some modifications. If step 7 of POUCMP is carried out rigorously, then it is prone to the limitations inherent to inspections (Wiegers, 2002). The description of POUCMP can evolve and become more granular with the introduction of patterns from other collections. The resources pertaining to any software project are limited: there is no *a priori* guarantee that an organization may be able to allocate resources (such as the time or budget for training personnel) to deploy patterns as means for improvement of the quality of use case models. Furthermore, for a given problem there simply may not be any suitable pattern available. In general, the level of organizational process maturity (Paulk, Weber, Curtis, & Chrissis, 1995) may inhibit the extent (if at all) of an adoption of patterns.

FUTURE TRENDS

The work presented in this article can be extended in a few different directions, which is briefly discussed next.

First, POUCMP could benefit from empirical validation in both academic and industrial contexts, in particular alignment with requirements engineering processes. Second, it appears that for certain aspects of a use case process (such as conducting interviews with the client or suggesting what is to be done if the use case modeling team is not working optimally) or of a use case model (such as post-conditions or for a pre-requisite/co-requisite to a use case model such as a domain model), there are currently no corresponding patterns available. Therefore, these aspects have not been addressed in POUCMP and constitute a direction for future research.

CONCLUSION

If there is any constant in the evolution of today's information-driven software systems, it is the movement towards interaction. The conceptual models of these services, namely the use case models, must strive for high quality to be amenable to their stakeholders throughout the software development process.

A pattern-oriented approach encapsulates both the artistic (Lieberman, 2007) and the scientific aspects of conceptual modeling. A systematic approach towards modeling such as POUCMP that incorporates past expertise and experience in the form of patterns and anti-patterns can, when deployed appropriately, help construct high-quality use case models.

In conclusion, use case models are becoming first-class members of organizations and software process environments that embrace them. An investment in a quality-centric approach to use case modeling can benefit all stakeholders and in the long term can outweigh the costs.

KEY TERMS

Pattern: A proven solution to a recurring problem in a given context.

Refactoring: A structural transformation that provides a systematic way of eradicating the undesirable(s) from an artifact while preserving its behavioral semantics.

Semiotics: The field of study of signs and the communicative properties of their representations.

Software Engineering: A discipline that advocates a systematic approach of developing high-quality software on a large scale while taking into account the factors of sustainability and longevity, as well as organizational constraints of time and resources.

Use Case Model: A behavioral model that captures typical interactions between actors and the software system under development.

Use Case Model Quality: The totality of characteristics of a use case model that bear on its ability to satisfy stated and implied needs.

Use Case Modeling Process: A set of activities and practices that are used to develop and maintain a use case model.

INTRODUCTION

In the mid 1960's, the architect Christopher Alexander (1964) came up with the idea of Patterns, as "a solution to a problem within a defined context" and developed this concept. He explains, in a very original way, his ideas of urban planning and building architecture, using patterns to explain the "what", "when", and "how" of a design.

Alexander invented a Pattern Language that is the fundamental to good building and city designs, and describes it in a collection of repetitive schemas called *patterns*.

In Computer Science, software is susceptible to conceptual patterns. Consequently, Ward Cunningham and Kent Beck, used Alexander's idea to develop a programming pattern language composed of five patterns as an initiation guide for Smalltalk programming. This work was presented at the Object-Oriented Programming, Systems, Languages & Applications Conference (OOPSLA) in 1987.

In the early 1990's, Erich Gamma and Richard Helm did a joint research that resulted in the first specific design patterns catalog. They identified four patterns: Composite, Decider, Observer, and Constrainer patterns.

According to many authors, OOPSLA '91 highlighted the evolutionary process of design patterns. The synergy between Erich Gamma, Richard Helm, Rala Johnson, and John Vlissides (better known as the "Gang of Four" or GoF) and other reputable researchers (Ward Cunningham, Kant Beck or Doug Lea) definitively launched the study of and research into Object Oriented Design Patterns.

At the same time, James Coplien, another software engineer, was compiling and shaping a programming patterns catalogue in C++, which was a significant advance in the implementation phase in software development. Coplien's catalog was published in 1991 under the title "Advanced C++ Programming Styles and Idioms".

Between 1991 and 1994 the concept of pattern design was discussed at international congresses and conferences. All of these encounters culminated in OOPSLA '94. The GoF took advantage of this event to present their compilation (Gamma, Helm, Johnson & Vlissides, 1995). This publication, considered at that time as the best book on Object Orientation, compiled a 23-pattern catalog, founding the basis of patterns design.

The number of pattern-related works, studies and publications in general, but especially in design, has exponentially grown since. However, the different research groups being born must be cataloged into three fundamental paradigms:

- Theoretical approximations to the software pattern design concept and pattern languages. Coplien's work (Coplien, 1996; 2004; Coplien & Douglas, 1995) stands out in this field.
- Analysis and compilation of software applications design patterns. Rising's efforts (Rising, 1998; 2000) and Buschmman (Buschmann, Meunier, Rohnert, Sommerlad & Stal, 1996; Buschmann, Rohnert, Stal & Schmidt, 2000) are included in this classification.
- The study of special purpose patterns, like antipatterns (Brown, 1998).

As has been explained, the pattern concept has clear origins, and an important value as a reuse tool. The main

problem is that the word pattern has been used almost for everything, thus losing its original meaning. The goal of this work is to go back to the definition of patterns and present how software engineering is working with this concept.

The remainder of this chapter is structured as follows. Section two provides both, formal and informal definitions of pattern as well as the formats used to describe them. Section three presents a classification of existing patterns in the field of software engineering. In section four, the authors describe their conclusions and present the future trends in section five. A selection of key terms is defined at the end of the chapter.

BACKGROUND

Pattern Definition

The knowledge and use of pattern improves communication between the designer and the developer. According to Erich Gamma et al. (1995):

"Designers know that you do not have to solve each problem starting from scratch….you must reuse solutions which previously worked. When you find a good solution, you must use it continuously. This experience makes you an expert."

Although software engineers knew about design patterns, it was a tremendous boost for them when design patterns were systematized and categorized by four engineers Erich Gamma, Richard Helm, Ralph Johnson, and John Vlissides, known as the Gang of Tour (GoF):

They schematized 23 software design patterns through templates and used the Unified Modeling Language (UML) to describe them. They also provided examples of implementation written in Smalltalk and in C++. These patterns were later written in oriented-object language such as Java (Cooper, 1998).

FORMAL DEFINITION OF SOFTWARE PATTERNS

In this section, the most significant definitions of the software pattern have been gathered.

The first ever definition, is the one proposed by Alexander:

"A recurring solution to a common problem in a given context and system of forces" (Alexander, 1979).

Less literary but more concrete is the one proposed by Riehle and Zullighoven (1996):

"A pattern is the abstraction from a concrete form which keeps recurring in specific non-arbitrary contexts."

Nevertheless, the most precise one many authors followed is that of Gabriel (1998):

"Each pattern is a three-part rule, which expresses a relation between a certain context, a certain system of forces which occurs repeatedly in that context, and a certain software configuration which allows these forces to resolve themselves."

Gabriel defined concepts that make up the terminology of software patterns:

- Forces System: a set of objects and restrictions that have to be satisfied by the application, such as portability, flexibility, reuse, and so forth.
- Software Configuration: a set of design rules to be applied to solve the problem forces.

James Coplien (1996) enumerated the requirements that a "good" pattern has to carry out:

- Solve a problem: the patterns capture solutions, not principles or strategy.
- Provide tested solutions: the patterns show neither theories nor speculations. Simple solutions are not provided.
- Describe a relation: the patterns describe systems, structures and mechanism. They do not provide a simple module.
- Have a human component: the best patterns have to be useful.

PATTERN DESCRIPTION

Patterns must be described formally so that their content is available to all. A pattern format is a template with sections, a formal structure that eases learning, comparison among other patterns and their use. There are different formats for describing patterns such as: the Alexander, GoF and canonical formats.

The Alexander Format

Alexander explained his patterns, in a narrative style, in terms of problem to be solved, described the context in which the pattern is applied and the proposed solution. So, each Alexander's pattern is described according to the following elements:

- Name
- Problem
- Context
- Forces
- Solution

Table 1. GoF format

Field	Description
Pattern name and classification	The pattern's name conveys the essence of the pattern succinctly. The proposal and field is defined.
Intent	A short statement that answers the following questions: What does this pattern do? What is its rationale or intent? What particular issue or problem does it address?
Also Known As	Other well-known names for the pattern, if any.
Motivation	A scenario that illustrates the problem.
Applicability	Situations where the pattern can be used.
Structure	A graphical representation of the structure of classes and objects in the patterns.
Participants	The classes and/or objects participating in the pattern and their responsibilities.
Collaborations	How the participants collaborate to carry out their responsibilities.
Consequences	How does the pattern support its objectives? What are the trade-offs and results of using the pattern? What aspect of system structure does it let you vary independently?
Implementation	Techniques or tricks that you must considerer in the implementation.
Sample Code	Code that illustrates the implementation of pattern.
Known Uses	Examples of pattern in real systems.
Related Patterns	The relationships between this pattern and others and the differences among them.

The GoF Format

The Gang of Four described the patterns catalogued in their work (Gamma et al., 1995) as shown in Table 1.

The Canonical Format

The canonical format, also known as the POSA format, was proposed by Buschmann et al. (1996). Basically, it takes into account the Alexander format but is more detailed. This format is described in Table 2.

PATTERNS IN THE FIELD OF SOFTWARE ENGINEERING

In this section, we describe a classification of existing patterns in the field of software engineering.

PATTERNS CLASSIFICATION

As the Pattern concept is used in different disciplines, there are many kinds. This work has gathered the main patterns in the field of software engineering. Seven kinds of patterns with different domain applications in this area have been identified:

- Implementation patterns

1. Reference architectural patterns
2. Architectural patterns
3. Analysis patterns
4. Design patterns

- Process and improvement patterns

1. Process patterns
2. Software process improvement patterns

Table 2. Canonical format

Section	Description
Name	A meaningful and memorable way to refer to the pattern.
Problem	A description of the problem indicating the intent in applying the pattern, the intended goals and objectives.
Context	The preconditions under which the pattern is applicable.
Forces	A description of the relevant forces and constraints and how they interact/ conflict with each other and with the intended goals and objectives.
Solution	A description, using text and/or graphics of how to achieve the intended goals and objectives.
Examples	One or more sample applications of the pattern.
Resulting Context	The postconditions after pattern application..
Rationale	An explanation / justification of the pattern as a whole, or of individual components within it, indicating how the pattern actually works.
Related Patterns	The relationships between this pattern and others
Known uses	Known applications of the pattern within existing systems.

- Configuration management patterns

1. Software configuration management patterns

Implementation Patterns

Reference Architectural Patterns

These patterns correspond to the most abstract level in the category of patterns. A reference architecture is an architecture created for a specific domain.

In software terms, it can be said that these patterns affect the subsystems architecture. There is no single classification of these patterns, but a list of the most important ones follows:

- Two tier
- Multitier
- Workflow
- Forms oriented
- Hypertext oriented
- Video/imaging/multimedia
- Data warehouse
- Real time systems
- Process control systems
- Thin client

These kinds of patterns are widespread and widely used because systems architectures are identified and described in depth. However, the main inconvenience with using these patterns is the nonexistence of tools to allow the integration among subsystems.

Architectural Patterns

An Architectural Pattern expresses a fundamental structural organization or schema for software systems. It provides a set of predefined subsystems, specifies their responsibilities, and includes rules and guidelines for organizing the relationships among them (Buschmann et al., 1996).

The technical literature in this field is complicated because of the fact that many people in the software area use the term “architecture” to refer to software, and many patterns described as “architecture patterns” are high-level software design patterns.

Although the interest in architectural patterns is recent, it has been increasing in this field—extending the principles and concepts of design patterns to the architecture domain. There are two main approaches to architectural patterns proposed by Buschmann et al. (1996) and Shaw and Garlan (1996). Both describe more or less the same patterns with slight differences. According to Buschmann et al. (1996), an architectural pattern defines the following elements:

- A vocabulary of components and connectors.
- A topology that describes the way components and connectors must be combined.
- A set of requirements and constraints on components and connectors combinations.
- Semantic models that allow the specification of the global system behavior starting with the behavior of the components.

The main feature of architectural patterns is that it allows the systems designs, focusing on system features such as performance, reliability and efficiency.

Examples of Architectural patterns are Model View Controller (MVC), Presentation Abstraction Control (PAC).

These patterns are properly described and documented based on software engineering design techniques of separation. The main deficiencies of these patterns are the natural language used to define them and the absence of tools that support their implementation.

Analysis Patterns

Analysis patterns (Fowler, 1997) represent business structures that embody a similar internal structure. These patterns are linked to interfaces or data, but not to implementation. This is one the most important differences with other kinds of patterns.

There are many classifications of analysis patterns, but the most relevant ones are described by Fowler (1997).

Fowler does not use a formal format to represent the analysis pattern. However, in 2001, Geyer-Schulz and Hahslerwe defined a template for this pattern:

- Pattern Name (Gamma et al., 1995; Buschmann et al., 1996)
- Intent (Gamma et al., 1995)
- Motivation (Gamma et al., 1995)
- Forces and Context (Alexander, 1979)
- Solution (Buschmann et al., 1996)
- Consequences (Gamma et al., 1995; Buschmann et al., 1996)
- Design (Geyer-Schulz & Hahslerwe, 2001) How can the analysis pattern be realized by design patterns? Sample design suggestions.
- Known Uses (Gamma et al., 1995;Buschmann et al., 1996)

Kodaganallur and Shim (2006) developed a taxonomy of analysis patterns used for specifying system requirements.

Table 3. Analysis patterns classification

Group	Description	Pattern
Accountability	When a person or organization is responsible to another	Party Organization hierarchies Hierarchic accountability Operating scopes
Observations and Measurements	Record information about measurements	Quantity Conversion ratio Measurement Observation
Referring to Objects	Identify objects and schemes	Name Identification scheme Object equivalence
Inventory and Accounting	Basis for financial accounting, inventory or resource management	Account Transactions Summary account Posting rules
Trading	Buying and selling of goods	Contract Portfolio Quote

They explained the key characteristics, which are patterns used in the analysis phase, and whose main purpose is to help specify the requirements and relate the objects and concepts in the real world.

Design Patterns

Design patterns systematically define and explain a general design for a recurrent design problem in an object-oriented system. These patterns describe the problem, the solution, the instant the solution must be applied and the consequences. Solution is an ordered set of objects and classes to solve the problem in a context (Gamma et al., 1995). The patterns also provide tips and examples of implementation, although they are independent of the programming language.

Gamma et al. (1995) defined 23 software design patterns, independent of language and platform. They used examples which were written in Smalltalk and C++. Some years later, these 23 patterns were written in Java (Cooper, 1998). These patterns focused on common problems in object-oriented development. Currently, these design patterns are widely used and are classified by their functionality in:

- Creational patterns: to deal with the creation of object instants or classes.
- Structural patterns: to define the design of objects to develop specific tasks.
- Behavioral patterns: to define how a set of objects interact among themselves to develop specific tasks.

UML is used to express the pattern description, and in some object-oriented languages another element of design patterns is “application examples”.

The main advantages of design patterns are:

- High-quality design results: due to the experience acquired.
- Improvement of communication within the development life cycle: providing names of design structures which establish a common vocabulary to reduce the complexity.
- Design information is captured and preserved: design decisions are faster and documentation is improved.
- Restructuring is made easier: design is more flexible.
- Design patterns are related among themselves so they can be used as parts of a structure, as for example, the patterns defined in J2EE (Alur, Crupi & Malks, 2003). Assembling design patterns allow you to define the framework of an application.

On the other hand, design patterns have some negative aspects. Some of them are:

- To name everything pattern: this eliminates the capability of abstraction and reuse of pattern. The correct pattern must be chosen through the rules of selection to avoid this (to specify benefits, to demonstrate extend applicability, to check if there are two real examples or more, etc.).
- To apply the patterns blindly: sometimes the design patterns are applied without the right criteria, increasing the cost and complexity. In this way, the design of patterns is more expensive and difficult than the development of an object- oriented system without patterns.

Process and Improvement Patterns

Process Patterns

A process pattern provides a guide to show how carry to out specific tasks in the development of a process. A process pattern (Garson, 2006) is an approach to a specific task that has been tried with positive results. The experiences of other people who have performed a specific task in several ways are stored in a process pattern so that users of process patterns will benefit from these experiences.

According to Ambler (1998) a process pattern describes a proven successful approach in a set of actions in software development. The focus here is on process pattern for object-oriented and three levels or types of patterns have been provided: task, stage, and phase process patterns. The aim of these patterns is to guide the developer in developing object-oriented software at different levels.

The formal documentation of a process pattern includes the following elements:

- Name.
- Intent.
- Type.
- Initial Context.
- Solution.
- Resulting Context.
- Related Patterns.
- Known Uses/Examples.

Process patterns researchers disagree on how to document the process patterns elements, but all the patterns involve variations of the previously defined elements

Process patterns are organized in taxonomies that allow the user to find alternative patterns which are more appropriate for a specific project or phase. There are several approaches to formalize process patterns: Hagen and Gruhn (2004) defined a language, called PROPEL, based on Unified Modeling Language (UML) to describe Process Patterns; a metamodel was defined to represent process model and

process patterns in different levels of abstraction (Tran, Coulette & Dong, 2006)

The authors of this contribution think that Ambler's patterns are not intuitive so, the efficiency of use is low, and they do not allow the user to work fast, easily and dynamically.

Software Process Improvement Patterns

Software process improvement is a mechanism for continuous, improvement of quality applying the good practices and eliminating problematic ones. The good practices are those which produce people good results when applied (Appleton, 1997).

The elements to define software process improvement patterns are:

- Name
- Context
- Problem
- Forces
- Solution
- Resulting Context
- Rationale
- Related Patterns
- Known Uses

Appleton classified the software process improvement patterns into organizational structure, and process and communication patterns (Table 4):

These patterns are appropriate for an organization or department in which management has already made a genuine commitment to sponsor and support process improvement efforts. The main deficiencies of these patterns are the absence of tools to support their implementation.

CONFIGURATION MANAGEMENT PATTERNS

Software Configuration Management Patterns

Software configuration management (SCM) must be developed during the whole lifecycle and must be integrated with the rest of the development processes. Berczuk (2003) described a pattern language that allows the implementation of software configuration management practices through the use of a set of heuristics. These patterns are not described formally so they can be used as the basis for the understanding of the SCM process and as an inspiration to apply this process.

FUTURE TRENDS

The conclusions extracted from the existing software patterns demonstrate their low efficiency. It is true that patterns are more interesting for beginners than for experts but the authors believe that they should not be written to teach beginners only. Patterns are intended to empower the reuse of knowledge in order to help software engineering be more an "engineer" than an "artisan". The main cue for the success of patterns is that they should be accessible and operative. This means:

- They must follow a formal description in order to have a repository of them and, thus, can be shared with the rest of the interested community if needed. Knowledge management mechanisms should be applied in order to retrieve or upload them.

Table 4. Process improvement patterns classification

Organization Patterns	Process and Communication Patterns
Local Heroes Center PEG PIT also Practices Dedicated Improvement Processors Improvement Action Teams	Process is Product (process) Virtual Forum (communication) Process follows Practice (process) Improvement follows Process (process) Improvement follows Spiral (process)

- They must also provide, on the spot, all they information necessary for their execution. This means that even when a formal representation is being used, the descriptive information in natural language must be provided.
- Their execution must be software supported
- The patterns execution must provide feedback in order to:
  - Provide measurements of the pattern execution
  - Provide new knowledge after its execution, or even new patterns.

The low success of the patterns described in this work is based on the fact that it was forgotten that patterns should be used by humans while developing projects. The human factor is a very important element for the success of a software project.

Our vision of software patterns, oriented to attaining the above-mentioned features, is focused on patterns to help people in projects development. In this sense the authors believe in product patterns as a tool to help in the development of any software product throughout the software development lifecycle, independently of the nature of the product. Product patterns are designed to gather the know-how of the enterprise, that is, where they are going to be deployed so that everybody in the organization is involved on their use (Amescua, Garcia, Segura-Sanchez & Medina-Dominguez, 2006; Medina-Dominguez, Sanchez-Segura, Amescua & Garcia, 2007). These patterns are designed and implemented to be useful for all.

Product patterns could cohabit with existing software engineering patterns because:

- Architectural patterns provide the knowledge to define system features.
- Process patterns provide the methodology, phases and tasks framework to execute a project.
- Design patterns are the most mature ones and provide the knowledge to reuse solutions at a low level design

The rest of the existing patterns could be embedded in the term product pattern in order to be used. Otherwise, existing patterns is knowledge that, although available in electronic format, does not reach the people involved in the development of a project when needed. As a result, they are hardly ever going to be used.

CONCLUSION

In this work the authors summarized the origin of patterns, their definitions and descriptions in software engineering and present a classification of software engineering patterns, including a description of each.

It is clear that the origin of software engineering patterns and the concept have been widely used. However, the formalization of patterns is very poor and, without formalization, there is no systematization, which is one of the bases of software engineering.

KEY TERMS

Analysis Pattern: Is an idea that has been useful in one practical context and will probably be useful in others (Fowler, 1997).

Design Pattern: Defines and explains systematically a general design to a recurrent problem of design in object oriented system.

Pattern: Is a recurring solution to a common problem in a given context and system of forces (Alexander, 1979).

Process: Is a set of sequential practices that are functionally coherent and reusable for software engineering organization, implementation, and management. It is usually referred to as the software process, or simply the process.

Process Improvement: Is an activity that seeks to identify and rectify "common causes" of poor quality in software systems by making basic changes in the underlying software management process (available at: http://www.sei.cmu.edu/opensystems/glossary.html).

Process Pattern: Provides a guide to show how carry out specifics tasks in the development of a process. A process pattern (Garson, 2006) is an approach to a specific task that has been tried with good results.

Product: Is any thing to be produced during the whole software development process.

Product Pattern: Is an artefact that encapsulates the knowledge of software engineering experts to obtain a specific software product.

Software Engineering: Is the application of a systematic, disciplined, quantifiable approach to the development, operation, and maintenance of software.

Pedagogical Perspectives on M-Learning

Geraldine Torrisi-Steel
Griffith University, Australia

INTRODUCTION

The advent of multimedia on desktop computers in the late 1980s and early 1990s heralded an era of educational technology that held the promise of revolutionising the business of teaching and learning by facilitating a shift from traditional teacher-centred methods to more effective student-centred approaches. During the mid-late 1990s the popularisation of the Internet, added to educational technology a new dimension of "connectedness" between people and between people and information resources. Online learning and e-learning became icons of the era**.** In late 1990s and early 2000s major players in the mobile phone industry worked on developing a wireless infrastructure to allow for wireless communication between devices, WAP (wireless application protocol) being one of the principle outcomes. This set the stage for the wireless Internet and for another new dimension to educational technology, mobility**.** Thus, the maturation of multimedia, the Internet and communication technologies together with development and availability of ubiquitous computing devices and wireless networking birthed the notion of mobile learning (m-learning) or "learning on the move."

Like many other media technologies before, **m-learning** is considered to have the potential to reshape teaching and learning, in this instance, holding promise of unprecedented connectivity and learning interactions between learners, learners and educators, information and computing resources, anywhere, anytime. This article seeks to facilitate the realisation of the pedagogical potential of m-learning by proposing a model for the construction of m-learning spaces**.** The proposed model is founded upon a **pedagogical framework** directing attention to guiding philosophies, technology integration, and the capabilities of mobile devices.

BACKGROUND

The belief underlying the following discussion is that although technology use in educational contexts is not a requisite for positive change in teaching and learning practice, some degree of change in teaching practice is a requisite for effective technology use in educational contexts**.** The effective use of technology in educational contexts should precipitate significant and positive changes in teaching practice (Tearle, Dillon & Davis, 1999). History has shown that, the adoption of new technologies frequently occurs at a superficial level consequently failing to make significant impact on teaching and learning environments (Cuban, 1986; Hammond, 1994; Nichol & Watson, 2003; Conlon & Simpson, 2003). New technologies used inappropriately or in ways replicating traditional teacher centred approaches contribute little to improving the quality of the learning environment. From this perspective, effective integration of technology in the curriculum results from teaching practice informed by an awareness of available technologies within the context of pedagogical frameworks**.**

The manner in which m-learning is defined fosters certain perceptions and beliefs about its implementation (Laouris & Eteokleous, 2005). Of fundamental importance to pedagogical discussions surrounding m-learning is the provision of a teaching "centric" rather than "techno-centric" definition for m-learning (Laouris & Eteokleous, 2005). Techno-centric definitions of m-learning accentuate the technology as the focus rather than teaching and learning**.** The motivation for implementation of mobile technologies should be not be driven by the technology but rather driven by two phases of activities: Firstly, reflection on current teaching practice and learning outcomes in order to identify deficiencies or new avenues for new effective strategies. Secondly, consider if and how any of the array of **mobile devices** can be exploited in order to achieve more effective strategies and more effective, meaningful learning outcomes (Torrisi-Steele, 2004).

Congruent with this approach, m-learning may be defined as:

the integrative use of mobile devices into the curriculum in order to facilitate active and meaningful learning through the creation of learning spaces extending outside the physical and temporal constraints of the traditional classroom. These learning spaces (m-learning spaces) are characteristically dynamic, collaborative and focused on individual learner needs in the current context. (adapted from Torrisi-Steele, 2006)

The term "mobile devices" refers to laptop computers, tablet PCs, PDAs, mobile phones, smart phones, MP3 players and any other small portable or handheld devices technically capable of connectivity (ideally wireless) to each other, other devices or Internet.

M-learning is considered here as an extension of e-learning (Brown, 2005). M-learning may include all the features of e-learning (multimedia, information access, Internet

capability, collaboration) but with the distinguishing feature of being ubiquitous and mobile.

PEDAGOGICAL FRAMEWORK

In alignment with the definition of m-learning proposed above, the pedagogical framework for the design of effective m-learning spaces incorporates three key aspects for discussion: guiding philosophies, technology integration, and capabilities of mobile devices**.** Following a discussion of each of these aspects, a model for the implementation of m-learning spaces is provided.

Guiding Philosophies

It is well established in literature that constructivist approaches that actively engage learners by presenting them with authentic learning activities, lead to more meaningful learning outcomes and are congruent with lifelong learning goals (Strommen, 1999, p. 2). Emerging from the work of theorists including Piaget (1952), Bruner (1985), and Vygotsky (1978), the constructivist perspective describes a "theory of development whereby learners build their own knowledge by constructing mental models, or schemas, based on their own experiences" (Tse-Kian, 2003, p.295). **Constructivist learning** supports a learner centred philosophy. Learner centred philosophy promotes and allows for a high degree of learner control and the individual construction of learning pathways.

Meaningful learning is being used to refer to learning resulting in a deep understanding of complex ideas, and it is relevant to learners. Jonassen, Peck, and Wilson (1999) define meaningful learning to have the following characteristics:

- **Active:** Created by interactions and manipulations with the environment
- **Constructive:** Knowledge created by reflection and interpretation
- **Intentional:** Activity directed toward trying to achieve a goal encourages thinking and learning
- **Authentic:** Contextual clues found in "real situations" assist understanding and learning
- **Cooperative:** Conversation and interaction with others promotes understanding and exposure to ideas of others; negotiation of knowledge.

M-learning spaces are well suited to supporting principles meaningful learning and constructivist philosophies (Table 1). Mobile devices support a variety of personalised experiences. The mobility attribute enables learners to explore knowledge and situations in their own way, in a variety of places and often outside the time constraints of traditional classroom-based teaching. Mobile devices also increase motivation, provide for interactive leaning and facilitate control of the learning process and emphasise its relationship with the real world (Zurita & Nussbaum, 2004).

The ability of mobile devices to support ubiquitous communication brings the social aspects of learning into focus. M-learning is thus proving to be the catalyst for growing emphasis on **social constructivism**, and learning communities (Evans, 2005). M-learning allows for greater exploitation of collaboration and conversation as powerful learning strategies (Brown, 2005). Learning participants are able to communicate outside the bounds of physical locations and often from diverse learning contexts. Brown (2005) maintains that m-learning optimises the opportunities for interaction among learners, among educators, and among educators and learners. Consequently, communication and interaction should be exploited as critical factors for success of m-learning.

From this perspective, a valuable addition to the pedagogical toolbox for construction of m-learning spaces is the **conversational** framework proposed by **Diana Laurillard** (1993). The framework places emphasis on the role and importance of interactions in learning**.** The basic premise is that learner is more effective when learners converse with

Table 1. Congruency between aspects of constructivist learning principles and attributes of mobile devices

Constructivist principles supporting meaningful learning	**Attributes of mobile devices**
Learner-centred	Personal
Active	Includes tools for data gathering while on location e.g. image recording, sound recording, databases, spreadsheets. Impact of manipulations on environment can be recorded immediately often in multimodal manner
Constructive	Access to information through wireless to other information or mobile web allows interpretation of results in light of additional information resources (includes materials and human resoures
Intentional	Ubiquitous, goal directed activity specific to the context.
Authentic	Ubiquitous, explore information in the real world, in real contexts. Contextual clues assist understanding. Support for real-world case based learning rather than pre-determined sequence.
Co-operative	Connectivity May support multimodal interaction with others e.g. voice, video, text, images. Data can be shared and discussed spontaneously by learning participants in different locations. Allows for negotiation of knowledge through collaborative activity.

a partner and iteratively refining understanding by sharing and questioning their understandings. The "partner" may be another student or a teacher**.** The conversational space in which interactions take place can be enhanced by the use of mobile devices**.** Mobile devices free participants from the restrictions of physical location. Furthermore, mobile devices may enrich the conversational environment by providing access to data gathering, data analysis, visualisation and information retrieval tools**.**

Technology Integration

As was alluded to earlier, in order for technology to go beyond the simple acquisition of information and facilitate meaningful learning, it must be integrated into the curriculum, not used merely at a superficial level (Tearle et al., 1999). Integration of mobile technology into the curriculum presupposes reflection on teaching practice. Reflection in turn, precipitates a degree of change/innovation in existing practice.

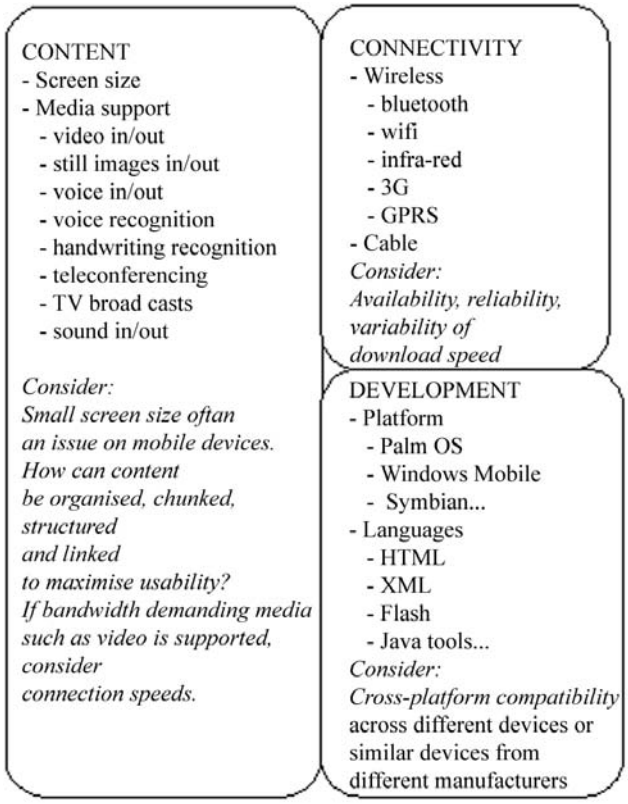
The process of reflection, change and curriculum integration is driven by the perceived need to improve the quality of teaching. The learning environment is constructed on the foundation of knowledge of the learning context (discipline requirements, learning outcomes and goals, learner needs) intertwined with knowledge of the attributes of available mobile devices. The design and development of m-learning spaces is driven by questions such as: What strategies have been used? Have they been effective in producing meaningful and desired learning outcomes? How can they be made more effective? What new strategies can be devised, given the new tools that will enrich the learning environment? How can these new strategies exploit the attributes of mobile devices in order to provide for engaging learning and more meaningful learning outcomes? (Torrisi-Steele, 2006). It is the educators' knowledge, assumptions and perceptions regarding the technology and its implementation in the specific learning context, rather than the technology itself, that will determine its implementation and hence its effectiveness (Jackson & Anagnotopoulou, 2000; Bennet, Priest, & Macpherson, 1999).

Capabilities of Mobile Devices

In order to assist the selection of mobile devices for enriching teaching and learning environments, it is useful to consider the capabilities of mobile devices in terms of three categories: content, connectivity and development (Figure 1).

In a discussion of mobile device selection it must be noted that while the capabilities of mobile devices may be desirable as driving the decision of selection, the principle driving force is often cost. The cost of devices and infrastructure costs are key challenges. Mobile devices are being identified as a means

Figure 1. Categorising the capabilities of mobile devices to assist in device selection and key relevant considerations



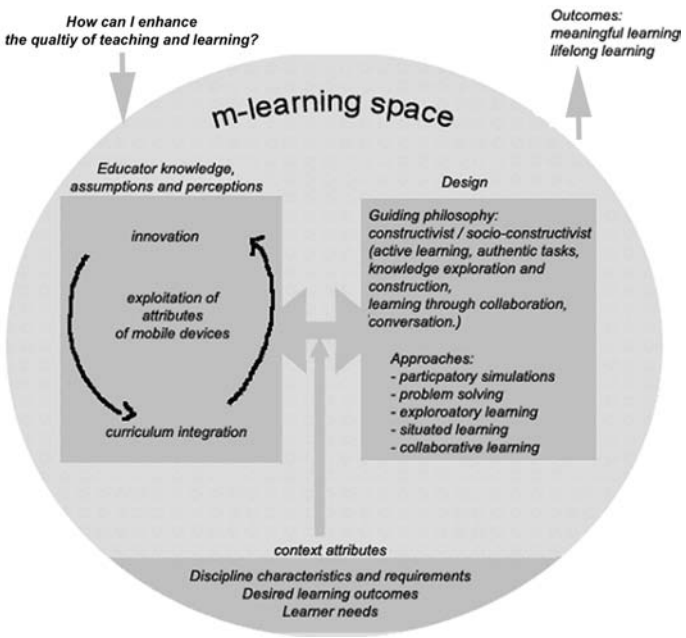
to narrow the "digital divide" given that PDAs and mobile phones are generally cheaper than computers**.** The United Nations at its World Summit on Information Society in 2005 recognised mobile devices as a way to disseminate learning among disadvantaged groups (Thomas, 2006a)**.** However, the cost and politics of establishing infrastructure to support wireless connectivity is still a significant consideration. How to design and implement a cost effective and secure system that is fast and reliable within a large service area remains a major area of consideration for educational institutions wishing to implement m-learning environments within their local area networks (Thomas, 2006b).

A Model for the Design of M-Learning Spaces

Against the background of the preceding discussion, the following model to guide the design of m-learning spaces precipitates.

The model proposed above, may be refined further by drawing attention to Parsons and Ryu's (2006) guide for pedagogical design requirements for mobile environments. The guide draws attention to ubiquity and personalisation as

Figure 2. A model for the design of m-learning spaces. The model emphasises: firstly, the process is driven by a motivation to improving effectiveness of learning environments rather than by the technology itself; secondly, the requirement for curriculum integration and innovation in practice; and thirdly, constructivist, particularly socioconstructivist philosophies to guide the design of the m-learning space (Torrisi-Steele, 2006).



key aspects of mobile environments and suggests m-learning environments should:

- Be sensitive to learner needs, learning styles, because m-learning tends to be targeted to individuals
- Be up to date in terms of content – the ubiquitousness of m-learning demands dynamic content
- Be highly interactive
- Enable mutual feedback with instructors in order to provide learner support and guidance
- Enable learners to explores knowledge
- Enable learners to collaborate with peers
- Enable learners to take a higher degree of control over their own learning
- Be goal directed and specific to the learning context at the time of use

FUTURE TRENDS

The vast majority of today's learners are digitally literate and increasingly community-orientated (Oblinger, 2004). "Connectedness" is becoming a strong theme in everyday life for these learners and will conceivably continue to do so. The inclusion of m-learning strategies in learning environments is as thus as much a response to learner expectations and the "way they do things" as it is to the search for more effective ways of conducting teaching and learning. Thus, the key concern for future discussion on m-learning is not focused on whether or not to use but rather on "how it can best be successfully used."

Two forces will shape the effectiveness of future of m-learning scenarios: technical and pedagogical. Technically, following on from current trends there is the expectation of increases in sophistication and capabilities. Context aware devices and options for synchronisation are two key areas of development. Existing networks for mobile phones are offered by a variety of service providers and support a variety of protocols. To some extent the future of m-learning lies in the ability of service providers to provide high quality, cheap, reliable and compatible networks.

From a pedagogical perspective, now more than ever, in such a varied and dynamic environment there is a need for ongoing reflection on teaching practice, focus on appropriate professional development and on fostering continuous aspirations for improving the quality of teaching and learning. Professional practice must place emphasis on teaching and learning rather than devices themselves. Knowledge of device capabilities is essential but useless if it is disconnected from the business of teaching and learning. Useful

future research will thus focus on gaining insight into the experience of learners using mobile devices, the evaluation of the effectiveness of m-learning devices in a variety of learning contexts and the documentation of cases illustrating how mobile devices have been successfully or unsuccessfully integrated into learning environments. The design and implementation of m-learning spaces must be inextricably linked with evaluation if they are to be successful (Kukulska-Hulme & Traxler, 2005).

CONCLUSION

The preceding discussion has sought to highlight some of the key pedagogical aspects of implementing m-learning. Three key themes related to pedagogy arose:

Firstly, m-learning must be considered from a learning-centric rather than technology-centric perspective. The motivation for using m-learning strategies stems from a desire to enrich the learning environment, and thus it should be integrated into meaningful learning activities rather than used superficially.

Secondly, the integration of mobile devices into learning contexts occurs as result of reflection on practice and careful consideration of discipline requirements, learner needs, context attributes along with knowledge of the capabilities of various mobile devices. Positive change in practice is seen as an unavoidable consequence of such reflection and consideration.

Thirdly, Social constructivism and conversation should form the guiding philosophy for shaping m-learning spaces. The defining characteristics of mobile devices are "connectedness" and "mobility." Social constructivist principles and conversational approaches to learning are heavily congruent with these characteristics. Furthermore, today's learners are immersed in "connectedness" and a sense of community is becoming embedded in their lives.

The notion of learning outside the constraints of the traditional classroom is not a novel approach, especially when one considers the degree of informal learning experienced outside the classroom. Learning in the field activities have been undertaken for a long time as part of many learning contexts. Mobile devices offer unprecedented access to information, communication, collaboration and manipulation of data, and thus have the capacity to enrich learning experiences outside the confines of physical and temporal parameters. The use of mobile devices in teaching and learning contexts is still in its infancy. Effective use of the technology will be driven by informed practice, attention to issues of content delivery, instructional design, as well as issues of network capabilities and infrastructure.

KEY TERMS

Constructivism: A philosophy for teaching and learning based on the notion of individuals generating their own understanding of the world in "their own way." Constructivist theories of learning espouse learner-centred approaches that actively engage the learner in order to facilitate meaningful learning**.** Key theorists include Piaget and Bruner.

Connectedness: The feeling of "being in touch." "It is an emotional experience invoked by, but independent of others' presence (Rettie, 2003). Feelings of connectedness can range from general awareness of the presence of others (e.g., being online) to stronger awareness of social presence (e.g., exchange of text messages).

Meaningful Learning: Achieving a deep understanding of complex ideas**.** Meaningful learning implies that knowledge can be manipulated and applied to a variety of situations and contexts.

Mobile Devices: Any small portable or handheld computing devices technically capable of connectivity (ideally wireless) to each other, other devices or Internet. Includes laptop computers, tablet PCs, PDAs, mobile phones, smart phones and MP3 players.

Mobile Learning (M-Learning): The integrative use of mobile devices into the curriculum in order to facilitate active and meaningful learning through the creation of learning spaces which extend outside the physical and temporal constraints of the traditional classroom.

M-Learning Space: The learning environment within which learning activities are enriched by the use of mobile devices. M-learning spaces are supportive of meaningful learning. M-learning spaces are characteristically dynamic, collaborative and focused on individual learner needs in the current context.

Socioconstructivism: Like constructivism active, learner-centred learning is emphasised**.** Interaction and communication are considered important for engaging in the active construction of knowledge through a process of negotiation**.** Collaborative learning is an important strategy within this view. Socioconstructivism is becoming an important guiding philosophy for the design of m-learning spaces.

Ubiquitous: Present and available anywhere, anytime**.** Used in computing to refer to access to computing technology away from the constraints of the desktop**.** M-learning is characterised by being ubiquitous.

Peer-to-Peer Computing

Manuela Pereira
University of Beira Interior, Portugal

INTRODUCTION

The term peer-to-peer (P2P) was originally used to refer to network protocols where all the nodes had the same role and there were no nodes with specific responsibilities to act as the administrators or supervisors of a network (Ye, Makedon, & Ford, 2004). However, with the evolution of Internet as the dominant architecture for applications, contents, and services, applications and services have gradually migrated from the client-server paradigm to the edge services paradigm and now to the P2P computing paradigm. Therefore, nowadays, the term P2P refers to a class of systems and applications that use distributed resources to perform some function in a decentralized manner, where every participating node can act as both a client and a server (Ye et al., 2004).

This article provides an overview of P2P computing, being focused on the types of multimedia distribution services and cooperation models in P2P systems. These models are classified regarding the functionality, the degree of decentralization, and the degree of structure of the information system.

BACKGROUND

The P2P Working Group (http://www.peer-to-peerwg.org), a consortium for the development of P2P technology, defines P2P as the sharing of computer resources by direct exchange.

P2P systems have advantages regarding client-server systems, namely: (1) improved scalability and reliability since they avoid the dependency of centralized servers, which are often points of failure; (2) cheaper infrastructures due to direct communication among peers; and (3) easiness of resource aggregation in order to provide, for instance, massive processing power (Ye et al., 2004). However, P2P systems also have some drawbacks namely considerably more complex searching and node organization and security issues (Aberer, Punceva, Hauswirth, & Schmidt, 2002).

P2P networks have been deployed in several application areas, such as distributed grid computing (http://www.entropia.com), storage (Cohen, 2003), Web cache (Dabek, Kaashoek, Karger, Morris, & Stoica, 2001), and service directory (Iyer, Rowstron, & Druschel, 2002; Ratnasamy, Francis, Handley, Karp, & Shenker, 2001; Stoica, Morris, Karger, Kaashoek, & Balakrishman, 2001). However, P2P systems were popularized due to the applications of file sharing: Many different P2P file sharing systems, such as Gnutella (http://www.gnutella.com), KaZaA (http://www.kazaa.com.), eDonkey (http://www.overnet.com), and BitTorrent (http://bitconjurer.org/bittorrent/) have recently experienced dramatic growth in popularity and are currently responsible for a large amount of the Internet traffic (Saroiu, Gummadi, & Gribble, 2002; SD-NAP, 2002). As a result of the increasing popularity, P2P file sharing systems became more complex in order to provide services to millions of users. The original centralized architecture of Napster (http://www.napster.com) has been replaced by unstructured decentralized systems such as Freenet (http://freenet.sourceforge.net) and Gnutella. A detailed performance evaluation of the main features of current unstructured P2P architectures may be found in Benevenuto, Ismael, and Almeida (2004). Due to scalability limitations of the unstructured P2P approaches, structured P2P systems have been developed to manage huge amounts of data in a scalable way in overlay networks. One type of structured P2P systems is Distributed Hash Tables (DHTs) (Rieche, Wehrle, Landsiedel, Gotz, & Petrak, 2004). Examples of these DHTs include Chord (Stoica et al., 2001), Content-Addressable Network (CAN) (Ratnasamy et al., 2001), DKS(N,k,f) (Alima, El-Ansary, Brand, & Haridi, 2003), or Pastry (Rowstron & Druschel, 2001).

MULTIMEDIA DISTRIBUTION SERVICES

The demand of delivering multimedia content over the Internet has become increasingly high for scientific, educational, entertainment, and commercial applications. However delivering streaming media content over best effort, packet-switched networks has to deal with high bit rates, delay, loss sensitivity, and heterogeneous client resources. The expensive growth of multimedia applications over the Internet lead to an increasing interest to provide low cost, efficient, and scalable multimedia distribution services. Recently, P2P systems have received a great amount of interest as a promising scalable and cost-effective solution for next-generation multimedia content distribution.

Multimedia distribution services may be classified into three categories (Xiang, Zhang, Zhu, Zhang, & Zhang, 2004) as follows:

1. **Centralized Multimedia Distribution:** A centralized multimedia server is deployed to support a client to access multimedia content across the Internet. In order to extend the storage and Input/Output capacity of the centralized server and to improve the service availability, server clustering or mirroring are often used. This strategy is widely used in traditional Web-based distribution services, although they are unable to reduce the network bottleneck problem, which has significant impacts on the performance of multimedia distribution. As reported by Kangasharju, Roberts, and Ross (2002), a centralized system is not suitable neither scalable for multimedia distribution services. The use of proxy caches (Xiang, Zhang, Zhu, & Zhong, 2001; Zhang, Wang, Du, & Su, 2000) can alleviate the bottleneck problem by caching popular contents from origin servers to proxy servers located at the edge of network. Clients receive the content from edge servers without consuming the network bandwidth. However, the cache policies that influence the effectiveness of proxy caching are suboptimal for streaming media since they were not developed with new video coders in mind. Moreover, proxy caching has scalability limitations for multimedia distribution services.
2. **Multimedia Distribution Based on Content Distribution Networks:** This technique is a server-oriented approach based on content distribution networks (CDNs) (also known as content delivery networks) platforms. The original server is replicated and placed locally or remotely in geographical or network spaces. CDN-based architectures have a limited performance for large-scale multimedia distribution services, since the capacity of the edge server is not large enough to support multimedia services, specially the streaming media service. Furthermore, the decision of the number and location of edge servers is a difficult problem, which has not yet been solved efficiently (Chen, Katz, & Kubiatowicz, 2002; Cohen, Katzir, & Raz, 2002; Qiu, Padmanabhan, & Voelker, 2001)
3. **P2P Networks:** In P2P networks, clients host contents in their local storage and distribute contents to other clients, allowing the sharing of data and resources by a large community at low cost and small network management. Furthermore, the availability of distribution services relies on the reliability of each peer, but peers may not guarantee service persistence. Some current P2P systems also have scalability limitations such as Napster, CenterSpan (http://www.centerspan.com), and Vtrails (http://www.vtrails.com), which are centralized. However, new P2P scalable frameworks have also been developed, and P2P-based multimedia distribution services have started to appear and are considered as the most scalable, efficient, and low-cost solution for future multimedia applications and services. The next section is devoted to P2P systems.

P2P COMPUTING

Since there are about 70 different P2P applications, this section provides an overview of those P2P applications regarding their models of cooperation and how they may be classified according to the following criteria: functionality, degree of decentralization, and degree of structure of the information system.

Functional Classification

P2P systems may be classified from a functional point of view into three basic subcategories: (1) management and contents-sharing applications; (2) distributed processing and; (3) collaboration and communication (Benayoune & Lancieri, 2004). However, there are also platforms, such as JXTA (Gong, 2001), and Globus, that aim at facilitating the development of these applications by offering a set of common basic services such as the authentication or research and routing services. Table 1 summarizes this classification. The file-sharing applications are extremely popular on the Internet and have a large user base. Recent statistics show that the activities of these applications consume more than 60% of Internet service provider (ISP) traffic.

Degree of Decentralization

The Internet is nowadays largely based on the client-server paradigm but the use of central servers leads to a waste of

Table 1. Functional classification of P2P systems

Management and Contents Sharing Applications	Distributed Processing	Collaboration and Communication
Napster	Seti@Home	Groove,
Audiogalaxy, GNUtella	Genome@Home	NextPage,
KaZaA	Folding@Home	Kanari,
Grokster	Evolutionary@Home	Magi,

resources, creates bottlenecks, and is very sensitive to failures in the server. P2P systems increase the scalability and fault tolerance due to the decentralization. P2P systems may be classified into three categories regarding the degree of decentralization (Benayoune & Lancieri, 2004; Tsoumakos & Roussopoulos, 2003):

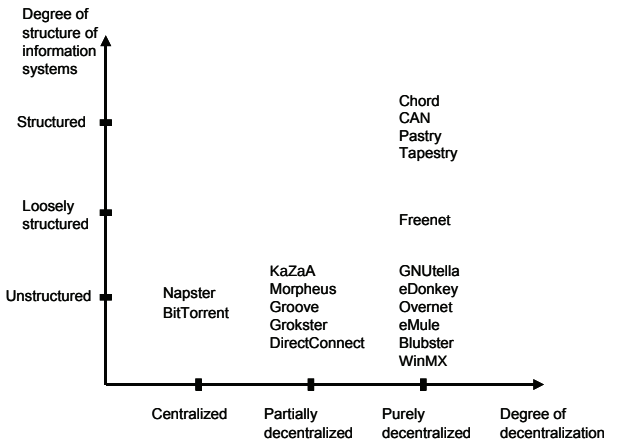
1. **Purely Decentralized Systems:** These systems, also called pure P2P, became popular with GNUtella, Freenet, Plaxton, Blubster, and so forth. The nodes within such systems communicate together without any intermediate central point. In fact, each node termed Servent (**server** and **client** at the same time) performs research and routing functions. This model is more robust than the centralized one because the failure of any particular node does not have impact on the system, resulting in high service availability at reduced costs. However, this model has two main drawbacks. First, the localization of an object is not guaranteed because of the directory decentralization. Second, the mechanism of research by flooding (set of broadcast) wastes high amounts of network bandwidth. In fact, the increase of the number of the peers generates an exponential increase of requests, which may cause network congestion, slow down downloads and poses scalability problems.
2. **Partially Decentralized Systems:** A new wave of P2P systems is born from a purely decentralized system combined with a centralized one (e.g., FastTrack: KaZaA, Morpheus, Grokster, iMech, etc.). This model is based on a Super-Node (or Super Peer) that acts as a centralized server for a set of nodes. The nodes send their queries to the Super-Node that provide the content or relay requests to other nodes. Such a system solves the problem of networks extensibility of purely decentralized systems by keeping the efficiency of the centralized ones. In case of failures of the primary Super-node, others are defined to automatically replace it. However, the process of selection of the Super-Nodes is still complex. They can be elected according to their own capacities, in particular in terms of bandwidth and persistence in the system (time of connection), but each user can decide to be or not to be a Super-Node. Moreover, being a Super-Node can lead to increased security problems.
3. **Centralized Systems:** In this model a central server is responsible for answering the queries, hence all the query traffic is directed to it (e.g., Napster, BitTorrent, etc.). Before using the network, a peer must connect to a central server, which manages a central directory of shared resources and users that indicates from which node the files should be downloaded. This mode is a very efficient way to locate resources and to have a complete view of the network. However, although shared files are more easily managed, there is a single access point which may lead to several problems such failure, overload, copyright, or security. Moreover, the central server limits the network scalability.

Structure of the Information System

P2P systems use several techniques of references publication, contents search, and routing requests. Therefore, it is possible to build another classification of P2P systems according to the mode of management of meta-information in order to discover distributed data or evaluate its level of accessibility. P2P systems may be classified into three categories regarding the degree of structure of the information system (Benayoune & Lancieri, 2004; Tsoumakos & Roussopoulos, 2003):

1. **Unstructured Systems:** In some P2P systems such as GNUtella, KaZaA, Morpheus, DirectConnect, BitTorrent, and so forth, nodes have no information about the location of the required files. Therefore, the research will be random and the used discovery methods are known as blind. Nodes relay requests from node to node towards all the neighbors in order to seek the maximum of objects on the maximum of nodes. Thus, the network will be flooded by duplicated messages and the partial answers will be limited to a zone of locality defined by the time-to-live (TTL) field.
2. **Structured Systems:** The hash-based systems such as Chord (Stoica et al., 2001), CAN (Ratnasamy et al., 2001), Tapestry (Zhao et al., 2004), or Tornado are supposed to correct the lack of scalability of the prior systems. The objective is to add more dynamics to P2P network by proposing at the same time an algorithm of localization and routing in an entirely distributed environment. In these kinds of networks, the files or their references are placed in quite precise places. Node and files have identifiers independent of their localization and contents semantics. Each node of the network has a routing table containing two parts: (1) set of neighbors and (2) set of pointers towards the nodes. The major weakness of these systems is that it is difficult to maintain the structure in a context of a changing population where users often join and leave the system.
3. **Loosely Structured Systems:** P2P networks like Freenet can be classified between the two preceding types of P2P systems. Indices are provided on the localization of the files to select the next peer to query. Therefore, the searches will be guided but without guaranties of success. Freenet is also fault tolerant due to the strategy for the replication of files, since every

Figure 1. Overview of the classification of P2P systems regarding both the degree of decentralization and the degree of structure of the information system



time a file is requested it is replicated in the neighborhood of nodes that frequently make requests.

Figure 1 presents an overview of the last two classifications.

FUTURE TRENDS

Novel frameworks for multimedia distribution services based on P2P networks are now starting to appear. Most of them are based on new multimedia coding technologies that allow to reach scalability, robustness, and to circumvent frequent peer going downs (Pouwelse, Taal, Lagendijk, Epema, & Sips, 2004; Xu, Wang, Panwar, & Ross, 2004). Some of these techniques are layered coding and/or multiple description coding (MDC). Layer coding is usually used to construct a scalable framework, while MDC can also provide adaptivity to packet loss and variable transmissions (Pereira, Antonini, & Barlaud, 2003). Coopnet (Padmanabhan, Wang, Chou, & Sripanidkulchai, 2002) considers MDC which enables graceful QoS degradation when packet losses occur due to node or link failure or link state change.

Although most P2P systems do not yet take security into account, security and trust are key issues in P2P computing. Besides the occurrence of improper handling by users of sensitive personal information, a number of security attacks on P2P systems are possible including denial-of-service attacks, replay attacks, collaborated or un-collaborated attacks by malicious nodes, incorrect routing updates, black hole attacks (modifying the routing message to say a node has the shortest path to some nodes), and worm hole attacks (collusion by two malicious nodes to make the packets they want flow through them). In addition, management of trust information of nodes and access control to resources are two important issues that need to be addressed (Sieka, Kshemkalyani, & Singhal, 2004).

CONCLUSION

Multimedia distribution services have been discussed and P2P systems were identified as the most scalable, efficient, and low-cost solution for future multimedia applications and services. These systems were analyzed and classified regarding the functionality, the degree of decentralization, and the degree of structure of the information system. The improvements of the new generation of P2P frameworks were tackled. These new frameworks pretend to be scalable, robust, reliable, and secure. Some of the techniques used to reach each one of these goals were discussed.

KEY TERMS

Distributed Hash Table (DHT) Scheme: The basic idea of a DHT scheme is to use a hash table-like interface to locate the objects and to distribute the duty of maintaining

the hash table data structure, in the face of node joins/leaves, to all participating P2P nodes.

Gnutella: Gnutella is a decentralized file-sharing system whose participants form a virtual network and communicate peer-to-peer via the Gnutella protocol for distributed file search. To participate, a peer first connects to a known Gnutella host. Upon receiving a message, the servent decrements the time-to-live (TTL) field of the message. If the TTL is greater than 0 and the servent has never seen the identifier of the message (loop detection), it resends the message to all known peers. The servent also checks whether it should respond to the message. If it receives a Query, for example, it checks its local file store and responds with a QueryHit if it can satisfy the request. Responses are routed along the same path as the originating message.

JXTA: JXTA is a suite of protocols that facilitates P2P communication. It provides a common network architecture layer for a wide variety of network services and applications. Peers on a JXTA network are arbitrary devices and can be anything with an electronic heartbeat.

JXTA Search: JXTA search is a decentralized peer-to-peer search engine. It provides a common distributed query interface for peer devices, exposing services and content for a network of information providers and consumers.

Peer, Party, or Node: These terms are used interchangeably and all refer to an entity in a P2P system.

Peer-to-Peer (P2P): This term refers to any exchange system characterized by direct interaction and data exchange between its entities (called nodes or peers).

Servent: This word is composed by the first four and last three letters of **server** and **client**. It is used to designate a node that is server and client at the same time.

Performance Implications of Pure, Applied, and Fully Formalized Communities of Practice

INTRODUCTION

Interest in knowledge-based perspectives on the firm has grown in both practitioner and academic realms, spurred by management bestsellers such as Senge's *Fifth Discipline* (1990) and the acknowledgement that intangible assets are key to the firm's sustainable competitive advantage. Knowledge management tools and processes are used by organizations to identify, create, represent, and distribute knowledge for reuse, awareness, and learning. One component of knowledge management is the "communities of practice" (CoPs) concept. CoPs are informal networks of individuals who possess various levels of a common capability and apply their knowledge in pursuit of a similar endeavor (Brown & Duguid, 1991). For example, Xerox technicians solve problems by relying on informal communication with colleagues in addition to formal user user manuals. Created as a response to bureaucratization, CoPs emerge from individuals' passions for a particular activity and the term is used to describe a formal of organization that is distinct from traditional formal boundaries around geographic and functional business units or other institutional affiliations and divisions.

For the most part, managers use the CoP concept to encourage informal, situated learning (e.g., Hildreth & Kimble, 2004). However, some managers developed highly formalized structures with regulated membership, prescribed roles, scheduled meetings, and technical tools. This formalization distorts the original concept—that CoPs are created as a response to bureaucracy and are, by definition, emergent. The formalization of CoPs defeats both the original intent and the ability to reap full benefits for the firm. The chapter reviews three models of communities of practice — pure, applied, and formalized — and explores how coordination, opportunity, and knowledge flow costs in formalized CoPs can impede organizational performance.

BACKGROUND

In practice, CoPs can take three forms. In the first "pure" case, the original construct is adhered to and CoPs are emergent in nature. A second, mid-spectrum "applied" group exists when original CoP theory has been slightly tweaked. Next, a mid-spectrum "applied" group in which original CoP Theory has

Table 1. CoPs: Pure, applied, and fully formalized constructs

	CoP: Pure Construct	CoP: Applied Construct	CoP: Fully Formalized Construct
Organization Type	Emergent Community	Supported Community	Formalized Community
How is the CoP born?	Emergent, from individuals' passion, bottom-up	Emergent, especially in firm-enabled spaces	Emergent, but with strong top-down directives
Who are CoP members?	Self-selected individuals; choice	Both self-selected and strongly encouraged by others	Corporate assignations; restricted membership
How many CoP members?	Small core group	Small to medium-sized group	Small to large group
What is the goal of the CoP?	Learn and share knowledge about passionate individual interest	Share knowledge about area of strong individual interest that the firm also deems interesting	Share knowledge about area of interest that the firm also deems especially interesting
Who is in charge?	Individuals	Individuals and organization	Organization and individuals
What holds CoP together?	Shared interest and passion	Interest oriented to project goal	Some interest, also job requirement
Where is resource level?	Individual's own time	Individual time, some funding at various organization levels	Funding at various organization levels, especially corporate
When are CoP interactions?	Spontaneous interactions	More regular, but spontaneous interactions possible	Scheduled meetings; spontaneous interactions if time
What type of learning?	Situated	Situated and classroom	Classroom
When does the CoP die?	Naturally, when interest fades	When project completed	When firm resources extinguished

been slightly tweaked. For example, a firm might establish a common area such as a water cooler, coffee pot, or plate of cookies where individuals meet spontaneously. In the third fully "formalized" case, CoPs are no longer chiefly fueled by individual passion, but rather by organizational mechanization. For example, spontaneous get-togethers are supplemented by set monthly meetings and agendas. Thus formally recognized CoPs function just like any other formal unit within the firm. The shift from the original pure intent to applied (in which there are some costs and benefits) and fully formalized (only negatives) construct is depicted in Table 1.

Pure Construct

Lave and Wenger (1991) formally coined the term CoPs, which was later incorporated into an organizational framework by Brown and Duguid (1991). CoP theory is based on the value of informal structures to organizational development, learning, and performance (Barnard, 1938, among others), epistemological perspectives on the importance of tacit and action-oriented knowledge (Polanyi, 1966), and the key role of situated learning, social processes (March & Olsen, 1975), and community (Daft & Weick, 1984).

As emergent organizations, CoPs encourage informal situated learning that is unobtainable in a structured organizational bureaucracy. Brown and Duguid (1991) note this difference: "Work practice and learning needs to be understood not in terms of the groups that are ordained (e.g., 'task forces' or 'trainees') but in terms of the communities that emerge" (p. 49). Wenger (1998) also notes: "Unlike more formal types of organizational structures, it is not so clear where [CoPs] begin and end…Whereas a task force or a team starts with an assignment and ends with it, a community of practice may not congeal for a while after an assignment has started, and it may continue in unofficial ways far beyond the original assignment" (p. 96).

CoPs extend beyond traditional classrooms to work environments, hobbies, and families (Lave & Wenger, 1991; Wenger, 1998). Individuals become members of CoPs through narration, social construction, and collaboration (Brown & Duguid, 1991). Narration involves the telling of stories and encourages individuals to develop a socially constructed world. Through collaboration, individuals learn from one another. Strong communities are characterized by trust and a sense of identity and belonging. Knowledge transfer is both "leaky" within and "sticky" across communities (Brown & Duguid, 2001). CoPs are distinct from (but are subsets of) large groups which perform similar activities but are not in direct contact. These groups have been variously termed "networks of practice" (Brown & Duguid, 1991), "occupational groups" (Van Maanen & Barley, 1984), "social worlds" (Strauss, 1978), or "constellations of practice" (Wenger, 1998). In these large networks, individuals share knowledge and practice, but are unknown to one another except through Web sites, listservs, or other indirect communication.

Applied and Corrupted Construct

In *Cultivating Communities of Practice*, Wenger, McDermott, and Snyder (2002) provide a gardening analogy for these emergent organizations:

A plant does its own growing, whether its seed was carefully planted or blown into place by the wind. You cannot pull the stem, leaves, or petals to make a plant grow faster or taller. However, you can do much to encourage healthy plants: till the soil, ensure they have enough nutrients, supply water, secure the right amount of sun exposure, and protect them from pests and weeds. There are also a few things we know not to do, like pulling up a plant to check if it has good roots. Similarly, some communities of practice grow spontaneously while others may require careful seeding. (p. 12-13)

In formalizing CoPs, some practitioners have tugged, over-watered, or otherwise too zealously attended to these emergent communities.

The mid-spectrum group can be described as "applied," the gray area in which original CoP theory has been slightly tweaked. The organization may establish systems enabling CoPs to emerge naturally. For example, a firm might establish a common area such as a water cooler, coffee pot, or plate of cookies where individuals can meet spontaneously. In the garden analogy, this is the equivalent of cultivating the soil by adding nutrients.

In the corrupted construct, CoPs are no longer chiefly fueled by individual passion, but by organizational mechanization. During this process, pure CoP theory is mutated into prescriptive formulas bureaucratizing these emergent communities. For example, some management consultants advocate regulated membership, prescribed roles, scheduled meetings, and even distribute CoP-printed pins and pens to identify members. Spontaneous get-togethers are supplemented by set monthly meetings and agendas. Once CoPs are formally recognized, they become just like any other formal unit within the firm.

An example of formalized CoPs existed at the Fairfax, Virginia-based global consultancy, American Management Systems (AMS). In the late 1990s, then-CEO Charles Rossotti asked business units to nominate "thought leaders" who were then mandated to establish CoPs. AMS paid for two to three weeks per year of the leaders' time. CoP membership was a privilege and extended only to those individuals recognized as "experts" by their managers. Every CoP member was required to write one knowledge white paper per year. Business units funded participation, meeting attendance, projects, and an annual conference with members of all CoPs. At one point, 900 of AMS' 9,000 employees were members of one

of the CoPs. AMS estimated that these efforts saved $2 to $5 million per year. In the January/February 2000 *Harvard Business Review,* Wenger and Snyder highlighted AMS as an example of CoP success. Barely six months after the article was published, AMS completely disbanded CoPs in favor of a more flexible organization enabling individuals to work across different areas. AMS' Director of Knowledge Management Susan Hanley moved to another consultancy, and most of the identified CoP leaders are also no longer with the firm.

MAIN FOCUS: HOW CAN FORMALIZATION DECREASE PERFORMANCE?

Formalization describes the degree of activity bureaucratization such as the number of scheduled meetings, extent of reporting, regulation of member selection and retention, and mandated linkages to firm hierarchy (such as division reporting relationships). The decrease in organizational performance of CoP formalization can be attributed to hefty coordination, opportunity, and knowledge flow costs.

Coordination Costs

In complex environments, organizations require more integration and coordination efforts such as rules, plans, and mutual adjustment. Rational organizations create hierarchies to alleviate organization uncertainty from complex coordination and interdependence requirements, lower communication costs, and align interests. If interdependence is not limited by this organization, remaining coordination problems are assigned to community, task, project, or other self-contained teams. While bureaucracy does minimize coordination costs, CoPs emerged as a rebellion against bureaucracies. CoP members accept entropy in the system because perceived benefits of this workaround outweigh costs of dealing with the hierarchy. For example, CoP formalization reduces the costs of interacting with a given set of people, but individuals may still need to interface with others informally. Formalization of CoP routines may upset the internal CoP and drive members to look outside the CoP for new knowledge-oriented routines. Finally, CoPs are a social context characterized by spontaneous interactions that have naturally low costs. Additional formalization becomes unnecessary. In formalized CoPs, individuals would continue to seek social contexts outside of the formal structure, creating additional coordination costs.

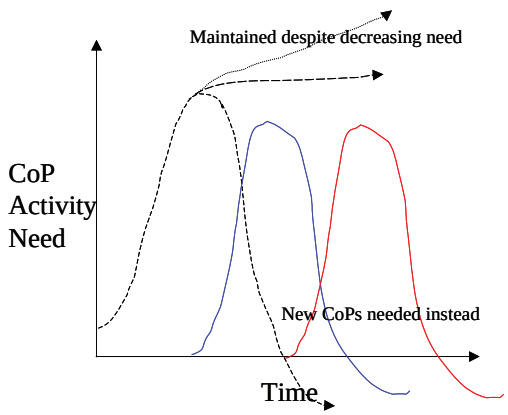
Opportunity Costs

Organizations have a limited amount of resources available for internal distribution and use. As formalized entities, CoPs receive resources such as dedicated employee time, physical space, and technical tools. These resources may be budgeted for an entire fiscal year, even if the need only exists for the next two to three weeks or months. Meanwhile, the budget process may not be able to aid CoPs that emerge outside the fiscal cycle. When reinforced with resources, formalized CoPs are made artificial and do not follow the normal course of spontaneous birth, growth, maturity, decline of usefulness, and death. For example, a firm may formalize a CoP dedicated to Java programming when individual interests (and perhaps also future competitiveness) have shifted to a new technology such as ActiveX. Firm resources would maintain the old CoP, even in the face of decreasing need. Meanwhile, the ActiveX CoP could not emerge because individuals are unable to access key resources. There are dire opportunity costs for individuals and the firm. Figure 1 illustrates how a formalized CoP is not able to follow a normal lifecycle. In the normal cycle of a CoP, resource activity needs decrease over time (Gongla & Rizzuto, 2004). In the case of a formalized CoP, however, resources are maintained despite decreasing need and the organization is perpetuated. Meanwhile, new CoPs are not able to gain the resources they need.

Furthermore, human resource requirements may pull individuals away from the actual work at hand and push them into community maintenance roles. A recent study examining 10 different formal and informal CoP roles found that members, depending on their roles, spent between 5.0% (mentor) and 53.4% (facilitator) of their time on community activities. Across all 10 roles (subject matter expert, core team member, community member, community leader, sponsor, facilitator, content coordinator, mentor, administrative/events coordinator, and technologist), each CoP member spent an average of 20% of her or his time on community activities (Fontaine, 2001).

Finally, an organization might formalize a CoP and effectively kill it, deterring other emergent CoPs. Individual and organizational resources could be devoted to other activities,

Figure 1. Formalized CoP receives resources despite decreasing need



such as the emergence of potentially new CoPs. The dedication of formalized CoP resources, as a percentage of total firm resources available, is a dire opportunity cost.

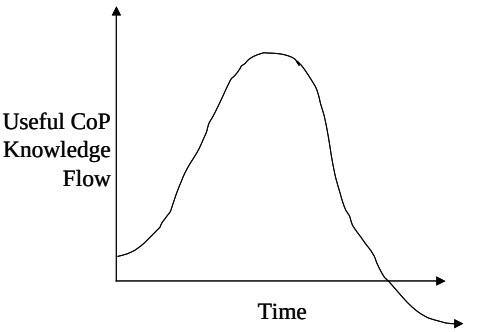
Knowledge Flow Costs

Communities maintain themselves by adding new members who introduce new practices. Early on, formalized CoPs benefit from new joiners. Structures in which individuals are in closed circles can create "silos" that prevent knowledge sharing among groups in an organization (Pfeffer & Sutton, 2000). Over time, formalized CoPs may become cliquish and suffer from the "liability of competence" as new members are unable to join because they do not speak the same advanced language. Formalization reduces the costs of interacting with certain individuals. Individuals may choose to interact only with those with whom it is easiest to interact, and not with those to whom they most need to speak.

In this community, individuals may spend their time talking about work (or other issues), rather than performing required work. For example, in formalized CoP meetings, individuals are no longer necessarily engaged in the "practice" of learning by doing, such as the Xerox technicians who discussed problems and solutions one on one or in small groups with the copiers in front of them. Instead, formalized CoP members might sit in large groups listening to one speaker, akin to a traditional classroom environment. Furthermore, formalized CoPs often require members to document knowledge that is subsequently archived in electronic repositories. Storing and transferring information is not the same as understanding and using knowledge. Employees may have limited attention, but unlimited access to good information. CoPs may add more to the information explosion than they dedicate to needed specialized attention.

Furthermore, formalized CoPs may suffer from a "liability of expertise" as firm experts become primarily one-way (outward) communicators. For example, in a CoP of programmers, a few key individuals may serve as expert resources. These individuals may spend the bulk of their day playing "expert" and solving others' problems, leaving little time to perform their real tasks. Meanwhile, "receivers" benefit from this information and may come to rely on experts rather than learn how to sort out problems themselves. When CoPs cross firm boundaries such as the Experts Exchange (*www.experts-exchange.com*), individual experts from Firm A may spend most of their day informing Firm B receivers, with no reciprocation. Figure 2 depicts the possibility of diminishing returns to scale from formalized CoP activities.

Figure 2. Useful CoP knowledge flows decrease over time in formalized CoPs



FUTURE TRENDS

Viewing organizations as embedded in their environment, institutional theory examines how isomorphic pressures from the environment lead to homogeneity among firms, for example, within a particular industry. The cultivation of CoPs (in the original construct) and formalization of CoPs could be described as a case of institutionalization using DiMaggio and Powell's (1983) three institutional pressure framework: (1) coercive (from political influence and problems of legitimacy), (2) mimetic (response to uncertainty), and (3) normative (result from professionalization). Coercive institutionalism describes the influence of formal and informal pressures and cultural expectations. In the case of CoP cultivation, informal pressures such as individual interest may lead to their formation. In the case of corrupted formalized CoPs, well-meaning CEOs could mandate the establishment of new communities or formalize support of existing communities. Mimetic institutionalism describes how uncertainty may, with or without intent, drive an organization to mould itself after other organizations. A firm might replicate a successful industry competitor's CoP initiative. In the worse-case scenario, this institutionalization might include mimicking extremely formalized CoPs. Finally, professionalism describes how the spread of formal and informal professional networks help diffuse organizational norms rapidly. Informed management consultants who are well versed in the original theory may help firms put processes into place, such as creating a common water cooler-type space, to cultivate CoPs. Other consulting professionals may institute formalized CoPs through prescriptives for formulaic rules around membership and process.

CONCLUSION

Communities of practice are informal networks of individuals who possess various levels of a common capability and apply this knowledge in pursuit of a similar endeavor. In practice, managers have implemented CoPs in three forms: the original "pure" construct of informality, an applied model, and a fully formalized structure. Formalized CoPs have high

coordination, opportunity, and knowledge flow costs that impede organizational performance. Managers interested in reaping the benefits of informal knowledge sharing should resist the temptation to formalize CoPs through mandatory meetings, roles, and routines.

Orr's (1990) seminal doctoral thesis cautioned against corporate interference in communities:

The process of working and learning together creates a work situation which the workers value, and they resist having it disrupted by their employers through events such as a reorganization of the work. This resistance can surprise employers who think of labor as a commodity to arrange to suit their ends. The problem for the workers is that this community which they have created was not part of the series of discrete employment agreements by which the employer populated the work place, nor is the role of the community in doing the work acknowledged. The work can only continue free of disruption if the employer can be persuaded to see the community as necessary to accomplishing work. (p. 48; also cited by Brown & Duguid, 1991)

Wenger (1998, p. 243) also warned against formalization:

Institutionalization must be in the service of practice. Institutionalization in itself cannot make anything happen. Communities of practice are the locus of 'real work'…excessive institutionalization stalls the organization insofar as the practices end up serving the institutional apparatus, rather than the other way around.

KEY TERMS

Community of Practice: Informal network of individuals who possess various levels of a common capability and apply their knowledge in pursuit of a similar endeavor.

Coordination Cost: Cost of processing information in an organization.

Formalization: Act of making formal, often for the sake of official or authorized acceptance.

Knowledge Management: Set of practices used by organizations to identify, create, represent, and distribute knowledge for reuse, awareness, and learning.

Opportunity Costs: Set of costs of passing up the next best choice when making a decision.

Tacit Knowledge: Knowledge that people carry in their minds and is difficult to share with others.

Personalization in the Information Era

INTRODUCTION

We are witnessing the development of new communication technologies (e.g., DTV networks [digital TV], 3G [third-generation] telephony, and DSL [digital subscriber line]) and a rapid growth in the amount of information available. In this scenario, users were supposed to benefit extensively from services delivering news, entertainment, education, commercial functionalities, and so forth. However, the current situation may be better referred to as *information overload;* as it frequently happens that users are faced with an overwhelming amount of information. A similar situation was noticeable in the 1990s with the exponential growth of the Internet, which made users feel disoriented among the myriad of contents available through their PCs. This gave birth to *search engines* (e.g., Google and Yahoo) that would retrieve relevant Web pages in response to user-entered queries. These tools proved effective, with millions of people using them to find pieces of information and services. However, the advent of new devices (DTV receivers, mobile phones, media players, etc.) introduces consumption and usage habits that render the search-engine paradigm insufficient. It is no longer realistic to think that users will bother to visit a site, enter queries describing what they want, and select particular contents from among those in a list. The reasons may relate to users adopting a predominantly passive role (e.g., while driving or watching TV), the absence of bidirectional communication (as in broadcasting environments), or users feeling uneasy with the interfaces provided. To tackle these issues, a large body of research is being devoted nowadays to the design and provision of personalized information services, with a new paradigm of *recommender systems* proactively selecting the contents that match the interests and needs of each individual at any time. This article describes the evolution of these services, followed by an overview of the functionalities available in diverse areas of application and a discussion of open problems.

BACKGROUND

The development of personalized information services brings together diverse areas of technology, plus a significant body of legislation. The following subsections group these aspects into five major topics.

User Modeling

To identify the most suitable contents for a user, it is necessary to handle profiles that capture the user's preferences and needs. Such profiles can be represented in many different ways: consumption histories, ontologies, neural networks, decision trees, and so on (Conati, McCoy, & Paliouras, 2007). Besides these, there exist many *de jure* or *de fact*o application-dependent standards to manage data: *learner information packaging* (LIP) to track educational activities, TV-Anytime for TV programs, *Integrating the Healthcare Enterprise* (IHE) for health records, and so forth.

The initialization of the user profiles can be done manually, with the user entering a description of his or her interests, or automatically, with the program retrieving information from his or her interactions with other systems (e.g., commonly, from Web navigation histories). Whichever the approach, a recommender system must implement mechanisms to capture new data (*relevance feedback*) and discard obsolete information (*gradual forgetting*). For relevance feedback, some systems use explicit mechanisms that require the user to rate contents as interesting or not interesting; others provide implicit mechanisms that infer information from ongoing interactions (Montaner, López, & de la Rosa, 2003). In gradual forgetting, the common approach is to measure the obsolescence of data in the profiles as a function of time.

Context Awareness

Context awareness aims at acquiring information about physical and social situations to maximize the value of the information delivered to the user. Knowledge about context is added to that in the user's profile to drive the selection of contents. Regarding format and length, it is necessary to match the time the user will have to read or watch material, the size of the screens where it will be presented, the input mechanisms available, and so forth. As for the semantics, the goal is to identify the topics the user may welcome at a given moment.

The first possibility explored was to develop location-sensitive mobile applications that would display different contents following the users' moves in indoor environments (e.g., museums) or outdoors (e.g., city tours) (Baldauf, Dustdar, & Rosenberg, 2007). Other dimensions were progressively added, like the informational context (e.g., inferred from the words on screen), infrastructure (e.g., surrounding communication resources), and physical conditions (noise, light, etc.). Recent works on affective computing (Picard & Daily, 2005) bring the user's feelings (mood, stress, etc.) into consideration, too.

Characterization of Contents and Services

To enable automatic selection of contents, it is necessary to characterize the available resources regarding format, length, and semantics. The MPEG-7 standard (Manjunath, Salembier, & Sikora, 2002) here appears as a common umbrella for previously existing purpose-specific metadata specifications, such as the Dublin core for Web pages, TV-Anytime for programs, or *shared content object repository model* (SCORM) for educational resources. MPEG-7 provides descriptors for low-level audiovisual features (like color or texture) that can be annotated automatically, and for high-level characteristics of objects, events, and concepts. Furthermore, contents can be split into segments that can be handled separately: audio clips, video sequences, 3-D objects, and many others.

In the characterization of interactive services, the reference is the architecture of Web services (Cerami, 2002), which includes solutions for automatic discovery, invocation, and composition, covering practically the whole spectrum of applications over the Internet. At the core of most proposals, the Web service description language (WSDL) allows one to describe the operations offered by a service and the formats to follow in their invocation. Other initiatives, like the ontology Web language for services (OWL-S), focus on describing what the services do with a common conceptualization to reason about the functionalities delivered to the users. These solutions are now being extended to other platforms (e.g., mobile devices or DTV set-top boxes), where the services have been typically monolithic and purpose built.

Filtering

Personalization is achieved by matching the information in the user's profile with his or her context and the contents available. The first possibility explored in this regard was content-based filtering to make recommendations by looking at contents that gained the user's interest in the past (Balabanovic & Shoham, 1997). This approach is easy to adopt, but the recommendations tend to be repetitive for considering that a user will always appreciate the same kind of content. Alternatively, collaborative filtering (Mobasher, Jin, & Zhou, 2003) evaluates not only the profile of the target user, but also those of users with similar interests (his or her neighbors). This approach solves the lack of diversity, but faces problems like sparsity when the number of contents is high (which makes it hard to find users with similar evaluations for the same contents) or problems in the treatment of users whose preferences are dissimilar to the majority. To neutralize these shortcomings, there exist hybrid approaches (Burke, 2002), such as recommending contents similar to the ones stored in the target user's profile, but considering two items similar if the users who show interest in the one tend to be interested in the other (item neighborhoods).

Regardless of the filtering strategy, the first recommender systems relied on syntactic matching techniques, comparing textual strings. This approach missed the ability to discover semantic relationships between preferences, context, and contents. Nowadays, research is focused on applying techniques from the Semantic Web (Antoniou & van Harmelen, 2004), which enable processes that gain insight into the meaning of words and sentences. The reasoning can be done directly over textual contents, and over metadata descriptions in the case of images, audiovisual material, or interactive programs.

Legal Aspects

Personalization is typically opposed to privacy. The effectiveness of the former depends on accumulating information about a user, while the latter aims at restricting the management of personal information by commercial or administrative entities. Since privacy is a right in itself, there is a legal framework that must be taken in account when implementing personalization. Globally, this is delimited by OECD guidelines, which lie at the core of more specific laws for different countries worldwide. These guidelines pose restrictions to the management of user data in such aspects as the necessary levels of the user's consent, the exchange and aggregation of data from different sources, the limits to granting access to third parties or to trade information, the requirement to keep the user informed of what his or her data will be used for, and so forth. In-depth details about these requirements can be found in Wang, Zhaoqi, and Kobsa (2006).

PERSONALIZED INFORMATION SERVICES

Personalized information services are emerging in diverse areas, considering a range of consumer devices and com-

munication networks. Next, we provide a brief survey of the functionalities available.

Adaptive Hypermedia

The first studies on personalized services arose on adaptive hypermedia to improve the usability of the World Wide Web. There have been countless approaches to Web page recommenders (Chen & Magoulas, 2005), usually relying on navigation histories as the main source of information about the users' interests and context; a few ones would also tailor the presentation of contents to device characteristics such as screen size and input facilities (Bandelloni & Paternò, 2004). Recent works have extended the scope to embrace incipient research on the automatic composition of interactive services (O'Keeffe, Conlan, & Wade, 2006).

Personalized Learning

Personalized learning over the Internet developed hand in hand with adaptive hypermedia, with many systems exploring the whole spectrum of personalization technologies (Papanikolaou & Grigoriadou, 2003) and developing standards for student profiling, content description, and so on. These standards have been adopted in personalized TV-based learning (t-learning), which delivers education through simple interactions and audiovisual contents (Rey-López, Fernández-Vilas, & Díaz-Redondo, 2006). Also, many authors are working to provide personalized learning through mobile devices (m-learning), with systems that analyze the user's preferences and location to recommend the best-suited educational activities (Silander & Rytkönen, 2005).

Personalized Commerce

Personalized e-commerce has been around on the Internet for some years (Markellou, Mousourouli, Sirmakessis, & Tsakalidis, 2005), but it was absent until very recently in other platforms. The first developments arose in digital TV, with approaches to present personalized advertisements retrieved from broadcast emissions (Lekakos & Giaglis, 2004). López-Nores, Pazos-Arias, García-Duque, and Blanco-Fernández (2007) recently presented an approach to automatically assemble interactive services that provide personalized commercial functionalities. Also, systems have been demonstrated that deliver personalized and location-aware advertisements over devices like PDAs (personal digital assistants) and car radios (IST, 2006).

Recommenders of Audiovisual Contents

Maybe the first application area for personalization beyond the PC was that of personalized programming guides to help TV viewers find interesting programs among the growing number of channels available. This is now a relatively mature field of research in what concerns TV watching at home, with various recommenders featuring semantic reasoning capabilities (Ardissono, Kobsa, & Maybury, 2004). Some systems can adapt their recommendations depending on whether the user is watching TV alone or in a group. As for the delivery of audiovisual contents over mobile devices, there are incipient approaches to build music recommenders and personalized video channels, for example, for podcasting (Billsus & Pazzani, 2007).

Personalized E-Government

The need for personalization in e-government arises from the fact that users often get lost in the information space of portals, needing specific hints that are easily obtained in administrative buildings (e.g., finding the office responsible for a given service or asking for assistance to fill out certain fields of a form). Approaches to fight this problem include strategies to help discover administrative proceedings one has to fulfill (Sacco, 2007) and solutions to identify contexts in which a given proceeding is applicable (Grandi, Mandreoli, Martoglia, Ronchetti, Scalas, & Tiberio, 2006). User profiles here usually consist of structures to gather demographical data such as age, gender, job, or level of income.

Personalized Health Care

Personalized health care aims at supporting users' well-being and medical treatments, considering the individual's unique biological, social, and cultural characteristics. The related research ranges from the design of wearable or implantable devices that sense physiological parameters (Winters & Wang, 2003) to technologies for ambient-assisted living (López-Nores, Pazos-Arias, García-Duque, & Blanco-Fernández, 2008) and expert systems for information processing and diagnosis (James, Wilcox, & Naguib, 2001). Although the research activity is hectic, health care remains one of the areas where information technologies have attained lowest penetration, yet it is also the one in which personalization may report the greatest benefits in social and economical terms.

Other Services

Personalization is progressively gaining new areas of application. Just to enhance the picture of the preceding subsections, we can cite works about location-aware restaurant recommenders (Lee, Kim, Jung, & Jo, 2006), personalized tourism (Kang, Kim, & Cho, 2006), and personalized friend making (Lo & Lin, 2006).

FUTURE TRENDS

There is much place for innovation in the development of personalized information services to enhance technical aspects of user modeling, context awareness, and filtering. Notwithstanding, the greatest challenge may be to find sustainable exploitation models for the already existing solutions. Currently, content and service providers bear the brunt of all the personalization tasks, which poses problems related to increases in production costs and computational requirements as the number of users grows. To solve them, it is necessary to move part of the complexity to the users. For example, the users' devices could keep their profiles and run the filtering algorithms, which would foster privacy while harnessing the power of millions of consumer devices. However, this idea precludes the application of collaborative filtering techniques, which depend on matching multiple profiles to delimit neighborhoods. Besides this, it would be necessary to enhance many consumer devices with data processing capabilities, which may be hard to realize in some cases.

Possibly the most complex part of gaining users' involvement is to get them to contribute metadata for recommender systems to reason about. This is necessary because content and service providers are already incapable of characterizing the growing amount of information available. Therefore, just as new tools such as blogs and YouTube have turned users into active producers of information, there is an urgent need for means that will make them active agents for information retrieval as well. After all, without a scalable approach to produce metadata, most of the research on personalization is doomed to collapse for lack of input. The recent advances on collaborative tagging (Grahl, Hotho, & Stumme, 2007) and the experiences of social sites like Flickr and del.icio.us provide insight on how this could be solved on the Internet, but other platforms may require much further innovation.

CONCLUSION

The success of information technologies depends ultimately on the services provided to the users, which can be rendered useless by the growth in the amount of information available. Personalization aims at solving this problem by providing users with information services that match their preferences and needs in any context within the reach of technology. This requires a shift from the traditional search engines to recommender systems working in behalf of each user, within the limits imposed by privacy concerns. The range of applications is enormous, covering many new communication networks, consumer devices, and consumption models. However, it is still an open issue to find viable and scalable exploitation models for personalized information services to become a ubiquitous reality.

KEY TERMS

Collaborative Filtering: Collaborative filtering includes techniques to estimate the relevance of a given service or piece of content for a target user, considering the ratings given by other users with similar profiles to the same resource or to similar ones.

Content-Based Filtering: This includes techniques to estimate the relevance of a given service or piece of content for a target user, considering that user's previous ratings for resources consumed in the past.

Context Awareness: It is the ability of an information system to adapt to a user's changing attention, location, and physical environment.

Information Overload: It is a situation in which it is hard for a user to stay informed or make decisions about a given topic due to being exposed to an excessive amount of information.

Personalized Information Service: It is a system that delivers information tailored to the interests, preferences, needs, and context of a user or a group of users.

Recommender Systems: These are software systems that proactively look for services and pieces of content that may be relevant for a target user or group of users, matching

user profiles, contextual information, and metadata describing the resources available.

User Profiles: User profiles are data structures containing information that may be used to characterize the interests, preferences, and needs of a user.

Personalization Technologies in Cyberspace

Shuk Ying Ho

INTRODUCTION

Hundreds of thousands of companies worldwide are using the Web as a major channel to interact with their customers for brand promotion, product marketing, order fulfillment, and after-sales support. Competition is extremely keen among online merchants.[1] In doing business online, the question that lurks in the back of their mind is, are we maximizing our business opportunities*?*

With the high interactivity of e-commerce, online merchants now adopt various differentiating strategies to attract and retain customers in the hope of remaining competitive. To provide a differentiated service, online merchants first identify each individual, and then acquire more information about each individual's interests. Then, they can tailor Web content directly to a specific user by having the user provide information to the Web site either directly or through tracking devices on the site. The software can then modify the content to the needs of the user. Ultimately, highly focused and relevant products or services are delivered to each customer, who is treated in a unique way to fit marketing and advertising with his or her needs. This process is generally named *personalization*.

There is a wide range of personalization strategies used nowadays. For instance, My Yahoo! provides a personalized "space" for each user. It automatically generates personalized content (e.g., information on the horoscope for the correct star sign) matched with users' profiles (e.g., a person's date of birth). Apart from automatic personalization, it also presents the users with an array of choices and allows the users to select what is of interest to them. The users can personalize not only the content (e.g., weather, finance) but also the layout (e.g., color, background). My Yahoo! was considered to be one of the forerunners among the growing number of personalized Web sites that have been springing up on the Internet over the last few years (Manber, Patel, & Robison, 2000). Amazon.com greets returning customers with a personalized message and offers a hyperlink to book recommendations congruent with their past purchases. These recommendations are generated based on the customers' previous purchases and the preferences of like-minded people, and there is no extra work imposed on the customers. Amazon continues to establish its personalization system, and more filtering mechanisms are being added to make the book recommendations be more relevant and useful. Recently, there has been the introduction of a personalized search engine, A9.com by Amazon.com, which recommends relevant Web sites to each individual by analyzing his or her browsing history and bookmarks. Expedia.com asks users for their desired destinations and then e-mails them information about special discounts to the place where they like to travel. It is expected that corporate investment in personalization technologies will continue to surge in the future (Awad & Krishnan, 2006; Poulin, Montreuil, & Martel, 2006; Rust & Lemon, 2001).

Given the proliferation of personalization, this chapter will address the key issues related to personalization and provide definitions to some keywords, such as rule-based personalization and collaborative filtering.

BACKGROUND

Definition of Personalization

Personalization is one of the rapidly emerging technologies in the field of information systems (IS) and is drawing increasing attention in academia (Adomavicius & Tuzhilin, 2005). Due to its fast emergence, there is still no globally agreed definition from researchers and practitioners as to what personalization actually is. Here are some of the representative ones:

- Wikipedia defines personalization to be a means of changing Web pages based on the interests of an individual. Personalization implies that the changes are based on implicit data, such as items purchased or pages viewed.
- As defined by Personalization Consortium in 2003, personalization is "the use of technology and customer information to tailor electronic commerce interactions between a business and each individual customer."
- According to Bitpipe,[2] personalization is a process of creating a means of communication (Web site, letter, etc.) that is specific to your readers in order to improve customer relationships and loyalty.

Generally speaking, we agree with the previous definitions. In this chapter we would reference personalization to be a process of matching products, services, and advertising content with each individual. The matching process is

based on what an online merchant knows about a user. With this knowledge, online merchants construct a user profile, which defines users' preferences and their interaction behaviors. Personalization technologies can be applied not only on e-commerce, but also mobile commerce or other business channels in the hope of generating more business opportunities.

The technology enabler is generally referred to as a *personalization agent*, which is a collection of software modules that provides tools to collect and analyze user data and adapt the content to Web users' objectives and facilitate their navigation or buying process (Cingil, Dogac, & Azgin, 2000). This is accomplished by deploying pattern recognition software to collect and analyze Web semantics, navigation activities, and purchase transactions of the individuals. Then, content and presentation format is adapted for each individual. Examples of software modules include customer relationship management, data mining, collaborative technology, and clickstream analysis components. With the help of personalization agents, online merchants can now exert control and manipulate content-related parameters at a very fine level not previously possible. In this way, they can ensure the right person receives the right content in the right format at the right time.

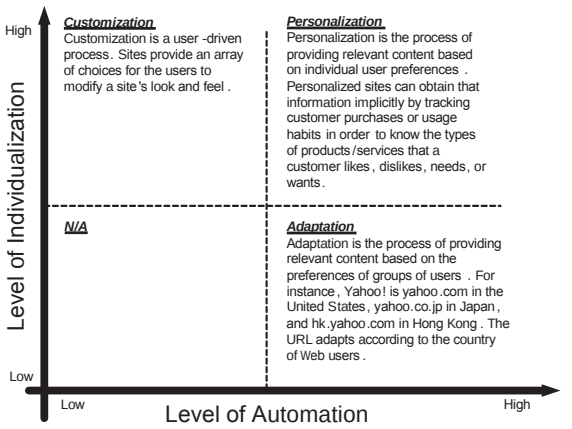
Adaptation, Customization, and Personalization

When researchers and practitioners start a project on personalization, they might ask whether the terms, *adaptation*, *customization,* and *personalization*, are interchangeable. So far, there are few studies that clearly distinguish these three terms. We modify the definition by Ho (2006) and distinguish these terms with two dimensions: level of automation and level of individualization. Level of automation refers to user control in the process of generating recommendations. The two ends are user-driven and machine-driven. Level of individualization refers to the degree of differentiation of recommendations from one person to another person. Some recommendations are offered for a group of people, whereas some are tailored for each individual.

Customization focuses on direct user control. In this user-controlled process, the user is given a set of options, and he or she chooses specific interests on a checklist so that the site can display the requested information. In some sophisticated settings, based on these user preferences, the merchant's system recommends additional products to the user. This technique is fairly complicated because the merchant has to map among different product categories in advance.

Adaptation is driven by intelligent software programs, and a group of users receives the same outcome of adaptation. For instance, a global brand differentiates itself in each market segment by the domain name. For example, Yahoo is yahoo.com in the United States, and yahoo.co.jp in Japan. Each regional portal provides local news and weather reports relevant to the local users.

Figure 1. Taxonomy of customer relationship management systems for e-commerce



Personalization is driven by the software package. The online merchants extract, combine, and integrate data taken from multiple sources before personalization becomes operational. Then personalization software packages mine a Web site's data and attempt to serve up individualized pages to the user based on a model of that user's preferences. By definition, personalization will generate different recommendations to different individuals.

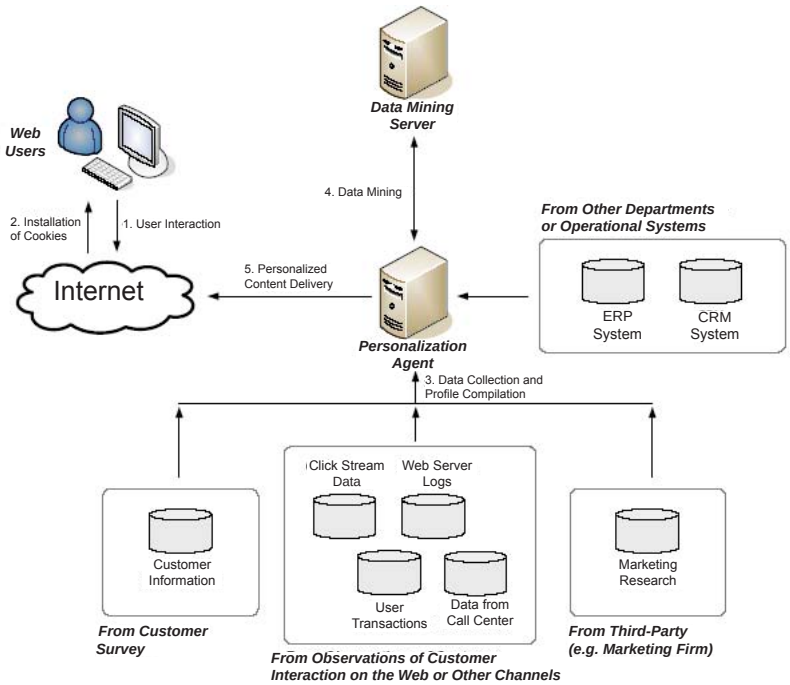
Figure 1 presents a summary of these three terms. Nowadays, these technologies are powerful tools in the battle for customer loyalty.

Personalization Process

Figure 2 shows the process to operate personalization. It also specifies the data and the machine components to support the process. The five key steps are:

1. **User Interaction:** Web users interact with the Web site and gradually provide information that profiles them in terms of browsing habits and product needs. In many cases, the site requests the users to fill out a survey stating their preferences.
2. **Installation of Cookies:** A cookie is a set of small text files stored on users' hard drives, and it is usually installed without the users' consent when the users first visit a Web server (Goldsborough, 2005). When the users revisit the site and request a page from that Web server, the cookie sends a message to that server. In this way, online merchants can identify each user.

Figure 2. Procedures of personalization process



A cookie allows the merchants to implement a simple personalization strategy, such as name greeting.

3. **Data Collection and Profile Compilation:** The processes of extracting, transforming, and loading are activated. Online merchants extract data from various sources to compile a user profile.

   a. User Surveys. Questionnaires and interviews are used to solicit information directly from the users. General information, such as user demographics, is collected. With a well-designed survey instrument, the data is easy to analyze (Ho, 2005).

   b. Observations. Server logs provide descriptive statistics on the page popularity, and user transactions are important indicators of what users are actually interested in. Richer data include clickstream data, which refers to lines of code stored in a file every time a user views a page. Possible measurements include the pages they browse, how long they navigate on each page, the products explored and bought. Clickstream analysis makes it possible for an online merchant to construct all users' browsing transitions. As a whole, observations provide more objective and reliable data than a user survey (Ho, 2005).

   c. Third-Party Data. Marketing firms, such as ACNielsen.com,[3] provide services to online merchants to help them research the market segment. The amount of data used and the kinds of data to be used are dependent on online merchants' constraints and their needs.

4. **Data Mining:** With a compiled profile, online merchants can use data mining techniques to analyze large volumes of data and discover subtle relationships between data items (Dobler, 2005). Patterns that accurately predict behaviors in users are identified (Eirinaki & Vazirgiannis, 2003). The prediction rules mined are sent to the personalization agent.
5. **Personalized Content Delivery:** After the production details and marketing strategies retrieved from other operational systems are integrated with the prediction rules, personalization agents can generate and deliver recommendations to the users.

Personalization Approaches

Once an online merchant knows a user's browsing habits and preferences, it would be useful if the merchant could predict what other products or services this user might enjoy. Much personalization work focuses on how to use existing data to infer if users are interested in other products or services.

This refers to step 4 in the previous section. This prediction is based on special formulas derived from behavioral science. The merchant usually does not ask the users; otherwise, this may impose an extra workload on the users and reduce their satisfaction. In the following sections, we introduce two typical approaches used in personalization.

Collaborative Filtering Personalization

Collaborative filtering systems usually take two steps: First, it keeps track of users' behaviors and transactions across the Web. The software interprets their preferences by comparing the information about a user's behavior against data gathered about other users with similar behaviors. Second, it finds the closest peers for each user, that is, people with the most similar preferences, and uses the ratings from those like-minded users found in the previous step to calculate a prediction for this user. A typical example is the feature "customers who bought this book also bought …" provided by Amazon.com. Currently, many personalization systems are based on collaborative filtering. One of these commercial systems is Firefly, which is now embedded in Microsoft's Passport System.

Rule-Based Personalization

The merchants ask users a series of predefined questions. Certain behavioral patterns are predicted using the collected information. For instance, an insurance company can use a rule, "If customer age is greater than 35 with annual income greater than $200,000, then we should ask this customer to buy a premium insurance package." Users are divided into segments based on business rules that generate certain types of information from a user's profile. One of the popular commercial products is BroadVision,[4] which invites users to fill out a questionnaire to determine the type of product or service they like. A user profile is formed based on the questionnaire result and stored in the database by user segment (e.g., age and income). The decision to give personalized information is based on these business rules.

IS PERSONALIZATION EFFECTIVE?

Debates on the Effectiveness of Personalization

Online merchants adopt personalization technology in the hope of better communicating with their users and generating more business opportunities. Nowadays, while personalization technology has become a crucial component of relationship management solutions, our understanding of the effectiveness of personalization is far from conclusive.

Advocates of personalization claim that personalization agents have changed the Web into a personal communication medium. By providing individualized content, offerings, and services, personalization helps to control aimless surfing activity (Hanson & Crayne, 2005; Light & Maybury, 2002; Loia, Pedcrycz, Senatore, & Sessa, 2006; Shahabi & Banaei-Kashani, 2003) and to facilitate business-to-consumer interaction (Ardissono, Goy, Petrone, & Segnan, 2002; Tam & Ho, 2005). Also, personalizing Web content empowers merchants to deliver customer value and to achieve profitable growth (Greer & Murtaza, 2003). It was reported that e-commerce sites using personalization technology have seen annual revenue increases of up to 52% (Parkes, 2001).

On the other hand, there remains skepticism on the prospects of personalization. On the side of consumers, a report by Jupiter Research (2003) indicated that only 14% think that personalized offers or recommendations on shopping Web sites lead them to purchase more frequently. Nunes and Kambil (2001) conducted a survey and found that half of the online users of various e-commerce Web sites would rather customize a Web site themselves than have it automatically personalized for them. On the side of online merchants, Festa (2003) remarked that online merchants seeking to personalize their Web sites in the hope of boosting online sales are not getting the expected payback. It costs about four times as much to personalize a Web site than to run a comparable adaptive site. Nielsen (1998) also had the criticism that most badly-designed Web sites were incorporated with personalization agents in the hope of smoothing user navigation. However, this was unnecessary, and a redesign of information architecture of the Web site could solve the problem equally well.

Gaps in Personalization Research

Why are there conflicting findings in personalization research? We identify three reasons which lead to these inconsistencies. First, most studies on personalization focus on one single system, and these systems use various strategies to personalize the users and are applied in different contexts. Their users have different needs, interests, knowledge, goals, and working tasks. This greatly reduces the ability to generalize their findings. For instance, Manber et al. (2000) intensively studied the personalization functions in My Yahoo!. The users are provided with a choice collection and customize the content and the layout of their individual site on their own. Also, they use My Yahoo! for different proposes. Some may look for specific information, whereas some may just randomly browse to kill time. Their paper highlighted the strength of information architecture and user-friendly functions of this system. However, they did not provide any empirical evidence showing the user

evaluation on My Yahoo! In a study by Smyth and Cotter (2000), a personalization system, which tailored television listings service for real users, was examined. Rather than user-driven customization, their personalization engine integrated collaborative filtering and content-based filtering to generate a personalized list and *predict* what the users want. The users browse the personalized list for television program recommendations.

Second, these studies use a variety of tasks and measurements to justify the effectiveness of personalization. For instance, in the study by Smyth and Cotter (2000), subjects were not required to perform any specific tasks, and they were asked to write down their perception of the personalization system in terms of content precision, ease of use, and speed of service. Though the evaluation of each quality variable was high and they argued that the personalization system attracted more than 20,000 registered users one year after launch, this might not be a good indicator of its success. A better judgment of a user's interest in the personalized program is whether the user actually watches the program. Besides, Te'eni and Feldman (2001) conducted a study on how an adaptive Web facilitates the searching process in a decision-making context. Performance and user satisfaction were used as the dependent variables. When working with an adaptive Web site, subjects were found to have better performance, but less user satisfaction because of the interface inconsistencies. In their study, the Web site provided content personalization, but at the same time, degraded layout personalization. A better approach is to personalize content, but minimize the change of layout (i.e., fix the layout personalization variable). This may come up with different findings from theirs. The study by Festa (2003) focused on advice-giving personalization systems and evaluated the revenue-generating variables to evaluate personalization systems, but ignored user satisfaction, loyalty, and shopping decision performance.

Last, personalization research lacks any adequately developed theoretical basis. Researchers do not have a common ground for developing hypotheses and interpreting results, and hence, the lack of underlying theory leads to the current state of inconclusive results in the IS literature. The current trend in personalization research is on the information architecture and technical implementation of the systems (e.g., Cingil et al., 2000; Desouza, 2003; Eirinaki & Vazirgiannis, 2003) and case analysis of individual system performance (e.g., Manber et al., 2000; Perkowitz & Etzioni, 2000). Researchers put little effort to build relatedness among studies. To improve this situation, researchers can achieve an acceptable level of understanding of personalization and ultimately formulate an underlying theory by first building a framework that defines the boundary for research to be conducted.

FUTURE TRENDS

Although most examples in this chapter are based on e-commerce, we believe that personalization is also useful in other communication channels, such as mobile commerce. Further research can be conducted to improve the process of personalization. Attempts by researchers and practitioners can be made to use artificial intelligence to match the product with users' needs. For instance, users have different preferences at different times and contexts, and thus it is difficult for personalization to be perfect all of the time. User context is an important factor in a personalization model. Additional variables, such as personality traits, can also be incorporated into the model to increase prediction accuracy. Metrics should be developed to measure the impact of personalization.

In order to generate personalized recommendations highly matched with users' preferences, online merchants have to collect much information from users. If the data collection is without users' knowledge or consent, then this raises ethical and legal concerns, such as invasion of privacy issues (Awad & Krishnan, 2006). In the future, research efforts could be spent on developing permission-based personalization tools. With these, online merchants and users can control how much information is given from the users to the merchants for personalization.

CONCLUSION

This article describes the concept of personalization, particularly the personalization process and its major components. We also provide explanations to address one of the most controversial topics in personalization—the effectiveness of personalization. Currently, personalization is still considered to be a costly and highly sophisticated technology, which requires knowledge of human behavior, statistical techniques, and marketing strategies. With advances in technologies and development of good metrics to measure its impact, we believe better personalization solutions will emerge in the near future.

KEY TERMS

Adaptation: It is the process of providing relevant content based on the preferences of groups of users.

Collaborative Filtering: It is a process to keep track of users' behaviors and transactions across the Web, and finds the closest peers for each user. Recommendations are made based on the behaviors of the closest peers.

Customization: It is a user-driven process, and Web sites provide an array of choices for the users to modify a Web site's look and feel.

Data Mining: It is a process to use statistical techniques to analyze large volumes of data and discover subtle relationships between data items.

Personalization: It is the process of providing relevant content based on individual user preferences. The objective is to ensure the right person receives the right content in the right format at the right time.

Personalization Agent: It is the technology enabler for personalization, and it is a collection of software modules that provides tools to collect and analyze user data and adapt the content to Web users' objectives.

Rule-Based Personalization: Users are asked a series of predefined questions and the answers are divided into segments. Recommendations are given based on the business rules.

User Profile: It defines users' preferences and their interaction behaviors on a Web site.

Perspectives of Transnational Education

Iwona Miliszewska
Victoria University, Australia

INTRODUCTION

In recent years, a particular stream of distance education called *transnational education* has become widespread (Davis, Olson, & Bohm, 2000; van der Vende, 2003). Transnational education, often referred to as offshore education, describes all programs in which the learners are located in a country different from the one where the awarding institution is based. This article discusses various aspects of transnational education. It reviews the definition of transnational education, its typology, growth, factors determining demand and supply, and characteristics of typical programs. The article concludes with a discussion on the role that face-to-face interaction plays in transnational programs.

BACKGROUND

Reviewing recent studies of transnational education reveals that there is little agreement about what to include in this category. Similarly, there is no agreement on the various subdefinitions that inform the subject. For the purpose of this article, a working definition of transnational education produced by UNESCO and the Council of Europe for their Code of Practice in the Provision of Transnational Education was used (UNESCO & Council of Europe, 2001). This states that transnational education includes:

All types of higher education study programme, or sets of courses of study, or educational services (including those of distance education) in which the learners are located in a country different from the one where the awarding institution is based. Such programmes may belong to the educational system of a State different from the State in which it operates, or may operate independently of any national system. (UNESCO & Council of Europe, 2001)

This definition includes education that is provided by collaborative arrangements, such as franchising, twinning, joint degrees where study programs are provided in collaboration with a partner institution, as well as noncollaborative arrangements such as branch campuses, offshore institutions, and corporate universities.

The Australian Department of Education Science and Training (DEST, 2005) provides a definition of *Australian Transnational Education*; this definition includes two additional requirements:

1. That the transnational program be delivered or assessed by an accredited Australian provider; and
2. That the delivery include a face-to-face component.

It further stresses that, in contrast to distance education provided in purely distance mode, transnational education includes a physical presence of instructors offshore, either directly by the Australian provider, or indirectly through a formal agreement with a local institution (DEST, 2005).

Transnational Education: Perspectives and Characteristics

There are a great number of different relationships between different types of transnational education providers, delivery mechanisms, and programs/awards. Charting these types is a difficult task, as the constantly evolving, highly complex situation includes an array of partnerships, consortia, articulation agreements, modes of delivery, public, private, off-shore, for-profit and corporate elements. Various models of teaching can also be found, ranging from full program delivery at an offshore campus, combined face-to-face and flexible delivery option, and e-learning (Goodfellow, Lea, Gonzales, & Mason, 2001).

Typology of Transnational Education

Transnational education is constantly evolving. Wilson and Vlãsceanu (2000) distinguished between three interrelated perspectives of this evolution adding that:

all these new developments in higher education share certain common characteristics and similarities, mainly in terms of the ways they cross the borders of national higher education systems. It is for this reason that they are usually identified by the generic phrase of transnational education. (Wilson & Vlãsceanu, 2000, p. 75)

The first perspective relates to the delivery mechanisms and arrangements including franchising, corporate universities, international institutions, distance learning, and virtual universities (Machado dos Santos, 2002). Wilson and Vlãsceanu (2000) noted:

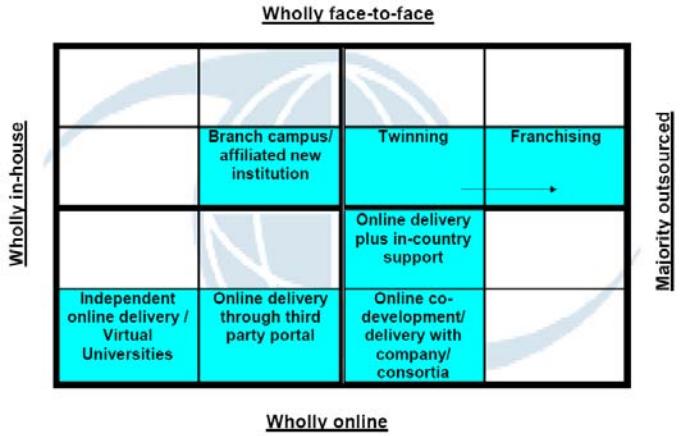
One form of development refers to a modality of delivering an educational programme (i.e., distance education), others to ways of establishing a programme/institution (i.e., franchising or twinning/branch campus), and others again to ways of offering primarily continuing education to certain new groups of students. There seems to be no limit to the proliferation of such modalities or arrangements, as long as the demand for higher education is still growing, and the possibilities for a global market continue to emerge. (Wilson & Vlãsceanu, 2000, p. 78)

The second perspective relates to the institutional and organisational arrangements that result from the adopted delivery mechanisms. This can be either a new institution, a branch, or a franchised program or course of study offering an award within an existing institution or other organisation. The third perspective refers to the nature and quality of qualifications awarded through transnational education, for example, degrees, certificates, or study credits (Wilson & Vlãsceanu, 2002).

Following on Wilson and Vlãsceanu's (2002) categorisation of transnational programs according to their delivery mechanism, Adam (2001) and Vignoli (2004) have described the most common forms of such programs as follows:

- **"Franchising:** The process whereby a higher education institution (franchiser) from a certain country grants another institution (franchisee) in another country the right to provide the franchiser's programmes/qualifications in the franchisee's host country, irrespective of the students' provenance; in many cases, the franchisee only provides the first part of the educational programme, which can be recognised as partial credits toward a qualification at the franchiser's in the context of a *programme articulation*.
- **Programme articulations:** Inter-institutional arrangements whereby two or more institutions agree to define jointly a study programme in terms of study credits and credit transfer, so that students pursuing their studies in one institution have their credits recognised by the other in order to continue their studies (*twinning programmes, articulation agreements*, etc.). These may—or may not—lead to joint or double degrees.
- **Branch campus:** A campus established by a higher education institution from one country in another country (host country) to offer its own educational programmes/qualifications, irrespective of the students' provenance; the arrangement is similar to franchising, but the franchisee is a campus of the franchiser.
- **Off-shore institution:** An autonomous institution established in a host country but said to belong, in terms of its organisation and educational contents, to the education system of some other country, without (necessarily) having a campus in the mother country.
- **Corporate universities:** They are usually parts of big transnational corporations and organise their own higher education institutions or study programmes offering qualifications that do not belong to any national system of higher education.
- **International institutions:** Institutions offering so-called *international* programmes/qualifications that are not part of a specific education system.
- **Distance learning arrangements and virtual universities:** Where the learner is provided with course material via post or Web-based solutions, and self-administers the learning process at home; the only contact with the student is by remote means." (Vignoli, 2004, p. 2)

Figure 1. Types of transnational provision (as presented in Bjarnason, 2005)



Bjarnason (2005) further qualified the various types of transnational education programs according to two scales. One scale indicated the extent of online reliance of a program and ranged from *wholly face-to-face* to *wholly online*; the other indicated the extent of institutional involvement in program development and delivery, ranging from *wholly in-house* to *majority outsource*. Figure 1 presents placement of transnational programs according to the two scales.

Davis, Olsen, and Böhm (2000) suggested a typology for Australian transnational education programs in which they separate the provider dimension from the student dimension. The provider dimension of the model spans a range where the increasing responsibility of the partner institution varies across academic teaching, assessment, and support; curriculum; provision of study location; student support; financial administration; and marketing and promotion. The student dimension includes various modes of delivery from fully face-to-face through supported distance and independent distance to fully online. The two-dimensional model is presented in Figure 2.

According to Davis et al. (2000), this two-dimensional model offers several advantages. First, it gives the ability to examine transnational programs without having to draw distinction between the student perspective and the provider perspective. Second, it separates the characteristics that describe business models from those that describe teaching and learning models. And finally, it enables the examination of the relationship between the transnational program provider and its partner institution.

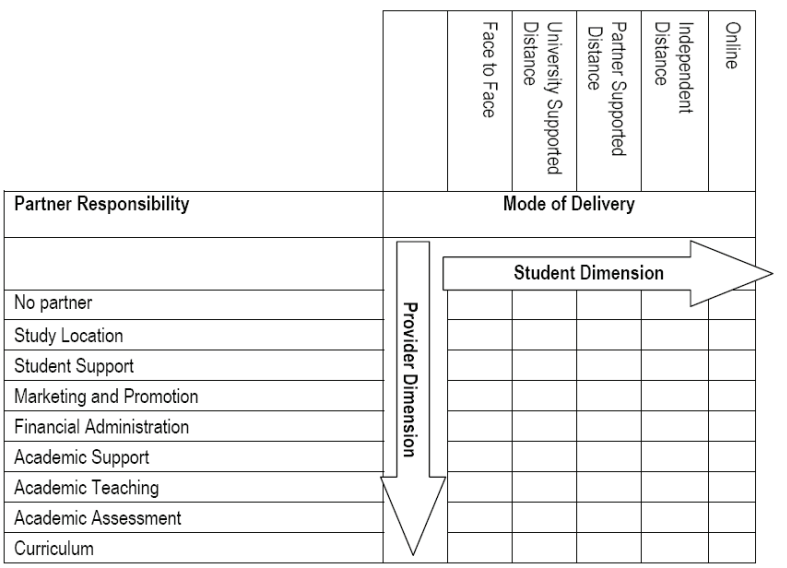
Factors Determining the Demand for and Supply of Transnational Education

The changing nature of demand and supply in transnational tertiary education that has emerged since the late 1990s has been described as the "business of borderless education" (Cunningham et al., 2000). The demand varies between countries, whereby countries with more rigid education systems tend to attract more transnational providers. Here, it often acts as a significant access route to higher education and the acquisition of internationally recognised qualifications (although not necessarily nationally recognised ones). According to Adam (2001), the main determinants of demand include: cost of the program; brand name of the provider and product; value-added from the program; reputation, quality and perceptions of the program; the national/international recognition of the program; the convenience and nature of delivery; and, the level of competition (dissatisfaction/failings of traditional education provision). These determinants can be further separated into *pull factors* that attract students to imported education and *push factors* that repel students from home provision.

According to Marginson (2004) demand for transnational, or *cross-border*, tertiary education in Asia-Pacific is driven by three factors: (1) insufficient supply of places in local universities, (2) globalisation of work force, and (3) potential status and mobility associated with and acquisition of a foreign degree.

Demand is driven by three factors. First, in many nations there are insufficient places in reputable degree-granting institutions at home. Second, there are expanding opportu-

Figure 2. Two-dimensional model of offshore provision (as presented in Davis et al., 2000, p. 41)



nities for globally mobile labour in fields such as business services, ICTs and scientific research. Education in the USA or another English-language nation provides favourable positioning in global labour markets. Third, graduates can use foreign degrees to secure status and mobility benefits. They enhance employment potential at home and abroad, and may open the way to migration to the nation of education or elsewhere. (Marginson, 2004, p. 85)

Research reveals three main determinants of the supply of transnational education: costs of production of programs (that decrease with increasing scale); the nature of the national market; and, the existence of legal regulation and controls (Marginson, 2002). According to Knight (2004), much of the impetus for transnational education comes directly from the need to raise income by both traditional and *for profit* education providers–the former are increasingly seeking new ways to increase their funding. The supply of transnational education provision is also encouraged by the increasing technical ease of delivery through the use of the Internet and other technologies.

Typical Transnational Program: Operational Characteristics

According to the Confederation of European Union Rectors' Conferences (2001) report, transnational education in Europe is largely confined to business subjects (especially MBAs), information technology, computer science and the teaching of widely spoken languages, for example, English, Spanish, and German. A typical transnational program offered by Australian universities is also in the field of the study of business, information technology, and education (Davis et al., 2000; Welch, 2002); in the past few years, health has emerged as a popular field of study for transnational students (AVCC, 2005).

Davis et al. (Davis et al., 2000), having conducted a survey of Australia's offshore programs, provide a list of further characteristics of a typical Australian transnational education program. Such a program is offered in Hong Kong, Malaysia or Singapore; these countries host the largest number of Australian transnational programs, as evidenced in Table 1; they also provide the largest number of transnational students, as evidenced in Table 2; together, these markets account for 65% of students in Australian transnational programs.

Table 1. Current offshore programs of Australian universities (by year of first intake), pre-2000–2003 (AVCC, 2005, p. 11)

COUNTRY	Pre - 2000	2000	2001	2002	2003	Total
China	98	30	22	24	24	**200**
Hong Kong	154	21	26	23	16	**227**
Indonesia	15	3	2	1	3	**25**
Malaysia	174	59	28	24	29	**321**
Singapore	194	43	30	58	53	**375**
Other	260	62	39	43	18	**421**
TOTAL	895	218	147	173	143	1,569

Table 2. International students: Top 5 markets by detailed transnational mode (IDP Education Australia, 2004, p. 12)

Rank	Distance online	Number	Growth	Offshore on-campus	Number	Growth
1	Malaysia	3,846	-29%	Singapore	19,986	3%
2	Singapore	2,952	-16%	Hong Kong	9,351	-17%
3	Hong Kong	1,952	-25%	Malaysia	8,126	17%
4	China	1,867	23%	China	5,472	18%
5	Canada	807	-15%	Vietnam	955	47%
	Total	16,053	-15%	Total	41,162	1%

A typical Australian transnational education program involves full-time attendance and, in terms of delivery mode, relies on face-to-face teaching or supported distance education; involves a partner which is a private education institution or public education institution; and, awards an Australian qualification (Davis et al., 2000). Recent statistics, presented in Table 2, confirm the prevalence of transnational programs that rely on face-to-face interaction and, with the exception of the Hong Kong market, their increasing growth; the figures also indicate a decline, with the exception of China, in the demand for online programs. Overall, in 2004 the number of distance online students declined by 15% on semester two, 2003, while there was a 1% growth in on-campus students (IDP Education Australia, 2004).

In terms of responsibility, the Australian university is responsible for curriculum, teaching assessment, and quality assurance, and allocates to the offshore partner responsibility for provision of study location, marketing, promotion and financial administration. Although, on the whole, the Australian university is responsible for the quality assurance of the program, partner institutions, overseas governments, and international organisations also participate in this responsibility (IDP Education Australia, 2000).

The Importance of the Face-to-Face Component

Although many universities view online learning as an economic alternative to face-to-face teaching (Davis & Meares, 2001), online learning cannot be regarded as a suitable alternative in transnational settings (Emil, 2001). This view is also supported by Tomasic who claims that:

Electronic delivery of courses to off-shore destinations is unlikely to be seen as an acceptable substitute for face-to-face delivery, although greater use of electronic means to deliver parts of courses may be acceptable. (Tomasic, 2002, p. 11)

Fully-online provision of transnational programs raises many concerns regarding the learning experience, particularly about the extent of feedback and guidance that can be provided to students (Knipe, 2002). Debowski (2003) agrees that fully-online provision of offshore programs is generally perceived to be less effective than options including a face-to-face component. She emphasises the strong recognition of the value of (Australian) academics meeting and interacting with their offshore student population; such regular teaching input by these academics significantly enriches the transnational program (Debowski, 2003).

Another aspect of transnational education that benefits from face-to-face interactions is localisation of teaching. As Ziguras (2000) pointed out, the curriculum of a transnational program is usually standardised across several campuses, which may be located in different countries. While the curriculum is sometimes tailored to local conditions, the modifications are usually minimal; they may only involve assignment questions, for example. In such circumstances, teachers, through face-to-face interaction, can play an important role contextualising and interpreting the content of study materials to make it useful for their students.

The importance of the face-to-face communication and the need for localisation of transnational programs was also raised by Evans and Tregenza (2002) who examined a range of transnational programs offered in Hong Kong by Australian universities in collaboration with Hong Kong partner institutions. They concluded that Hong Kong students seek and expect face-to-face contact. These findings are supported by Miliszewska (2007) who reports on a recent study of the perceptions of transnational students in Hong Kong on fully-online provision of transnational programs. The study found that the students overwhelmingly opposed an online-based delivery model–the opposition ranged from 84% to 100%–and, instead, preferred a blended delivery format; they emphasized the importance of face-to-face interaction, and regarded the Internet as a useful, but only supplementary, means of support.

FUTURE TRENDS

Given the importance of face-to-face interaction and decreasing interest in transnational programs if provided fully online, the future belongs to programs that include face-to-face interaction facilitated largely by an offshore partner of the educational provider (Davis & Meares, 2001; Emil, 2001; Tomasic, 2002; Ziguras & Rizvi, 2001). Ziguras (2002) uses the term *joint delivery* to describe such programs:

Evidence internationally shows that fully on-line delivery is proving unpopular except in small niche programmes, due to the lack of face-to-face contact ... Perhaps the best approach, both in terms of mode of delivery and financial risk, is seen to be "joint delivery" with local, established partners, using on-line delivery in some form. (Ziguras, 2002)

The shift in perception of providing transnational education is also likely to continue. Already, the emphasis has moved from educational aid and promotion of international understanding to educational trade; the focus is on expanding access, and packaging and marketing higher education offshore (Leask, 2004; Marginson, 2004). De Vita and Case (2003, p. 384) further argue that transnational education in particular is a consequence of the marketisation of higher education and *the competitive rush for international students and their money*. This view is also supported by Feast and

Bretag who, commenting on the increasing financial motivation of transnational education programs, concluded:

Distasteful as it may be to the many educators working in transnational settings who are committed to genuine cross-cultural exchange, transnational education is a multi-million dollar 'business', motivated as much by profits as by teaching and learning objectives. (Feast & Bretag, 2005, p. 64)

CONCLUSION

The growth of the transnational education market is set to continue, particularly in South East Asia. It is estimated that the demand for transnational higher education in Asian countries (excluding China) will reach nearly 500,000 students by 2020 (GATE, 2000). In addition, a 2002 report by IDP Education Australia (2002) predicts that the demand for international education will increase four-fold from 1.8 million students in the year 2000 to 7.2 million students in 2025, and Hyam (2003) concludes that *by 2025 approximately half of all international students enrolled in Australian universities will be transnational* (p. 8). With rapid expansion of the transnational education market, more and more universities will join the ranks of transnational education providers, or expand their transnational education offerings (Leask, 2004).

Advances in technology, and the Internet in particular, have created new ways of delivering education, and fully-online provision of transnational programs has been viewed by many providers as an economic alternative to face-to-face teaching (Davis & Meares, 2001). However, it appears that despite earlier predictions that globally offered fully-online programs would dominate the transnational education market, Web-supported face-to-face delivery is likely to continue as a principal model of transnational tertiary education programs. As Ziguras and Rizvi (2001) pointed out:

Transnational education providers need to remember that the habitual ways of teaching and learning are resilient not because they are the most effective means of 'delivering information', but because of the richness of the learning relationship that are developed through ongoing face-to-face interaction. (Ziguras & Rizvi, 2001, p. 10)

KEY TERMS

Educational Program/Course: A set of units/subjects, which lead to an academic qualification, for example, a degree.

Franchise Programmes: Study units of one higher education institution adopted by and taught at another institution, although the students formally obtain their qualification from the originating institution.

Fully-Online Education: Mode of education with no traditional campus component and no face-to-face interaction. All interactions with study content, as well as staff and students is conducted online.

Joint Degree: A degree awarded by more than one higher education institution.

Offshore Provision: Offshore provision is the export of higher education programs from one country to another.

Transnational Education: All programs in which students are studying in a country other than the one in which the institution providing the program is located. Australian transnational education includes a mandatory face-to-face component.

Web-Supported Education: Mode of education in which online information is used to supplement traditional forms of delivery (face-to-face), and student participation online is optional.

INTRODUCTION

Throughout the history of computing, there has been a trend for the ratio of processing elements to people to increase, resulting in the creation and popularization of new usage paradigms. At the start of the modern computer age, many individual users shared a single mainframe in one central location. In the early 1980s, however, significant developments in microprocessor technologies ushered in the desktop era, resulting in a one-to-one correspondence between individual users and their computers. Computer resources were now intrinsically distributed. The growth of the internet allowed these resources to connect to each other. The *pervasive computing* paradigm is the next logical stage in this trend, resulting in the original computer-human ratio reversing, so that multiple computational devices are available to each individual user. In reality, this point was passed a number of years ago. Mobile phones, personal digital assistants (PDAs), portable music players, as well as numerous embedded devices that people now take for granted, has resulted in computing technologies being embedded into the fabric of everyday life. Thus, for the first time, the desire of computing resources being available on an anywhere, anytime basis is a realistic objective.

In addition to computing being available everywhere, *pervasive computing* has a second key element. This tenet states that user interaction with these universal computing elements should occur in as natural and intuitive a manner as possible. Thus, *pervasive computing* technology should be assimilated transparently into the user's natural environment.

Rather than deal with the entirety of this broad topic, the focus of this article is to provide an overview of the key developments on one particular technology which is essential to the realization of the *pervasive computing* vision: the *wireless sensor network*.

BACKGROUND

The original vision for *pervasive computing*, originally termed ubiquitous computing and frequently referred to as such, was articulated in 1988 by *Mark Weiser* (1952-1999), then of Xerox's *Palo Alto Research Center* (PARC) in California. The fundamental concept underlying his proposal was that a person's interactions with computers should be as natural and intuitive as possible. One important consequence of this is that interactions should not be localized to a desktop-style interface, but rather, should be embedded within everyday objects, thus facilitating access to computational resources when and where necessary. In essence, it is a fusion of the anytime, anywhere computing concept augmented with an inherent need for embedded and intelligent user interfaces. Weiser observed that the technologies which have the greatest impact are those that people do not regard as technology *per se*, but, rather, as an integral component of their environment. He used writing, perhaps the original precursor to the information technology revolution, to illustrate his concept (Weiser, 1991, p. 94).

Pervasive computing technologies should be seen as an extension of an individual's own capabilities, rather than an interface to a restricted set of predefined abilities. Instead of limiting people to a standard interface, *pervasive computing* envisages many different kinds of devices and interfaces for a myriad of tasks (Abowd, Mynatt, & Rodden, 2002). As an demonstration, *Weiser's* team at *PARC* developed three kinds of devices corresponding to the inch, the foot, and the yard scale, which they entitled tabs, pads, and boards, respectively. These devices were designed to emulate commonly used office objects like post-it notes, paper note books, and bulletin boards, while providing enhanced computational capacities tailored to the scale of the device in question, and portability where appropriate (Weiser, 1991, p. 103).

With the benefit of hindsight, it can be seen that *Weiser's* vision was ahead of its time. Early attempts to construct pro-

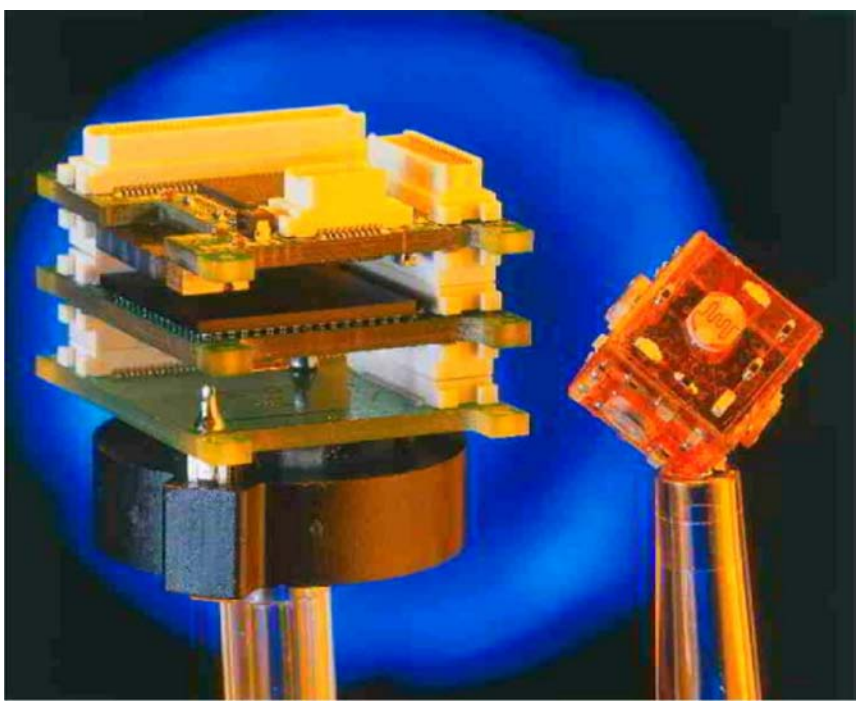
totype systems ran into constant technological hurdles, both in the hardware and software realms. Among the problems encountered were the non-existence of high-capacity wireless networks, display units which struggled to produce output of acceptable quality, a lack of software support for roaming *user contexts* (which had to be developed from scratch), and the absence of practical, easily deployable *sensor networks* to collect the prerequisite information necessary to determine the prevailing context for pervasive systems to adapt their services accordingly. Because of this, the initial focus of pervasive computing researchers was primarily addressed towards remedying the perceived technological deficiencies, rather than on design and usability issues. However, a cross-disciplinary approach is necessary to realize the full *pervasive computing* vision. Thus, research must continue in diverse areas such as Human Computer Interaction (HCI) and software development methodologies.

In the time since Weiser's paper, the parameters and goals of *pervasive computing* have become more clearly defined, so much so that it is already being incorporated into related research areas, such as ambient intelligence (AmI) (Raisinghani, Benoit, Ding, Gomez, Gupta, Gusila, Power, & Schmedding, 2004). With regard to the engineering and software design issues, *pervasive computing* can be seen as an extension of distributed systems and mobile computing (Satyanarayanan, 2001, p. 11). The *wireless sensor network* is a clear product of these areas, as well as energy-efficiency research, *sensor* miniaturization, and a widespread desire for better information gathering technologies. This article is concerned with the technical engineering and software design issues of WSNs, rather than any anthropocentric matters.

WIRELESS SENSOR NETWORKS

The study of *wireless sensor networks* (WSNs) started in earnest in the late 1990s (Pottie, 1998). It was only then that a practical combination of processing, communications, and sensing capabilities could be integrated into a single battery-powered miniature device (see Figure 1). Early research focused on creating networks of these devices, usually through automated, cooperative means initiated by the *sensor nodes* themselves (Intanagonwiwat, Govindan, & Estrin, 2000). Later, research expanded into network security, power management, ensuring adequate sensing coverage, distributed signal processing, and *sensor* fusion, querying and reprogramming nodes, and *sensor* localisztion. Although ongoing development unveils large-scale *sensor*

Figure 1. Examples of sensor nodes: 25mm and 10mm wireless sensor modules - courtesy of Tyndall National Institute, Cork, Ireland. Copyright 2006 Tyndall.



applications on military, industrial, environmental, and home tasks (Akyildiz, Su, Sankarasubramaniam, & Cayirci, 2002; Hill, 2003), the hardware generally available is tailored more towards research environments rather than being optimized for widespread deployment. Indeed, there are differing lines of thought on the direction which this development should follow; some advocate a reduction of *sensors* to near microscopic size (Pister, Kahn, & Boser, 1999), with reliability coming from redundancy, while others see a need for larger, more capable devices (Patra, Kot, & Panda, 2000). Realistically, both of these viewpoints must coexist to provide the continuum of devices needed to fulfil the constraints of the diverse pervasive applications foreseen by *Weiser*.

One example where *wireless sensor networks* have been integrated into a pervasive information system is at the Great Duck Island project (Mainwaring, Polastre, Szewczyk, Culler, & Anderson, 2002). *Sensors* were deployed to monitor environmental weather conditions (such as temperature and humidity) in a nature reserve where a population of cormorants were being studied. The network was designed so that the function of the *nodes* could be altered remotely after deployment. This was very important so that the researchers could avoid disturbing the wildlife. The data gathered from these *sensors* was made available both to PC users (through relational databases) and via a PDA interface, allowing field access to the scientists involved.

Context-Awareness and Adaptation

Contextual awareness and adaptation has been identified as one of the most important features of a *pervasive computing* application (Mattern, 2000). The most commonly cited example of a person's *context* is their actual physical location. When this is known, appropriate information can delivered to the person that is pertinent to their immediate location. A classic example is that of an electronic yellow pages service that sorts its entries according to their distance from the user. However, there are many other elements that can constitute a person's *context*, including those characterized as "when, what and why" (Abowd, et al., 2002, p. 52), as well as with whom, and so on. Without an effective and transparent ability to collect data for use in determining the salient aspects of a user's *context*, a *pervasive computing* application is significantly functionally restricted. While collection of *context* can occasionally occur in an implicit manner, in practice, a *sensor network* is essential for many applications. Traditional *sensor networks* usually have a centralized architecture, with the *sensors* wired to a central work station where all the processing takes place. However, the requirements of *pervasive computing* are such that a less obtrusive sensor network, one that employs wireless communication, is preferable in order to provide the necessary level of sampling density and ease of deployment that is not feasible with wired sensor networks.

POWER MANAGEMENT IN WIRELESS SENSOR NETWORKS

Pervasive computing systems consist of electronic components, many of which are mobile. *Power management* of such mobile systems, where reliable power is not guaranteed, is of great importance. The energy issue is addressed through either intelligently reducing power consumption or developing new energy sources (Want, Farkas, & Narayanaswami, 2005).

Energy scarcity is the single most crucial issue in WSN research at present. All other concerns are viewed within the context of energy consumption. At present, commercially available hardware operates for only days or weeks without any power *management*. While battery capacity is increasing, it is starting from a woefully inadequate level from the point of view of the long term deployment of pervasive systems. Two key strategies have been identified for tackling this problem – seeking alternative energy resources, and reducing power consumption, respectively.

Acquiring Energy From Environmental Sources

Acquiring energy from environmental sources, such as solar or vibrational energy, has potential (Roundy, Wright, & Rabaey, 2003). Unfortunately, these sources usually only generate tens/hundreds of microwatts per second, falling short of the power consumption of a typical *sensor node* by orders of magnitude. This necessitates the use of batteries as a supplementary (or often sole) power source. Because of their fixed energy capacity, relying on batteries limits the energy available to the *sensor node*, and hence, the operational lifetime. Because of this energy constraint, almost all WSN research has been framed by the trade-off between performance and operational lifetime.

Reducing Power Consumption

While creating more efficient hardware helps reduce the demand placed on a battery, the primary method for reducing power consumption is to activate a *sensor node's* components only when they are needed (Hill, 2003). This can extend as far as suspending the processor until an external stimulus reactivates it. The choice to activate/deactivate components (radio, sensors, etc.) is not difficult for a single *sensor* to evaluate. However, as part of a network, each element must also consider the effects of this choice on the operation of neighbouring nodes, and of the network as a whole. This requires coordination between *nodes* to ensure the network can continue operating at a sufficient level to provide the required quality of service demanded by the pervasive application. However, network-wide coordination is con-

sidered harmful in the majority of cases since the energy and bandwidth cost exceed the benefits gained by using a network-level optimal solution. This leads to the use of distributed algorithms and protocols which don not oblige the *sensor nodes* to know any more about the network than they can detect locally (so called "localized algorithms") (Qi, Kuruganti, & Xu, 2002, p. 286).

Because of the many competing factors involved in making a decision about whether to activate/deactivate a component, or indeed an entire *sensor node*, and the lack of system-wide information, *power management* methods profit from the use of intelligent decision making. One technology proposed to handle this is intelligent *agents* (Tynan, O'Hare, Marsh, & O'Kane, 2005; Fok, Roman, & Lu, 2005). *Agents* are independent, autonomous software entities capable of cooperative behavior. They can deliberate on the set of information they possess, and can act on this information in a way that will bring about their goals. Given the dual goals of reducing local power usage and preserving the operation of the surrounding area of the network, appropriately programmed *agents* can find the balance point that best satisfies these conditions.

The issue of *power management* covers many separate and often competing concerns. All *sensor nodes* have a radio, a CPU with memory, and a set of *sensors*. Other components, such as various actuators for influencing the environment of the pervasive application, may also be included. The radio is often the most power hungry component, so minimizing the time that the radio is active is often the first step in reducing battery depletion. Striking a balance between low radio usage and maintaining the communications capacity of the network is a much studied topic (Papadopoulos & McCann, 2004). If a node decides when it will deactivate its radio independently of other matters such as information generated by its *sensors*, it may not be able to communicate when most needed. Furthermore, if a *node* is deemed to be redundant for the purposes of preserving the network topology by its network control software, this does not mean it can be deactivated. Sensing coverage must also be sustained.

AUTONOMIC WIRELESS SENSOR NETWORKS

Since one of the primary goals of pervasive computing is to make the computer "disappear", *sensor networks* must be designed in such a way so as to require minimum human intervention. Self-management, encompassing self-configuration, self-optimization, self-healing, and self-protection (Kephart & Chess, 2003), are integral to the autonomous operation of this core component of a pervasive system. These standards could be applied to the rest of the system too, but since a *sensor network* is likely to have the greatest number of elements, each with a relatively high chance of failing, it is of particular importance in this part of the system. Most protocols for *WSNs* are self-configuring. Self-optimization is also attempted, though usually within the constraints of local knowledge. Self-healing, that is the ability of the network to overcome damage, is usually achieved by ensuring redundancy (deploying more than the minimum number of sensor nodes that are needed). These additional nodes can be activated when a subset of the network is lost, for instance through energy exhaustion. There are many protocols for networking (Cerpa, & Estrin, 2002; Hsin & Liu, 2004) and sensing coverage (Zhang & Hou, 2005; Wang, Xing, Zhang, Lu, Pless, & Gill, 2003) which exploit this mechanism. Self-healing can also be realized if there is a reserve of self-deploying mobile *nodes* available to replace any lost nodes. Self-protection, mainly dealing with security issues, has received much attention (Perrig, Szewczyk, Wen, Cullar, & Tygar, 2001), not least because *sensor networks* have potential as a military tool.

Mobility and Intelligence

Increasingly, personal computers and mobile devices in the form of portable telephones, personal digital assistants, and embedded microchips in cars, appliances, and other technical artefacts with which people interact everyday, are emerging as crucial enabling elements for *pervasive computing*. In order to make these devices useful, such mobile computers should be sufficiently smart to interact with each other effectively.

There are three forms of mobile intelligence which are relevant to *pervasive computing*. These are:

1. when an intelligent device is passively mobile, as in a mobile phone or PDA;
2. when a piece of software is capable of migrating from device to device in a network of some kind; and
3. when a device is independently mobile, for instance an autonomous unmanned aerial vehicle.

In all instances, *agents* provide a useful computational paradigm which offers intelligence and mobility (when they are migration-capable) in an integrated package. In the first case, the software can use information such as location, orientation, velocity, and so on, as inputs to location-reliant pervasive applications. It must have an idea of the objectives of the user, for example, to get to a train station by a certain time, and relies on the user to act on this information.

The second instance is especially useful for pervasive networks in general, and *sensor networks* in particular, because a mobile *agent* can travel around a network, deciding where to move to next based on the latest information in order to perform management functions or collect data.

This is in contrast to a client-server architecture, in which a reliable connection is required between the server and any other devices which must be controlled. The mobile *agent* method is more robust and has a lower latency (because the agent is located on or near the *nodes* with which it must interact), and so is better equipped to respond to events in the network.

In the third case, the software on the device has its own set of goals, and is capable of performing actions which will fulfill these goals. Wireless *sensor nodes*, once laid out in the environment, might be damaged by environmental factors or expire from energy depletion. Therefore, it is desirable to have *sensor nodes* that are geographically mobile in nature. These *nodes* can move to an area that has become impaired through *node* loss, thus supplementing the extant fixed *nodes*. Additionally, the *nodes* can move to areas where events of interest are occurring to boost the sensing quality there.

FUTURE TRENDS

Driven by the technological achievements on microelectronics, *pervasive computing* will remain a hot topic in the information industry. Future trends will likely deal with the following crucial problems so that *pervasive computing* can be truly ubiquitous. One of the most vital concerns is the management of billions of software entities with different purposes, deployed in multiple locations, and based on different platforms. A further problem is how to protect hosts and applications from malicious attacks. Security of *pervasive computing* will attract more and more attention with the explosion of the amount of information available via pervasive technologies and the increasing maliciousness of attacks. If the public's perception of ubiquitous services sours because of weak security measures, the wide-spread roll-out of *pervasive computing* systems could be delayed by many years, thus, robbing the world of a technology of great potential.

CONCLUSION

Wireless sensor networks will form an essential component of the embedded electronic infrastructure necessary to realize the *pervasive computing* vision. The successful realization of this vision is anticipated to result in significant economic benefits. More than this, however, is the potential of *WSNs* to provide a solid foundation for context-awareness, adaptivity, and personalization of services. In doing this, significant benefits will accrue to end users as a new era of dedicated services, which up until now could only be speculated about, will become embedded in the fabric of everyday life.

P

KEY TERMS

Actuator: In the context of sensor networks, any output device. Actuators allow a WSN node to influence its environment, providing a feedback channel through which its decisions can be enacted.

Agents: In this article, the word *agent* refers to software entities which are capable of displaying autonomous, cooperative, and flexible behavior directed towards achieving a set of internal goals. A group of agents which operate together is called a multi-agent system (MAS).

Context-Awareness: The property of a system that allows it to adjust its behavior based on physical environmental cues, such as location, or user presence or absence. This necessitates the use of sensor networks which can monitor the relevant properties of the environment.

Human Computer Interaction (HCI): The study of how people and computers interact, the effects of these interactions on both the users and the computers, and the design and testing of new user interfaces for the purpose of improving the computer's user-friendliness. HCI combines aspects of computer science, engineering, psychology, sociology, aesthetics, and ergonomics, as well as many other fields.

Pervasive Computing: Also known as ubiquitous computing, this is the study of how computing can be integrated into the environment in a way that makes it easily accessible to users. It includes an emphasis on ease and naturalness of use, and unobtrusiveness is paramount.

Sensor: In the context of sensor networks, any input device other than the communications transceiver, for example, a microphone or barometer. The sensors and transceiver produce a sensor node's input data, which is used to inform its actions.

Wireless Sensor Network: A network comprised of small, communication-enabled microcontrollers with an array of sensors and actuators which rely on batteries or ambient environmental energy for power. These components are often referred to as sensor nodes.

Physiologic Adaptation by Means of Antagonistic Dynamics

Juergen Perl
University of Mainz, Germany

INTRODUCTION

In particular in technical contexts, information systems and analysing techniques help a lot for gathering data and making information available. Regarding dynamic behavioral systems like athletes or teams in sports, however, the situation is difficult: data from training and competition do not give much information about current and future performance without an appropriate model of interaction and adaptation.

Physiologic adaptation is one major aspect of target-oriented behavior, in physical training as well as in mental learning. In a simplified way it can be described by a stimulus-response-model, where external stimuli change situation or status of an organism and so cause activities in order to adapt. This aspect can appear in quite different dimensions like individual biochemical adaptation that needs only milliseconds up to selection of the fittest of a species, which can last millions of years.

Well-known examples can be taken from learning processes or other mental work as well as from sport and exercising. Most of those examples are characterized by a phenomenon that we call antagonism: The input stimulus causes two contradicting responses, which control each other and – by balancing out – finally enable to reach a given target. For example, the move of a limb is controlled by antagonistic groups of muscles, and the result of a game is controlled by the efforts of competing teams.

In order to understand and eventually improve such adaptation, models are necessary that make the processes transparent and help for simulating dynamics like for example, the increase of heart rate as an reaction of speeding up in jogging. With such models it becomes possible not only to analyze past processes but also to predict and schedule indented future ones.

In the Background section, main aspects of modeling antagonistic adaptation systems are briefly discussed, which is followed by a more detailed description of the developed PerPot-model and a number of examples of application in the Main Focus section.

BACKGROUND

Undisturbed limited growth processes in biological systems often are asymptotic, oriented in specific target values. This behavior reflects adaptation to limited resources and delays caused by resource production and transport. Processes of this type theoretically can be modeled rather easily by means of exponential functions – for example, $f(t) = c - \exp(-s \times t/d)$, where c is the target value, s characterizes the deceleration, and d characterizes the delay (see Banister & Calvert, 1980; Banister, Calvert, Savage & Bach, 1975). In practice, however, situations are more complex (see Lames, 1996; Viru & Viru, 1993): The growth process normally is disturbed (stopped, restarted, reduced, intensified) by external effects; capacity limitations cause changes of the temporary process type (phase changes); buffers cause delays of the internal dynamics; seemingly constant parameters turn out to be time-depending. Therefore, often such processes cannot be modeled using continuous functions (e.g., as solutions of differential equations) but have to be calculated iteratively using discrete level-rate-equations, which only piecewise could be approximated by exponential functions.

Physiologic adaptation is a kind of limited biological growth and therefore can be modeled and simulated using such an iterative approach – as we have successfully done with load-performance-interaction and learning in sport. To this aim we developed an approach (PerPot: Performance Potential Metamodel, see Mester & Perl, 2000; Perl, 2002; Perl & Mester, 2001), the central idea of which is that of antagonism: A load input flow feeds in the same way two internal buffers – the strain potential and the response potential. These buffers are connected with a performance potential, the level of which is decreased by a negative strain flow and increased by a positive response flow. Both flows are delayed. The relations between the strain delay and the response delay characterize the interaction of load input and performance output. In case of training or learning the strain delay can be interpreted as fatigue delay, while response delay stands for the delay of recovery.

MAIN FOCUS OF THE CHAPTER

Applying such a model to a test person, after a short phase of calibration the delay parameters are known and the behavior of the test person can be analysed and simulated using PerPot. This approach has successfully been used for detecting striking features like contra-productive overtraining, doping abuse, or threatening collapses as results of overload. PerPot

can predict performance output depending on training or learning input and so can be used for scheduling optimal training or learning processes.

The PerPot Concept

The metamodel PerPot describes physiologic adaptation on an abstract level as an antagonistic process, as is shown in Figure 1. An input flow (which usually is called "load" rate) is feeding identically a strain potential as well as a response potential. From the response potential the performance potential is increased by a positive flow, while the strain potential reduces it by a negative flow. Additionally, there are the following two effects:

If the strain potential is filled over its upper limit, it produces an overflow, which acts on the performance potential as a reducing negative flow. In turn, the difference between the upper limit of the strain potential and its current level indicates how far the situation is from such a dangerous overflow. This difference is called the "reserve" of the system.

Finally, in order to model atrophy, the performance potential continuously looses substance. By mathematical reasons, this loss has to be fed back to the response potential to preserve the potential balance of the system (see Perl, 2003). (From the mathematical point of view, the load rate only plays the role of a pump, which moves the system potential around without violating this balance property.)

All flows show specific delays modelling the time that components need to react. Possible physiologic interpretations are production and transport of biochemical stuff on the micro-level or fatigue and recovery effects on the macrolevel.

Delays are model parameters the model behavior depends on in a quite characteristic way. For instance, the fitness of an athlete can be measured by the correlation of fatigue and recovery delays.

PerPot-Based Simulation and Analysis

Based on the model, a simulation tool has been developed, which in an iterative way calculates the model's behavior in order to follow individual and temporary profiles of load and delays. Basic simulations and analyses can be run using the PerPot-tool by just varying delay parameters and load profiles. As is shown in Figure 2, there are mainly three types of characteristic behavior, which normally are mixed up to a complex behavioral profile:

In the left graphic, the normal adaptation is shown, depending on the relation between the delays DR and DS: If DS is less than DR then the performance reducing strain comes faster then the performance increasing response, therefore causing the well-known super-compensation effect (see Clijsen, van de Linden, Welbergen & Boer, 1988; Friedrich & Moeller, 1999). In turn, if DS is greater than DR, the response effect comes first, causing increasing performance, which later is balanced out with increasing strain.

The graphic in the middle demonstrates how a switch on of load starts the performance development (like in the left graphic) and a switch off causes a characteristic decrease of development, which is a combination of recovery and atrophy.

The right graphic shows the effect of overload, which causes internal load overflow with collapsing reserve and performance (see Hartmann & Mester, 2000).

Figure 1. PerPot: Structure and parameters

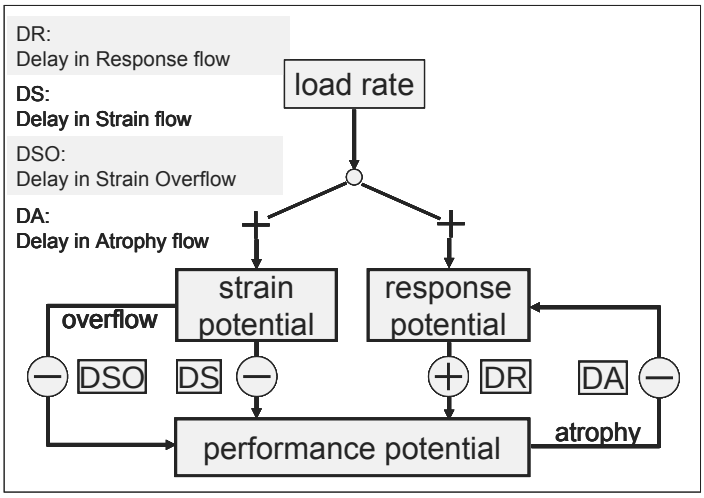

Figure 2. Characteristic types of PerPot behavior

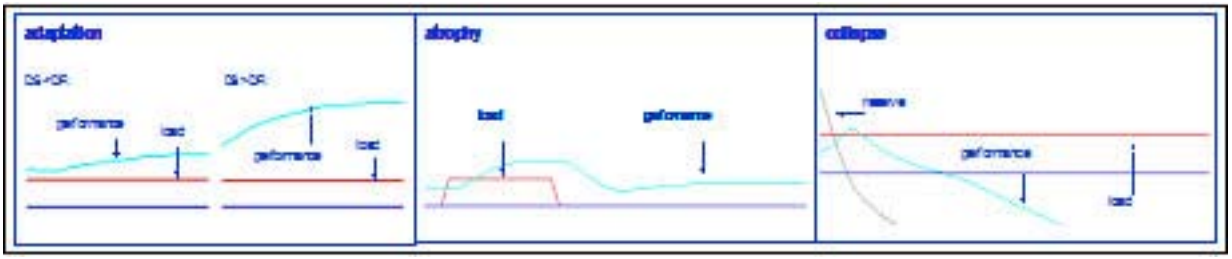

Figure 3. Precision of prediction depending on the load dynamics and/or the number of data used for delay calculation (violet dots on the bottom mark the interval of used data)

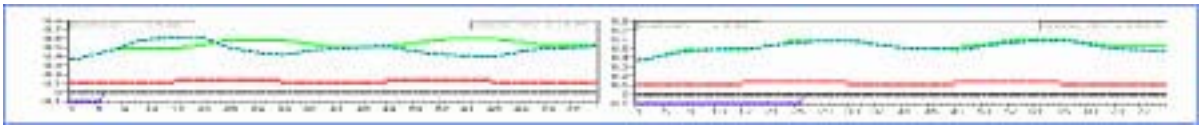


By means of the described simulation features, also future behavior of an adapting system can be predicted – if the respective load profile, as well as the delay time series is known for example, from a schedule.

PerPot-Based Prediction

In the simplest way, constant delay values can be deduced from the past load and performance profiles by calibration. Consequently it can be asked how many "current" data are necessary to calculate delay parameters, which not only allow for simulating the current but also the future performance values (see Ganter, Witte & Edelmann-Nusser, 2006; Perl, 2004; Perl, 2005).

In Figure 3 it is demonstrated that 5 data seem not to be sufficient for a proper prediction, while 25 data seem to fit rather well. The truth is that the typical dynamic changes, for example, from low to high and/or from high to low load, are necessary to give the model enough information about the characteristic adaptation behavior. Moreover, this method of prediction can be used for online adaptation, where every new pair of load and performance values can be used for adapting the delay values to the changing situation respectively to the changing status of the athlete.

One reason for a changing status of the athlete can be a decrease of condition and should influence the delay values. In turn, changing delay parameters can be indicators of effects like this. For example, a closer look to the right graphic of Figure 3 shows a significant deviation between original and simulated performance in the "far future" (rightmost area). One could think that prediction becomes worse the more the point in time is different from the available values. The truth is that the calculated mean delay values do not reflect the situation correctly, even if all values are used for delay calculation (marked by violet dots on the bottom line): Instead, stepwise online adaptation results in a nonconstant DS-profile which gives a rough idea of the tendency of decreasing shape.

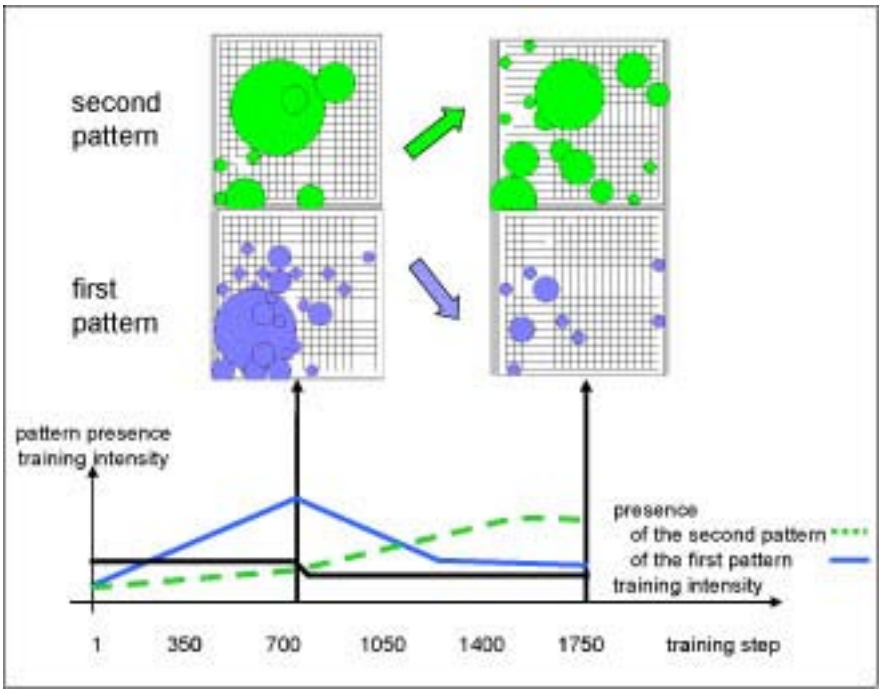
Example "Jogging": Online Speed Control

Load-performance-interaction can be analyzed by means of a special tool that was derived from PerPot (see Perl & Endler, 2006), where speed is taken as load input and heart rate is taken as performance output. Additional impact parameters are positive and negative slopes from the course profile, age and fitness of the athlete, and current position from the run. For example, the recovery delay DR will increase by fatigue, which depends on age and fitness as well as on the time already used on the run.

Based on this information, the optimal speed profile can be calculated given a heart rate profile as objective function, which can help for improving respectively saving the runner's performance and health.

In turn, the correspondence between speed and heart rate can be used for controlling the run just watching the heart rate – that is, optimizing the speed by matching the intended heart rate. This approach exemplarily was got to work successfully in a test, where the test person in the first hill marathon missed the scheduled time of three hours by only 10 minutes or 5.6% – using a heart rate meter as only control instrument.

Figure 4. Cooperative learning (left) vs. replacing learning (right)



Example "Learning": Dynamic Network Control

Because of its positive effect on configuring learning processes, PerPot has been used successfully for improving the functionality of neural networks of type Kohonen Feature Map (see Kohonen, 1995): Supporting every neuron with an individual PerPot, which controls the learning process of the neuron, results in a Dynamically Controlled Network (DyCoN, see Perl, 2002) that can learn continuously and can adapt its learning behavior dynamically to the flow of learning stimuli (see Memmert & Perl, 2006).

Not least, this approach enables for analysing and simulating types of learning processes like cooperative or replacing learning (see Perl & Weber, 2004), as is demonstrated in Figure 4. In the first phase the blue pattern, which contains a lot of information of the green one, is trained to the net. In the second phase the green pattern, which contains only few information of the blue one, is trained to the net. Even though the second training is done with rather low intensity, the green pattern quickly becomes dominant, while the blue one begins to fade out by atrophy.

Obviously, those effects remind on aspects of natural learning and therefore have been subject to respective investigations.

Example "Interaction": Feed Back Control in Games

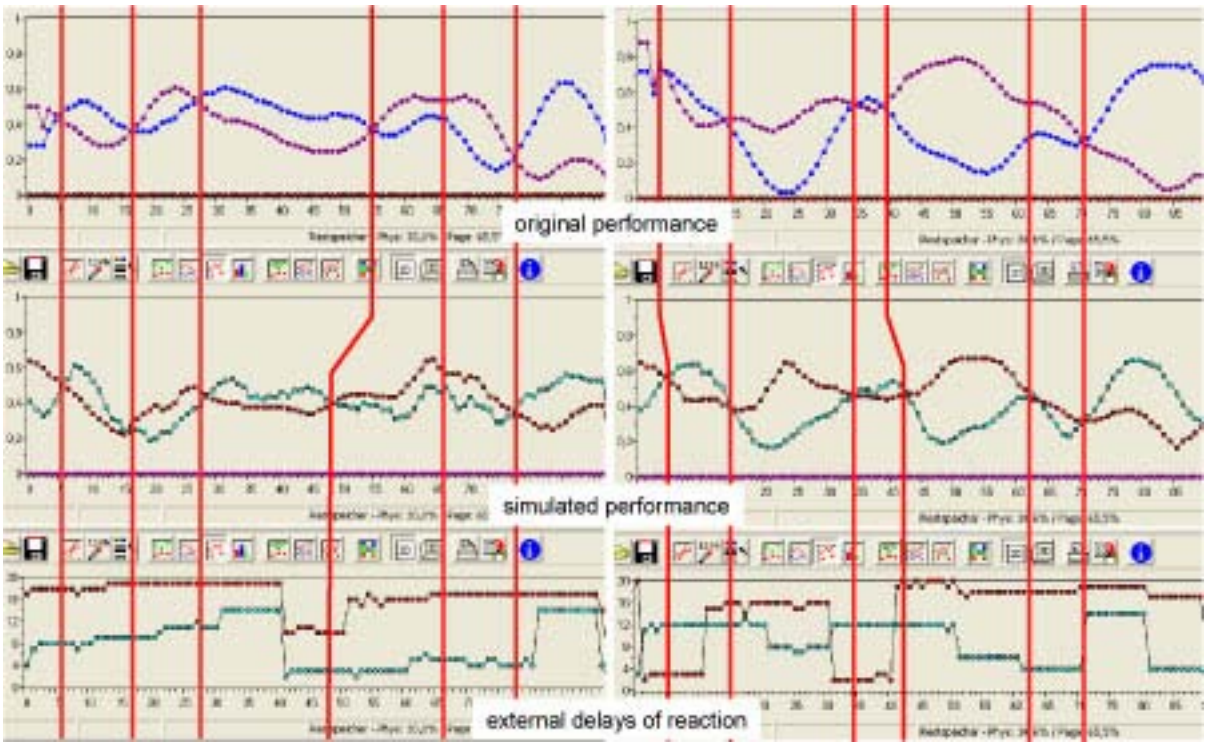
The dynamics of team behavior in games show rather inhomogeneous distributions of the levels of activity and effectiveness, where phases of great effort are followed by phases of reduced activities, which are used by the opponent team for increasing its pressure (see Lames, 2006).

Based on the interpretation that the subsequent effectiveness of the one team is a kind of performance, which in a delayed way is caused by the past and present pressure or load from the opponent team – that is, its activities and scoring – the game can be understood as a symmetric process of load-performance-interaction. Such symmetric feed-back-systems very often show an oscillating-circuit-behavior, where both components show oscillations that are in antiphase to each other. Therefore an approach has been used for modeling, where two exemplars of PerPot model the respective dynamics of each team, the interaction of which is controlled by team-specific delays of reaction (see Perl, 2006).

In Figure 5, two games of Germany haven been analyzed exemplarily:

In the first game against Denmark, the German team shows two long phases of large delay of reaction with respectively corresponding maxima of performance. In contrast, the Danish team shows smaller delays that cause comparably small fluctuations of performance.

Figure 5. Left: Germany (red) vs. Denmark (blue) (22 : 20). Right: Germany (blue) vs. Croatia (red) (23 : 23)



In the second game the Croatian team plays more or less the role of Germany from the first example: Large external delays cause comparably high performance. In contrast, the German team shows smaller delay values, which however are not as small as those of Denmark. The result is a German performance profile, which lies between those of Denmark and Croatia and the frequency of which is smaller than that of Denmark

The main question is whether there in general are significant differences between the profiles of reaction delays, which then could be used for classifying and predicting a team's tactical behavior in a game.

FUTURE TRENDS

As some of our advanced projects show, the presented approach can improve the understanding of delayed antagonistic reaction and interaction not only in sports but also in a wide range of "real-life"-processes like learning or weight-watching, where knowledge acquisition or weight-reduction are delayed antagonistic reactions to knowledge resp. food input. Last but not least first investigation has successfully been done in the field of rehabilitation, where the patient's state is characterized by a complex adaptation process the prediction of which could be improved if its antagonistic dynamics could be better understood and modeled.

CONCLUSION

Antagonistic dynamics makes a system's behavior complicate and difficult to predict. Simple mathematical approximation or stochastic analyses like crosscorrelation approaches cannot provide process-related interpretations and understanding and therefore fail in prediction.

There are two major fields of application of antagonistic adaptation analysis: From the theoretical point of view, complex system behavior can be analysed and understood in a more dynamic way, were the last two approaches dealing with learning and handball can be taken as examples for. From the practical point of view, predicting developed performance depending on given load profiles can improve training scheduling, exercising, and even leisure activities a lot. Model-based scheduling of adaptation processes so can improve efficiency and effectiveness of exercises and training processes and help for avoiding overload and critical situations.

In general, the experience from a lot of applications show that the developed approach can help for improving analysis as well as prediction of the behavior of antagonistic adaptation systems.

KEY TERMS

Adaptation: If the situation of a physiologic system is changed to a nonoptimal or unstable one – for example by external stimuli – the system tries to balancing out the disturbance by changing its state. This process is called adaptation.

Antagonism: Normally, in particular in technical systems, a target position or situation is reached by an asymptotic approach "from one side", where one-directional impulses with decreasing intensity control the adaptation process. In most physiologic (and also in some technical) systems the control is completed by a countercontrol, where the same input activates two contradicting activities, which are controlling each other.

Delay: Adaptation processes can be thought of as time-consuming (stepwise or continuous) changes of the system's state. This means that the reaction on a state disturbance does not takes place at once but shows a certain delay.

Strain Potential: If a load input stream is fed into an organism, it normally cannot be handled at once but is stored

in buffers (e.g.,, organs) for being processed after certain delays. The abstract model of the load buffer here is called strain potential.

Response Potential: The antagonistic counter-part of the strain potential here is called the response potential.

Performance Potential: The result of load input under antagonistic control is modeled by the performance potential, which indicates the current performance state of the modeled physiologic system.

PerPot: PerPot is a model of dynamic adaptation, where an input flow feeds an internal strain potential as well as an internal response potential, from which an output potential is fed by specifically delayed flows. Since the strain flow is negative and the response flow is positive, resulting in an oscillating stabilizing adaptation, the model is called antagonistic (see Perl, 2002).

Kohonen Feature Map (KFM): A KFM consists of a (normally: 2-dimensional) matrix of neurons, each of which can contain information. During a training phase, those neurons are fed with information, which then is learned and organized by means of training algorithms. In the productive or test phase the learned information can be used for attaching or classifying test input (see Kohonen, 1995).

DyCoN: A DyCoN is a KFM-type network, where each neuron contains an individual PerPot-based self-control of its learning behaviour. The DyCoN-concept enables for continuous learning and therefore supports continuous training and testing, training in phases and with generated data, online-adaptation during tests and analyses, and flexible adaptation to new information patterns (see Perl, 2002).

Policy Frameworks for Secure Electronic Business

Andreas Mitrakas
Ubizen, Belgium

INTRODUCTION

Terms conveyed by means of policy in electronic business have become a common way to express permissions and limitations in online transactions. Doctrine and standards have contributed to determining policy frameworks and making them mandatory in certain areas such as electronic signatures. A typical example of limitations conveyed through policy in electronic signatures includes certificate policies that Certification Authorities (CAs) typically make available to subscribers and relying parties. Trade partners might also use policies to convey limitations to the way electronic signatures are accepted within specific business frameworks. Examples of transaction constraints might include limitations in roles undertaken to carry out an action in a given context, which can be introduced by means of attribute certificates. Relying parties might also use signature policies to denote the conditions for the validation and verification of electronic signatures they accept. Furthermore, signature policies might contain additional transaction-specific limitations in validating an electronic signature addressed to end users. Large-scale transactions that involve the processing of electronic signatures in a mass scale within diverse applications rely on policies to convey signature-related information and limitations in a transaction. As legally binding statements, policies are used to convey *trust* in electronic business. Extending further the use of policy in transaction environments can enhance security, legal safety, and transparency in a transaction. Additional improvements are required, however, in order to render applicable terms that are conveyed through policy and enforce them unambiguously in a transaction. The remainder of this article discusses common concepts of policies and certain applications thereof.

BACKGROUND

An early example of a transaction framework is open EDI (Electronic Data Interchange) that aims at using openly available structured data formats and is delivered over open networks. While the main goal of open EDI has been to enable short-term or *ad hoc* commercial transactions among organisations (Kalakota & Whinson, 1996), it has also aimed at lowering the entry barriers of establishing structured data links between trading partners by minimising the need for bilateral framework agreements, known as interchange agreements. One specific requirement of open EDI is to set up the operational and contract framework within which a transaction is carried out. Automating the process of negotiating and executing agreements regarding the legal and technical conditions for open EDI can significantly lower the entry barriers, especially for non-recurrent transactions (Mitrakas, 2000).

Building on the model for open EDI, the Business Collaboration Framework is a set of specifications and guides, the centre of which is the UN/CEFACT; it aims at further lowering the entry barriers of electronic commerce based on structured data formats. The need for flexibility and versatility to loosely coupled applications and communication on the Internet has led to the emergence of Web services. A Web service is a collection of protocols and standards that are used to exchange data between applications. While applications can be written in various languages and run on various platforms, they can use Web services to exchange data over the Internet.

In Web services, using open standards ensures interoperability. These standards also include formal descriptions of models of business procedures to specify classes of business transactions that all serve the same goal. A trade procedure stipulates the actions, the parties, the order, and the timing constraints on performing actions (Lee, 1996). In complex business situations, transaction scenarios typically might belong to a different trade partner that each one owns a piece of that scenario. Associating a scenario with a trade partner often requires electronic signatures. When a trade partner signs with an electronic signature, she might validate or approve of the way that individual procedural components might operate within a transaction. The signatory of an electronic document or a transaction procedure depends on the performance of complex and often opaque-to-the-end-user systems.

Trust in the transaction procedures and the provision of services is a requirement that ensures that the signatory eventually adheres to transparent contract terms that cannot be repudiated (Mitrakas, 2003). Policy is seen as a way to formalise a transaction by highlighting those aspects of a

transaction that are essential to the end user (Mitrakas, 2004). The immediate effect of using policies to convey limitations is that the party that relies on a signed transaction adheres to the limitations of that policy. Policy is, therefore, used to convey limitations to a large number of users in a way that makes a transaction enforceable. While these limitations are mostly meaningful at the operational or technical level of the transaction, they often have a binding legal effect and are used to convey contractual terms. Although these terms are not necessarily legal by nature, they are likely to have a binding effect. Sometimes they can be more far reaching by constraining relying parties that validate electronic signatures. Limitations might be mandated by law or merely by agreement, as in the case of limitations of qualified signatures according to European Directive 1999/93/EC on a common framework for electronic signatures (ETSI TS 101 456).

POLICY CONSTRAINTS IN ELECTRONIC BUSINESS

Electronic signatures have been seen as a lynchpin of trust in electronic transactions. The subject matter of current electronic signature regulation addresses the requirements on the legal recognition of electronic signatures used for non-repudiation and authentication (Adams & Lloyd, 1999). Non-repudiation is addressed in both technical standards such as X.509 and legislation. Non-repudiation addresses the requirement for electronic signing in a transaction in such a way that an uncontested link to the declaration of will of the signatory is established. Non-repudiation is the attribute of a communication that protects against a successful dispute of its origin, submission, delivery, or content (Ford & Baum, 2001). From a business perspective non-repudiation can be seen as a service that provides a high level of assurance on information being genuine and non-refutable (Pfleeger, 2000). From a legal perspective non-repudiation, in the meaning of the Directive 1999/93/EC on a common framework on electronic signatures, has been coined by the term, *qualified signature*, which is often used to describe an electronic signature that uses a secure signature creation device and is supported by a qualified certificate. A qualified signature is defined in the annexes of the directive and is granted the same legal effect as hand-written signatures where law requires them in the transactions.

Policies aim at invoking trust in transactions to ensure transparency and a spread of risk among the transacting parties. Policies are unilateral declarations of will that complement transaction frameworks based on private law. Policies can be seen as guidelines that relate to the technical organizational and legal aspects of a transaction, and they are rendered enforceable by means of an agreement that binds the transacting parties.

In Public Key Infrastructure (PKI), a CA typically uses policy in the form of a certification practice statement (CPS) to convey legally binding limitations to certificate users, being subscribers and relying parties. A CPS is a statement of the practices that a CA employs in issuing certificates (ABA, 1996). A CPS is a comprehensive treatment of how the CA makes its services available and delimiting the domain of providing electronic signature services to subscribers and relying parties. A certificate policy (CP) is sometimes used with a CPS to address the certification objectives of the CA implementation. While the CPS is typically seen as answering "how" security objectives are met, the CP is the document that sets these objectives (ABA, 2001). A CP and a CPS are used to convey information needed to subscribers and parties relying on electronic signatures, in order to assess the level of trustworthiness of a certificate that supports an electronic signature. By providing detailed information on security and procedures required in managing the life cycle of a certificate, policies become of paramount importance in transactions. Sometimes, a PKI Disclosure Statement (PDS) distils certain important policy aspects and services the purpose of notice and conspicuousness of communicating applicable terms (ABA, 2001). The Internet Engineering Task Force (IETF) has specified a model framework for certificate policies (RFC 3647).

Assessing the validity of electronic signatures is yet another requirement of the end user, most importantly, the relying parties. A signature policy describes the scope and usage of such electronic signature with a view to address the operational conditions of a given transaction context (ETSI TR 102 041). A signature policy is a set of rules under which an electronic signature can be created and determined to be valid (ETSI TS 101 733). A signature policy determines the validation conditions of an electronic signature within a given context. A context may include a business transaction, a legal regime, a role assumed by the signing party, and so forth. In a broader perspective, a signature policy can be seen as a means to invoke trust and convey information in electronic commerce by defining appropriately indicated trust conditions.

In signature policies it is also desirable to include additional elements of information associated with certain aspects of general terms and conditions to relate with the scope of the performed action as it applies in the transaction at hand (Mitrakas, 2004). A signature policy might, therefore, include content that relates it to the general conditions prevailing in a transaction, the discreet elements of a transaction procedure as provided by the various parties involved in building a transaction, as well as the prevailing certificate policy (ETSI TS 102 041).

Trade parties might use transaction constraints to designate roles or other attributes undertaken to carry out an action within a transaction framework. Attribute certificates are used to convey such role constraints and are used to indicate a

role, a function, or a transaction type constraint. Attribute policies are used to convey limitations associated with the use and life cycle of such attributes (ETSI TS 101 058).

Processing signed electronic invoices is an application area of using policies. By means of a signature policy, the recipient of an invoice might mandate a specific signature format and associated validation rules. The sender of the invoice might require that signing an invoice might only be carried out under a certain role; therefore, an attribute certificate issued under a specific attribute policy might be mandated. This attribute policy complements the certification practice statement that the issuer of electronic certificates makes available. It is expected that certificate policies shall influence the requirements to make a signature policy binding (Mitrakas, 2003).

BINDING POLICIES IN ELECTRONIC BUSINESS

Communicating and rendering policies binding has been an issue of significant importance in electronic transactions. Inherent limitations in the space available for digital certificates dictate that policies are often conveyed and used in a transaction by incorporating them by reference (Wu, 1998). Incorporation by reference is to make one message part of another message by identifying the message to be incorporated, providing information that enables the receiving party to access and obtain the incorporated message in its entirety, expressing the intention that it be part of the other message (ABA, 1996). The incorporation of policies for electronic signatures into the agreement between signatory and recipient can take place by referencing the intent to use such policy in transactions. When the recipient accepts the signed document of the signatory, he implicitly agrees on the conditions of the underlying signature policy. In practice, incorporating policy into the agreement between signatory and recipient can also be effected by:

- Referring to a policy in a parties' agreement that explicitly refers to such policy.
- Accepting a signed document and implicitly agreeing on the conditions of the underlying policy, although this option might be more restrictive in case of a dispute.

An issue arises with regard to how and under which conditions a particular policy framework can be incorporated into an agreement of a signatory in a way that binds a relying party, regardless of its capacity to act as consumer or business partner. Incorporation of contract terms into consumer contracts and incorporation of contract terms into business contracts follow different rules. Incorporation by reference in a business contract is comparatively straightforward, whereas in a consumer contract stricter rules have to be followed as mandated by consumer protection regulations. Limitations to the enforceability of legal terms that are conveyed by means of policy are applied as a result of consumer protection legislation. In Europe, consumer protection legislation includes the Council Directive 93/13/EC on unfair terms in consumer contracts, Directive 97/7/EC on the protection consumers in distance transactions, and Directive 1999/44/EEC on certain aspects of the sale of consumer goods and associated guarantees (Hoernle, Sutter & Walden, 2002). In an effort to proactively implement these legal requirements, service providers strive to set up specific consumer protection frameworks (GlobalSign, 2004).

Sometimes the scope of the underlying certificate policy frameworks is to equip the transacting parties with the ability to use a certificate as evidence in a court of law. It is necessary to also provide transacting parties with assurance that allows a certificate to be admitted in legal proceedings and that it provides binding evidence against the parties involved in it, including the CA, the subscriber, and relying parties (Reed, 2000). Qualified electronic signatures in the meaning of Directive 1999/93/EC establish a rebuttable presumption that reverses the burden of proof. In other words the court may at first admit a signature that claims to be qualified as an equivalent of a handwritten signature. The counter-party is allowed to prove that such signature does not meet the requirements for qualified signatures, and could therefore be insecure for signing documents requiring a handwritten signature (UNCITRAL, 2000). To further answer the question of admissibility, it is necessary to examine the admissibility of electronic data as evidence in court, which is a matter that has been addressed in Directive 2000/31/EC on electronic commerce. Consequently, electronic data can be admitted as evidence as long as certain warranties are provided with regard to the production and retention of such data. In assessing the reliability of a certificate, a Court will have to examine the possibility of a certificate being the product of erroneous or fraudulent issuance, and if is not, the Court should proclaim it as sufficient evidence against the parties involved within the boundaries of conveyed and binding policy.

FUTURE TRENDS

While case law is expected to determine and enhance the conditions of admissibility and evidential value of policy in transactions based on electronic signatures, additional technological features such as the use of object identifiers (OIDs) and hashing are expected to further enhance the certainty required to accept policies. Remarkably, to date there has been little done to address in a common manner the practical aspects of identifying individual policies and distinguishing among the versions thereof. Additionally, mapping and reconciling policy frameworks in overlapping

transactions also threaten transactions, which are based on the use and acceptance of varying terms. A typical hard case might involve for example overlapping policy conditions, which apply to certificates issued by different CAs. The situation is exacerbated if those CAs do not have the means to recognise one another, while they issue certificates that can be used in the same transaction frameworks (ETSI TS 102 231). Although such certificates may well be complementary to a transaction framework, the varying assurance levels they provide might threaten the reliability of the transaction framework as a whole. The immediate risk for the transacting parties can be an unwarranted transaction environment that threatens to render otherwise legitimate practices unenforceable. Reconciling the methods used across various electronic signing environments is likely to contribute to creating trust in electronic business.

An additional area of future attention may address policy frameworks related to the application layer in a transaction. As present-day requirements for transparency are likely to be further raised, it is expected that online applications will increasingly become more demanding in explaining to the end user what they do and actually warranting the performance. To date general conditions and subscriber agreements cover part of this requirement; however, it is further needed to provide a comprehensive description of the technical features and functionality of the online application. In electronic business, consumers and trade partners are likely to benefit from it. Policies for the application layer are likely to become more in demand in electronic government applications, where the requirement for transparency in the transaction is even higher than in electronic business. Finally, specifying policies further to meet the needs of particular groups of organisations is an additional expectation. Again in electronic government it is expected that interoperability will be enhanced through best practices and standards regarding policy in specific vertical areas.

CONCLUSION

While policies emerge as a necessary piece in the puzzle of invoking trust and legal safety in electronic transactions, policy frameworks can still have repercussions that reach well beyond the scope of single transaction elements and procedures in isolated electronic business environments. Formal policy frameworks require additional attention to ensure that apparently loosely linked policy elements do not threaten to overturn the requirements of transaction security and legal safety, which are the original objectives of using policy frameworks. Electronic transaction frameworks for diverse application areas can benefit from the processing of data on the basis of policy-invoked constraints among the parties involved. Large-scale processing that requires policy to convey operational and legal conditions in electronic transactions benefits from a combination of policy instruments, including certificate polices, signature policies, attribute certificate policies, and so forth, to enhance the outlining of the transaction framework and allow the transacting parties to further rely on electronic business for carrying out binding transactions.

KEY TERMS

Certification Authority: An authority such as GlobalSign that issues, suspends, or revokes a digital certificate.

Certification Practice Statement: A statement of the practices of a certificate authority and the conditions of issuance, suspension, revocation, and so forth of a certificate.

Electronic Data Interchange (EDI): The interchange of data message structured under a certain format between business applications.

Incorporation by Reference: To make one document a part of another by identifying the document to be incorporated, with information that allows the recipient to access and obtain the incorporated message in its entirety, and by expressing the intention that it be part of the incorporating message. Such an incorporated message shall have the same effect as if it had been fully stated in the message.

Public Key Infrastructure (PKI): The architecture, organization, techniques, practices, and procedures that collectively support the implementation and operation of a certificate-based public key cryptographic system.

Relying Party: A recipient who acts by relying on a certificate and an electronic signature.

Signature Policy: A set of rules for the creation and validation of an electronic signature, under which the signature can be determined to be valid.

Policy Options for E-Education in Nigeria

Wole Michael Olatokun
University of Ibadan, Nigeria

INTRODUCTION

Information and communication technology (ICT) has turned the world into a global village, and its impact is being felt in all spheres of life. Though it has been rightly said that what is wrong with education cannot be fixed with technology; there is no doubt that modern life is dominated by technology. In today's globalized world, there is a universal recognition of the need to use ICT in education because the free flow of information via satellite and the Internet hold sway in global information dissemination of knowledge. The application of ICT to education brought about the concept of **e-education**. This chapter considers the concept of e-education *vis a vis* the provisions of the national policy for information technology, and gives a state of the art with regard to some e-education initiatives that have been embarked upon by the government, nongovernmental organizations, and other stakeholders in the country. It also identified the challenges constraining the effective deployment and exploitation of ICT for teaching and learning in the Nigerian education system, and recommends some policy options for the development of e-education in the country. The next section gives a background to the concept of e-education.

BACKGROUND

E-education and e-learning are terms sometimes used interchangeably to describe learning through electronic devices or media. That is, a technologically based enhanced learning mechanism that is packaged and targeted towards a broad based population. In other words, the scope of e-education is enhanced on efforts at reaching a widely dispersed population. According to Mac-Ikemenjima (2005), e-education is "an electronic mode of knowledge sharing and transmission, which may not necessarily involve physical contact between teachers and students" (p. 5). Thus, e-education is an alternative to conventional classroom educational system of face-to-face, dynamic, ongoing interaction between teachers and learners, and it is both a computer-aided teaching and computer-aided learning, which ultimately lead to computer-aided instruction. Nenad, Tibor, and Sabina (2005) have noted that e-learning is characterized by the following terms (which give the "e" in e-learning):

- Electronic learning – the main medium of the learning is a computer, with all the advantages of the Internet, intranet, database systems, and applications that make the system easy-to-use and easy-to-manage,
- Everywhere learning – the student is not bound to one place; the computer can be used wherever there is a computer and Internet access,
- Enterprise learning – education is of the utmost importance for the academic community, this way we can offer the materials even to the graduated students to help them improve their knowledge even after graduation,
- Experience learning – the system treats the student as a solver of the problem; it simulates real life situations, thus making the education interactive and exciting; it enables the student to test the knowledge and, if needed, to get help from the mentor (Nenad et al., 2005).

In essence, e-education is a learning system that rises above the confines of space and time, as it does not require physical contact between teacher and student. In this case, learning could be done without classrooms, since instructions and learning materials are accessed through the Internet, CD-ROM, specialized software, and other media. Information and communication technology (ICT) provides the platform on which e-education runs. The use of ICT in e-education makes schools more efficient and creative in knowledge transmission. It produces a variety of tools to enhance teachers' professional skills. However, as Hicks, Reid, and George (1999) have noted, technology by itself, or in itself, is inadequate to provide quality learning. Accordingly, quality is perceived as the function of the way technology is deployed to provide access to germane learning opportunities at the appropriate time. According to them, the main features of online education include computer-mediation, potential for accessing large amounts of dynamic information through WWW, use of hypertext and working with materials in nonlinear way, and access to real-world contexts via Internet. Others include capacity to communicate via e-mail and other electronic technologies with lecturers and other students, new methods for administration of learning, for example, submitting assignments, getting results, networking, and internationalizing the curriculum (Hicks et al., 1999). Also, NetTOM (2007) submitted that cognitive gains from e-learning include hypertext learning, which is nonlinear and

can be structured to engage learners into making greater use of critical thinking skills.

MAIN THRUST OF THE ARTICLE

E-Education and Nigeria's National Policy for Information Technology

In 2001, the Federal Government of Nigeria approved a **National Policy for Information Technology (IT)**. Its implementation started in the same year. The vision statement of the policy is "to make Nigeria an IT capable country in Africa and a key player in the information society by the year 2005, using IT as the engine for sustainable development and global competitiveness." Its mission statement is "to use IT for education, creation of wealth, poverty eradication, job creation and global competitiveness" (Nigerian National Policy for Information Technology, 2001). Some questions worth asking are: What are the provisions of the policy vis-à-vis the implementation of e-education in Nigeria? How adequate is the policy for the integration of ICT in the Nigerian education system? The policy, judging from its mission, general objectives and strategies recognized the importance of ICT in education. Some deficiencies observed however are as follows:

a. The document lacks any sectoral application to education. While sectoral application exist for health, governance, agriculture, legislation, and others, issues on education are grouped under sectoral application for human resources development.
b. The impact of ICT on education is limited to its economic competitiveness. In the sectoral application for human resource development, its objective is basically for students to learn about computers and prepare them to acquire knowledge and skills that would position them for future competitive jobs. It ignores the potential of ICT as a means of solving issues in teaching and learning. No focus is given to the integration of ICT for the development and management of teaching and learning in Nigerian schools.
c. Students cannot acquire knowledge in a vacuum; they must be taught by teachers. However, the policy does not address the issue of teachers' ICT education. Many teachers are incompetent in using ICT to impart knowledge because they also lack such education.
d. Fourth, the national IT policy does not acknowledge the need to develop nationally relevant context software for the education system. The available software in the country are foreign with no local content.

The reality is that the national policy is not focused on the basic issues involved in quality ICT application in education (Olatokun, 2006). It is limited to the market-driven goal of the application of ICT in education, and this can be seen from its emphasis on learning about ICT and not learning through ICT. However, the simple fact is that application of e-education can only be successful when not just learning, but learning and teaching through ICTs are encouraged. In the next section, we describe some e-education initiatives in Nigeria.

E-Education Initiatives in Nigeria

1. Government Initiatives

National Open University of Nigeria

Mac-Ikemenjima (2005) reported that the National Open University (NOU) was initially established on 22nd July 1983 but became functional in April 2001. The aim of the institution is to train professionals in various disciplines through the distance learning mode. The institution was set up on the premise that every year almost 1.5 million students apply to the various universities in the country but only about 20% can be absorbed by the university system. NOU is expected to take care of the remaining 80%. The course delivery is through a combination of Web-based modules, textual materials, audio and video tapes, as well as CD ROMs. The university currently has 18 study centers and plans to have at least one study center in each of the 774 local governments of Nigeria. It runs programmes in education, arts and humanities, business and human resource management, and science and technology.

The NOU is designed to increase the access of all Nigerians to formal and nonformal education in a manner convenient to their circumstances, and cater to the continuous educational development of professionals. The range of target clientele is elastic and is to be continually reviewed to meet Nigeria's ever-changing needs (National Open University of Nigeria, 2008). It employs a range of delivery methods to take education to the people and make learning an enjoyable activity, including printed instructional materials, audio, video tapes, and CD-ROMs; television and radio broadcast of educational programmes and electronic transmission of materials in multimedia (voice, data, graphics, video) over fixed line (telephone or leased lines), terrestrial, and VSAT wireless communication systems. For the take off of the university, pioneer student enrolment was 32,400 and it is believed that with time, more people will benefit from the programmes of the NOU (National Open University of Nigeria, 2008).

Nigerian Universities Network (NUNet) Project

The **NUNet** project was conceived in 1994 by the **National Universities Commission** (NUC) when it was realized that Nigerian academic staff and students should not be isolated from each other and from the global academic community (Mac-Ikemenjima, 2005). The decision was made that all Universities should be linked at least through e-mail through Trieste via a dial-up system. Apart from e-mail, the project is also to solve the problems of resource sharing among Nigerian Universities and their counterparts all over the world, provide access to electronic journals and books, many of which are only available in such forms, and serve as vehicle to expand access to education at minimal cost. Thus, in 1996, with the help of the International Centre for Theoretical Physics (ICTP), NUNet established the e-mail gateway with the purpose of providing an dedicated international direct dial (IDD) line for NUC, together with a mail exchange and server. While this dial-up technology has been surpassed by other ICT developments, NUNet still keeps it operational (and indeed some universities still use it as their sole electronic communications means) as a back-up system. By 2000, NUNet had established its own VSAT set-up to real-time Internet access (at least within the NUC building). In an attempt to transform itself, NUNet is concentrating on IT training policies for universities (UNESCO, 2002). In order to meet these needs, several partnerships were built with various institutions, and NUC staffs were trained in various IT-related skills. The NUNet system has been fluctuating in its operations but it is hoped that within a few years, its performance would have improved. It is expected that partnership among Nigerian institutions would improve and drive down the cost of Internet connections through economies of scale.

2. Virtual Library Initiatives

The objectives of the national virtual library include improving the quality of teaching and research institutions through the provision of current books, journals, and other library resources; enhancing access of academic libraries to global library and information resources; enhancing scholarship and lifelong learning through the establishment of permanent access to shared digital archival collections; provision of guidance to academic libraries on ways of applying appropriate technologies for production of digital library resources; and to advance the use and usability of globally distributed networks library resources. Virtual library initiatives in Nigeria include:

- **The National Virtual (Digital) Library Project** of the Ministry of Education, which is supervised by the National Universities Commission (National Universities Commission, 2007).
- The National Virtual Library Project of the Ministry of Science and Technology is supervised by the National Information Technology Development Agency (NITDA)
- An ongoing effort by UNESCO to develop a virtual Library for all Nigerian Higher Education Institutions in Nigeria (National Universities Commission, 2007).

3. Civil Society (NGO led) E-education Initiatives

Several NGOs have had a notable impact on the development of **telecenters**. Telecenters are places that usually have rudimentary ICT facilities designed to acquaint people with these technologies, and to begin educational programs to teach people in marginalized regions about how to use them (Mac-Ikemenjima, 2005). Examples include community teaching and learning centers, Lagos Digital Village by Junior Achievement Nigeria, Owerri Digital Village by Youth for Technology Foundation, Computer Literacy for Older Persons Programme by Mercy Mission, and so forth. The impact of these telecentres is felt in the immediate rural location, where they are sited in terms of increasing access to ICT facilities. However, due to the fact that they are very few, they are grossly inadequate in providing access to ICT facilities to the country's large rural populations. Other challenges include low level of general and ICT literacy, poor energy supply, and lack of local content.

Challenges of E-Education in Nigeria

Nigeria, like most developing nations, is yet to fully integrate ICT into its educational system and is thus incapacitated to benefit from e-education. Although the benefits of the implementation of e-education in any society are numerous, yet there are also many attendant challenges. The problem most often noted is the availability of adequate ICT infrastructure and poor maintenance culture (Mac-Ikemenjima, 2005; Ololube, 2005a; Yusuf, 2005). An efficient e-educational system requires adequate functional specialized software, unlimited access to the Internet, and the stability of other infrastructure, such as electricity and telecommunications (Aduwa-Ogiegbaen & Iyamu, 2005). The quality of teachers is known in virtually all countries to be a key predictor of student learning (Ololube, 2005a; Ololube, 2005b). Teachers need training not only in computer literacy, but also in the application of various kinds of educational software in teaching and learning (Ololube, 2006). It is pertinent to note that in some societies like Nigeria, many teachers lack access to basic ICT infrastructure, like computer hardware. Worse still, many hardly come in contact with ICT-aided instructional materials. Most of the identified challenges of

e-education are those associated with the use of ICT infrastructure. These hindrances are discussednext.

Inadequate ICT Infrastructure

The implementation of e-education would only have the desirable result if people have direct access to ICT infrastructure, a situation which is not obtainable in Nigeria at present. Most times, users of ICT infrastructure depend on the limited facilities available at their workplaces, while a large number patronize commercial providers of such facilities; these are either unreliable or inefficient. The situation is worse for the rural dwellers. It is pertinent to say that most rural dwellers lack basic ICT infrastructure such as radio, television, and telephone services. It is all the more so with more complex ICT infrastructure, such as computer hardware, software, and other accessories required to facilitate their access to e-education.

Inadequate Manpower Skills

Nigeria, like its other African counterparts, is basically a consumer of ICT. Not only does it lack adequate ICT infrastructure, but also has a dearth of experienced skills needed to manage such infrastructure (Aduwa-Ogiegbaen, & Iyamu, 2005). There is severe scarcity of qualified computer software designers and other trained personnel in the management of operating systems. Networking and local workers to service and repair computer facilities are also grossly inadequate. Worthy of note is the fact that educators, who are expected to be the main force for the implementation of e-education, similarly lack the skills to fully utilize ICT in curriculum implementation.

Poor Energy Supply

While ICT is the platform on which e-education is implemented, electricity is the backbone for all ICT infrastructure. It follows then that there cannot be any efficient e-educational system without a functional electricity facility. However, it can be observed that no area in Nigeria is confident of regular electricity supply except areas inhabited by high level government officials. The government has not succeeded in providing stable and reliable electricity supply to every part of the country (Olatokun, 2006). In addition is the fact that, in Nigeria, most rural inhabitants do not have access to electricity, hence, implementation of e-education in such areas becomes a hurdle.

Poor Telecommunication Facilities

The Nigerian telecommunication sector is one of the fastest growing among African countries (Aduwa-Ogiegbaen, & Iyamu, 2005). This has especially been the case with the liberalization of Nigerian telecommunication sector in 2001, and the subsequent licensing of the **Global System of Mobile Communication (GSM)** and other fixed wireless operators. Prior to 2001, there were only some 700,000 lines in the country, with only 450 connected. However, since 2001, more than 3 million landlines and 5 million GSM subscribers have been added to the existing telephone capacity. Despite this increment in the number of land and GSM lines, they are still inadequate for Nigeria's over 140 million population (National Population Commission, 2006). Besides, most users of the GSM and landlines are in the urban areas. In addition, there is the high cost of using these facilities. Although this has significantly reduced over the years, it is still beyond the comfortable reach of many Nigerians. However, the recent acquisition of the nation's first national carrier, Nigeria Telecommunication, by Transnational Corporation has raised the hope of Nigerians that there would be further increase in competition among telecom operators, and ultimately, reduction in prices (Aduwa-Ogiegbaen, & Iyamu, 2005).

Underfunding of the Educational System

In Nigeria, the overall educational system is dependent on the government. However, it is apparent that the government lacks what it takes to adequately provide for the entire education system. As a result of underfunding, most institutions are not oriented towards the provision of e-education. Rather, such limited resources are used in meeting more urgent and survival needs of the institutions. Moreover, overdependence of educational institutions on government for virtually everything has beclouded their ability to partner with the private sector or other alternative funding sources for ICT education initiatives, except in a few private institutions.

Limited Internet Access

A major challenge to e-education in Nigeria is how to establish reliable cost-effective Internet connectivity that ensures easy access to information at all times (Aduwa-Ogiegbaen, & Iyamu, 2005). The limitation stems from the fact that in Nigeria, there are no indigenous ISPs. The available ones are usually Nigerian companies in partnership with foreign IT companies. Most times, the relationship does not translate into efficient services, as one would expect, but poor services and exploitation of customers. The few reputable ISPs that have invested so much usually charge high fees due to very small customer base occasioned by high fees. A contributory factor to the high Internet connectivity fees is the high cost of telecommunication services (Aduwa-Ogiegbaen, & Iyamu, 2005). The monopoly in the Nigerian telecommunication sector for many years negatively affected the penetration of Internet services in the country.

FUTURE TRENDS

Various challenges to e-education have been identified. Deficiencies in the national policy on information technology in relation to implementation of e-education have also been described. What then does the future portend for Nigeria?

The E-Education Initiatives

To answer these questions, it is very important to place the future of e-education in Nigeria within the context of the overall objectives of various e-education initiatives. The stated objectives are a step in the right direction. Aside from this, the spread of **National Open University** in over 18 study centers, and the projection for the establishment of a study center in each of the 774 local governments in Nigeria, is a welcome development. Also, the recent and ongoing proposal of 100-dollar laptops, equivalent of thirteen thousand five hundred naira (117 naira is equivalent to 1 dollar), is an attempt to increase wider access to media technology.

Increasing the Level of Awareness of Nigerians about ICT

It is important also to observe the increase in level of awareness of Nigerians (public, private) of various IT products in relation to available opportunities. Awareness often leads to curiosity, familiarity, and eventually interactions, which in turn leads to skill acquisition and development. The contribution of Nigerian software development companies is becoming noticeable. This would produce the much-emphasized local content in the areas of applications and packages, thereby bridging the much-referenced digital divide existing between the developed and less developed or developing nations.

Human Resources Development and Skills Upgrading

The introduction of computer education in the academic curriculum and campaign for mass training and participation in information technology is an effective tool in the development of highly skilled workforce and drastic reduction in the level of illiteracy prevalent in the country both in the traditional and formal education system, but especially e-education (Aduwa-Ogiegbaen, & Iyamu, 2005).

Liberalization of the Telecommunication Sector

Access to reliable telecommunications systems is critical to the implementation of e-education. The liberalization of the telecommunication sector is a positive move towards achieving a stable telecommunication network and expanding access. This has broken the monopoly enjoyed by the Nigerian Telecommunications and stirred up competition among the different operators. Although the cost of connectivity to these facilities is still high, it is expected that in the nearest future, more operators would be forced to reduce their prices, especially with the acquisition of the Nigerian Telecommunications by Transnational Corporation of Nigeria Plc. It would be remarkable to witness considerable reduction in telecommunication tariffs arising from stiff competition among the operators.

Investments in Telecenters

The activities of some nongovernmental organizations (NGO) have been observed in the provision of **telecenters,** which are places that have basic ICT facilities designed to acquaint people with these technologies in order to increase the flow of information to and from the poorest and the marginalized. It has been effective in bridging the gap between those who have access to computer and Internet and those who do not. Telecenters are particularly useful for rural development. As discussed earlier, there are few NGOs that have been providing such telecenters. One such is the Owerri Digital Village, which is based in the Eastern part of the country. Owerri Digital Village was launched in September 2001 by the Youth for Technology Foundation (YTF), an international nonprofit organization based in the United States and Nigeria. It is a community technology and learning center that offers IT skills development and training for Nigerian youth in an effort to develop entrepreneurial spirit and passion for technology. Community teaching and learning center is another initiative by the nongovernmental organizations. It is an initiative of Teachers Without Borders (TWB), an international US-based NGO that seeks to connect teachers globally, to each other and to resources through ICT. The centers currently exist in various parts of Nigeria and are yielding some results in terms of increasing access.

CONCLUSION

E-education is about IT infrastructures and content. The factors of inadequate infrastructures to support the IT of e-education in Nigeria have been established. To harness the opportunities inherent in e-education, conscious effort is required and necessary to create an enabling environment that would promote the participation of all stakeholders in terms of funding, training, and development. Increase campaign in collaboration with NGOs, communities, and relevant agents would assist in the realization of the vision of e-education. In addition, it is very crucial that every citizen has access

to the pursuit of education irrespective of age, level of experience and qualification, and location. It is obvious that Nigeria is on the right track towards the implementation of e-education owing to the numerous initiatives discussed. Specific sectoral applications to education in the objectives of the national policy have been suggested. The Government should focus on the integration of ICT into every aspect of teaching and learning. Since educational institutions are generally underfunded, government should increase funding of these institutions. Specific budget for ICT should be set aside annually for all institutions of learning, and its use should effectively be monitored. Additionally, all institutions should intensify efforts to generate more funds from donor organizations to supplement whatever they receive from the Federal Government. Private sector partnership should be considered in the application of ICT. If these suggestions could be adopted with the right policies, Nigeria will soon begin to reap the benefits and opportunities offered by e-education.

KEY TERMS

E-Education: Use of computers and electronics to assist learning

E-Learning: Learning that is facilitated by the use of digital tools and content. Typically, it involves some form of interactivity that may include online interaction between the learner and their teacher or peers.

Information and Communication Technology (ICT): Includes technologies such as desktop and laptop computers, software, peripherals, and connections to the Internet that are intended to fulfill information processing and communications functions.

Information Technology Policy: Policy guidelines that concern all forms of technology used in processing and disseminating information.

Initiative: An organized and coordinated strategy to address the needs, issues, or desires of a population or community.

Policy: An overarching plan of action developed for the achievement of a set of goals.

Strategy: A plan or method for obtaining a specific result.

Predictive Data Mining: A Survey of Regression Methods

INTRODUCTION

Data mining is the extraction of implicit, previously unknown, and potentially useful information from data. The idea is to build computer programs that sift through databases automatically, seeking regularities or patterns. Strong patterns, if found, will likely generalize to make accurate predictions on future data. Machine learning (ML) provides the technical basis of data mining. It is used to extract information from the raw data in databases—information that is expressed in a comprehensible form and can be used for a variety of purposes.

Every instance in any data set used by ML algorithms is represented using the same set of features. The features may be continuous, categorical, or binary. If instances are given with known labels (the corresponding correct outputs), then the learning is called supervised in contrast to unsupervised learning, where instances are unlabeled (Kotsiantis & Pintelas, 2004). This work is concerned with regression problems in which the output of instances admits real values instead of discrete values in classification problems.

BACKGROUND

A brief review of what ML includes can be found in Dutton and Conroy (1996). A historical survey of logic and instance-based learning is also presented in De Mantaras and Armengol (1998). The first step of predictive data mining is collecting the data set. If a requisite expert is available, then he or she can suggest which fields (attributes, features) are the most informative. If not, then the simplest method is that of "brute force," which means measuring everything available in the hope that the right (informative, relevant) features can be isolated. However, a data set collected by the brute-force method is not directly suitable for induction. It contains, in most cases, noise and missing feature values, and therefore requires significant preprocessing (Zhang, Zhang, & Yang, 2002). Hodge and Austin (2004) have recently introduced a survey of contemporary techniques for outlier (noise) detection. Depending on the circumstances, researchers have a number of methods to choose from to handle missing data (Batista & Monard, 2003). Feature subset selection is the process of identifying and removing as many irrelevant and redundant features as possible (Yu & Liu, 2004). The fact that many features depend on one another often unduly influences the accuracy of supervised ML models. This problem can be addressed by constructing new features from the basic feature set (Markovitch & Rosenstein, 2002).

The problem of regression consists of obtaining a functional model that relates the value of a target continuous-variable y with the values of variables x_1, x_2...x_n (the predictors). This model is obtained using samples of the unknown regression function. These samples describe different mappings between the predictor and the target variables. The traditional approach for prediction of a continuous target is the classical linear least-squares regression (Fox, 1997). The model constructed for regression in this traditional approach is a linear equation. By estimating the parameters of this equation with a computationally simple process on the training set, a model is created. However, the linearity assumption between input features and predicted value introduces a large bias error for most domains. That is why most studies are directed to nonlinear and nonparametric techniques for the regression problem.

Murthy (1998) provided an overview of work in decision trees and a sample of their usefulness to newcomers as well as practitioners in the field of data mining. Decision trees are trees that classify instances by sorting them based on feature values. Each node in a decision tree represents a feature in an instance to be classified, and each branch represents a value that the node can assume. Regression trees are the counterpart of decision trees for regression tasks. A regression tree, or any learned hypothesis h, is said to overfit training data if another hypothesis h´ exists that has a larger error than h when tested on the training data, but a smaller error than h when tested on the entire data set. There are two common approaches that regression-tree induction algorithms can use to avoid overfitting training data: (a) Stop the training algorithm before it reaches a point at which it perfectly fits the training data, and (b) prune the induced regression tree.

Most algorithms use a pruning method. Model trees generalize the concepts of regression trees, which have constant values at their leaves (Torgo, 2000). Thus, they are analogous to piecewise linear functions (and hence nonlinear functions). The major advantage of model trees over regression trees is that model trees are much smaller than regression trees, the decision strength is clear, and regression functions do not normally involve many variables. The most well-known model-tree inducer is the M5´ (Wang & Witten, 1997). Model trees can tackle tasks with very high dimensionality—up to hundreds of attributes; however, computational requirements grow rapidly with dimensionality.

Regression trees can be translated into a set of rules by creating a separate rule for each path from the root to a leaf in the tree (Torgo, 1995). The M5´ rules algorithm produces propositional regression rules using routines for generating a decision list from M5´ model trees (Witten & Frank, 2005). The algorithm is able to deal with both continuous and nominal variables, and obtains a piecewise linear model of the data. However, rules can also be directly induced from training data using a variety of rule-based algorithms. Furnkranz (1999) provided an excellent overview of existing work in rule-based methods. Regression rules represent each result by a disjunctive normal form (DNF). A *k*-DNF expression is of the form $(X_1 \wedge X_2 \wedge \ldots \wedge X_n) \vee (X_{n+1} \wedge X_{n+2} \wedge \ldots X_{2n}) \vee \ldots \vee (X_{(k-1)n+1} \wedge X_{(k-1)n+2} \wedge \ldots \wedge X_{kn})$, where k is the number of disjunctions, n is the number of conjunctions in each disjunction, and X_n is defined over the alphabet $X_1, X_2 \ldots X_j \cup \sim X_1, \sim X_2 \ldots \sim X_j$. The goal is to construct the smallest rule set that is consistent with the training data. A large number of learned rules is usually a sign that the learning algorithm is attempting to remember the training set instead of discovering the assumptions that govern it. The difference between heuristics for rule learning and heuristics for regression trees is that the latter evaluate the average quality of a number of disjointed sets (one for each value of the feature that is tested), while rule learners only evaluate the quality of the set of instances that is covered by the candidate rule (Torgo, 1995).

Artificial neural networks (ANNs) are another method of inductive learning based on computational models of biological neurons and networks of neurons as found in the central nervous system of humans (Witten & Frank, 2005). A multilayer neural network consists of a large number of units (neurons) joined together in a pattern of connections. Units in a net are usually segregated into three classes: input units, which receive information to be processed; output units, where the results of the processing are found; and units in between known as hidden units. Feed-forward ANNs allow signals to travel one way only, from input to output. First, the network is trained on a set of paired data to determine input-output mapping. The weights of the connections between neurons are then fixed and the network is used to predict the value of a new set of data. Generally, properly determining the size of the hidden layer is a problem. An excellent argument regarding this topic can be found in Camargo and Yoneyama (2001). Kon and Plaskota (2000) also studied the minimum amount of neurons and the number of instances necessary to program a given task into feed-forward neural networks. ANN depends upon three fundamental aspects: input and activation functions of the unit, network architecture, and the weight of each input connection. Given that the first two aspects are fixed, the behavior of the ANN is defined by the current values of the weights. The weights of the net to be trained are initially set to random values, and then instances of the training set are repeatedly exposed to the net. The values for the input of an instance are placed on the input units and the output of the net is compared with the desired output for this instance. Then, all the weights in the net are adjusted slightly in the direction that would bring the output values of the net closer to the values for the desired output. There are several algorithms with which a network can be trained (Neocleous & Schizas, 2002). However, the most well-known and widely used learning algorithm to estimate the values of the weights is the back-propagation (BP) algorithm.

Instance-based learning algorithms are lazy learning algorithms as they delay the induction or generalization process until the regression process is performed. *k*-nearest neighbor (k-NN) is based on the principle that the instances within a data set will generally exist in close proximity with other instances that have similar properties (Aha, 1997). The k-NN algorithm first finds the closest instances to the query point in the instance space according to a distance measure, and then outputs the average of the target values of those instances as the prediction for that query instance. Many different metrics for the relative distance between instances have been presented (Witten & Frank, 2005). For more accurate results, several algorithms use weighting schemes that alter the distance measurements and voting influence of each instance. A survey of weighting schemes is given by Wettschereck, Aha, and Mohri (1997). As the prediction of the target value of a query instance requires one to measure its distance to all training instances, which might be a very huge set, the prediction in k-NN is very costly.

An excellent survey of support vector machines (SVMs) can be found in (Burges, 1998). The sequential minimal optimization (SMO) algorithm has been shown to be an effective method for training support vector machines on classification tasks defined on sparse data sets (Platt, 1999). SMO differs from most SVM algorithms in that it does not require a quadratic programming solver. In Shevade, Keerthi, Bhattacharyya, and Murthy (2000) and Flake and Lawrence (2002), SMO is generalized so that it can handle regression problems. This implementation globally replaces all missing values and transforms nominal attributes into binary ones.

MAIN FOCUS OF THE ARTICLE

No single learning algorithm can uniformly outperform other algorithms over all data sets. When faced with the question "Which algorithm will be most accurate on our regression problem?" the simplest approach is to estimate the success rate of the candidate algorithms on the problem and select the one that appears to be most accurate. The success of regression can be judged by trying out the concept description that is learned on an independent set of test data for which the true values are known but not made available to the machine. The success rate on test data gives an objective measure of how well the concept has been learned. For the regression methods, there is more than one regressor criterion. Table 1

Table 1. Regressor criteria (p is the predicted value, and a is the actual value, $\bar{a} = \frac{1}{n}\sum_i a_i$)

Mean absolute error	$\frac{\lvert p_1 - a_1\rvert + \ldots + \lvert p_n - a_n\rvert}{n}$
Root mean squared error	$\sqrt{\frac{(p_1 - a_1)^2 + \ldots + (p_1 - a_1)^2}{n}}$
Relative absolute error	$\frac{\lvert p_1 - a_1\rvert + \ldots + \lvert p_n - a_n\rvert}{\lvert a_1 - \bar{a}\rvert + \ldots + \lvert a_n - \bar{a}\rvert}$
Root relative squared error	$\sqrt{\frac{(p_1 - a_1)^2 + \ldots + (p_1 - a_1)^2}{(a_1 - \bar{a})^2 + \ldots + (a_1 - \bar{a})^2}}$

*Table 2. Comparing learning algorithms (Note: **** the best performance, * the worst performance)*

	Regression Trees	Neural Networks	k-NN	SVM	Rule Learners
Accuracy in general	**	***	**	****	**
Speed of learning with respect to number of attributes and the number of instances	***	*	****	*	**
Speed of prediction	****	****	*	****	****
Tolerance to missing values	***	*	*	**	**
Tolerance to irrelevant attributes	***	*	**	****	**
Tolerance to redundant attributes	**	**	**	***	**
Tolerance to noise	**	**	*	**	*
Dealing with danger of overfitting	**	*	***	**	**
Explanation ability/transparency of knowledge/predictions	****	*	**	*	****
Model parameter handling	***	*	***	*	***

represents the most well known. Fortunately, it turns out that for in most practical situations, the best regression method is still the best no matter which error measure is used.

Generally, logic-based algorithms (regression trees and rule learners) are all considered very easy to interpret, whereas neural networks and SVMs have notoriously poor interpretability. k-NN is also considered to have very poor interpretability because an unstructured collection of training instances is far from readable, especially if there are many of them. Moreover, k-NN is generally considered intolerant of noise; its similarity measures can be easily distorted by errors in attribute values, thus leading it to misclassify a new instance on the basis of the wrong nearest neighbors. Contrary to k-NN, rule learners and regression trees are considered resistant to noise because their pruning strategies avoid overfitting the data in general and noisy data in particular. Features of learning techniques are compared in Table 2.

FUTURE TRENDS

The use of multiple regression models has gained momentum in the recent years, and researchers have continuously argued for the benefits of using multiple regression models to solve complex problems (Hjort & Claeskens, 2003). The main motivation for combining models is based upon the assumption that different models using different data representations, different concepts, and different modeling techniques are likely to arrive at results with different patterns of generalization. As most combination functions benefit from disagreement to errors of individual models, the greater this disagreement, the lower the impact of individual errors on the final decision, and effectively the lower the combined error.

Ensemble learning consists of two problems: ensemble generation, which is how the base models are generated, and ensemble integration, which is how the base models' predictions are integrated to improve performance. Ensemble generation can be characterized as homogeneous if each base learning model uses the same learning algorithm or heterogeneous if the base models can be built from a range of learning algorithms.

Bagging (Breiman, 1996) is a "bootstrap" ensemble method that creates individual regression models by training the same learning algorithm on a random redistribution of the training set. Each regression model's training set is generated by randomly drawing, with replacement, N instances, where N is the size of the original training set. Many of the original instances may be repeated in the resulting training set while others may be left out. After the construction of several regression models, taking the average value of the predictions of each regression model gives the final prediction. A more sophisticated version of bagging is described in Breiman (2001). Another method that uses different subsets of training data with a single learning method is the boosting approach (Duffy & Helmbold, 2002). The boosting approach uses the base models in sequential collaboration, where each new model concentrates more on the examples where the previous models had high error.

The simplest approach for building heterogeneous ensembles is to use a variety of learning algorithms on all of the training data and combine their predictions according to an averaging scheme (Kotsiantis & Pintelas, 2005). Among the combination methods, the averaging rule is the simplest to implement since it requires no prior training (Hjort & Claeskens, 2003). Stacked generalization (Ting & Witten, 1999), or stacking, is another heterogeneous approach. Stacking combines multiple regression models to induce a higher level regression model with improved performance. A learning algorithm is used to determine how the outputs of the base regression models should be combined. The original data set constitutes the Level 0 data. All the base regression models run at this level. The Level 1 data are the outputs of the base regression models. Another learning process occurs using as input the Level 1 data and as output the final prediction. Multiresponse linear regression (MLR) was used for metalevel learning (Ting & Witten).

Finally, there are some open problems in ensembles of learners, such as how to understand and interpret the decision made by an ensemble of learners because an ensemble provides little insight into how it makes its decision. For learning tasks such as data mining applications where comprehensibility is crucial, averaging methods normally result in incomprehensible learners that cannot be easily understood by end users.

CONCLUSION

The key question when dealing with ML regression problems is not whether a learning algorithm is superior to others, but under which conditions a particular method can significantly outperform others on a given application problem. One of the most active areas of research in supervised learning has been to study methods for constructing good ensembles of learners. Even if the learning algorithm can in principle find the best hypothesis, we actually may not be able to find it. Building an ensemble may achieve a better approximation, even if no assurance of this is given.

KEY TERMS

Artificial Neural Networks: They are nonlinear predictive models that learn through training and resemble biological neural networks in structure.

Data Cleansing: This is the process of ensuring that all values in a data set are consistent and correctly recorded.

Nearest Neighbor: It is a technique that predicts the value of each record in a data set based on a combination of the values of the *k* record(s) most similar to it.

Predictive Model: A predictive model is a structure and process for predicting the values of specified variables in a data set.

Regression Analysis: It is a technique that examines the relation of a dependent variable to specified independent variables.

Regression Tree: It is a tree-shaped structure that represents a set of decisions.

Rule Induction: It is the extraction of useful if-then rules from data based on statistical significance.

A Primer on Text-Data Analysis

INTRODUCTION

Since the invention of the printing press, text has been the predominate mode for collecting, storing and disseminating a vast, rich range of information. With the unprecedented increase of electronic storage and dissemination, document collections have grown rapidly, increasing the need to manage and analyze this form of data in spite of its unstructured or semistructured form. **Text-data analysis** (Hearst, 1999) has emerged as an interdisciplinary research area forming a junction of a number of older fields like machine learning, natural language processing, and information retrieval (Grobelnik, Mladenic, & Milic-Frayling, 2000). It is sometimes viewed as an adapted form of a very similar research field that has also emerged recently, namely, data mining, which focuses primarily on structured data mostly represented in relational tables or multidimensional cubes.

This article provides an overview of the various research directions in text-data analysis. After the "Introduction," the "Background" section provides a description of a ubiquitous text-data representation model along with preprocessing steps employed for achieving better text-data representations and applications. The focal section, "Text-Data Analysis," presents a detailed treatment of various text-data analysis subprocesses such as ***information extraction***, ***information retrieval*** and ***information filtering***, ***document clustering*** and ***document categorization***. The article closes with a "Future Trends" section followed by a "Conclusion" section.

BACKGROUND

Text-data analysis is defined as the computerized process of automatically extracting useful knowledge from enormous collections of natural text documents (a.k.a. document collections) usually coming from various dynamic sources. It is a broad process embedding a number of subprocesses, all of which deal with textual resources which are naturally unstructured or semistructured, as in the case of HTML (HyperText Markup Language) and XML (eXtensible Markup Language) documents; a fact that makes it extremely difficult to apply computational solutions to real life text-based problems.

In order to alleviate the difficulty faced by computers when dealing with the unstructured nature of text-data resources, a process called *indexing* is utilized. This process is normally preceded by a number of preprocessing steps that attempt to optimize the indexing process mainly by feature reduction, as explained in this section.

Indexing Textual Data

Indexing is the process of mapping a document into a structured format that captures its content. It can be applied to the whole document or some parts of it, though the former is usually the case. In indexing, the terms occurring in the given collection of documents are used to represent the documents. It is widely known that text documents contain large numbers of terms that have no significant relationship to the context in which they exist. Using all the terms would certainly result in high inefficiencies; therefore, many unrelated terms are usually eliminated through some preprocessing steps, as we shall discuss later.

One very widely used indexing model is the *vector space model* (Salton & Buckley, 1988) which is based on the bag-of-words (or set-of-words) approach. This model has the advantages of relative computational efficiency and conceptual simplicity (Salton & Buckley, 1988); nonetheless, it suffers from the loss of important information about the original text, such as information on the order of the terms in the text or about the boundaries between sentences or paragraphs. In this model, each document is represented as a vector, the dimensions of which are the terms in the initial document collection. The set of terms used as dimensions is referred to collectively as the *term space*. Each vector coordinate is a term having a numeric value representing its relevance to the corresponding document with higher values implying higher relevance. The process of giving numeric

values to vector coordinates is referred to as *weighting*. From an indexing point of view, weighting is the process of giving more emphasis to more important terms.

Three popular weighting schemes have been thoroughly studied in the literature: *binary*, *term frequency (TF)*, and *term frequency by* ***inverse document frequency*** (*TF*IDF*). For a term *t* in document *d*, the binary scheme records binary coordinate values, where a 1 is given to *t* if it occurs at least once in *d*, and a 0 is given otherwise. The TF scheme records *t*'s frequency of occurrence in *d*. It is common to normalize TF measurements in order to help overcome problems associated with document sizes. Normalization may be achieved by dividing all coordinate measurements for every document by the highest coordinate measure for that document. The TF*IDF scheme simply weights TF measurements with a global weight, the IDF (inverse document frequency) measurement. The IDF measure for a term *t* is defined as $log_2 (N/N_t)$, where *N* is the total number of documents in the collection, and N_t is the total number of documents containing at least one occurrence of *t*. The reader should note that IDF increases as N_t decreases, that is, as the uniqueness of the term among the documents in the given collection increases. As with TF, normalization is usually done here too. To normalize measurements based on the TF*IDF scheme, the cosine normalization is usually utilized as shown below:

$$W_{tk,dj} = \frac{TF * IDF(tk, dj)}{\sqrt{\sum_{s=1}^{|T|}(TF * IDF(ts, dj))(TF * IDF(ts, dj))}},$$

where *tk* and *dj* are the term and document under consideration, respectively, TF*IDF (*ts*,*dj*) is the coordinate measure of *ts* in *dj*, and |T| is total number of terms in term space.

Preprocessing

Various preprocessing steps are usually performed on the text corpus prior to indexing in order to optimize the indexing process primarily by reducing the number of terms used, thus leading to faster processing at the application level later on.

Case folding is the process of converting all the characters in a document into the same ***case***, either all upper ***case*** or lower ***case***. This step has the advantage of speeding up comparisons during the indexing process. ***Stemming*** is the process of removing prefixes and suffixes from words to reduce them to ***stem***s, thus eliminating tag-of-speech and other verbal or plural inflections. For example, the words "Computing," "Computer," and "Computational" all map to "Compute." It is worth noting that stemming algorithms have the disadvantage of requiring a great deal of linguistics and are, thus, language dependent. ***Stop words*** are words having no significant semantic relation to the context in which they exist. Stop words can be terms that occur frequently in most of the documents in a given collection (i.e., have low uniqueness and thus low IDF measurements) and as a result, must not be included as indexing terms. For example, articles and propositions such as "the," "on," and "with" are usually stop words. Stop words may also be document-collection specific. For example, the word "blood" would probably be a stop word in a collection of articles addressing blood infections, but certainly not in a collection describing the events of the 2006 FIFA World Cup that took place Germany.

TEXT-DATA ANALYSIS

Text-data analysis (a.k.a. text mining) is a very broad process that can be refined into a number of task-oriented subprocesses. A treatment of the major **text-data analysis** subprocesses follows.

Information Extraction

Many regard *information extraction (IE)* (Cowie & Lehnert, 1996) as the central text-data analysis subprocess largely owing to the success of its applications. IE has emerged as a joint research area between text-data analysis and natural language processing (NLP). It is the process of extracting predefined information on known entities and relationships among those entities from streams of documents and usually storing this information in predesigned templates. Information extraction is associated with streams of documents rather than static collections. One popular application of IE is the extraction of promotions and sales from streams of newspaper documents; the extracted information might be the event, the companies involved, or the event dates. Systems employing such technologies are usually referred to as news-skimming systems.

The IE process is twofold; first, it divides every document into relevant and irrelevant portions, and then, fills the predefined templates with the information extracted from the relevant portions. Simple IE applications, such as extracting proper names or companies from text, is currently being performed with very high precision; however, this is still not the case for more complex tasks, like determining the sequences of events from a document. In such complex tasks, IE systems are usually defined and applied on very restricted domains, normally with the help of domain experts which obviously hinders their portability to other domains. To summarize, IE systems scan streams of documents in order to transform the associated documents into much smaller bits of extracted relevant information that can be more easily maintained and comprehended. A number of very popular IE applications are briefly outlined as follows.

Template filling fills templates with information extracted from a document. Those templates are then stored in structured environments such as databases for fast information retrieval later. Zechner (1997) discusses template-filling systems.

Question answering is a variant of template filling where applications can answer questions like, "Where is Lebanon?" This area is still in its infancy and cannot answer more complex questions such as, "Which country had the lowest inflation in 1999?" However, some systems might be able to point the user to documents that discuss the posed question. BORIS (Lehnert, Dyer, Johnson, yang, & Harley, 1983) is a question-answering IE system which attempts to understand short domain-specific documents and answer questions on them.

Summarization maps documents into extracts (Neto, Santos, Kaestner, & Freitas, 2000) which are machine-made summaries, as opposed to abstracts which are man-made summaries. Applications usually extract a group of highly relevant sentences and present them as summaries. Some systems for this purpose are described in Zechner (1997).

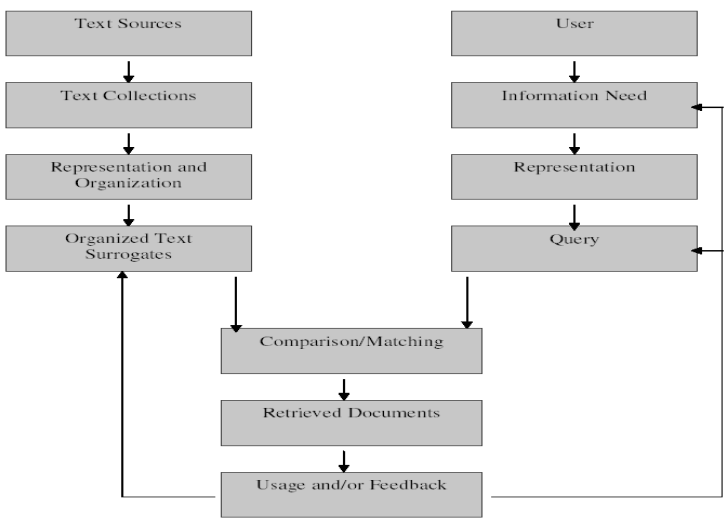
Information Retrieval and Information Filtering

Information retrieval (**IR**) and *information filtering* (IF) (O' Riordan & Sorensen, 2003) are two distinct processes having the same underlying goals. Given an *information need* represented by the user in a suitable manner, they are concerned with discovering a set of documents that satisfy that need. An information need is represented via *queries* in IR systems and *profiles* in IF systems. In the literature, IR is viewed as the ancestor of IF (and of text-data analysis as a whole). The reason for this is that IR is older, and IF bases much of its foundations on IR. Most of the research done in IR has been adapted to fit IF.

In spite of the fact that these two processes are very similar from a foundations point of view, many differences exist between the two that render them as two distinct subprocesses. A comparison between IR and IF is drawn next to highlight the main differences between the two in regard to goals, users, usage, and the type of the data on which they operate. First, the primary goal of IR is to collect and organize documents that match a given query according to some ranking function. IF, on the other hand, operates on document streams and is more concerned with routing newly received documents to interested users. Second, IR systems are usually used once by a one-time query user (Belkin & Croft, 1992) with short-term needs while IF serves a subscribed audience whose needs do not change much over long periods of time. Third, IR systems are developed to tolerate some inadequacies in the query representation of the information need; on the other hand, profiles are assumed be highly accurate in IF systems. Finally, IR systems usually operate over static collections of documents, while IF systems deal with dynamic streams of documents.

IR retrieves a set of documents from a collection that match a certain query. The retrieved documents are then rank ordered and presented to the user. Figure 1 presents a general model for IR as described in Belkin (Belkin & Croft, 1992). In this model, a user with some information need presents a query to the IR system. As mentioned earlier, a query is a simple representation of the user's information need in a language understood by the system. This representation is considered as an approximation due to the difficulty associated with representing information needs accurately. The query is then matched against the documents, which are organized into *text surrogates*. The collection of text surrogates

Figure 1. A general IR model



can be viewed as a summarized structured representation of unstructured text data, such as document vectors in the vector space model. Thus, they provide an alternative to the original documents as they take far less time to examine, and, at the same time, encode enough semantic cues to be used for matching instead of the original documents. As a result of matching, a set of documents would be selected and presented to the user. The user either uses the returned documents or provides *relevance feedback* to the system resulting in modifications to the query and the original information need or, in rare cases, to the text surrogates (Belkin & Croft, 1992). Google is one of the most popular systems using the IR model.

IF systems deal with large streams of incoming documents, usually broadcasted via remote sources. It is sometimes referred to as *document routing*. The system maintains profiles created by subscribed users to describe their long-term interests. Profiles may describe what the user likes or dislikes. New incoming documents are removed from the stream routed to a subscribed user if those documents do not match the user's profile. As a result, the user only views what is left in the stream after the mismatching documents have been removed; an e-mail filter, for example, removes all "junk" e-mail. Figure 2 depicts a general model for IF (Belkin & Croft, 1992).

The first step in using an IF system is to create a profile for a new subscribed user. A profile represents a user's (or a group of users') information need, which is assumed to be static over a long period of time. Whenever a new document is received through the document stream, the system represents it as text surrogates and compares it against every profile stored in the system. If the document matches a profile, it will be routed to the corresponding user. The user can then use the received documents or provide relevance feedback. The feedback provided may lead to modifications in the profile and the information need as Figure 2 shows.

Document Clustering

Document clustering (Neto et al., 2000; Steinbach, Karypis, & Kumar, 2000) is the process of grouping similar documents into partitions where documents within the same partition exhibit higher degree of similarity among each other than to any other document in any other partition. Clusters are usually mutually exclusive and collectively exhaustive. Figure 3 depicts a general clustering scheme. Clustering has been employed in a number of text-based applications such document categorization (Rahal & Perrizo, 2004) and IR (Kowalski, 1997). Some examples of applications that employ document clustering include browsing a collection of documents (Cutting, Karger, Pedersen, & Tukey, 1992), organizing documents returned by a search engine for some query (Zamir, Etzioni, Madami, & Karp, 1997), and automatically generating hierarchical clusters of documents (Koller & Sahami, 1997).

The two most popular techniques for document clustering are *hierarchical* and *k-means* clustering. Hierarchical clustering techniques produce a hierarchy of partitions with a single partition including all documents, at one end, and singleton clusters, each composed of an individual document, at the other end. The tree depicting the hierarchy of clusters is referred to as a *dendrogram*. Each cluster along the hierarchy is viewed as a combination of two clusters from the next lower or higher level, depending on the type of hierarchical clustering used, that is *divisive* or *agglomerative*, respectively. Agglomerative clustering starts with the set of all singleton clusters (i.e., each cluster includes one document) at the root of the tree, and then combines the most similar pair of clusters together at every tree level

Figure 2. A general IF model

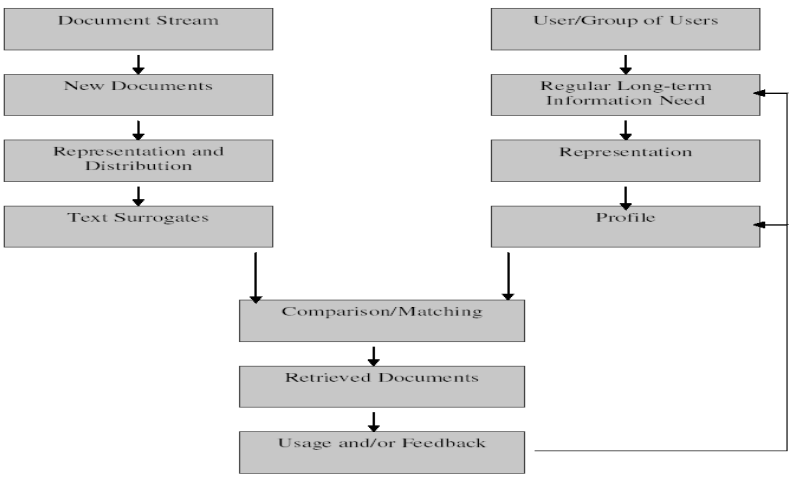


Figure 3. A general depiction of the clustering process

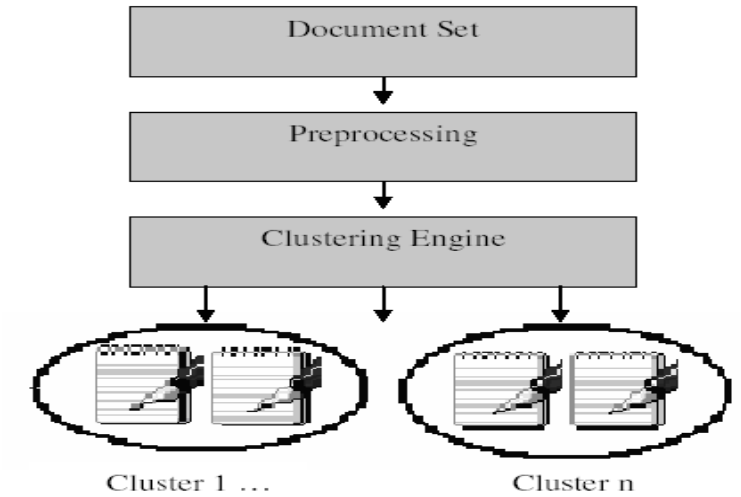

until it forms one cluster containing all documents at the leaf level. Divisive clustering, on the other hand, starts with a single cluster containing all documents at the root level and then splits one cluster into two clusters at every level of the tree until it forms a set of clusters, at the leaf level, each containing one and only one document.

Given a fixed number k, k-means clustering creates a set of k clusters and distributes the set of given documents among those clusters using the similarity between the document vectors and the cluster means. A mean for a given cluster is the average vector of all document vectors in that cluster. Every time a document is added to a cluster, the mean of that cluster must be recalculated. Similarity between a document and a mean can be computed using cosine similarity between the corresponding vectors. The mean does not always correspond to an actual document; as a result, a variant of k-means, called *k-mediods*, requires the mean to be an actual document vector. To do this, the document vector in the cluster that is closest to the mean is selected to serve as the mean of the cluster (Han & Kamber, 2006, pp.383-406).

In general, it is believed that hierarchical clustering techniques produce better cluster quality than their k-means counterparts while suffering from quadratic time complexity. On the other hand, k-means clustering and its variants have complexities linear to the number of documents, but produce clusters with lower quality (Steinbach, et al., 2000). The entropy (Steinbach et al., 2000) and the F-measure (Steinbach et al., 2000) measures are two very popular schemes used in evaluating the quality of the clusters produced by a clustering technique.

Document Categorization

Given a set of predefined document labels or categories, *document categorization* (Rahal & Perrizo, 2004), sometimes referred to as *topic spotting* or *text classification*, is the process of labeling unlabeled text documents with their corresponding category (or categories) based entirely on their content; in other words, the categorization process relies entirely on endogenous knowledge (knowledge extracted from the document) as opposed to exogenous knowledge (knowledge extracted from external resources). Categories are chosen to correspond to the topics or themes of the documents. The ultimate purpose of document categorization is automatic organization. Some categorizations systems (or classifiers) return one category per document, while others return multiple categories. Sometimes, a classifier might return no category or a number of categories but with very low confidence which results in flagging the document for manual inspection. The following is a brief account of two major applications in document categorization.

In *document organization* applications, document categorization is used for the purpose of organizing documents into categories for personal or corporate use. For example, newspapers receive a number of ads everyday and would benefit from an automatic system that can assign those ads to their corresponding categories, such as Real Estate or Autos. An important consequence of document organization is ease of search. Larkey (1999) provides an interesting example of this type of application.

Word sense disambiguation (WSD) is the process through which a system is able to find the sense of an ambiguous word (i.e., has more than one meaning) based on the context in which it occurs. For example, the word “class” might

mean a place where students study, or a category. Given a text containing an ambiguous word, a WSD application returns which of the meanings associated with the word is intended by the given text. WSD is heavily used in natural language processing (NLP) and in indexing documents by using word senses. See Roth (1998) for more details.

Regardless of the application, a text classifier can be either *eager* or *example-based*. In eager categorization, a set of precategorized documents is used to build the classifier. This data set is divided into a *training set*, TR, and *testing set*, TS. The two partitions need not be equal in size (and usually are not). The TR is used to build or train the classifier, and then the TS is used to test the accuracy of the classifier. This process is repeated until an acceptable classifier is attained. Some popular approaches that fall under this category include, *decision-tree* classifiers such ID3, C4.5 and C5 (Han & Kamber, 2006, pp. 291-309), *Rocchio* classifiers (Cohen & Singer, 1999; Sebastiani, 2003), *neural networks* (NN) (Lam & Lee, 1999), and *support vector machines* (SVMs) (Joachims, 1999).

On the other hand, in example-based categorization, no classifier is built in advance; rather, the set of all labeled samples is used to categorize new unlabeled samples. One very popular classifier under this category is the *k*-nearest neighbors (*k*NN) classifier (Yang, 1994) which, given a new sample d_j, tries to find k documents that are the most similar to d_j among the given set of samples using some distance measure, such as the *Euclidean* distance. Then a process, such as *plurality voting*, is performed by the selected neighbors to decide on the most appropriate label for d_j.

It is worth noting that almost all current text classifiers suffer from performance considerations related to accuracy and speed. Perhaps this fact is the main reason for the huge amount of research currently being invested in this promising area.

FUTURE TRENDS

With this vast and continuous spread of text information over the Internet, text-data analysis continues to attract attention with the promise of delivering critical hidden nuggets of knowledge extracted from huge text resources. From a business standpoint, this might mean better decision-making processes leading to increased profitability in market competitions based on Aristotle Onassis's maxim: "*The secret of success is to know something that nobody else knows*." (Prionas et al., 1996). This potential coupled with the present unsatisfactory text-application reliability will continue to push researchers in the near future to dedicate more financial and time resources to achieve higher degrees of accuracy for what once was viewed as a seemingly far-fetched objective.

The World Wide Web (WWW) is a dynamic entity that continues to evolve in order to accommodate our needs and ambitions. A recent observed trend has been the spread of multimedia data over the Internet intermixed with text data. The result is push for the adaptation and expansion of text-data analysis to deal with new forms of "text," such as audio, video and images.

CONCLUSION

This article has presented an overview of text-data analysis including text indexing, text preprocessing, and various text-data analysis subprocesses. Text-data analysis is an infant interdisciplinary field that lies at the junction of a number of older and more established fields like machine learning, natural language processing, information retrieval and the like. Its remarkable functional similarity to data mining is balanced off by the fact that each of those two fields deals with a different type of data: unstructured text data vs. structured data represented via relational tables or multidimensional cubes. Consequently, text-data analysis faces an additional challenge due to the unstructured or semistructured nature of text data.

KEY TERMS

Case Folding: The process of converting all the characters in a document into the same case, either all upper case or lower case, in order to speed up comparisons during the indexing process.

Document Categorization: The process of labeling unlabeled text documents with their corresponding category based entirely on their content.

Document Clustering: The process of grouping similar documents into partitions where documents within the same partition exhibit higher degree of similarity among each other than to any other document in any other partition.

Indexing: Indexing is the process of mapping a document into a structured (tabular) format that captures its content.

Information Extraction: The process of extracting predefined information on known entities and relationships among those entities from streams of documents and storing this information in pre-designed *templates.*

Information Filtering: The process of eliminating documents from a document stream routed to a subscribed user based on the user's profile.

Information Retrieval: The process of discovering a set of documents from static collection which satisfy a user's temporary information need defined by a query.

Stemming: The process of removing prefixes and suffixes from words to reduce them to stems thus eliminating tag-of-speech and other verbal or plural inflections.

INTRODUCTION

Multimedia applications and services have already possessed a major portion of today's traffic over communication networks. The revolution and evolution of the World Wide Web has enabled the wide provision of multimedia content over the Internet and any other autonomous network.

Among the various types of multimedia, video services (transmission of moving images and sound) are proven dominant for present and future communication networks. Although the available network bandwidth and the corresponding supporting bit rates continue to increase, the raw video data necessitate high bandwidth requirements for its transmission. For example, current commercial communication networks throughput rates are insufficient to handle raw video in real time, even if low spatial and temporal resolution (i.e., frame size and frame rate) has been selected. Towards alleviating the network bandwidth requirements for efficient transmission of audiovisual content, coding techniques have been applied on raw video data, which perform compression by exploiting both temporal and spatial redundancy in video sequences.

Video coding is defined as the process of compressing and decompressing a raw digital video sequence, which results in lower data volumes, besides enabling the transmission of video signals over bandwidth-limited means, where uncompressed video signals would not be possible to be transmitted. The use of coding and compression techniques leads to better exploitation and more efficient management of the available bandwidth.

Video compression algorithms exploit the fact that a video signal consists of sequence series with high similarity in the spatial, temporal, and frequency domain. Thus, by removing this redundancy in these three different domain types, it is possible to achieve high compression of the deduced data, sacrificing a certain amount of visual information, which however it is not highly noticeable by the mechanisms of the *human visual system*, which is not sensitive at this type of visual degradation (Richardson, 2003).

Thus, the research area of video compression has been a very active field during the last few years by proposing various algorithms and techniques for video coding (International Telecommunications Union [ITU], 1993; ITU 2005a, 2005b; Moving Picture Experts Group [MPEG], 1998; MPEG, 2005a, 2005b). In general video compression techniques can be classified into two classes: (1) the *lossy* ones and (2) information preserving (*lossless*). The first methods, although maintaining the video quality of the original/uncompressed signal, do not succeed high compression ratios, while the lossless ones compress more efficiently the data volume of initial raw video signal with the cost of degrading the perceived quality of the video service.

The lossy video coding techniques are widely used, in contrast to lossless ones, due to their better performance. More specifically, by enhancing the encoding algorithms and techniques, the latest proposed coding methods try to perform in a more efficient way both the data compression and the maintenance of the deduced perceived quality of the encoded signal at high levels. In this framework, many of these coding techniques and algorithms have been standardized, encouraging by this way the interoperability between various products designed and developed by different manufacturers.

This article deals with the fundamentals of the video coding process of the lossy encoding techniques that are common on the great majority of today's video coding standards and techniques.

BACKGROUND

The majority of the compression standards have been proposed by the ITU and the International Organization for Standardization (ISO) bodies, by introducing the fol-

lowing standards H.261, H.263, H.263+, H.263++, H.264, MPEG-1, MPEG-2, MPEG-4 and MPEG-4 Advanced Video Coding (AVC).

Some of the aforementioned standards were developed in partnership of ITU with MPEG, exploiting similar coding techniques developed by each body separately.

Each standard was designed and proposed targeting a specific service and application, featuring therefore specific parameters and characteristics. For example H.261 was proposed in 1990 for transmission of video signals over Integrated Services Digital Network (ISDN) lines on which data rates are multiples of 64 kbit/sec. The H.263 standard was designed as a low bit rate encoding solution for video-conferencing applications.

Similarly MPEG-1 was proposed by MPEG in order to be used by the video compact disc (VCD) medium, which stores digital video on a compact disc (CD) with a quality almost similar to that of an analog VHS video. In 1994 MPEG-2 was proposed for encoding audio and video for broadcast signals, exploiting interlace format. MPEG-2 is also the coding format used by the widely successful commercial digital versatile disc (DVD) medium.

Regarding the latest H.264, or MPEG-4 Part 10 AVC, it was proposed in common by the ITU Telecommunication Standardization Sector (ITU-T) Video Coding Experts Group (VCEG) and the ISO MPEG as the outcome of a joint venture effort known as the Joint Video Team (JVT). The scope of H.264/AVC project is to create a standard that would be capable of providing broadcast video quality at very low bit rates on a wide variety of applications, networks and systems.

Finally, in order to create a framework, which will reassure the interoperability of the codec implementation among the various developers, the standards include the concept of profiles and levels, defining a specific set of capabilities to be defined and implemented for a specific subset of applications and services.

VIDEO CODING

All the aforementioned video coding standards are based on the same basic coding scheme, which briefly consists of the following stages: (1) the temporal, (2) the spatial, (3) the transform, (4) the quantization and (5) the entropy coding stage.

The temporal stage exploits the similarities between successive frames with scope to reduce the temporal redundancy in a video sequence. The spatial stage exploits spatial similarities located on the same frame, reducing by this way the spatial redundancy. Then the output parameters of the temporal and spatial stages are further quantized and compressed by an entropy encoder, which removes the statistical redundancy in the data, producing an even more compressed video stream.

More analysis of each stage follows.

TEMPORAL STAGE

As input to the temporal stage of the encoding process, the uncompressed video sequence is used, which contains a lot of redundancy between its successive frames. The scope of this stage is to remove this redundancy by constructing a prediction of each frame based on previous or future frames, enhanced by compensating for fine differences between the selected reference frames. Depending on the prediction level, by which each frame is constructed, each frame is classified to three discrete types, namely:

(1) Intra-frame (I), (2) Predictive (P) and (3) Bidirectional predictive (B), widely referred as I, P, and B. The I-frames are also called Intra frames, while B and P are known as Inter frames.

- I-frames do not contain any prediction from any other coded frame.
- P-frames are coded based on prediction from previously encoded I- or P-frames.
- B- frames are coded based on prediction from previously or future encoded I- or P-frames.

The pattern of successive types of frames like IBBPBBPBBP… forms a Group of Pictures (GOP), whose length is mainly described by the distance of two successive I-frames.

Therefore, in order to perform this temporal compression, two discrete processes are performed at this stage—the motion estimation and motion compensation. Both these processes are usually applied on specific rectangular regions of a frame, called blocks if their size is 8 x 8 pixels or macroblocks if they are 16 x 16 rectangular pixel regions. At the latest standards (i.e., H.264) as Figure 1 depicts, variable block sizes are used for motion compensation depending on the content, achieving better coding efficiency.

During motion estimation, the encoding algorithm searches for an area in the reference frame (past or future frame) in order to find a corresponding matching region. The process of specifying the best match between a current frame and a reference one, which will be used as a predictor of the current frame, is called motion estimation. This is performed by comparing specific rectangular areas (i.e., blocks/macroblocks) in the reference and current frame, until the best match is detected. Due to this, their spatial differences are calculated, using the Sum of Absolute Differences (SAD):

$$SAD(d_x,d_y)=\sum_{i=0}^{15}\sum_{j=0}^{15}|f(i,j)-g(i-d_x, j-d_y)|$$

Figure 1. Example of variable block size coding

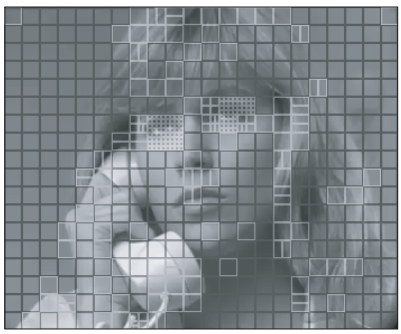

Figure 2. A frame where motion vectors appear denoting the position of the best matching region

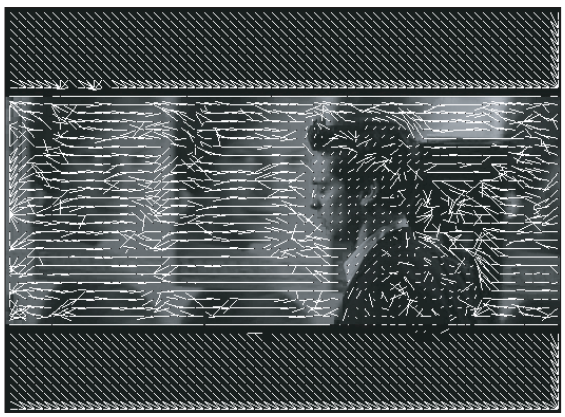


where *f(i,j)* and *g(i,j)* denote the luminance pixels of the current rectangular area (in this case a Macroblock) and the reference one respectively. The reference area is relatively defined by the current one using the motion vectors (d_x,d_y), denoting the position of the best matching region (see Figure 2).

When the best match has been performed, then the motion compensation follows. During this process the selected optimal matching region in the reference frame (i.e., the region that sets the SAD minimum) is subtracted from the corresponding region in the current frame with scope to produce a luminance and chrominance residual block/macroblock that is transmitted and encoded along with the reference motion vectors. The deduced frame by the motion compensation process is called residual frame, which contains the result of the subtraction of the reference regions from the corresponding ones of the current frame. In the residual frame the static areas correspond to difference equal to zero, while darker areas denote negative differences and lighter areas positive differences respectively. A typical example of a residual frame is represented in Figure 3.

Thus motion compensation enhances the efficiency of the motion estimation by adding at the predicted frame the fine differences that may contain the motion estimated predicted regions in comparison to the actual frame. Thus, during motion estimation the best matches between reference and current frames are detected and this match is further improved by motion compensation, which calculates the residuals of the motion estimated frame and the actual frame. So, by adding this motion compensated residual information on the motion estimated frame, an accurate and efficient prediction of the current frame can be performed, using regions of past or future frames.

SPATIAL STAGE

Similarly to the temporal stage, where predictive coding is performed between successive frames, a prediction of an image region may be also performed based on samples located within the same image or frame, which is usually referred to as Intra coding. At spatial stage, the encoder performs a prediction for a pixel-based pattern on a combina-

Figure 3. A residual frame denoting the differences between two successive frames for the fireman reference sequence

tion of previously coded pixels located on the same frame. Especially for frames that contain homogeneous areas, the spatial prediction can be quite efficient. In the case of a good prediction then the residual energy is small and the corresponding compression ratio high.

TRANSFORM CODING STAGE

At this stage the spatially/temporally encoded frames or the motion compensated, residual data are converted into another domain, usually called the transformed domain, where the optically correlated data become decorrelated. The use of transformation facilitates the exploitation in the compression technique of the various psycho-visual redundancies by transforming the picture to a domain where different frequency ranges with dissimilar sensitivities at the human visual system (HVS) can be accessed independently (Winkler, 2005).

The most commonly used transformation is the Discrete Cosine Transform (DCT). The DCT operates on an X block of N X N image samples or residual values after prediction and creates Y, which is a N X N block of coefficients. The action of the DCT can be described in terms of a transform matrix A. The forward DCT is given by:

$$Y=AXA^T$$

where X is a matrix of samples, Y is a matrix of coefficients and A is an N X N transform matrix. The elements of A are:

$$A_{ij} = C_i \cos\frac{(2j+1)i\pi}{2N} \text{ where } C_i \begin{cases} \sqrt{1/N}, & i=0 \\ \sqrt{2/N}, & i>0 \end{cases}$$

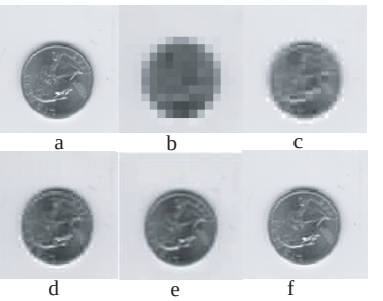
Therefore the DCT can be written as:

$$Y_{xy} = C_x C_y \sum_{i=0}^{N-1} \sum_{j=0}^{N-1} X_{ij} \cos\frac{(2j+1)y\pi}{2N} \cos\frac{(2i+1)x\pi}{2N}$$

The advantage of the DCT transform is that it is possible to reconstruct quite satisfactorily the original image, applying the reverse DCT on a subset of the DCT coefficients, without taking under consideration the rest coefficients with insignificant magnitudes (see Figure 4).

Thus, with the cost of some quality degradation, the original image can be satisfactorily reconstructed with a reduced number of coefficient values. This DCT property is exploited by the following stage where quantization of the DCT coefficients is performed.

Figure 4. Example of DCT efficiency. Figure a is the source image, while b is reconstructed using only 1 DCT coefficient, b exploits 4 coefficients, c uses 8 coefficients, d uses 12, e uses 18, and f 32 out of the 64 total DCT coefficients for each block (i.e., 8 x 8).



QUANTIZATION

Quantization is the process of approximating the continuous range of DCT coefficients by a relatively small set of discrete integer values. The best-known form of quantization is the scalar quantizer, which maps one sample of the input to one quantized output value. A scalar quantization operator *Q()* can be mathematically represented as

$$Q(x) = g(\lfloor f(x) \rfloor)$$

where

- x is a real number
- $\lfloor x \rfloor$ is the floor function
- *f(x)* and *g(i)* are arbitrary real-valued functions.

The integer value $i=\lfloor f(x) \rfloor$ is the representation that is usually stored or transmitted, but the final interpretation may be further modified using also *g*(*i*). Thus, typically during a scalar quantization process, it has performed the rounding of a fractional number to its nearest integer:

$$Y=QP\ round\left(\frac{X}{QP}\right)$$

where QP is the quantization parameter (i.e., quantization step size), X the initial integer value, and Y the deduced quantized number. Table 1 depicts some representative examples of the scalar quantization process for various quantization parameters.

Table 1. Quantization examples

X	Y		
	QP=1	QP=2	QP=3
0	0	0	0
1	1	0	0
2	2	2	3
3	3	2	3
4	4	4	3
5	5	4	6
6	6	6	6
7	7	6	6
8	8	8	9
9	9	8	9

Applying quantization on the aforementioned DCT coefficients is the main reason for the quality degradation and the appearance of artifacts, like the blockiness effect, at the digitally encoded videos. The blockiness effect refers to a block pattern of size 8 x 8 pixels in the compressed sequence, which is the result of the independent quantization of individual blocks of block-based DCT. Due to the quantized DCT coefficients, within a block (8 x 8 pixels), the luminance differences and discontinuities between any pair of adjacent pixels are reduced. On the contrary, for all the pairs of adjacent pixels, which are located across and on both edge sides of the border of adjacent DCT blocks, the luminance discontinuities are increased, by the coding process. This happens because the quantization process is lossy (i.e., not totally reversible) since it is not possible to determine the accurate fractional number from the deduced rounded integer. So it is somewhat equivalent with the case of not exploiting the entire DCT coefficient set for the reconstruction of the original image, as in Figure 4, because some low DCT values may have been quantized to zero.

It must be noted that the quantization stage is the only lossy stage at the described coding chain and is mainly responsible for any visual artifact and quality degradation that may appear on the deduced coded video signal.

ENTROPY CODING STAGE

At this final stage it has performed a transformation of the video sequence symbols into a compressed stream. The term video sequence symbol stands for all the aforementioned encoding parameters, such as quantization coefficients, motion vectors, and so forth. Basically, two widely known variable length coding techniques are exploited at this stage: The Huffman Coding (Huffman, 1952) and the Arithmetic Coding (Witten, Neal, & Cleary, 1987).

The variable length coding methods assign to each video sequence symbol a variable length code, based on the probability of its appearance. Symbols appearing frequently are represented with short variable length codes while less common symbols are represented with long variable length codes. Over a large number of encoded symbols, this replacement of video sequence symbols by variable length codes leads to efficient compression of the data. (Held & Marshall, 1991)

BLOCK DIAGRAM OF A DIGITAL VIDEO ENCODER

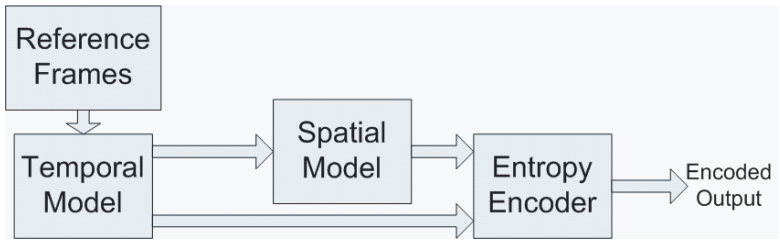
Based on the aforementioned description and analysis of the digital video coding stages, the following generalized block diagram of a video coded is presented in Figure 5 (Richardson, 2003).

In this diagram, we present the interconnection between the various stages that a typical video encoder follows during the digital video coding process, considering the transform and the quantization stage as internal processes of the spatiotemporal stages.

FUTURE TRENDS

Digital video coding techniques will prevail in the upcoming multimedia services and applications, because they will

Figure 5. Generalized block diagram of digital video encoder



enable the provision of such content over various bandwidth limited means and terminals. Towards this, the research community has been focused on developing video coding methods, which will be based on the aforementioned described encoding chain, but will be able to adapt dynamically to the coded video stream depending on the available bandwidth and the terminal characteristics. Dynamic video adaptation schemes will enable the seamless distribution of multimedia content over heterogeneous networks and terminal devices.

CONCLUSION

Video compression algorithms exploit the redundancy that a video signal contains in the spatial, temporal, and frequency domain. Thus, by removing this redundancy in these three different domain types, it is possible to achieve high compression of the deduced data. Briefly the encoding process consists of the following stages: (1) the temporal, (2) the spatial, (3) the transform, (4) the quantization, and (5) the entropy coding stage. This article has presented, explained, and analyzed the principles of each encoding stage, which remain the common basis over any existing video coding standard.

KEY TERMS

Bit Rate: Bit rate is the frequency at which bits are passing over a given physical medium. It is quantified by using the *bit per second* (*bit/s*) unit.

Frame: Frame is one of the many still images that as a sequence compose a video signal,

Integrated Services Digital Network (ISDN): ISDN is a type of circuit-switched, telephone network system designed to allow digital transmission of voice and data over ordinary telephone copper wires resulting in better quality and higher speeds than available with analog systems.

International Organization for Standardization (ISO): ISO is an international standard-setting body composed of representatives from national standards bodies. Founded in 1947, the organization produces worldwide industrial and commercial standards.

Moving Picture Experts Group (MPEG): MPEG is a working group of ISO charged with the development of audiovisual encoding standards. MPEG includes many members from various industries and universities related to audiovisual coding research.

Multimedia: Multimedia is the several different media types (e.g., text, audio, graphics, animation, video).

Pixel: A pixel is considered the smallest sample of a digital image or video.

Video Codec: Video codec is the device or software that enables the compression/decompression of digital video.

Video Coding: Video coding is the process of compressing and decompressing a raw digital video sequence.

Process-Aware Information Systems for Virtual Teamwork

Schahram Dustdar
Vienna University of Technology, Austria

INTRODUCTION

The question of the "right" organizational form and the appropriate information systems support remains of paramount importance and still constitutes a challenge for virtually all organizations, regardless of industrial background. Organizations distribute their required work activities among groups of people (teams), with teams constituting the main building block for implementing the work (tasks). In most cases, team members are organized as "virtual (project) teams." These teams are under heavy pressure to reduce time to market of their products and services and lower their coordination costs. Some characteristics of distributed virtual teams are that team (member) configurations change quite frequently and that team members report to different managers, maybe even in different organizations. From an information systems' point of view, distributed virtual teams often are self-configuring networks of mobile and "fixed" people, devices, as well as applications. A newly emerging requirement is to facilitate not just mobility of content (i.e., to support a multitude of devices and connectivity modes) to team members, but also to provide contextual information on work activities to all distributed virtual team members (Dustdar, 2002a, 2002b, 2002c). By context, we mean traceable and continuous views of associations (relationships) between artifacts (e.g., documents, database records), resources (e.g., people, roles, skills), and business processes. Context is composed of information on the "who, when, how, and why." The remainder of this chapter is organized as follows: The next section provides an overview of related work on classification systems of collaborative systems and provides an overview on evaluation aspects of current collaborative systems for virtual teamwork. Section 3 discusses some issues and problems related to the integration of artifacts, resources, and processes. Section 4 presents one proposed solution. Finally, Section 5 discusses some future trends and concludes the chapter.

FUNCTIONAL CLASSIFICATION OF COLLABORATIVE SYSTEMS

There has been a lot of work on classification models for collaborative systems. However, there is no one-and-agreed-upon taxonomy of analyzing and understanding collaborative systems. Academia and industry suggest various classification schemes. In industry, for example, people frequently use the term *e-mail* and *groupware* interchangeably. More generally, there is the tendency to classify categories of collaborative systems by naming a product (e.g., many use the terms *Lotus Notes* and *groupware* interchangeably). Academic research has suggested many different classification models. For a recent survey of collaborative application taxonomies, see Bafoutsou and Mentzas (2002). DeSanctis and Gallupe (1987), Ellis, Gibbs and Rein (1991), and Johansen (1988) suggest a two dimensional matrix based on time and place, where they differentiate between systems' usage at same place/same time (e.g., electronic meeting rooms), same place/different time (e.g., newsgroups), different place/different time (e.g., workflow, e-mail), different place/same time (e.g., audio/video conferencing, shared editors). This classification model helps one to easily analyze many tools on the market today; however, it fails to provide detailed insights on collaborative work activities themselves, as well as their relationship to business processes. Ellis (2000) provides a functionally oriented taxonomy of collaborative systems that helps one to understand the integration issues of workflow and groupware systems. The classification system of Ellis (2000) provides a framework in which to understand the characteristics of collaborative systems and their technical implementations.

The first category (Keepers) provides those functionalities related to storage and access to shared data (persistency). The metaphor used for systems based on this category is a "shared workspace." A shared workspace is basically a central repository where all team members put (upload) shared artifacts (in most cases, documents) and share those among the team members. Technical characteristics of "keepers" include database features, access control, versioning, and backup/recovery control. Examples of popular systems include *BSCW* (Bentley et al., 1997), IBM/Lotus *TeamRoom* (IBM, 2002), and the peer-to-peer workspace system *Groove* (Groove, 2002). The second category (Communicators) groups all functionality related to explicit communications among team members. This boils down to messaging systems (e-mail). Its fundamental nature is a point-to-point interaction model where team members are identified only by their name (e.g., e-mail address) and not by other means (e.g., skills, roles, or other constructs, as in some advanced workflow systems).

The third category (Coordinators) is related to the ordering and synchronization of individual activities that make up a whole process. Examples of Coordinator systems include workflow management systems. Finally, the fourth category (Team-Agents), refers to semi-intelligent software components that perform domain-specific functions and thereby help the group dynamics. An example of this category is a meeting scheduler agent. Most systems in this category are not off-the-shelf standard software. Both evaluation models presented above provide guidance to virtual teams on how to evaluate products based on the frameworks. Current systems for virtual teamwork have their strength in one or two categories of Ellis' framework. Most systems on the market today provide features for Keepers and Communicators support or are solely Coordinator systems (e.g., Workflow Management Systems) or Team-Agents. To the best of our knowledge, there is no system that integrates at least three of the above categories into one system. In the following section, we evaluate current collaborative systems categories for their usage in virtual teams and summarize their shortcomings with respect to the requirement for virtual teamwork.

Evaluation of Collaborative Systems for Virtual Teamwork

Cooperative tasks in virtual teams are increasing, and, as a consequence, the use of collaborative systems is becoming more pervasive. In recent years, it has increasingly become difficult to categorize systems according to the frameworks discussed previously, due to the increasing fuzziness of systems boundaries and to recent requirements for virtual teamwork. Traditional systems in the area of interest to virtual teamwork are groupware, project management (PM) and workflow management systems (WfMS). These system categories are based on different metaphors. Groupware systems mainly can be categorized along two lines (metaphors)—the *communications* or the *workspace* metaphor.

Communications-oriented groupware supports unstructured work activities using communications as the underlying interaction pattern. One very popular instance of communications-oriented groupware is e-mail. When e-mail is used as the main medium for virtual teams (as in most cases), data and associated information (e.g., attachments) remain on central mail servers and/or personal inboxes without any *context* information in which those e-mail communications were used (i.e., involved business processes, performed activities, created artifacts). Enterprise groupware systems generally focus on enterprise-wide messaging and discussion databases and do not support organizational components and structures, such as people and their associated roles, groups, tasks, and skills. This leads to "organizationally unaware" systems that treat all messages alike (semantically) and without any awareness of underlying business processes that are essential for efficient collaboration in project teams.

Workspace-oriented groupware, on the other hand, allows team members to upload or download artifacts using files and folders to organize their work. Groupware, as previously indicated, usually does not implement an underlying organizational model (i.e., providing information on the structure of a team, such as team members and their roles, skills, tasks, and responsibilities). The lack of explicit organizational structuring is a disadvantage and an advantage at the same time. It is disadvantageous because traditional groupware has no "hooks" for integrating business process information, which is important in order to integrate artifacts, resources, and processes. This will be discussed in more depth in the next section. The advantage of the lack of explicit organizational structure information is that these systems may be used in all organizational settings without much prior configuration efforts, and they lead to increased personal flexibility, as the proliferation of e-mail systems in teamwork demonstrates.

The second category, which we will briefly investigate in this section, is *project management systems*. As we have stated, virtual teamwork is, in most cases, organized as project work. Projects have well defined goals and are defined by their *begin* and *end* dates, as well as by the required resources and their tasks (work breakdown structure). It is interesting to note, however, that PM systems traditionally support the work of the project manager as the main (and sometimes the only) user of the PM system. They do not support dynamic interaction (instantiation) of processes. More recently, project management systems combine with information sharing tools (shared workspaces) to provide a persistent storage for artifacts. The enactment of the task by team members, as defined by the project manager, is not supported by PM systems. In other words, we can conclude that PM systems are not geared towards virtual teamwork, but focused more on the planning aspect. They provide "static" snapshots (usually in the form of GANNT charts) of projects and how they "should" be. There is no support for the work activities performed by the virtual team members.

The purpose of *workflow management systems* is to support the notion of processes within and, in some cases, between organizations (Aalst & Kumar, 2001; Bolcer, 2000; Bussler, 1999). However, WfMS' first requirement is to model a business process (build time) and then to enact this model (run time). This leads to substantial inflexibility for virtual teams (Ellis, 1995). In business, "exceptions are the rule;" therefore, modeling a process (project) is often not possible for creative, innovative virtual teams of knowledge workers such as in product development or consulting teams. A business process can be unstructured (ad hoc), semi-structured, or highly structured (modeled). For example, a business process such as "customer order entry" can be modeled using traditional WfMS. However, highly structured processes only can be enacted (instantiated) as they were designed. If an exception occurs, a workflow administrator needs to remodel the process before the execution can continue. This limits the

usability of WfMS in a world where constant adaptation to new situations is necessary and where teams are increasingly mobile and distributed. An example of an *ad hoc* process is discussion of a project's design review using Groupware. A semi-structured process consists of groups of activities that are modelled; however, in contrast to a structured (modelled) process, it may also consist of activities that are not predefined. A process is semi-structured when there might be one or more activities between already modeled activities such as *assign process*, which are not known beforehand and therefore cannot be modeled in advance.

It is important to note that requirements for virtual teamwork do not follow the traditional boundaries of systems already presented. We differentiate between synchronous and asynchronous technologies for teamwork support. During our case study requirements analysis, we came to the conclusion that distributed product development in virtual communities requires a blend of synchronous and asynchronous systems support for communications, as well a basic support for asynchronous coordination of team members and their activities. In summary, the requirements for virtual teams cannot be met simply by using a combination of traditional synchronous and asynchronous systems, since the criteria for successful systems in this area differ substantially with traditional "enterprise information systems." We identified and implemented (see Section 4) four fundamental feature sets for our virtual team software—device independence; process-awareness; integration of artifacts, resources, and processes; and organizational awareness. Most systems on the market do not cater to the requirements of virtual teams; namely, *dynamic views of relationships* between artifacts, resources, and process awareness are vital to the work organization of virtual teamwork.

ON THE INTEGRATION OF ARTEFACTS, RESOURCES, AND PROCESSES

Organizations increasingly define the work activities to be fulfilled in virtual teams where team members from within the organization cooperate (i.e., communicate and coordinate work activities) with outside experts, and therefore form virtual teams, which in many cases operate as geographically dispersed teams. In fact, team members work on business processes; however, in many instances, team members view their own work as a project and not necessarily as part of a larger business process fulfilling a business goal in a larger context. The work of virtual team members often results in artifacts (e.g., documents) that need to be shared among virtual team members. The underlying assumption of this chapter is that *process-awareness* is increasingly important to virtual teams. Teamwork is a fundamental property of many business processes. Business processes have well defined inputs and outputs and serve a meaningful purpose, either within or between organizations. Business processes in general and their corresponding workflows, in particular, exist as logical models (e.g., weighted directed graphs). When business process models are executed, they have specific instances. A business process consists of a sequence of work activities. An activity is a distinct process step and may be performed either by a human agent or by a machine (software). A workflow management system enacts the real world business process for each process instance (Craven & Mahling, 1995; Dayal et al., 2001; Schal, 1996). Any activity may consist of one or more tasks. A set of tasks to be worked on by a user (human agent or machine) is called *work list*. The work list itself is managed by the WfMS. The WfMC (WfMC, 1995) calls the individual task on the work list a work item. Software systems for workflow management—Groupware—process modeling (Puustjärvi & Laine, 2001), and project management has been used to automate or to augment business processes in organizations (Casati et al., 2001; Hausleitner & Dustdar, 1999). Workflow management systems have been defined as "technology based systems that define, manage, and execute workflow processes through the execution of software whose order of execution is driven by a computer representation of the workflow process logic" (WfMC, 1995). Workflow systems generally aim at helping organizations' team members to communicate, coordinate, and collaborate effectively, as well as efficiently. Therefore, WfMS possess temporal aspects such as activity sequencing, deadlines, routing conditions, and schedules. WfMS are typically "organizationally aware" because they contain an explicit representation of organizational processes (process model). However, traditional WfMS present a rigid work environment consisting of *roles* and their associated *activities* and *applications*. In this context, they do not provide support for virtual teams such as frequently changing process participants, ad hoc formation of groups collaborating on a business process, and device independent support of group activities. Unfortunately, today's WfMS assume that each *work item* is executed by a *single* worker (Aalst & Kumar, 2001). Most WfMS focus on automating structured (modeled) intra-organizational business processes. Groupware, on the other hand, typically does not contain any knowledge or representation of the *goals* or underlying business *processes* of the group. We argue that, considering the top three problems occurring in virtual teamwork, increasing contextual information in the form of building relationships between artifacts, resources, and business processes solves the fundamental problems and, as an implication, the most dominant problems such as "difficulties in team communications" and "unclear work activities." Our approach for integration of artifacts, resources, and processes comprises a communications and coordination building block where team members exchange "enriched" messages. Workflow

research has shown that modeling organizational structures has substantial benefits for business processes. Therefore, we allow modeling of organizational constructs such as groups, roles, skills, and organizational units. Each team member can be associated with those constructs, as shown in Section 4. Furthermore, an integrated database allows for attaching database objects to the communications and coordination activities of virtual team members, enabling integration of resources (organizational constructs) and artifacts. The process modeling component allows the creation of directed graphs consisting of tasks and their relationships with organizational constructs. The next section, therefore, discusses implementation issues on how to make context information (i.e., information about process instances), the team configuration (i.e., participants and their roles), their associated artifacts, and connectivity modes of group members (fixed, mobile, or ad hoc) accessible to all virtual team members.

THE CASE OF AN INTEGRATED INTERACTION MANAGEMENT SYSTEM FOR VIRTUAL TEAMS

In the following section, we will provide an overview of integration issues with which we are concerned, and design an integrated system for virtual teams called *Caramba* (Caramba Labs, 2002). An in-depth presentation of the conceptual foundations, the architecture, or the components is beyond the scope and focus of this chapter and can be found in Dustdar (2002b, 2002c, 2004). The Caramba software architecture is composed of multiple layers—middleware, client suite, and persistence store. Objects and services are accessed through the Transparent Access Layer (TAL) from the CarambaSpace platform (middleware). Depending on access mechanisms and the requested services (e.g., via Java client with RMI protocol or via Web browser with http), Caramba provides a unique way to handle requests using a metamodel framework to describe content and separate presentation, logic, and data. This model permits high flexibility and enables customization and extensions, as well as adopts new devices or technologies. The goal of this layer is to offer transparent access to a CarambaSpace. The TAL utilizes various services to transform, describe, manipulate, and observe objects. All objects managed through a CarambaSpace are described well using a metamodel description framework. Objects can be customized in their structure (e.g., adding columns to tables, adding relations to objects) and in their presentation by adopting their metamodel description. Any changes are dynamically reflected by client components. Based on the metamodel description framework Caramba enables various options to customize data and content and to integrate data from different resources (e.g., corporate databases). This layer also provides facilities for fine-grained object notification services and the implementation of customized services based on object observers. The middleware does not manage states and persistence of objects. Objects are stored, manipulated, and retrieved via the Persistence Layer (PEL). Caramba leverages and adopts standard Java-based technologies (e.g., JDBC, JNDI, HTTP, etc.) to access and integrate data.

An overall conceptual overview of how Caramba implements the requirements and how a work scenario of virtual teamwork may look is depicted in Figure 1. Virtual teams have one or more project managers and several resources (people) with various skill sets and professional backgrounds, as well as possibly different organizational affiliations. The daily teamwork consists of meetings, exchange of documents, and many communications (tasks, e-mails) being sent back and forth. For each project (business process), meetings, documents, and communications occur, and the trail of communications and interactions is depicted as lines between the team members. Without appropriate virtual team software, the relationship between artifacts, resources, and business processes is only available in the "heads" of the team members. For example, each team member has to remember *when* a particular document was sent to *whom* (e.g., a customer) and *why* (i.e., as a part of a particular business process). The goal of virtual team software should be to explicitly provide this relationship information to all team members based on their views and interests.

In order to provide one example of what an implementation looks like, we present the Caramba components. The ObjectCenter component provides mechanisms to link activities with artifacts. Based on a metamodel, Caramba provides a set of organizational objects: Persons, Roles, Groups, Skills, Units, Organization, Tasks, and Documents (i.e., Templates). Utilizing these organizational constructs, an administrator can model any organizational structure, such as hierarchical, flat, or matrix. Each object class consists of attributes describing the object. The object class *Persons* contains attributes about the person, such as name, address, and so forth. The object class *Roles* allows definition of organizational roles such as "Head of IT." The object class *Groups* defines project settings such as "Product Team IT-Solutions." *Skills* enables the definition of required skill sets such as "Certified Java Developer." *Units* describes permanent departments such as "Marketing." The Object Center provides a means (by drag and drop) to link rows of object classes with each other, as depicted in Figure 2. It allows users to view relationships between who (organizational constructs) is performing which activities (Tasks) and using what (Documents). A business process modeller component enables a project manager to model a process template, which may be instantiated later using the built-in Workflow engine. Exceptions to the model are possible, without the need to remodel the process template, by choosing the communications (coordination)

Figure 1. Conceptual view on virtual team software support

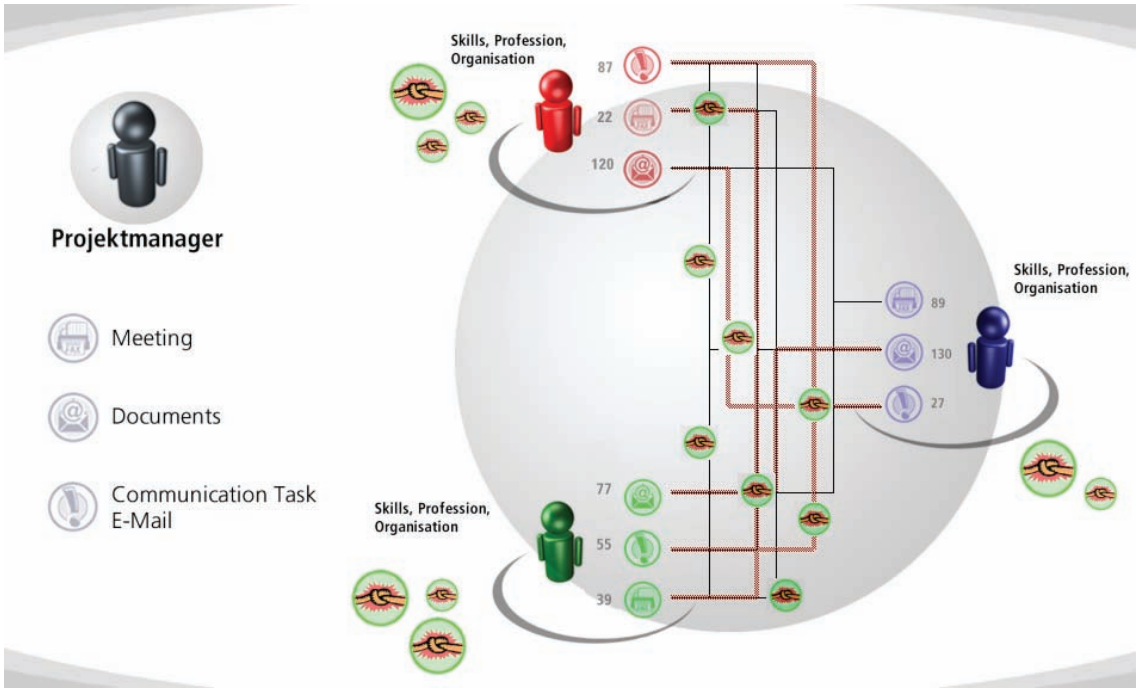

Figure 2. Modelling organizational resources and processes

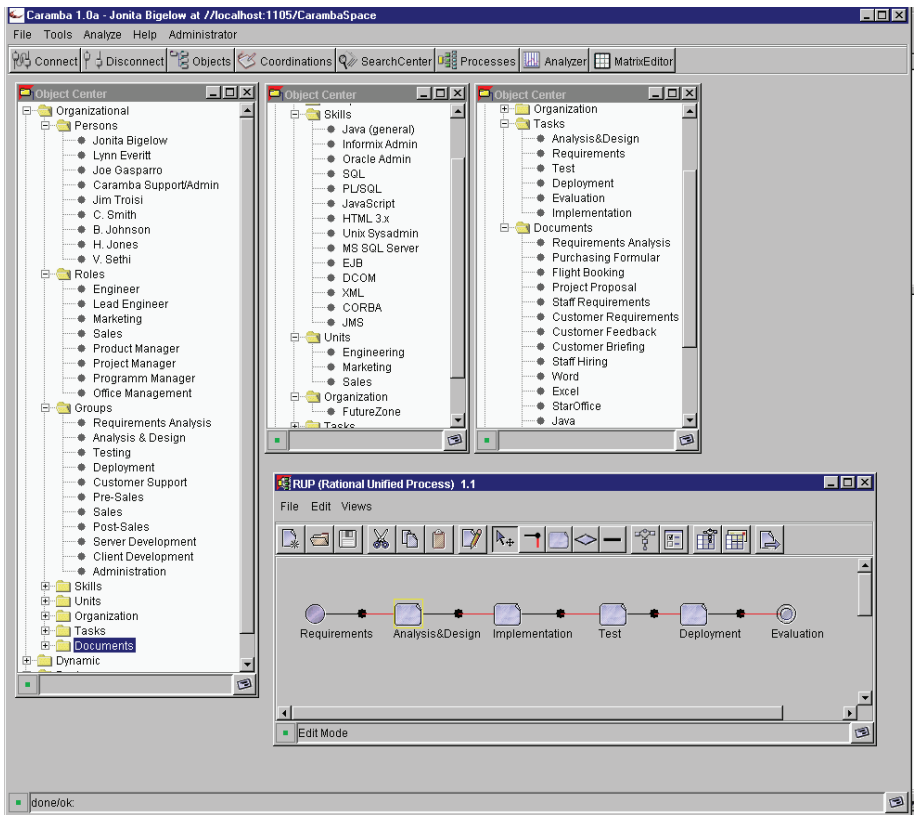

partner (from the ObjectCenter). The receiving end can read the appropriate message in his or her inbox.

CONCLUSION

During the last few years, virtually all business processes changed regarding their requirements for flexibility, interconnectivity, and coordination styles. Most business processes are based on teamwork. Most teams are organized as virtual teams, with team members coming from different organizations. In this chapter, we discussed the requirements of modern virtual teamwork and the problems associated with using traditional groupware, project, and workflow management systems for virtual teamwork. A fundamental need for distributed virtual teamwork is to have access to contextual information (i.e., to see a "knowledge trail" of who did what, when, how, and why). We presented the underlying conceptual issues and one implemented information system (Caramba) to support the integration of artifacts, resources, and business processes for virtual teams. Future virtual team systems should provide mechanisms for the integration of organizational models with artifacts and business processes in loosely coupled information systems. In our future work, we plan to design and implement support for definition, configuration, and composition of processes for virtual teams based on Web services. A Web service is an interface that describes a collection of operations that are network accessible through standardized XML messaging using Web servers or Application servers. A Web service is described using a standard, formal XML notion, called its *service description*. It can be published and found by other Web services. To summarize our recommendations and lessons learned, we think that for typical mid-size (e.g., 15-person) virtual teams (geographically dispersed), process-awareness, organizational awareness, and the integration of artifacts, resources, and processes is crucial. In most cases, we found that asynchronous systems support is of paramount importance when there are more team members in a virtual team and when more work occurs across different time zones.

ACKNOWLEDGMENT

The author thanks all team members of Caramba Labs Software AG for the fruitful and constructive discussions.

KEY TERMS

Knowledge Trail: Provides information on who did what, when, how, and why.

Interaction Management System: An information system providing an environment for communications and coordination of work activities for virtual teams.

Process: Indicates what tasks must be performed and in what order to complete a case.

Process-Awareness: (See knowledge trail)

Role: In order to perform tasks, skills are required. A role is a collection of complementary skills.

Task: An atomic process that is not divided further and is a logical unit of work.

Workflow: Comprises cases, resources, and triggers that relate to a particular process.

Process-Based Data Mining

Karim K. Hirji
AGF Management Ltd, Canada

INTRODUCTION

In contrast to the Industrial Revolution, the Digital Revolution is happening much more quickly. For example, in 1946, the world's first programmable computer, the Electronic Numerical Integrator and Computer (ENIAC), stood 10 feet tall, stretched 150 feet wide, cost millions of dollars, and could execute up to 5,000 operations per second. Twenty-five years later, Intel packed 12 times ENIAC's processing power into a 12–square-millimeter chip. Today's personal computers with Pentium processors perform in excess of 400 million instructions per second. Database systems, a subfield of computer science, has also met with notable accelerated advances. A major strength of database systems is their ability to store volumes of complex, hierarchical, heterogeneous, and time-variant data and to provide rapid access to information while correctly capturing and reflecting database updates.

Together with the advances in database systems, our relationship with data has evolved from the prerelational and relational period to the data-warehouse period. Today, we are in the knowledge-discovery and data-mining (KDDM) period where the emphasis is not so much on identifying ways to store data or on consolidating and aggregating data to provide a single, unified perspective. Rather, the emphasis of KDDM is on sifting through large volumes of historical data for new and valuable information that will lead to competitive advantage. The evolution to KDDM is natural since our capabilities to produce, collect, and store information have grown exponentially. Debit cards, electronic banking, e-commerce transactions, the widespread introduction of bar codes for commercial products, and advances in both mobile technology and remote sensing data-capture devices have all contributed to the mountains of data stored in business, government, and academic databases. Traditional analytical techniques, especially standard query and reporting and online analytical processing, are ineffective in situations involving large amounts of data and where the exact nature of information one wishes to extract is uncertain.

Data mining has thus emerged as a class of analytical techniques that go beyond statistics and that aim at examining large quantities of data; data mining is clearly relevant for the current KDDM period. According to Hirji (2001), data mining is the analysis and nontrivial extraction of data from databases for the purpose of discovering new and valuable information, in the form of patterns and rules, from relationships between data elements. Data mining is receiving widespread attention in the academic and public press literature (Berry & Linoff, 2000; Fayyad, Piatetsky-Shapiro, & Smyth, 1996; Kohavi, Rothleder, & Simoudis, 2002; Newton, Kendziorski, Richmond, & Blattner, 2001; Venter, Adams, & Myers, 2001; Zhang, Wang, Ravindranathan, & Miles, 2002), and case studies and anecdotal evidence to date suggest that organizations are increasingly investigating the potential of data-mining technology to deliver competitive advantage.

As a multidisciplinary field, data mining draws from many diverse areas such as artificial intelligence, database theory, data visualization, marketing, mathematics, operations research, pattern recognition, and statistics. Research into data mining has thus far focused on developing new algorithms and tools (Dehaspe & Toivonen, 1999; Deutsch, 2003; Jiang, Pei, & Zhang, 2003; Lee, Stolfo, & Mok, 2000; Washio & Motoda, 2003) and on identifying future application areas (Alizadeh et al., 2000; Li, Li, Zhu, & Ogihara, 2002; Page & Craven, 2003; Spangler, May, & Vargas, 1999). As a relatively new field of study, it is not surprising that data-mining research is not equally well developed in all areas. To date, no theory-based process model of data mining has emerged. The lack of a formal process model to guide the data-mining effort as well as identification of relevant factors that contribute to effectiveness is becoming more critical as data-mining interest and deployment intensifies. The emphasis of this article is to present a process for executing data-mining projects.

BACKGROUND

The fields of machine learning, pattern recognition, and statistics have formed the basis for much of the developments in data-mining algorithms. The field of statistics is one of the oldest disciplines concerned with automatically finding structure in examples. Discriminant analysis (Fisher, 1936), for example, is the oldest mathematical classification technique used to separate data into classes by generating lines, planes, or hyperplanes. Through the pioneering work on classification and regression trees (CART) by Breiman, Friedman, Olshen, and Stone (1984), the statistical community has made an important contribution in legitimizing

the use of decision trees, in data mining, for classification and regression. Pattern-recognition research emphasizes the creation of machines that can perform tasks more accurately, faster, and cheaper than humans (Fukunaga, 1972; Ripley, 1993), and has made an important contribution to data mining by popularizing the use of neural networks. A feed-forward neural network is a network in which the nodes (or processing units) are numbered so that all connections go from a node to one with a higher number. In practice, the nodes are arranged in layers with connections only to higher layers. Back propagation is an implementation for a feed-forward neural network in which error terms, from the output layer, are propagated back to the input layer so that the resulting connection weights at each node adjusted can be adjusted by means of an error-minimization method called gradient descent.

The multitude of data-mining algorithms can be linked to three main data-mining-problem approaches: clustering, association and sequential pattern discovery, and predictive modeling. Clustering (or segmentation) is concerned with partitioning data records into subsets. The *K*-means clustering algorithm is used for demographic clustering because categorical data are predominant. This algorithm, which is efficient for large databases, clusters a data set by determining the cluster to which a record fits best. Once clusters have been found in a data set, they can be used to classify new data. To uncover affinities among transaction records consisting of several variables, association algorithms are used. These algorithms are used to solve problems where it is important to understand the extent to which the presence of some variables implies the existence of other variables and the prevalence of this particular pattern across all data records. Sequential-pattern-discovery algorithms are related to association algorithms except that the related items are spread over time. Finally, the predictive-modeling data-mining-problem approach involves the use of a number of algorithms (e.g., binary decision tree, linear discriminant function analysis, radial basis function, back-propagation neural network, logistic regression, and standard linear regression) to classify data into one of several predefined categorical classes or to use selected fields from historical data to predict target fields.

The initial implementation of data-mining applications has been in the banking, consumer marketing, insurance, and telecommunications industries. Credit scoring, direct-mail target marketing, policy-holder risk assessment, and call graph analysis are but a few of the "killer" applications of data mining in these respective industries. As a result of some of the realized benefits of data mining, new applications are emerging in a number of areas including biomedicine where molecular data are combined with clinical medical data to achieve a deeper understanding of the causes for and treatment of disease, national security where unusual patterns and fraudulent behavior play a role in identifying and tracking activities that undermine security, pharmaceuticals where interest in understanding the 3D substructure of a molecule and how it interacts with the target is a crucial step in the design of new drug molecules, and ecology where large amounts of climate data, terrestrial observations, and ecosystem models offer an unprecedented opportunity for predicting and possibly preventing future ecological problems. Although the frontiers of data-mining applications continue to expand, focus on developing a data-mining process has not met with similar enthusiasm.

DATA-MINING PROCESS OVERVIEW

New product development (NPD) is a well-researched area (e.g., Hauptman & Hirji, 1999) and, thus, it is the foundation for the data-mining process model because NPD projects, by their very nature, are the most complex as they include systems, subsystems, components, and modules, as well as physical product and software aspects. Focusing on the NPD literature and synthesizing the elements of the various process models allows for the development of an information-centric process model for performing data-mining projects. Table 1 provides a baseline of what an inclusive process for performing data-mining projects might look like.

The phases in the baseline data-mining process include Phase 0, Phase 1, Phase 2, and Phase 3. Phase 0 is the *discovery* phase that supports the subsequent three phases. The set of proposed activities in this phase include (a) assessment of the organization's orientation toward data-centricity, (b) assessment of the capability of the organization to apply a portfolio of analytical techniques, and (c) strategy development for the use of analytics throughout the department or organization. Phase 1 is the *entry* phase. The underlying intent of this phase is to define the candidate business problem that is solvable and that can at least partially use existing data resident in the organization's databases. Prospecting and domain analysis, business problem generation and preliminary assessment, and data sensing are the proposed set of activities in this phase. Data sensing in particular is concerned with the representational faithfulness of the data set in question. Phase 2 is the *launch* phase. In this phase the data-mining project becomes a formal project with an associated capital and operational budget. The set of proposed activities in this phase include (a) secure project sponsorship, (b) project planning and project-team resourcing, (c) business problem refinement and validation of business assumptions and constraints, (d) development of the data strategy (i.e., explore the possible need for purchasing data from a third-party provider), and (e) formulation of the data-mining approach. Phase 3, the final phase, is the *execution and infusion* phase. The actual execution of data-mining algorithms takes place here as well as results analysis. The proposed set of activities in this final phase are (a) detailed

business-problem definition, (b) data sourcing and enrichment, (c) execution of data-mining algorithms, (d) results interpretation, synthesis, and validation, and (e) information harvesting and business-strategy formulation. This final activity focuses on developing a strategy to tactically leverage the new insight and to communicate this on a department-, division-, or perhaps enterprise-wide basis.

APPLICATION IN BUSINESS

The 1990s are referred to as the "heyday" of the mutual-fund industry in North America. Falling yields from fixed-rate investments, new product creation, and the hope of higher returns drove investors to purchase mutual funds. It is not surprising that mutual-fund companies therefore experienced double-digit growth rates in the range of 25% to 65%. The picture today is vastly different as industry consolidation, a mature business cycle, and flat market growth are causing gross sales to increase at a decreasing rate. Retail investors are now more than ever before scrutinizing management expense ratios (MERs) and fund performance reporting and returns. Competition among the various fund companies is fierce and thus there is a renewed focus on both stealing market share and developing a compelling story about future sales growth rates across multiple product lines. Some of the tactics employed to achieve various business goals are product innovation and quality, superior fund performance, and exceptional sales, marketing, and client service.

The experiences to date of the application of the proposed data-mining process to an analytics project in the mutual-fund industry suggests that the model is playing a role in contributing to a successful outcome. The project is in the early aspects of Phase 3 and therefore because it is ongoing and no actual positive net present value has been realized, conclusions cannot be made at this time. However, some of the key accomplishments that can be attributed to the process model are as follow.

- Project has been formally approved as a result of the capital-budgeting process
- Project team and stakeholders are in place
- Business problem related to effective channel management is understood and defined
- Business entity and data models have been developed
- Strategies to close data gaps and augment data where necessary are in place
- Data-mining approach with an emphasis on clustering exists

FUTURE TRENDS

The need for near-real-time information to support business decision making is becoming more and more critical. Data are benign and therefore there is more focus on understanding the "story" behind the data and the relationships among them. From the vantage point of practitioners and managers, there appear to be new patterns emerging specifically in three areas. The software and enterprise-wide-package-implementation industry is experiencing major consolidation, and software companies are realigning their sales efforts to focus on the ever-growing mid-market segment. Once this shakedown is complete, many business intelligence software and solution

Table 1. A summary of a data–mining process

Phase Name	Phase Identifier	Key Activity
Discovery	0	• Assess data centricity • Assess analytics capability • Develop analytics strategy
Entry	1	• Prospecting and domain analysis • Problem generation • Problem assessment • Data sensing
Launch	2	• Project sponsorship • Project planning and core project team • Problem refinement • Problem validation • Data strategy • Data-mining approach
Execution & Infusion	3	• Business-problem definition • Data sourcing and enrichment • Run data-mining algorithms • Results interpretation, synthesis, and validation • Information harvesting • Business-strategy formulation

providers will begin to bundle data-mining solutions with their existing offerings as a response to the already-established demand by customers in this market segment.

The data-mining process today is more akin to craft than interdisciplinary team-based problem solving. Once data mining gains acceptance and has a critical mass in organizations, there will undoubtedly be a shift to using this technology as part of a repertoire of tools to assist planners, product developers, managers, and others to develop strategies and tactical implementation plans for the organization. In this respect, improvement to existing tools in the areas of human interaction and visual presentation of information are expected. Finally, with the realities of virtual teams now solidified, the question of how virtual teams can effectively execute data-mining implementation projects will become relevant.

CONCLUSION

The paramount objective of publicly traded organizations is to focus on creating and maximizing shareholder wealth. However, recently well-publicized corporate shenanigans have shown that single-mindedly pursuing largesse at the expense of corporate social responsibility is not only fundamentally wrong, but also something that cannot be sustained indefinitely. Managers, C-suite executives, and corporate directors are now once again facing increasing scrutiny about revenue, profit, and earnings quality; adoption of accounting rules; and timely disclosures regarding the going concern of business entities. As managers craft, implement, and execute various growth, talent management, cost reduction, and competitive differentiation strategies, information technology will without a doubt continue to play an important role in enabling, supporting, leading, and transforming business, government, and not-for-profit organizations. Data mining as a technology is not an end, but rather a means to an end. Through the use of a disciplined and structured process, data-mining benefits can be obtained by the operationalization of data-mining results, via a business strategy, to achieve specific business-unit and enterprise-wide objectives.

KEY TERMS

Classification Trees: Type of decision tree that is used to predict categorical variables, whereas regression trees are decision trees used to predict continuous variables.

Cluster: Subset of data records; the goal of clustering is to partition a database into clusters of similar records such that records that share a number of properties are considered to be homogeneous.

Data Mart: Scaled-down version of an enterprise-wide data warehouse that is created for the purpose of supporting the analytical requirements of a specific business segment or department.

Data Mining: Analysis and nontrivial extraction of data from databases for the purpose of discovering new and valuable information, in the form of patterns and rules, from relationships between data elements.

Data Warehouse: A platform consisting of a repository of selected information drawn from remote databases or other information sources, which forms the infrastructural basis for supporting business decision making.

Information: Interpreted symbols and symbol structures that reduce both uncertainty and equivocality over a defined period of time.

Knowledge: Information combined with experience, context, interpretation, and reflection.

Operational Data Store: An integrated repository of transaction-processing systems that uses data-warehouse concepts to provide "clean" data in support of day-to-day operations of a business.

Project Management and Graduate Education

Daniel Brandon, Jr.
Christian Brothers University, USA

INTRODUCTION

Project Management is "the application of knowledge, skills, tools, and techniques to the project activities in order to meet or exceed stakeholder needs and expectations from a project" (Duncan, 1996). A project is defined as "a temporary endeavor undertaken to create a unique product or service" (Duncan, 1996). This article provides an overview of the coverage of the project management discipline in academic graduate education.

BACKGROUND

A number of professional organizations have developed around the world to address and foster this specific discipline. Most notable is the Project Management Institute (PMI, www.pmi.org) with about 100,000 members worldwide. Other major international organizations are the Association for Project Management (APM) and the International Project Management Association (IPMA) (Morris, 2001). These organizations have recognized there is a distinct skill set necessary for successful project managers, and the organizations are devoted to assisting their members develop, improve, and keep current these skills (Boyatzis, 1982; Caupin, Knopfel & Morris, 1998).

Several universities have also recognized the fact that project management involves distinct skills, and that the traditional degree programs and courses in both business schools and other schools do not adequately cover and/or integrate these skills. The *Chronicle of Higher Education* recently reported that seven Philadelphia-area corporations established ties with four universities in that region to improve the business skills of computer science and IT students; most of these key skills involved the project management skill sets, which are specifically identified later in this document (*Chronicles of Higher Education*, 2001).

Perhaps self-evident from the previous paragraph is the fact that the knowledge and training needed by project managers covers both traditional business disciplines and disciplines involved with building or making things. Often the skills involved with building or making things would be found in an engineering curriculum, and also in information technology or computer science curriculums.

Since the skill sets needed by project managers are extensive, and since these skills involve both business and engineering disciplines, and also since most candidate students are degreed working adults, most schools have developed their project management curriculums as graduate school programs. A number of universities also have a single "project management" course offered as a graduate or undergraduate course.

TYPES OF GRADUATE DEGREE PROGRAMS

An analysis of universities currently offering graduate project management programs indicates several types of programs being offered:

1. A master's level general degree program (such as an MBA) with a specialization in Project Management;
2. A full masters level (generally MS) program in project management; and
3. A "certification program" of several project management courses.

Some universities offer more than one of these program types. Also in some universities the program is offered in the School of Business (or Management) and in some schools the program is offered in the School of Engineering. In most universities, many of the courses appeared to be shared with other graduate degree programs; in other words, not all of the courses in the program are focused on project management.

PMI (and the other international project management organizations) have a certification program, and for PMI the designation is "Project Management Professional" (PMP). To obtain PMP certification, an individual must have 4,500 hours of documented project management experience over a period of six years, have a BS level college degree, and pass a rigorous 4-hour examination. The first PMP exam was given in 1984 to about 30 people, and today there are over 30,000 PMPs worldwide (Foti, 2001). Once the PMP status is obtained, an individual must earn 60 PDUs (Professional Development Units) every three years. Some universities offer a PMP Exam Preparation course or cover exam prep material in one of their project management courses. However, most graduate programs do not cover exam prep; in

fact, the graduate programs studied herein are more geared to providing the PDU credits for PMPs.

Figure 1 summarizes the program types for most of the U.S. universities offering project management programs "certified" by PMI. The list of such schools is on the PMI website (www.pmi.org). Out of the 19 schools listed, 11 offer a certificate program, six offer an MBA/MS specialization, and eight off a full Master's is project management. In 14 of the 19 schools, the program is entirely in the Business (or Management) school.

PROJECT MANAGEMENT KNOWLEDGE ORGANIZATION

PMI has developed an index of project management skills and knowledge called the "Project Management Body of Knowledge" (PMBOK). The PMBOK has been developed through several iterations over many years; the first version was developed in 1976 (Cook, 2004). The latest version (PMBOK, 2000) has been released (for certification testing beginning 1/2002) (PMI, 2000). It defines nine "knowledge area" which are organized into 37 "processes". The processes are grouped into five "process groups". This is illustrated in Figure 2 (for PMBOK, 1996) (Duncan, 1996).

Since so many resources have been put into the development and refinement of the PMBOK and it has been so well received by the project management community, it seemed prudent to us to organize our graduate program courses around the processes defined within PMBOK. The issue then became how do we "slice and dice" the processes as shown in Figure 2 into distinct (but integrated) courses. The PMBOK document itself organizes its write-up by knowledge area. However, most classic overall project management books and textbooks are organized by process groups (Badiru, 1989; Cleland & King, 1988; Hajek, 1984; Kerzner, 1980; Meredith & Mantel, 1989; Royce, 1988; Verzuh, 1999). There are however a number of books concerning particular parts of project management, and these cover particular knowledge areas, but they are not specifically written as "textbooks" (Fisher & Fisher, 2000; Fleming & Koppelman, 2000; Pinto & Trailer, 1999; Schuyer, 2001; Verma & Thamhain, 1996).

Looking at the universities currently offering degree programs to see how their curricula were organized, we defined three general types of organization:

1. "Step" – Courses are organized in the traditional manner from less depth to more depth over most of the knowledge areas. For example, the first course might be "Introduction to Project Management"; the next might be "Intermediate Project Management"; and the next would be "Advanced Project Management";
2. "KA" – Follows the PMBOK knowledge areas (Scope, Time, Cost, …); and
3. "PG" – Follows the PMBOK process groups (Initiation, Planning, …).

Figure 2. PMI process groups and knowledge areas

	Initiation	Planning	Executing	Controlling	Closing
Integration		Project Plan Development	Project Plan Execution	Overall Change Control	
Scope	Initiation	Scope Planning	Scope Verification	Scope Change Control	Scope Verification
		Scope Definition			
Time		Activity Definition		Schedule Control	
		Activity Sequencing			
		Activity Duration Estimation			
		Schedule Development			
Cost		Resource Planning		Cost Control	
		Cost Estimating			
		Cost Budgetting			
Quality		Quality Planning	Quality Assurance	Quality Control	
Human Resources		Organizational Planning	Staff Acquisition	Team Development	
Communications		Communications Planning	Information Distribution	Performance Reporting	Administrative Closure
Risk	Risk Identification	Risk Identification		Risk Response Control	
		Risk Quantification			
		Risk Response Development			
Procurement		Procurement Planning	Solicitation	Contract Administration	Contract Closeout
		Soliciation Planning	Source Selection		
			Contract Administration		

Most programs do not fit entirely into one of these molds, but they were categorized according to the best fit. Overall, out of the 19 schools, 10 use primarily the Step method, six use primarily the KA method, and two use the PG area.

For schools offering certification, five use the Step method, six use the KA method, and none use the PG method. For schools offering the MBA/MS specialization, none use the KA method, one uses the PG method, and the rest use the Step method. For schools offering the full MS in Project Management, two use KA's, one uses PG's, and the rest (five) use the Step method.

The issue of course material organization is a difficult one for a university. As discussed earlier, universities offering these programs are taking different approaches in this area. We feel the "Step" approach is only useful for programs that have two or three project specific courses. The "KA" approach requires much more "course preparation" time, textbooks are limited, and instructors need depth in these skills. One possible curriculum design would be to use a combination of "PG" and "KA". For "PG", separation into two process "super-groups" may be appropriate: project planning and project control; both covering scope, time, and cost. Separate "KA" courses would likely involve: procurement, risk, quality, and human resources/communications.

PROJECT MANAGEMENT CONTENT IN PROGRAMS

As can be seen from Figure 1, not all of the courses in a project management program are project management specific courses. For most schools, the certification offering is made up of mostly project management specific courses (the #PM in Figure 1 is the number of project management specific courses). For the project management specialization, most schools use three to six project management specific courses. For the full MS Project Management degree, the number of project management specific courses is about one-third to one-half of the courses. These non-specific courses in the full MS degree program vary widely from school to school especially if the degree is in the Engineering school instead of the Business school. Some of these non-project management specific courses are typically: general management, organizational behavior, leadership, managerial accounting, information technology, finance, human resources, quantitative methods, quality assurance, procurement and contracting, and risk management.

DELIVERY

Some universities are offering some, all, or portions of their courses in the form of "distance learning". So the issue be-

comes: "where on the spectrum from 'bricks to clicks' should a program position itself." There are many pros and cons on both sides of this issue, and most of those pros and cons depend on exactly how a course is made available "online" and the university's overall vision, mission, and tradition. This issue encompasses most degree programs (not just project management), so we are not going to further debate it here, except to indicate it is highly dependent on a particular school's mission, tradition, and demographics. As discussed in the following section, the potential students for such a graduate program are working adults, so attention has to be given to the best delivery for that market. Many schools are holding classes on weekends or evenings to accommodate the adult audiences for these types of programs (*San Diego Business Journal*, 2001).

PROGRAM STAKEHOLDERS AND THEIR NEEDS

We have discussed and surveyed the needs of the stakeholders of a graduate program in our region. The external stakeholders we identified were those companies and those individuals who would benefit from such a program. The companies would benefit by the introduction or reinforcement of the specific project management methodologies into their organizations; this has both an educational and training perspective.

Our individual stakeholders are primarily degreed working professionals. This is similar to the market served by the other universities we investigated, since those other universities like ourselves are located in large metropolitan areas. These individuals benefit from a "continuing education" perspective that makes them individually more valuable. Those individuals having earned PMI PMP Certification would have another way to earn PDU credits (a credit course at a university earns 15 PDUs per semester credit hour). Currency of methods and tools is also quite important to both corporations and individuals.

FUTURE TRENDS

For future university programs in project management, four dimensions can be defined. The PMI PMBOK focuses on the dimension of breadth of the knowledge areas (and the 37 processes) but intentionally does not go into much depth. Going into depth gets into method and tool specifics. Thus, a future trend in university programs would be to address not only the breadth but also the depth of these key processes.

The next dimension identified is industry particulars. While there is much commonality to project management in all industries, there is also much that is specific to each area. For example, task estimation for an IT project is much different than task estimation in a construction project. So this should be considered as another added dimension to new programs, certainly not for all industries but for the major ones in a school's geographic region.

The next dimension we identified was that of time or "currency". This not only includes the use of current tools, but the practice of project management in the current business and technical environment. Issues such as "virtual teams", international coverage, and Web-based systems would be included in this dimension.

CONCLUSION

Herein, we have examined content, approach, and logistics issues in graduate education for project management. The university programs surveyed were all relatively new programs, so there is little or no data available for a statistical or comparative historical analysis at this time. In the future, one may be able to survey graduates from the different types of programs to determine the pros and cons of each type of program organization and the "best practices" for project management education.

KEY TERMS

APA: Association for Project Management.

IPMA: International Project Management Association.

Knowledge Area (KA): Project Management Knowledge Area; For PMI there are nine knowledge areas: Integration, Scope, Time, Cost, Quality, Human Resources, Communications, Risk, and Procurement.

Process Group (PG): A grouping of project management processes; for PMI, there are five process groups: Initiation, Planning, Executing, Controlling, Closing.

Professional Development Unit (PDU): A unit of continuing education for certified project managers.

Project Management: The application of knowledge, skills, tools, and techniques to project activities in order to meet or exceed stakeholder needs and expectations of that project.

Project Management Body of Knowledge (PMBOK): A consolidation and organization of information about project management including “best practices”.

Project Management Institute (PMI): The largest of the professional organizations which foster the discipline of project management.

Project Management Professional (PMP): The highest level of professional certification of project managers by PMI.

Project-Based Software Risk Management Approaches

Subhas C. Misra

INTRODUCTION

The last few decades—especially the end of 20th century and the beginning of 21st century—have shown an increase in the interest in automation of different activities. Automation is dependent in its core on sound functional software. The complexity of software development has increased significantly over the years. Articles showing the failure of projects in the software industry are not surprising. Standish Group (1994) reports show that about 53% of projects get completed, but they do not meet the cost and schedule requirements, and about 31% are canceled before the completion of the projects. These failure reports are significantly alarming.

With the tremendous growth in the complexity of software development in the last 10 to 15 years, the management of risks in software engineering activities is becoming an important and nontrivial issue from three perspectives: project, process, and product. Therefore, researchers and practitioners are continually trying to find effective risk management approaches.

This article should help the academicians, researchers, and practitioners interested in the area of risk management in software engineering to gain an overall understanding of the area.

BACKGROUND

Meaning of Risk Management

Simply put, risk management is a way to manage risks. In other words, it concerns all activities that are performed to reduce the uncertainties associated with certain tasks or events. Risk management reduces the impacts of undesirable events on a project or the final product. Risk management in any project requires undertaking decision-making activities.

Origin of Risk Management

Risk management has its roots in probability theory and decision making under uncertainty. Three well-known theories in these areas—*expected utility theory* (Bernoulli, 1954; Hogarth, 1987), *theory of bounded rationality* (Simon, 1979), and *prospect theory* (Kahneman & Tversky, 1973; Kahneman, Slovic, & Tversky, 1982)—were of the greatest influence. These theories may be considered as disciplines by themselves. Therefore, to put our discussions on risk management in context, we briefly state hereafter only what each of these theories propose.

In brief, the expected utility theory discusses how people make choices from different alternatives, based on their expected utility. The theory of bounded rationality states that for real life events the outcomes and their associated probabilities are very limitedly understood by people to make the required decisions to maximize their expected utility. Therefore, people have a tendency to set up targets of aspiration in life by eliminating alternatives from the different options they have. This theory is useful for modeling the behavior of project management personnel in charge of risk management. Prospect theory, which has its origin in psychology, helps to model how the perceptions of human beings influence their choices from the given options. Thus, it helps for understanding and estimating the utility losses of different alternatives while analyzing risks in risk management.

Purpose of Risk Management

Risk management in software has different uses. It helps to save projects or products from failing due to different factors such as noncompletion of projects within the specified schedule and budget constraints and not meeting the customer expectations of the final product.

In the context of projects, risk management looks at projects from different perspectives to ensure that the threats

to the projects are identified and analyzed, and appropriate strategies are undertaken to mitigate and control risks. The mitigation strategies may not necessarily mean the cancellation of tasks that involve risks. Many tasks are undertaken in the software industries even after knowing that undertaking them involves taking high risks. The high-risk tasks are sometimes important to provide the industries a leading edge over their competitors.

Software risk management takes a preventative approach leading to completion of projects or the development of products within predictable time, money, and according to the product specifications. In fact, risk-managed projects and products have the ability to reduce costs and time of completion and increase the overall quality of the project and product deliverables. Without these, organizations could risk loss of revenue and customer trust in an average case, or a complete bankruptcy of the participating organizations in the worst.

RISK MANAGEMENT IN SOFTWARE PROJECTS

The software development projects in the early years of the last century conducted risk management using different ad hoc approaches, without following any systematic methodologies. However, with the increasing complexity of software development, industries have realized the importance of risk management, because it helps in reducing the uncertainties involved in developing software and decreasing the chances of project or product failures.

In the context of projects, before applying any risk management method, the team members should be clear about the following dimensions of risks in their projects (Smith & Pichler, 2005):

- The nature of *uncertainty* involved, and the likelihood with which the risk will occur.
- The *loss* that will be incurred if the risk occurs. Loss in software projects can take many forms including loss of revenue, loss of market share, and loss of customer goodwill.
- The *severity* of the loss.
- The *duration* of the risks.

Different Approaches

Project Risk Management

Several software project risk management approaches have been proposed in the past, most of which assess risks during all the phases of software development, by integrating risk management practices along with the software development process. As a result, in these approaches the risk management approaches follow a disciplined process. These approaches are listed as follows:

- Boehm's risk management model (win-win) (Boehm & Ross, 1989; Boehm & Bose, 1994; Boehm et al. 1998),
- SEI's software risk management model (SRE Version 2.0) (Williams et al., 1999),
- Hall's risk management model (P^2I^2) (Hall, 1998)
- Karolak's risk management model (Just-In-Time Software) (Karolak, 1998), and
- Kontio's riskit methodology (Kontio, 2001).

A "horizontal" comparison of all of these approaches may not be fair because although each of them addresses risk management, they were developed under different circumstances for solving—may be related but different issues. For example, Hall's P^2I^2 was developed from a risk management capability modeling perspective. On the other hand, Boehm's win-win model (Boehm & Ross, 1989; Boehm & Bose, 1994; Boehm *et al*. 1998) was developed primarily as a novel software development process model ("spiral" development) taking a risk-based approach. However, we provide later on an overview of the characteristics of all these approaches.

Of all these approaches, Boehm's win-win (Boehm & Ross, 1989; Boehm & Bose, 1994; Boehm *et al*. 1998) is perhaps the most influential software engineering risk management process model, which became popular during the early 1990s. He developed the first software engineering risk management process model, which integrates seamlessly into the software development lifecycle.

SEI's software risk evaluation approach (called, SRE) (Williams et al., 1999) is also quite popular in practice. It has been applied in several software development projects of several government, and nongovernment organizations. SEI's SRE provides a systematic, detailed, and step-wise approach one could use in software development and acquisition projects. It is based on the idea of continuous risk management. Another characteristic of SRE is that it integrates team risk management principles into the core framework.

Hall (1998) proposed a framework from a different perspective. She proposed a comprehensive framework based on the notion of risk management capability maturity. Her approach is based on four critical success factors of risk management, namely, people, process, infrastructure, and implementation (P^2I^2). However, it is the "process" component of the framework which discusses the risk management processes.

Karolak (1996, 1998) looked at software engineering risk management from the just-in-time viewpoint, the idea of which was popular in the traditional manufacturing industries. Like Hall, he also provided a complete framework that one

could use for risk management in software development. His framework first identifies a set of highlevel risk categories, associates them with risk factors, specifies risks assessment measures for each of these factors to obtain quantitative estimates of risks.

Kontio took a stakeholder-oriented approach to risk management. He proposed a thorough process model that recognizes and manages risks by balancing the stakeholder expectations. According to this approach, the stakeholder goals and expectations are modeled as essential entities for defining risks.

Recently, there has been few mentionable works conducted in the area of software risk management. In this article, we mention below some of the following recent approaches:

- Software risk assessment model of Foo and Murugananthan (2000): It takes a quantitative approach to predict risks using situational factors.
- Source-based software risk assessment methodology of Deursen and Kuipers (2003): It is based on the collection of different types of facts.
- ProRisk risk management framework of Roy (2004): It provides a complete framework for risk management based on the Australian AS/NZS 4350 standard.
- One-minute risk assessment tool of Tiwana and Keil (2004): It provides a tool that project managers could use to assess risks in a very short time.

FUTURE TRENDS

Many of the approaches discussed in this article are limited by the lack of empirical evidences supporting them. This is an important area in which future work should be targeted. Focus should be made on comparing the competing approaches with respect to a predefined set of evaluation criteria.

Software development often involves contractors. None of the risk management approaches clearly address the issues related to such resources. Similarly, they do not address the several telecommuters who may be working on the project remotely. More so, the impact of recent changes like offshoring and outsourcing may have several impacts on software development, and their influence in the context of risk management in software engineering should be investigated. The major challenges lie in social and cultural differences between the different players on the project in an outsourced project environment. It might so happen that in a project there are two or more software developers doing similar jobs with vastly different cultural settings and vastly different pay scales. There are issues like time zone differences and, above all, the "perceived" quality by the customers due to outsourcing.

For most of the proposed approaches we need controlled case studies and actual field trials for assessing their effectiveness and applicability under modern contexts and shifting paradigms.

The volatility of software project risks has some negative impact on the acceptance of the risk models that suggest different risk mitigation strategies. Thus, we should perform future studies on software risks keeping the aforementioned factors in mind.

CONCLUSION

It is conjectured that the management of risks can lead to the success of projects. Risk management has been popular in non-software domains for several decades. However, it is primarily in the last few years that risk management in software domains has become popular. However, at present, risk management in software is a developing discipline—it is poorly understood and practiced. Compared to the risk management literature available in other disciplines (e.g., insurance and manufacturing), the volume of risk management literature available in software is scarce. In this article, we attempted to review the fundamentals of software risk management and the different popular risk management project and product-based approaches.

We have reviewed the principles of software project risk management, reviewed some of the risk management approaches popular in the software engineering community, provided a summary of some of the important works conducted recently in this area in the last 5 years, and finally, provided some thoughts on future works that can be done.

The article should help the academicians, researchers, and practitioners interested in the area of risk management in software engineering to gain an overall understanding of the area. The article should be of immense help to the software engineering community.

The implications for practitioners is that they can use risk management approaches to know all possible risks in a project, assess their severity and consequence, and then determine resolution steps depending on the nature of the risks. The idea is to minimize any unforeseen and unexpected issues arising during the course of the project or product by properly planning for eventualities. Proper planning leads to minimizing uncertainties, which might lead to a "turbulent" completion, or a complete cancellation of the projects.

KEY TERMS

P^2I^2: Elaine Hall's approach for risk management in projects. It is based on four critical success factors of risk management, namely, people, process, infrastructure, and implementation.

Product Risks: Risks related to products developed. These risks have the potential to affect the successful operation of the products. They are often associated with the reliability of operation of the products.

Project Risks: Risks related to projects. These risks have the potential to affect the successful completion of the projects. They are associated with project parameters such as the project time lines and budgets.

Risk: "Risk refers to a possibility of loss, the loss itself, or any characteristic, object, or action that is associated with that possibility" (Kontio, 2001).

Risk Management: The disciple of managing risks using strategies such as planning, assessment, analysis, and control of risks.

Software Reliability: A branch of software engineering dealing with the evaluation of how reliably a software system will perform when functional.

Software Risk Management: The disciple of managing risks in software projects, processes, and products.

PROLOG

Bernie Garrett
University of British Columbia, Canada

INTRODUCTION

Prolog is a logic based programming language, and was developed in the early 1970s and is a practical programming language particularly useful for knowledge representation and artificial intelligence (AI) applications. Prolog is different from many common computer languages in that it is not a procedural language (such as Basic, C, or Java). It is an interpreted logic based declarative language and as such has no loops, jumps, type declarations or arrays, and no fixed control constructs. In the past this has led to the impression that Prolog is a restricted language, useful only for highly specialized programming tasks by enthusiasts (Callear, 1994; Krzysztof, 1997). However, this is not the case and modern versions of Prolog are well equipped and versatile, and can be used for any programming task. The latest generations of the language (e.g., Visual Prolog) can also be integrated into more common object oriented languages.

BACKGROUND

Origins

The development and growth in the use of prolog has followed the expansion of interest in artificial intelligence and knowledge based/expert systems. These are computer systems that simulate human cognitive processes, and incorporate large volumes of information in a database using rules to attempt to encapsulate this information as knowledge (or the knowledge of a human expert in the case of expert systems).

Prolog was developed by Alain Colmerauer of Marseilles University, and Robert Kowalski of the University of Edinburgh, in the early 1970s as an alternative to the American Lisp programming languages (early mathematical notation based languages), and Planner (a procedural language representing "knowledge" in the form of high level procedural plans). Kowalski, was a primary advocate in the logic paradigm community (see Fundamental Ideas), and in collaboration with Alain Colmerauer they created a subset of the language "micro planner" called Prolog, Kowalski hoped to demonstrate with Prolog that the logic paradigm was a viable approach to programming. It was Philippe Roussel (also at Marseilles University) who came up with the name as an abbreviation for "PROgrammation en LOGique" to refer to this software tool which was originally devised as a man-machine interface using natural language.

Fundamental Ideas

Prolog is a declarative language in that all the facts and data relating to the subject domain are stored and statically declared in a Prolog database. Rules are created that draw out the information from the database as necessary. Problem solving is achieved from the perspective of the data rather than the procedure, and this can be highly efficient (Bratko, 1996). We can contrast this with the conventional procedural paradigm where the computer performs a sequence of instructions or procedures to resolve a problem. Prolog does not specify any data types in its structure in the way common programming languages do. It therefore has a very open data structure and does not distinguish integers from real numbers, for example. Prolog has two basic functional components. Firstly, a query interpreter program that searches the second component, a Prolog database of facts and rules. The database or program is normally in the form of a text file.

The Logic Paradigm

John McCarthy (1958) originally proposed that mathematical logic be used for representing the nature of knowledge in computer systems. Marvin Minsky and Seymour Papert developed a different approach based on procedural implementations at MIT where the program simply contains a series of computational steps to be carried out to reach a goal (Hewitt, 2006). The logic programming paradigm developed as an alternative to the procedural paradigm and incorporates the invocation of procedures from inferential and deductive processes. Many people were involved in the endeavor of deriving a computer programming language from the discipline of logic, notably Robert Kowalski at Edinburgh University.

Unlike most procedural languages, Prolog programs are not written in a way that models how a computer works, but incorporate techniques that reflect the logical principals of problem solving. In Prolog rather than describing how to compute a solution, the program consists of a data base of facts (or defined predicates about something) and logical relationships (rules) which describe the relationships which hold between those facts. Rather then running a program based on a set of procedures to find a solution to a problem, the logic paradigm makes the user ask a question. A runtime system then searches through a database of facts and rules using logical deduction to determine the answer to this

question, and then invocates a predetermined procedure as a result.

In reality Prolog is not a full implementation of logic programming as this would be purely declarative. It is more accurate to say that Prolog is a programming language based on logic as its implementation has distinct procedural aspects, such as backtracking (Hewitt & Agha, 1988). However, this is a useful aspect of the language as it makes it straightforward to write conventional computer programs in Prolog.

Backward and Forward Chaining

There are two main methods of reasoning when using inference rules in computer applications. These are forward and backward chaining. Forward chaining starts with the available data and uses inference rules to extract more data until a goal is reached. In backward chaining, the system starts with a list of goals and works backwards to see if there are data available that will support any of these goals. An inference engine using backward chaining searches all the inference rules until it finds one which has a then clause that matches a desired goal. If the if clause of that rule is not known to be true, then it is added to a list of goals to be searched for and the search continues until all the goals are met (or fail to be met). Backward chaining attempts to match the action rather than the conditions during its operation, and works from goals to facts. It eliminates the need to solve every possible outcome for a given set of rules. Forward chaining inference is often called data driven in contrast to backward chaining inference, which is referred to as goal driven reasoning. Prolog is based on mathematical logic, and the basis for this claim is that Prolog uses backward chaining processes in its operation from goal to sub-goal.

This process can be represented by the following code in Prolog:

$goal_X$:- $subgoal_1$, ..., $subgoal_n$.

This states that in order to prove $goal_X$, then you must prove $subgoal_1$ through to $subgoal_n$.

Unification

Unification is the built-in pattern-matching algorithm in Prolog, and one of the main concepts in behind it (Sterling & Shapiro, 1994). It is the mechanism by which variables are bound (or instantiated) to unique assignments. In Prolog, this operation is denoted by the equal symbol (=).

Queries in Prolog work by pattern matching. The query pattern is the goal, and if a fact in the Prolog database matches this goal, then the query succeeds and Prolog responds with 'yes.' If there is no matching fact, then the query fails and Prolog responds with 'no.'

Example:
In the following example Prolog unifies the variable "what" with the atom (a constant string of characters) "trees."

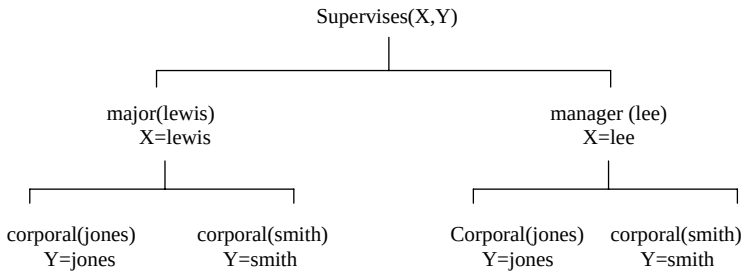
```
?- climbs(bear,What).
What=trees.
Prolog responds: yes
```

Prolog uses a capital letter to indicate a variable and a lowercase letter to indicate an atom. In older versions of Prolog a variable which is has not been instantiated yet can be unified with any atom, term, or another uninstantiated variable. In more modern versions a variable cannot be unified with a term that contains it. Binding a variable to a structure containing that variable can results in a cyclic structure which would cause the unification to loop forever. For example, A=f(A). This is a type of recursion. Modern versions of Prolog include an "occurs check" to prevent this happening.

Backtracking
In Prolog backtracking is a process that allows it to work through all the sub-goals in a rule if one sub-goal fails. In this case Prolog does not give up immediately and make the rule fail but it backtracks to previous sub-goals to try other instances of them in the database, then move forward again and see whether this causes the failed sub-goal to succeed. In this way it goes through a process that tries all the possible combinations of solutions, and finds the successful ones, before it finally reports that a rule has failed (Coehlo & Cotta, 1988).

In order to cope with the very limited memory systems and sequential computer architecture that were available when the language was developed, an efficient backtracking control structure was implemented so that only one possible computational path had to be stored at a time. This backtracking process is a method that has to be used on a sequential computer, which can only do one thing at a time and has to work through all the possibilities systematically. As it searches, Prolog leaves markers at points in the database to which it returns if a path down a particular branch fails to yield a resulting match. This exhaustive search method used by Prolog is called a depth first search method (Nilsson & Maluszynski, 1995). Diagram 1 demonstrates how this works in practice. The tree shows possible solutions for a supervision rule. Prolog finds "major(lewis)" first and then explores all possibilities of the "corporal" predicate before moving on to "major(lee)." It then explores all the possibilities of "corporal" again going as deep down the branches as possible.

Diagram 1. Depth first searching



Tail Recursion

In Prolog recursion involves a rule using itself as a sub-goal, with a fresh call made to the sub-goal each-time. This is memory stack intensive. Tail recursion (also known as tail-end recursion) is a type of recursion that converts a recursive function into an iterative function (O'Keefe, 1990). Iteration is commonly used for repetition of the same code in programs and is efficient. If a call is tail-recursive nothing has to be done after the call returns, that is, when the call returns, the returned value is immediately returned from the calling function. Here is an example.

For the rule "Int (Small, Big)" Big and Small are integers and Small =< Big. "Int" is uninstantiated and will be bound successively on backtracking to Small, Big+1, and Big. The recursive call 'for (Int, Next, Big), the last goal in the body of this clause, is tail-recursive:

```
for(Int, Int, _Big).
for (Int, Small, Big):-
      Small < Big,
      Next is Small + 1,
      for(Int, Next, Big).
```

Tail recursion is a form of recursion that can be implemented much more efficiently than general recursion. In Prolog it facilitates an efficient method of making a section of code repeat as there are no such conventional looping constructions such as UNTIL, WHILE, FOR, DO or GOTO.

CHALLENGES

Arguments over standards for Prolog implementations have been common since its inception. The original Edinburg standard was developed early on provides a basic minimum version of the language. This is sometimes also refered to as the Clocksin and Mellish standard (Callear, 1994; Cloksin & Mellish, 1994). However, there have been a variety of versions of Prolog and interpreters over the years such as LPA Prolog, and AMZI Prolog to name but two. Some versions (such as Visual Prolog) have implemented structural data types, and other procedural structures. These have radically altered the original open architecture of the language. All these versions of Prolog operate slightly differently depending on whose version you use. Therefore work on an international standard began in Britain in 1984, and the ISO Prolog standard: ISO/IEC 13211-1 was published in 1995. This standard defines a portable set of Prolog built-in predicates and their semantics. The original intention was, to standardize the existing practices of the many implementations of Prolog. However, the standard introduced an IO system which departed radically from the " see " and " tell " predicates of original Edinburgh Prolog. For these reasons the ISO Prolog standard has been suggested to not be taken seriously by the Prolog development community (Bagnara, 1999), and the different versions that still arise would tend to support this view.

In the early 1980s Prolog was selected (some would argue erroneously) as the language for the Fifth Generation Computer System project by the Japan Information Processing Development Center (JIPDEC). The project envisaged a parallel processing computer running massive databases using a Prolog to access the data (Feigenbaum & McCorduck, 1983). A primary problem was that their selected language, Prolog, did not support concurrency, (Shapiro, 1989) and this amongst other problems led to the eventual demise of this project in1993.

FUTURE TRENDS

Arguments between proponents of the logic paradigm and the procedural paradigm continue. Declarative database

query languages have been criticized by the computer research community (Hewitt, 2006; Manthey, 1990). Database programming and object-oriented database developers have recommended ending declarative means for organizing retrieval. On the converse deductive database and logic programmers want to extend declarative query languages into full programming languages while retaining declarative features. It is our most likely that neither approach will prevail, and both approaches offer significant advantages (Hewitt, 2006).

CONCLUSION

The unique and open nature of Prolog offers significant advantages in flexibility and efficiency for AI and natural language applications. Because of this niche in the programming world, the variety of open source versions available, and the ability to develop complex applications quickly with Prolog, it continues to remain popular it is likely that it will continue to be used and develop in the future. Indeed, Prolog remains one of the most common languages taught in Universities today.

KEY TERMS

Atom: A group of alphabetical characters in Prolog, similar to a string in other languages

Argument: A word or phrase that occurs in brackets after the head of the predicate, that makes up a fact in the Prolog database (really a predicate consists of a head and one or a number of arguments) for example, in this predicate "animal(mammal)." Mammal is the argument.

Facts: A type of statement made in Prolog. After you supply a database of facts and rules; and can then perform queries on the database. Facts consist of a predicate head and argument. For example "cat(meows)." could be a fact entered in the database that a cat meows. Facts together with rules are also known as "clauses."

Iteration: In computing is the repetition of a process within a computer program. It can be used both as a general term, synonymous with repetition, and to describe a specific form of repetition with a mutable state.

Instantiation: The process in prolog of making a variable equal to a constant, or giving it a value. For example, "X is 2+2" introduces X as a variable (as it is uppercase), and X is instantiated to 2+2. Prolog will respond X=4.

Occurs Check: A system built into some versions of Prolog to avoid never-ending loops with unification. Whenever an attempt is made to unify a variable with a compound term, a check is made by the system to see if the variable is contained within the structure of the compound term, and if this is so, the unification will fail. For efficiency most versions of Prolog do not perform an occurs check.

Predicate: Consists of a word in the Prolog database which succeeds in the Prolog interpreter by writing its argument. It consists of a predicate head (an atom) and one, or a number of arguments. The predicate is the basic unit of Prolog and is always defined to be true. Prolog has some standard built in Predicates to help in programming, such as "write" for example "write(jane)." Will succeed and Prolog will respond "Jane yes."

Recursion: In Prolog, recursion appears when a predicate contain a goal that refers to itself. When a rule is called Prolog creates a new query with new variables. A recursive definition always has at least two parts: facts that act like a stopping condition, and a rule that calls itself.

Rules: Are another type of statement made in Prolog (along with facts) and are also called "clauses." Rules are really extensions of facts in Prolog, with added sub-goals that also have to be satisfied to be found true by the interpreter. A rule consists of a head (a predicate and argument) and a body (sub-goals) separated by the :- symbol. For example, fault (electric):- car_will_not_start,no_lights. This rule has two sub-goals which must both be found in the database for the rule to succeed (the car will not start and has no lights).

Variables: Are quantities that can take any value, and in Prolog are introduced as strings of characters starting with a capital letter. For example, "animal" is an atom in Prolog whereas "Animal" is a variable and can be instantiated for any animal.

Extended and Derivative Versions of Prolog

Datalog: Is actually a subset of PROLOG. It is limited to relationships that may be stratified such that solutions on a large knowledge base return in finite time.

F-Logic: An extended version of Prolog with frames/objects for knowledge representation.

HiLog and λProlog: Are extended versions of Prolog with additional higher-order programming features.

InterProlog: A programming library bridge between Java and Prolog, incorporating bi-directional predicate/method calling between both languages.

Logtalk: An open source object-oriented extension to the Prolog programming language. Integrating logic programming with object-oriented and event-driven programming, it is compatible with most Prolog compilers. It supports both prototypes and classes. In addition, it supports component-based programming through category-based composition.

OW Prolog: A version of Prolog created in order to answer Prolog's lack of graphics and interface.

Prova: Provides native syntax integration with Java, agent messaging and reaction rules. Prova positions itself as a rule-based scripting (RBS) system for middleware. The language breaks new ground in combining imperative and declarative programming.

SWI-Prolog and YAP: Are both open source versions of Prolog offering a full development environment, including graphics, libraries and many interface packages and written in the C/C++. YAP is a high-performance Prolog compiler developed at LIACC/Universidade do Porto, Portugal.

Visual Prolog: Formerly known as PDC Prolog and Turbo Prolog: a strongly-typed object-oriented version of Prolog, which is considerably different than standard Prolog. Incorporates bi-directional predicate/method calling between Prolog and some other common object- oriented languages.

Prolonging the Aging of Software Systems

Constantinos Constantinides
Concordia University, Canada

Venera Arnaoudova
Concordia University, Canada

INTRODUCTION

The evolution of programming paradigms and languages allows us to manage the increasing complexity of systems. Furthermore, we have introduced (and demanded) increasingly complex requirements because various paradigms provide mechanisms to support their implementation. As a result, complex requirements constitute a driving factor for the evolution of languages which in turn can support system complexity. In this circular relationship, the maintenance phase of the software life cycle becomes increasingly important and factors which affect maintenance become vital.

In this chapter we review the notions of software aging and discuss activities undertaken during maintenance. We also discuss challenges and trends for the development of well-maintained systems as well as for aiding in the maintenance of legacy systems.

BACKGROUND

Aging in Software

In the literature, many authors tend to have drawn analogies between software systems and biological systems (ISO/IEC 12207:1995(E); Jones, 2007; Parnas, 1994). Two such notable examples are the widely used notions of aging and software life cycle, implying that we can view software systems as a category of organisms. This analogy is convenient because it creates certain realizations about software. First, we note that systems exist (by operating as a community of intercommunicating agents) inside a given environment. Furthermore, much like their biological counterparts, they evolve (to adapt to their environment) and they grow old. Finally, when speaking of the life cycle of software, we also imply the unavoidable fact that software systems eventually die.

However, the causes of software aging are very different from those of biological organisms or those that cause aging in other engineering artifacts. Unlike biological organisms (such as humans) software systems are not subjected to fatigue or physical deterioration. Unlike other engineering products (such as machinery and structures), software systems are not subjected to physical wear caused by factors such as friction and climate. Aging in software systems is predominantly (but not always) caused by changes that take place in their surrounding (operating) environment.

In his seminal paper on aging, author David Parnas (1994) describes two causes of software aging: The first factor, referred to as lack of movement, is the failure of owners to provide modifications to the software in order to meet changing needs (requirements) of its environment which results in end-users changing to newer products. The second factor, referred to as ignorant surgery, is the careless introduction of changes in the implementation which can cause the implementation to become inconsistent with the design, or even to introduce new bugs. This latter factor is associated with two significant implications: The first is a bloating of the implementation, resulting in a reduction in performance (memory demands, throughput and response time). This weight gain makes new changes difficult to be introduced quickly enough to meet market demands. The second implication is a phenomenon known as bad fix injection (Jones, 2007), which refers to the introduction of errors during maintenance resulting in a decrease in reliability. As a result, software systems become unable to be competitive in the market, thus loosing customers to newer products.

Measures to Prolong Aging

Certain measures are proposed in the literature (Parnas, 1994) to prolong aging such as:

1. The quality of documentation can be upgraded (retroactive documentation). For example, reverse engineering is a model transformation activity which can read implementation and produce an up-to-date design model.
2. Since we cannot really predict the actual changes, predictions can be made about the types of changes, such as changes to the graphical user interface. Parnas (1994) recommends re-organizing the software in such a way so that elements which are most likely to change, such as the user interface, are confined to small amounts of code (retroactive modularization). A similar view is shared by Fayad and Altman (2001) through an architectural pattern to support software stability where the architecture is built around two notions, conceptualized as two concentric circles. In

the inner circle, we have aspects of the environment that will not change. These aspects will constitute a stable core design (and thus a stable software product). In the outer circle, or periphery, we define a design which will allow changes to be introduced.

3. Eliminate components which are of very low quality (amputation).
4. Eliminate redundant components (major surgery).

These measures take place during the period of operability of a software system and are explicitly treated as a separate phase of the software life cycle which is discussed subsequently.

Software Maintenance

ISO/IEC and IEEE define maintenance as the modification of a software product after delivery to correct faults, improve performance (or other attributes) or to adapt the product to a modified environment (ISO/IEC 14764:2006(E); IEEE Std 14764-2006). The importance of maintenance lies on the following observations: (1) Surveys indicate that it is an activity which tends to consume a significant proportion of the resources utilized in the overall life cycle (consequently consuming a large part of the costs) and (2) Reliable changes to software tend to be time consuming. Prolonged delays during software change may result in a loss of business opportunities.

The objective of maintenance is not to stop the unavoidable effects of aging, but to provide techniques and tools to understand its causes, to limit its effects and to prolong the life of software systems.

Maintenance is not a uniform activity and as the type of required changes may vary, four different types of maintenance can be identified which are also defined in the ISO/IEC; IEEE international standard. Corrective maintenance includes all changes made to a system after deployment to correct problems. Preventive maintenance includes all changes made to a system after deployment to correct faults in order to prevent failures. Adaptive maintenance includes all changes made to a system after deployment to address new requirements. Perfective maintenance includes all changes made to a system after deployment to support operability in a different (software or hardware) environment. The ISO/IEC; IEEE international standard provides a classification scheme by grouping the former two under correction and the latter two under enhancement. Adaptive and perfective types of maintenance are shown in the literature to consume a significantly large proportion of all maintenance effort. Corrective and preventive types of maintenance are reported to consume a relatively small proportion of the overall maintenance effort. It is important to note, that the different types are not mutually exclusive but rather they can be combined concurrently to be mutually supportive.

Also, the four maintenance types do not refer to single activities. Jones (2007) lists 23 discrete topics which involve a modification of an existing system often described under maintenance.

Stages of Maintenance and the Staged Model of the Software Life Cycle

In the literature, Bennett and Rajlich (2000) define a model whereby a software system undergoes distinctive stages during its life: Initial development, evolution, servicing, phase-out, and closedown.

Initial development would produce a deployable system (the first operating version). After deployment, evolution would extend the capabilities of the system, possibly in major ways. Once evolution is no longer viable, the software would enter the servicing stage (often referred to as maturity, or most commonly legacy stage). As the term suggests, only small changes are possible during this stage.

Maintainers often encounter what Bennett (1995) describes as the legacy dilemma: On one hand, a system (or component) is valuable and replacing it may not be a viable (cost effective) solution (e.g., large volumes of data may have to be converted). On the other hand, the cost of maintenance is becoming high and requests for changes cannot be sustained. When faced with legacy systems, organizations have to adopt a strategy which is based on economics (i.e., cost of coping with the current system vs. the cost of investment of improvement) and management (e.g., a replacement system would normally require training of end-users). Table 1 summarizes various options based on two factors, namely business value and quality (adopted from Sommerville, 2007).

Finally, once servicing is no longer viable the system enters a phase-out stage where deficiencies are known but not addressed. At closedown, the system is withdrawn from the market. In an alternative model (versioned staged model), during evolution a version is publicly released and subsequently enters the servicing stage whereas the system continues to evolve in order to produce the next version.

Central to any maintenance activity is the notion of change, discussed in the next subsection.

SOFTWARE CHANGE

Whether new requirements are introduced or existing requirements are refined or dropped, the notion of change is a fundamental activity during evolution and servicing. Bennett and Rajlich (2000) describe a change mini-cycle as one which involves a number of activities: request for change, planning phase, change implementation, verification, and documentation update.

Table 1. Maintenance options based on business value and quality factors

		QUALITY	
		Low	High
BUSINESS VALUE	Low	Expensive to keep, with a low return. Scrap. Would require a modification of business processes which rely on it.	Continue with maintenance while it remains cost effective. Once maintenance becomes expensive, then scrap.
	High	Expensive to maintain. Options include reengineering or replacement by off-the-shelf systems.	No special measures required. Continue normal system maintenance.

1. Request for change: originates from a number of sources including bug reports, system enhancement requests from end-users or changes in standards.
2. Planning phase: Involves comprehension and change impact analysis.

Comprehension: It refers to activities that humans perform in order to understand, conceptualize and reason about a program or software system. It normally consumes a large proportion of resources during the overall maintenance phase.

Often it is the case that maintainers are not the initial designers. Furthermore, design artifacts, if at all present, are often incorrect or incomplete. For systems that have been undergone ignorant surgery, comprehension becomes particularly difficult, as it has to bridge the gap between what the original designers had envisioned (initially represented by a coherent and structured description of a model) and the actual system (whose structure may have disintegrated over time). This tendency of systems to experience a structural disintegration over time (also known as entropy) and the subsequent increase in complexity was discussed by Lehman (1980) as one of the laws that govern evolving systems (known as Lehman's second law).

One method to achieve comprehension is through reverse engineering (sometimes the two terms are used interchangeably), which transforms a representation of the system to a higher level of abstraction. This activity involves analysis only, without any modification. The objectives of reverse engineering include the recovery of information which is either not apparent in the code or it is difficult to detect as well as to facilitate reuse by detecting candidates for reusable components. A variation (or specialization) of reverse engineering is design recovery whose objective is to identify meaningful high-level abstractions, which are not identifiable by examining the implementation. Reverse engineering falls under the notion of translation in the model transformation taxonomy (Mens & Van Gorp, 2006), as the source and target languages are at a different level of abstraction.

For complex systems, comprehension methods rely on the study of the dependencies between program (or software) elements (see Tables 2 and 3), such as program slicing and formal concept analysis.

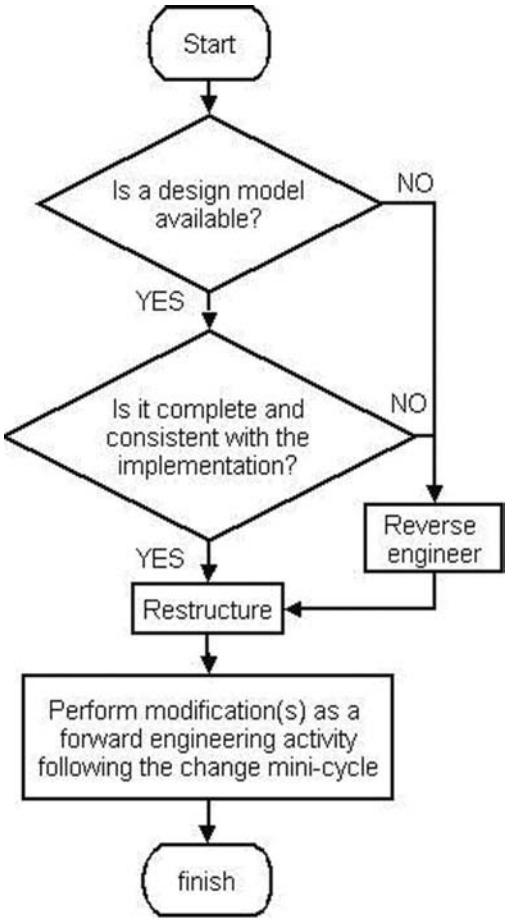
Change impact analysis: To identify impacted components and to assess the impact of change.

3. Change implementation: Involves restructuring and change propagation.

Often deployed to perform preventive maintenance and to simplify or optimize a model, restructuring (or its object-oriented equivalent: refactoring) involves the transformation of one representation form into another at the same level of abstraction. As such, it falls under the notion of rephrasing in the model transformation taxonomy. One important property of restructuring is that it must guarantee the preservation of the behavior of the system. It may also detect problems which would call for changes. In the object-oriented context, strategies for refactoring have been extensively documented in the literature (Fowler, Beck, Brant, Opdyke & Roberts, 1999) and are currently supported by a number of tools[a], perhaps the most notable of which is currently the Eclipse IDE[b].

Change propagation involves changes which may have to be made to dependent components to make sure that

Figure 1. Integration of reengineering activities in the change mini-cycle



changes made in the previous step have not violated the integrity of the system.

In implementing changes, we often involve a sequence of three activities: reverse engineering – restructuring – forward engineering, which are together referred to as reengineering (or renovation). Reengineering addresses system functionalities which need to be added, refined or deleted. Essentially reengineering uses program comprehension to reimplement the program in a new form (Figure 1). Reengineering can be advantageous only when a return of investment can be projected (cost of reengineering vs. increase of product and process quality and business value) (Sneed, 1995) and best candidates to undergo this transformation are components with low quality but strategic to the organization (high business value) (Table 1).

4. Verification: Once a change has been implemented, we need to argue about the preservation of the system behavior and correctness.
5. Documentation update: Artifacts need to retain their interconsistency. Computer-aided software engineering (CASE) tools[c] can automate this process.

FUTURE TRENDS

Reports in the literature indicate a disproportionately large amount of resources and time devoted to maintenance. Of that, a large proportion is reported to be spent on comprehension.

To ease the maintenance phase, we can follow two paths, which we feel exist in mutual support: The less obvious (or perhaps less appreciated) one is to look into development and focus on the provision of quality attributes which can affect maintainability. The obvious one is to improve current methods which are utilized to perform the various maintenance activities. We address challenges and related research along these two paths (we refer to them as pre and postdeployment) in the next subsections.

Predeployment Challenges

The challenge that we face during development is how to encourage and support the consideration of quality attributes which can later have an effect on maintenance. We will restrict the rest of the discussion to the context of object-oriented systems even though many of the ideas are applicable to other paradigms, such as procedural and functional programming.

Maintainability as a quality factor: The degree to which a software system can be easily modified (or alternatively, the effort required for it to be modified) is referred to as maintainability and it is defined as one of the six characteristics of the ISO/IEC 9126-1 quality model (2001) with the subcharacteristics of analyzability (the ease with which the cause of a failure can be detected), changeability (how easy it is to change the software), stability (low risk of modification having unexpected effects), testability (establishing test criteria and the performance of tests) and maintainability compliance (adhering to standards or conventions). Maintainability should be explicitly addressed as part of the nonfunctional requirements of a system. A related term is adaptability which is defined as the ability of a software system to allow changes. In their 1996 article, authors Fayad and Cline discuss factors which affect adaptability. High-level changes are addressed by extensibility (change amount of capabilities but not kind) and flexibility (change kind of capabilities). Low-level changes are addressed by performance tunability and fixability (the ability to fix one thing without breaking another).

Separation of concerns and modularity: The principle of separation of concerns (Parnas, 1972) refers to the real-

ization of system concepts into separate software units and it is a fundamental principle to software development. The associated benefits include better analysis and understanding of individual concerns, high readability of modular code, high-level of reuse, easy adaptability and good maintainability. Despite the success of object-orientation in the effort to achieve separation of concerns, certain properties cannot be directly mapped in a one-to-one fashion from the problem domain to the solution space, and thus cannot be localized in single modular units. Their implementation ends up cutting across the inheritance hierarchy of the system. Crosscutting concerns (or aspects) include persistence, authentication, synchronization, and logging. The crosscutting phenomenon creates two implications: (1) the scattering of concerns over a number of modular units and (2) the tangling of code in modular units. As a result, developers are faced with a number of problems including low level of cohesion of modular units, strong coupling between modular units and difficult comprehensibility, resulting in programs that are more error prone.

Aspect-Oriented Programming (AOP) (Kiczales, Lamping, Mendhekar, Maeda, Lopes, Loingtier et al., 1997) explicitly addresses those concerns which cannot be cleanly encapsulated in a generalized procedure (i.e., object, method, procedure, API) by introducing the notion of an aspect definition, which is a new modular unit of decomposition. There are currently a growing number of approaches and technologies to support AOP. One notable technology is AspectJ (Kiczales, Hilsdale, Hugunin, Kersten, Palm & Griswold, 2001), a general-purpose aspect-oriented extension to the Java programming language, which has influenced the design dimensions of several other general-purpose aspect-oriented languages, and has provided the community with a common vocabulary based on its own linguistic constructs. It is important to note that AOP is neither limited to Object-Oriented Programming (OOP) nor to the imperative programming paradigm.

During the construction of software, developers aim to produce a clean (tangled-free) system and achieve the maximum benefits of advanced separation of concerns. To meet this objective, the design artifacts themselves must in turn explicitly address crosscutting concerns. To this end, we need to provide the means to identify and model crosscutting concerns from the early stages of the software life cycle. As a result, the explicit capture of crosscutting concerns in code should be the natural consequence of good and clean modularity and not the result of a corrective measure (refactoring activity) due to a tangled implementation. One future development we should expect is the extension of the official UML specification to provide support for aspects[d].

Reusability and component-based software: As software products need to satisfy both technical and nontechnical criteria, developers find it essential to combine theory and experience in order to reuse proven designs. The importance of reuse lies on the fact that it can speed up the development process, cut down costs, increase productivity and improve the quality of software. Design-level reuse is viewed as the attempt to share certain aspects of an approach across various projects. Object and component-based systems offer a wide spectrum of techniques to reuse designs at different levels, ranging from frameworks and patterns that constitute approaches on how to best program in-the-large to libraries and programming languages that constitute approaches on how to best program in-the-small (Szyperski, 2002). On the higher level of the reuse spectrum, the literature for object-oriented systems includes discussions on frameworks (Fayad, Johnson & Schmidt, 1999) and design patterns (Gamma, Helm, Johnson & Vlissides, 1994). Discussions on frameworks (Constantinides, Elrad & Fayad, 2002) and design patterns (Hannemann & Kiczales, 2002) are also found in the literature for aspect-oriented systems. On the lower level of the reuse spectrum, the importance of the mechanism of inheritance and the contribution of OOP towards reusability has been extensively discussed in the literature. Inheritance allows non-invasive (incremental) modification of class definitions. Subclasses may introduce new attributes and methods whose definitions may be based on those of the superclasses. Furthermore, methods may be overloaded (providing different semantics for the same method names) or overridden (providing new semantics for the same method signatures).

Postdeployment Challenges

Both OOP and AOP introduced their own maintenance problems, particularly for comprehension of the entire system which comes as a tradeoff for increasing the level of separation of concerns and the increase of the level of comprehension of individual modules. Analysis methods have been deployed for OOP, but not much work has been done on AOP, particularly to address the difficulty to identify portions of the core functionality affected by the aspectual behavior.

There are currently a number of methods and tool support to ease the activities involved, focusing on comprehension, which tends to consume a large proportion of time. The analysis of artifacts can be categorized into static and dynamic (Table 2) based on the view over which an artifact is investigated (structural or behavioral respectively). Static analysis is performed by examining design or implementation artifacts and reasoning over possible behaviors that might arise during execution. Dynamic analysis is performed by executing a program and observing the executions. The latter is precise, because no approximation or abstraction need to be done and the analysis can examine the exact runtime behavior of the program. The analysis of an artifact is performed based on the dependencies between its elements. There are currently several different analysis methods avail-

Table 2. Analysis types

able (Table 3). Furthermore, a number of tools exist which focus on analysis for aspect mining (Table 4).

Maintenance model: Unlike development which is currently supported by two major process types (linear and iterative) under a number of various different models (such as the spiral model, the unified software development process, or extreme programming and agile methods), there are no equivalent models for maintenance. The question we need to answer is whether a model is required, or should maintenance be integrated as a sequence of postdeployment iterations in an existing model.

Reengineering of (object-oriented) legacy systems: One consequence of the adoption of UML support for aspects, is that we will be able to achieve reengineering of legacy object-oriented systems and their migration to an aspect-oriented context through aspect mining, refactoring, reverse engineering, and forward engineering. As an example, legacy Java code can be rejuvenated into AspectJ.

The following two quality attributes of methods and tools for comprehension should also be taken into consideration.

Adaptability: The degree to which current methods, techniques and tools can be adapted to address new aspects of comprehension, such as crosscutting concerns.

Scalability: In discussing difficulties associated with reverse engineering, Rugaber (1992) pointed out the need for powerful tool support. The increasing complexity of systems has motivated automation and today we can say that comprehension is largely automatic with a large collection of tools available[e]. However, a challenge is to make sure that current methods and tools to support comprehension can scale for large systems.

CONCLUSION

Not only the life of a software system does not end at the time of its deployment, but it can be argued that this is the time when software begins its productive life. In this chapter we discussed the notion of software aging as the driving force behind maintenance. As we face legacy systems, maintenance and evolution are becoming increasingly important and complex. The complexity of maintenance lies on the fact that comprehension of large systems is tedious, particularly in the cases where the source code is not supported by a consistent design model.

We have discussed challenges of maintenance from two viewpoints: first, during development, we aim at designing for change and capturing quality attributes to support well-maintained systems. We are, of course, aware that our ability to design for change can only be approximate, since it depends on our ability to predict the future and, despite the successful implementation of quality attributes, we cannot prevent aging but can merely prolong it. Second, for systems currently in operation, our goal is to design technologies to ease comprehension through static and dynamic analysis, such as declarative reasoning, program slicing and formal concept analysis.

KEY TERMS

Control-Flow Analysis (CFA): An investigation to determine properties of the program control structure such as possible control flow paths (branches) and to find basic blocks and loops.

Data-Flow Analysis (DFA): A process for collecting run-time information about data in a computer program without actually executing it. A program's control-flow graph is deployed to determine those parts of a program to which a particular value assigned to a variable might propagate.

Formal Concept Analysis (FCA): Mathematical technique for analyzing binary relations, capturing conceptual structures among data sets.

Program Dependency Graph (PDG): A refinement of DFA for a program routine with CFA information.

Program Slicing: A derivative of Program Dependency Graph (PDG) and System Dependency Graph (SDG).

Reengineering: An activity to reimplement a software in a new form. Normally comprised by reverse engineering (for comprehension), restructuring, and forward engineering.

Rephrasing: A model transformation activity where the source and target languages are at the same level of abstraction.

Reverse Engineering: A model transformation activity where the target language is at a higher level of abstraction.

System Dependency Graph (SDG): A refinement of DFA for a program with CFA information. It captures the union of all PDGs in a program.

Translation: A model transformation activity where the source and target languages are at a different level of abstraction.

Promotion of E-Government in Japan and Its Operation

Ikuo Kitagaki
Hiroshima University, Japan

INTRODUCTION

In Japan, e-government has been considered, since 2001, as one of the strategies of so called "e-Japan" (Ohyama, 2003). It had been decided that e-government shall be constructed within the fiscal year 2003. Preparation in terms of the legal system and technological developments made steady progress towards that goal. The construction of e-government should alleviate residents' burdens in terms of bureaucracy, enhance service quality rationalization, lean and transparent administrative agencies, countermeasures for natural calamities, more participation in policy making and administration by residents, and so forth. Various tasks have been carried out at many places. For example, in Autumn of 2002 a "basic residential register network" was established. Its initiation enjoyed broadly smooth operation. Residents had received administrative services only within certain jurisdiction limits until then. Now they are free to enjoy access to any administrative services from anywhere in Japan thanks to this e-system. Some local authorities introduced electronic tenders to enhance transparency of administration. Some local authorities adopted an electronic voting system in part of their areas. This paper explains the details of how the construction of the e-government came about and what the status of its operation is.

In constructing an e-government, basic researches in respect of relevant individual electronic chores are necessary. In reality, however, planning and drawing up an idea will often be brought about, depending on certain actual domestic social circumstances of the legal systems or certain consensus within and between relevant representative bodies of the government. Because of such circumstances, we have decided to list up general magazines easily available which report often on these themes and the most up-to-date URLs of relevant organizations of the Japanese government.

BACKGROUND

Information processing on the part of the public administration has progressed in line with each development of computers (Makiuchi, 2003). It followed the progress of information processing in the private sector. The first steps included, as early as 1970s, information processing for specified jobs such as accounting, salary payments. It also controlled systems of government offices on the basis of one PC per one person, as personal computers spread around 1990, and Internet technologies were introduced in the course of 1990s, and so forth. In particular, the Patent Office in Japan adopted an on-line system for patent application to speed up the processing of patent applications. And it did substantially increase.

Nevertheless, given the progress and more use of the information processing for administration, the mentality that it only simply meant computers would replace mechanical style jobs kept on living a long time. In addition, it exerted a negative influence in that the conventionally vertical administration confined the progress of the information processing for administration to specific ministries and offices. And it made services difficult to access from the standpoint of the people.

The Mori Cabinet came into power in 2000. He decided to shift the nation to the use of state-of-the-art information under his "e-Japan strategies". He would emphasis the importance of information processing in Japanese society in order to get out of the economic slump. Objectives were placed in five fields: broadband infrastructure, education, public/administration services, e-commerce, and security. Among the items, administration services are selected so that e-government will be realized within the fiscal year 2003. Preparation in terms of legal systems and technological developments have made progress in that respect. Legal systems were reviewed. Now, there are the On-line Transmission Regulations, Revised Basic Residential Register Law, Public Individual Certification Law, and so forth. On the technological front, there were also some new introductions of electronic systems for administrative procedures, for example all-purpose reception system for applications, the introduction of a one-stop system for import/export harbor and taxation procedures as well as the electronic tender system. Electronic systems for revenue bookings allows payment per Internet and an on-line transfer system. The purposes of the introduction of information processing for administrative chore and business operations are: simplification of work for human resources, salaries and so forth, and connection of the National Networks with LGWAN (Local Government Wide Area Network) owned by communalities.

Electronic procedures will be put into practice in various fields as described above. From their own perspectives, users consider more or less that the essential part of e-government is mainly the given opportunity of the electronic application and its ease.

E-government is one of the e-Japan Strategies in the Five Year Plan which started in 2000. Preparatory activities on legal systems and system construction are to be completed by March, 2004. On the other hand, as regards set-up of broadband infrastructure, the objective was set that 30 million households would use it by the end of the fiscal year 2005. In reality, though, 50 million households (the actual number of subscribers is about 5.70 million) were able to use it as early as June, 2002, due to the rapid progress of information telecommunication technologies. Partly as a result of such thanks to these unexpected circumstances, e-Japan Strategies could enjoy only after one and a half years of their inception another review.

SYSTEM DEVELOPMENT CASES

Here are some cases of e-governments established on national scheme or at local authorities.

Basic Residential Register Network System

Resident registration cards, tax payment certificates, and so forth, are normally applied for at the desk of an agency. The regional jurisdiction of a resident is responsible and issues them. E-government, any application at home or application and issuance from an office outside the resident district. Confirmation of the subject person beyond an administrative boundary and the necessary information exchange between administrative bodies in this respect becomes easier with the use of Basic Residential Register Network. The Basic Residential Register Law regulates undertakings for this system and how its operation should look at what its practical use is like. Information contained in this system are these four items: name, birth date, gender, and address. It also contains resident card code number and information for any changes to them. The resident card code allows an easy access to these four data items. It consist of eleven digits, selected at random, and will be issued as single and only in Japan without duplication for one person throughout Japan. This code can be changed at the request of the subject person. The system constellation is three-fold in vertical; the levels consist of national, prefecture and municipalities. Depending on the distance between the "clients" making use of the common contents from each other, the option would be made which of the three levels of networks be used. If two towns sit in the same prefecture, the communication server of one of the two towns, and the dedicated line in connection with this server on the level of the prefecture, would be used so as to come into communication with the other town magistrate. If the communication should go to the level of prefecture-prefecture, the network of this constellation level would be working plus the national network involved. Communication servers have firewalls both inside and outside to prevent illegal access (Inoue, 2003; Yoshida, Mizokami, & Watanabe, 2003)

Electronic Tender

Here is a case of Yokosuka City in Kanagawa Prefecture (Hirokawa, 2003). Up until 1997, order placement of civil works in the City took place mainly by public tender in which 7-10 specified and pre-selected bidders could join the tender. However, it became known that there had been some collusions on the bidding. It was considered that reform is necessary. The tender system was changed in the fiscal year 1998 to a conditionally open tender where any business entity could participate, if inspection standards prescribed were satisfied. In the fiscal year 1999, information on order placements started to be shown on the agency's homepage. It became possible for companies wishing to participate to confirm general picture of an order. Where is the site? What is the nature of this work? Firstly, a company wishing to bid will transmit a tender application form to the contracting section by facsimile. If confirmed that this company is qualified to participate, it will purchase design documents from a designated printing company and draw up an estimate. Then it sends the tender documents *poste restante* at the Yokosuka Post Office by registered mail with a delivery certificate by the deadline. On the date appointed, the contract section of the magistrate will open all the tender documents collected so far and decide the successful bidder with representatives of the participating companies witnessing. All the tender results will be publicized on the homepage after that. The effect is that the number of tender companies increased by 2.5 times on average before and after the reform. At the same time, the annual average success ratio (the ratio of a successful bid to the expected price) declined from 95.7% before the reform to 85.7%.

In the fiscal year 2001, the series of procedures as above were to be carried out by the Internet. The purpose is to further widen the door to bidding companies and save on administrative chore of the contract section. Companies put in a tender bid on the tender document transmission screen first and then transmit it by the Internet. The tender documents will at once be transmitted to the server of the authentication bureau, where the guarantee of originality and perception time stamps are added. Then it will be transmitted to the contract section. In other words, the function conventionally carried out at a post office has been transferred to an authentication

bureau. The average success bid ratio for this fiscal year fell as far as to 84.8%.

Noteworthy is the fact that the reform of the tender system was brought about only with the strong will on the part of the personnel. With the mayor on the top down to all those who worked on the reform who did not give up facing various forms of resistance.

Electronic Voting

For electronic voting there are two options: voting made from a household PC and another made at the ballot. Both are under examination now. The former is carried out where an electronic voting paper is obtained by a household from a voting server. Here, voting contents are filled in and transmitted to a sum-up server. However, a security problem has been pointed out in cases of electronic voting by household. Some people held the view that it should be limited to persons with physical disability. On the other hand, electronic voting at a ballot is carried out in that on voting contents decisions will be made via touch panels. Also an electronic pen can be used at the voting terminal. This has been put into practice in Niimi City, Okayama Prefecture, and part of the Hiroshima City. Various technologies for voting have been proposed, but none of them has been developed enough in any of the business in e-government. The reason appears to be that the frequency of an election itself is low. At most it is once in a year. Therefore, cost efficiency of system development is not clear as a result. Further, security must be perfect, and so forth.. A voting logic where contents, choice of an individual voter, will not be known, not only to others but also to the system itself, is under study. The system must cope with bribery and corruption, and misuse of strong power. There remain difficult issues to be solved (Kitagaki, 2003).

Various Resident Services

In Yokosuka City (Hirokawa, 2003) Geographical Information Service (GIS) was introduced to enhance and reach greater efficiency of administrative services in order to facilitate residents' participation in the regional community activities. Common use on the level of the municipal office was possible by integrating information owned by each division and bureau in the municipal office at one place, except for that information which would violate the protection of personal data. In the fiscal year 2002, Yokosuka City arranged so that citizens could obtain maps, using Web-GIS from home. That was a result of an alliance with a map company in the private sector. On the Web site, information on medical institutions, bargain sales at shopping centers, sightseeing information,, and so forth, became available. Many organizations and individuals such as the Chamber of Commerce and Industry, medical associations, SOHO workers, and so forth, are engaged in preparation of these data and operation in cooperation.

In Kochi Prefecture (Ishikawa, 2003), the information super-highway has been in operation since the fiscal 1997. Further improvement has been sought to accompany the preparation of the administrative networks further and the changes in the information environment. In the fiscal year 2001, telecommunication services at the private sector started to be carried out as well under a new basic conception. The main circuit of the information highway was changed from the previous 50Mbps to 2.4Gbps. Preservation control and stable operation throughout the year were guaranteed. In addition, main circuits were open to Internet service providers (ISP) and businesses in the private sector providing CATV services. They became compatible with IP v 6, and so forth.

Sapporo City in Hokkaido showed its basic policy in the fiscal year 2002 amid the progress of various businesses with information technology in mind. It considered a "city for cooperation between administration, citizens and enterprises". It should be an ideal state of city management. The city listens carefully to residents' voices. It started to operate a call center business to reflect this in administration. This is the center to deal with various kinds of inquiries from citizens. The city has made experiments with citizens monitoring. Trial operation has further expanded since the fiscal year 2003. On the other hand, the city attempted to distribute IC cards. For example, it has prepared the environment to be able to use them for all the municipally operated subways.

Further, payment of administrative services with IC credit cards (Endo, 2003), provision of various electronic municipality software developed with the residents' standpoint (Shimada, 2003) as well as technological issues of its operation (Maeda, Okawa, & Miyamoto, 2003) are under examination.

DISCUSSION AND CONCLUSIONS

The plan of e-Japan has been administrated during five years. Based upon the result, in January of 2006, the New Innovative Strategies was publicized. It declares that, by 2010, it will complete the innovation using IT, then change Japan to the cooperative society which is possible to develop sustainably, autonomic and enable everybody to independently participate in. To note, as for the e-government, it aims to build a society that computerizes administrative service as much as possible and to realize "the small government" that is convenient, efficient and transparent. The New Innovative Strategies consists of three parts below.

1. It is to realize the e-administration (e-government, e-local authorities) which actually feels convenience and

in its service improvement, then by 2010 to make the on-line use rate, more than 50 percent, in the process of application and notification for the government and local authorities.

2. It is to arrange the system of evaluation and installation of information systems, to arrange the evaluation method of the information system, then to optimize total task and system in all the government to realize the efficient e-government. It is to arrange the similar system in local authorities.
3. Relating to the system of government and local authorities, it is to maintain its reliability and safety while considering user's convenience, to propose the advance of security, then to foster and pervade the foremost technology through Japan's advance in e-administration.

For the objectives above, IT Strategic Headquarters also set several indicators in order to get how much the objectives would have been attained.

1. On-line use rate in application and notification and so on.
2. Time and cost which a user needs in application and notification.
3. The browsed number of the government portal site.
4. Reduced cost of IT relation. Reduced time and reduced capacity for processing the task.
5. Installation of IC card in public service and the improvement of the public service in its use.

KEY TERMS

Basic Residential Register Network: A network to confirm the being of a person, a subject. Its use is common throughout Japan and jointly operated by local authorities.

E-Government: The government and local authorities which construct an electronic processing system for administrative procedures with full command of information telecommunication technologies. It provides various kinds of services for residents in line with these.

E-Japan Strategies: The national strategies decided in the first conference of the Strategic Headquarters for the Promotion of an Advanced Information and Telecommunications Network Society (the IT Strategic Headquarters) held on the January 22, 2001. It was laid on the IT basic strategies decided at the Joint Conference of the IT Strategic Conference and the Strategic Headquarters for Information Telecommunications (IT) Technologies (November 27, 2000).

Electronic Tender System: A system to carry out a series of works from notification of order placement information on the homepage,, and so forth, application for tender participation, sending a tender document, opening tender documents to the public announcement of the result.

Electronic Voting System: A system to vote electronically, using an information terminal of a personal computer, and so forth. Various technologies have been created to prevent illegal actions such as alteration of voting contents or the use of abstainers' votes.

On-Line Communication Regulation Law: A law to enhance application in the administration, which is decided by laws exceeding 50,000, and cover all these laws for conducting application electronically. It is considered that this communication regulation law has completed the basic legal frameworks necessary for the e-government such as electronic signature law.

Public Individual Certification Law: A law to prepare a system to provide individual certification and authorization services in order to process on-line the public application and notification on-line.

Proxy Caching Strategies for Internet Media Streaming

Manuela Pereira
University of Beira Interior, Portugal

Mário M. Freire
University of Beira Interior, Portugal

INTRODUCTION

Media streaming consists in the viewing of dynamic media information while being downloaded by clients. With the explosive growth of the Web and the mature of digital video technology, *media streaming* has received a great deal of interest as a promising solution for multimedia delivery services. This approach allows that media objects can be accessed in a similar way to conventional text and images using a download-and-play mode. However, unlike static text-based content, proxy caching has difficulty in delivering streaming media content because media objects are usually very large and its transmission consumes a great amount of network resources, prolongs startup latency, and threatens the playback continuity. The size of a conventional *Web object* is typically on the order of 1–100 kbytes and, therefore, a decision regarding either caching or not an object in its totality is an easy task (Liu & Xu, 2004). However, the size of *media objects* is very large, reaching a size on the order of several hundreds of Mbytes or even Gbytes. Therefore, caching a whole media object at a Web proxy optimized for delivering conventional small-size Web objects is not feasible, since large streams would quickly exhaust the capacity of the proxy cache. Besides, the streaming of *media objects* requires a significant amount of resources such as disk space and network bandwidth, which need to be maintained during a long period of time. Moreover, the long playback duration of a streaming may allow several client-server interactions. Therefore, access rates might be different for different parts of a stream, which makes cache management potentially more complex, as pointed out by Liu and Xu (2004). On the other hand, a download-before-playing solution provides continuous playback, but it also introduces a large startup delay.

An effective solution to reduce client-perceived latencies and network congestion is to cache data at proxies widely deployed across the Internet. This solution, besides inexpensive, also leads to an improvement of both availability of objects and packet losses since redundant network transmission decreases while transmission efficiency increases. However, proxies are generally optimized for delivering conventional small-size Web objects, which may not satisfy the requirements of streaming applications. Due to these particular features of media objects, novel caching strategies have been proposed.

With the evolution of the Internet as the dominant architecture for applications, contents, and services, these are gradually migrating from the *client-server paradigm* to the edge services paradigm and to the peer-to-peer (P2P) computing paradigm. Recently, P2P system has received a great amount of interest as a promising scalable and cost-effective solution for next-generation multimedia content distribution. This kind of systems have advantages regarding systems based on the client-server paradigm, namely improved scalability and reliability, cheaper infrastructures due to direct communication among peers, and easiness of resource aggregation in order to provide, for instance, massive processing power (Ye, Makedon, & Ford, 2004). However, P2P systems also have some drawbacks, namely the considerably more complex searching and node organization and security issues (Aberer, Punceva, Hauswirth, & Schmidt., 2002). Therefore, this article limits the discussion to low-cost proxy caching strategies for *media streaming* over Internet.

BACKGROUND

As discussed earlier, media caching has different requisites regarding conventional Web caching due to the special features of media streaming. Since the content of a media object is rarely updated, management issues like cache consistency and coherence are less critical in media caching. However, it requires an effective management of proxy cache resources due to the resource requirements of media objects (Liu & Xu, 2004).

Roughly, there are two main types of caching strategies: the strategies focused on homogeneous clients and the strategies focused on heterogeneous clients. Most of the proposed strategies are focused on homogeneous clients, which have identical or similar configurations and capabilities behind a proxy. Figure 1 presents an overview of caching strategies

for media streaming. A brief description of these strategies is provided in the next sections.

CACHING STRATEGIES FOR HOMOGENEOUS CLIENTS

Strategies for homogeneous clients can be classified, regarding the parts of media objects to cache, as *prefix caching*, *sliding-interval caching*, *segment-based caching*, and *rate-split caching*. A brief description of these strategies follows.

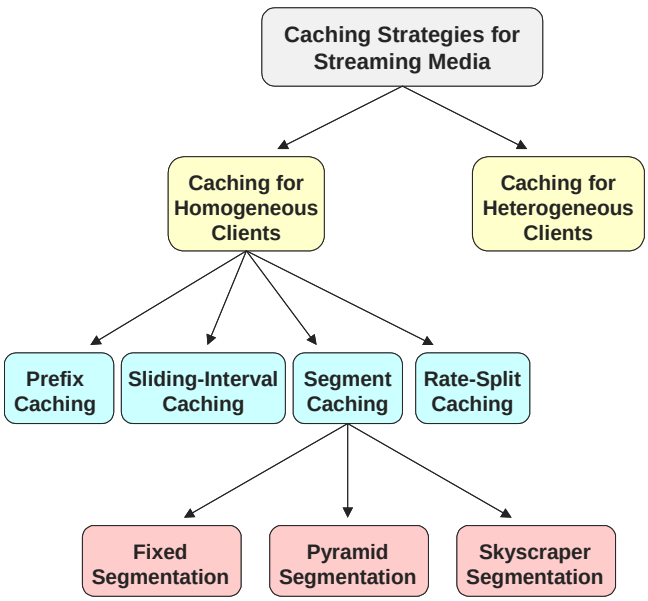
Prefix Caching

According to this strategy, the media object is divided into two parts: the prefix and the suffix. The prefix is cached at a proxy. After the reception of a client request, the proxy immediately delivers the prefix to the client and fetches the suffix from the source server to be further delivered to the client. This strategy leads to a significant reduction of the startup delay for a playback since the proxy is generally closer to the clients than the source server (Liu & Xu, 2004; Miao & Ortega, 1999; Sen, Rexford, & Towsley, 1999). In this strategy, the prefix size is a key issue for the system performance. In general, this strategy leads to a moderate bandwidth reduction but to a high startup latency reduction.

Sliding-Interval Caching

According to this strategy, a sliding interval of a media object is cached in order to exploit the sequential access of a streaming media. For instance, if two consecutive requests for the same object are received, the first request may access the object from the server and incrementally store it into the proxy cache, while the other request only needs to access the cached portion and release it after the access. In general, if multiple requests for a given object are received in a short period of time, a set of adjacent intervals may be grouped to form a run, of which the cached portion will be released only after the satisfaction of the last request. This strategy can substantially reduce the consumption of network bandwidth and the startup delay for subsequent accesses. However, it involves high disk bandwidth utilization because the cached portion is dynamically updated with the playback. Besides, the effectiveness of the sliding-interval caching strategy diminishes with increased access intervals. Moreover, in the case of the access interval of a given object be longer than the duration of the playback, it degenerates to the case of full-object caching (Liu & Xu, 2004; Tewari, 1998). These limitations may be mitigated if the cached content is retained over a relatively long period of time. Nevertheless, for a good cache design, this strategy may lead to a high bandwidth reduction and to a high startup latency reduction.

Figure 1. Overview of caching strategies for media streaming



Segment-Based Caching

Segment-based caching is a generalization of the prefix caching strategy by partitioning a media object into a set of segments, differentiating their respective utilities, and making a caching decision accordingly (Liu & Xu, 2004). Several segment-based caching approaches have been proposed (Chen, Wang, Zhang, Shen, & Wee, 2005; Wu, Yu, & Wolf, 2004). Here, we consider the fixed segmentation (also called uniform segmentation), the pyramid segmentation (also called exponential segmentation), and the skyscraper.

In the fixed segmentation approach, the size of segments is fixed. In the pyramid segmentation (Viswanathan & Imielinsky, 1996; Wu, Yu, & Wolf, 2004), segment size increases exponentially from the first segment. For instance, objects are segmented in a form that the size of a succeeding segment can double the size of its preceding one. Therefore, in this approach, the size of segments increases exponentially. This approach favors the caching of first segments of media objects due to the following reasons (Wu, Yu, & Wolf, 2004): First, the last portion of a media object is generally the least valuable for caching; second, it is more cost effective to quickly remove a large portion of a cached media object whose caching priority typically decreased from the beginning of the viewing. A hybrid approach taking into account both uniform lengths and exponentially increasing lengths has been considered by Chae, Guo, Buddhikot, Suri, and Zegura (2002). The skyscraper segmentation approach (Wu, Yu, & Wolf, 2004) is a variation of the pyramid segmentation, in which the segment size increases more slowly. For example, the size of a given segment is either the same as or twice of the previous segment. Skyscraper segmentation leads to a larger number of segments than pyramid segmentation, but it has less segments than fixed segmentation.

Using event-driven simulation, Wu, Yu, and Wolf (2004) evaluated the three segmentation approaches and have compared them with a full-object approach and with a prefix caching approach. They have shown that: 1) the three segment-based caching strategies are more effective in not only increasing the byte-hit ratio (i.e., reducing total traffic) but also lowering the fraction of requests that require delayed start; 2) pyramid segmentation is the best approach among the three segment-based caching strategies; and 3) segment-based caching strategies are particularly effective when the cache size is limited, when the set of hot media objects changes over time, when requests spread over a large number of media objects, when the size of the media file is large, and when there are a large number of distinct media objects (Wu, Yu, & Wolf, 2004).

Rate-Split Caching

Unlike the previously discussed caching strategies, in which the partition of a media object occurs horizontally along the time axis, the rate-split caching strategy partitions it vertically along the rate axis. It is established as a cutoff rate, whose part above the cutoff rate will be cached at the proxy, while the part below the cutoff rate will remain stored at the origin server. This type of partitioning is particularly attractive for variable bit rate streaming, since only the lower part of a nearly constant rate has to be delivered through the entire network path. A critical issue in this strategy is the selection of the cutoff rate (Liu & Xu, 2004; Zhang, Wang, Du, & Su, 2000). In general, this strategy leads to a moderate bandwidth reduction and to a moderate startup latency reduction.

CACHING STRATEGIES FOR HETEROGENEOUS CLIENTS

Due to diversity of network environments and device configurations, clients behind the same proxy often have quite different requirements for the same media object in terms of streaming rates or encoding formats. In order to accommodate such heterogeneity, a simple solution is to produce replicated streams of different rates or formats, each targeting the requirements of a subset of clients. Although widely used in commercial streaming systems, this approach is unattractive due to the storage and bandwidth demands (Liu, Chu, & Xu, 2004). An alternative strategy is based on the transcoding of a media object from one form to another of a lower rate or a different encoding format on demand (Tang, Zhang, & Chanson, 2002). However, the large computational overhead of transcoding limits the capability of the proxy to support a large and diverse client population (Liu & Xu, 2004).

A more efficient approach to this problem is based on the use of layered encoding and transmission. A layered coder compresses a media object into some layers. The most significant layer, the base layer, contains the data representing the most important features of the object, whereas additional enhancement layers contain data that can progressively refine the quality. Thus, a client can subscribe to a subset of cumulative layers to reconstruct a stream according to its capability or according to the desired quality (Kangasharju, Haranto, Reisslein, & Ross, 2002; Liu & Xu, 2004).

FUTURE TRENDS

Recently, two new approaches for segment-based caching have been reported: adaptive and lazy segmentation and active prefetching (Chen et al., 2005). However, those approaches need to be improved in a cost-effective way.

Proxy caching strategies discussed earlier are focused on unicast delivery. Although the discussed strategies can effectively reduce access latencies and network bandwidth, the scalability of proxy caching strategies is limited for media

content delivery. One strategy to alleviate this problem is the use of proxy caching with multicasting (Ramesh, Rhee, & Guo, 2001). However, this approach may lead to larger startup latencies and is geographically limited (Liu & Xu, 2004). Recently, Xu, Guo, Pan, and Wang (2004) proposed a dynamic cache-multicast algorithm for streaming media, which seems to effectively reduce the utilization of network resources and enhances the byte hit ratio of a proxy cache. An alternative to overcome these limitations is to purchase the services of proprietary content delivery networks (CDNs). However, besides expensive, this solution may have a limited performance for large-scale multimedia distribution services (Xiang, Zhang, Zhu, Zhang, & Zhang, 2004).

An alternative approach is based on the peer-to-peer content distribution in which a proxy and its clients can be structured into a peer-to-peer system (Guo et al., 2004) or where clients cooperate to distribute content (Padmanabhan, Wang, Chow, & Sripanidkulchai, 2002) using advanced video coding schemes such as multiple description coding (Pereira, Antonini, & Barlaud, 2003).

CONCLUSION

A discussion about particular requirements of media objects for media streaming was presented. Proxy caching strategies for media streaming have been discussed for both homogenous and heterogeneous clients. Regarding homogeneous clients, particular attention was paid to the following approaches: prefix caching, sliding-interval caching, segment-based caching, and rate-split caching. Advantages and limitations of these strategies were pointed out. A discussion about limitations of caching strategies and their evolution was also provided.

KEY TERMS

Content Delivery Networks (or Content Distribution Networks (CDNs): In this kind of networks, the origin server is replicated and placed locally close to the clients or remotely in suitable geographical or network spaces.

Media Streaming: Consists in the viewing of dynamic media information while being downloaded by clients

MPEG: Moving Picture Experts Group.

Multicast: The sender generates only a single data stream that will be transmitted to selected multiple receivers who have joined the appropriate multicast group. A multicast-enabled router will forward a multicast message to a particular network only if there are multicast receivers on that network.

Peer-to-Peer System: This term refers to any exchange system characterized by direct interaction and data exchange between its peers.

ProxyCache: Memory to store media objects.

Web: Also referred as World Wide Web, it is a multimedia system based on hypertext applications that use the client/server model to access to Internet resources.

Qualitative Methods in IS Research

Eileen M. Trauth
The Pennsylvania State University, USA

INTRODUCTION

As information technologies have evolved, so too has our understanding of the information systems that employ them. A significant part of this evolving understanding is the role of the human contexts within which information systems are situated. This, in turn, has led to the need for appropriate methods of studying information systems in their context of use. Just as decisions about information systems need to be considered within their contexts of use, so also do choices about the appropriate research methodologies to employ for studying them. Increasingly, qualitative methods are chosen as an appropriate method for studying contextual aspects of information systems development, use and impact.

Qualitative research refers to research methods that engage in the interpretation of words and images rather than the calculation of numbers. These methods include: ethnography, case study, action research, interviews, and text analysis (i.e., conversation analysis, discourse analysis, and hermeneutics). Qualitative research can be theory-driven in much the same way as quantitative analysis. However, it can also employ grounded theory techniques in order to develop theory (Glaser & Strauss, 1967).

Following some early uses of qualitative methods in the 1980s (e.g., Benbasat et al., 1987; Kaplan & Duchon, 1988; Lee, 1989; Mumford et al., 1985), there has been a significant growth in the use of qualitative methods for information systems research since the 1990s (e.g., *Journal of Information Technology*, 1998; Lee et al., 1997; *MIS Quarterly,* 1999, 2000; Nissen et al., 1991; Trauth, 2001).

Accompanying the increased use of qualitative methods for IS research has been a discussion of various methodological issues. Among the key aspects of this dialogue are discussions about the suitability of qualitative methods for various types of research and issues arising from a particular type of qualitative methods: interpretive methods. This article presents a reflection on some these discussions in the form of a consideration of five factors that can influence the choice of qualitative (particularly interpretive) methods for information systems research.

FACTORS INFLUENCING THE DECISION

The Research Problem

The research problem, *what* one wants to learn, should determine *how* one goes about learning it. Heaton (1998) chose observation, interview and document analysis to examine the social construction of computer-supported cooperative work in two different cultures in order to learn how the meaning of "culture" was reflected in the design of systems. Trauth (2000) used ethnographic methods to explore the influence of socio-cultural factors on the development of a nation's information economy. Bentley et al.'s (1992) ethnographic study of the work practices of air traffic controllers informed their design of an interface to an air traffic control database. Walsham and Sahay (1999) conducted extensive interviews to gain an in-depth understanding of the implementation of geographical information systems for administrative applications in India. Phillips (1998) employed public discourse analysis to reveal the way in which concerns about anonymity, surveillance, and privacy are integrated into public understanding of a consumer payment system.

The Epistemological Lens

Orlikowski and Baroudi (1991) considered the influence of the epistemological lens – positivist, interpretive or critical – on the conduct of IS research. While there is some positivist, qualitative IS research (e.g., Lee 1989), most qualitative IS research is either interpretive or critical because of the assumption that "our knowledge of reality is a social construction by human actors" that precludes obtaining objective, value-free data (Walsham, 1995, p. 376). The interpretive epistemology has also spawned IS research employing hermeneutic methods (e.g., Boland, 1985, 1991, and Trauth & Jessup, 2000). Ngwenyama and Lee (1997) used the critical lens to examine information richness theory.

The Uncertainty Surrounding the Phenomenon

According to Galliers and Land (1987), the added complexity from including relations with people and organizations in a view of information systems introduces greater imprecision

and the potential for multiple interpretations of the same phenomenon. Hence, alternatives to quantitative measurement are needed. Others argue that the less that is known about a phenomenon the more difficult it is to measure it. Benbasat et al. (1987) explained that the case study approach is appropriate for IS research areas in which few previous studies have been carried out. Paré and Elam (1997) built theories of IT implementation using case study methods. Orlikowski's (1993) rationale for choosing qualitative methods and grounded theory to study the adoption of CASE tools rested on the absence of systematic examination of the organizational changes accompanying the introduction of CASE.

The Researcher's Skills

The absence of formal study of qualitative methods may serve as a barrier to choosing these methods. Orlikowski (1991) suggested that institutional conditions have inhibited the teaching of qualitative methods because of the functionalist/positivist perspective of American business schools where IS is typically taught. These institutional conditions, within which doctoral studies are conducted and dissertations are written, have inhibited the use of alternative research paradigms and methodologies with long-term implications for the choice of methods used in IS research. Schultze's (2001) reflection on her decision to choose interpretive methods for her dissertation illustrates the importance of institutional influence. Exposure to advisors with expertise in interpretive methods gave her methodological opportunities not available to other students.

The Academic Politics

The choice of research methods is influenced by the country in which one works, whether one has completed the PhD, whether one has a tenured position, one's academic rank, and the particular inclinations of the university at which one works. The norms and values of the field are reinforced during one's education and beyond. What is taught in research methods seminars sets the standard for "acceptable" research. Advice to junior faculty, peer review of journal articles and the tenure review process all reinforce those norms and values. Fitzgerald and Howcroft (1998) described the polarization of positions into "hard" and "soft" perspectives. Klein and Myers (1999) contributed to closing this methodological divide by developing a set of principles for conducting and evaluating interpretive field studies.

FUTURE TRENDS

As our understanding of the context of information systems grows, our desire to understand and explain contextual factors will motivate researchers to explore new ways to employ qualitative methods. Therefore, we can expect greater use of the critical epistemological lens in the use of qualitative methods in IS research. We can also expect to see the increased use of *virtual* qualitative research methods. That is, the traditional face-to-face methods of data generation used in qualitative research will find increasing analogues in the virtual world. We can expect to see, for example, "virtual ethnographies," "virtual participant observation" and "online interviews".

CONCLUSION

The primary advantage of using qualitative, particularly interpretive, methods is the flexibility it affords the researcher during data generation and analysis. The main disadvantage of qualitative, particularly interpretive, methods is overcoming concerns about validity and generalization of findings. The concepts of both statistical validity and statistical generalization need to be redefined for qualitative research. The *MIS Quarterly* "Special Issue on Intensive Research" has addressed the validity issue by publishing exemplar research papers that provide evaluative criteria for other researchers to use in establishing validity. The generalizability issue is being addressed in thoughtful pieces such as the recent article by Lee and Baskerville (2003).

Despite these issues, the acceptance of qualitative methods for IS research is evidence of a growing consensus that these methods make a valuable contribution to the study of information systems in context. In making the decision to use qualitative methods a number of factors must be taking into consideration. These factors relate to the characteristics of the research problem, the researcher and the research environment.

KEY TERMS

Case Study: An examination of a phenomenon in its natural setting using fixed boundaries such as time.

Critical Research: Critique of the status quo through the exposure of what are believed to be deep-seated, structural contradictions within social systems.

Ethnography: Research characterized by an extended period in the field and which involves the researcher being immersed in the community being studied.

Grounded Theory: A method used to systematically derive theories of human behavior from empirical data.

Interpretive Research: Exploring the deeper structure of a phenomenon within its cultural context by examining the subjective meanings that people create.

Positivist Research: Research premised on the existence of a priori fixed relationships among phenomena.

Qualitative Methods: Methods for data collection and analysis that focus on understanding of text and observation rather than numeric calculation.

Qualitative Spatial Reasoning

Shyamanta M. Hazarika
Tezpur University, India

INTRODUCTION

Artificial Intelligence (AI) has, as one of its central topics, the ability to represent and reason with *common sense* knowledge. Early forays into common sense reasoning about the physical world involved solving textbook problems on physics and mathematics. These were not adequate for reasoning about most commonplace physical scenarios.

A system suggested by DeKleer, involving both quantitative knowledge and qualitative information concerning the physical situation marked the starting point for *qualitative physics* (Weld & DeKleer, 1990). Hayes' *Naive Physics Manifesto* (Hayes, 1985) paved the way for establishing qualitative physics (meantime re-christened *qualitative reasoning*) as an important topic of research within AI.

Qualitative Reasoning (QR) is an approach for dealing with common sense knowledge without recourse to complete quantitative knowledge. Representation of knowledge is through a limited repository of *qualitative abstractions*.

Space and spatial change is an important part of common sense reasoning. *Naive Physics Manifesto* proposed to represent space-time with four-dimensional *histories*. Despite early forays such as the *Naive Physics Manifesto*, representation of space within QR has been ill addressed. Nevertheless, there has been an increasing interest over the last few years in *qualitative spatial reasoning* - reasoning about space using qualitative abstractions.

BACKGROUND

Qualitative Spatial Representation and Reasoning is concerned with providing calculus which allow a machine to represent and reason with spatial entities without resort to traditional quantitative techniques. Reasoning is concerned with methods and techniques for decision-making using spatial knowledge and developing efficient algorithms for doing so. The term *Qualitative Spatial Reasoning* (QSR) subsumes both the sub-fields of representation and reasoning.

Conventional mathematical theories of space consider points as primitive spatial entities. Within QSR there is a strong tendency to take regions of space as the primitive spatial entity. The nature of the embedding space, that is, the universal spatial entity, is another important ontological commitment. One might take this to be R^n for some n, but one can imagine applications where discrete, finite or non-convex universes might be useful.

QUALITATIVE SPATIAL REASONING

Within QSR, *qualitative spatial representations* addressing different aspects of space including topology, orientation, shape, size, and distance have been put forward.

Different Approaches to QSR

Topology

Topology is the most elemental aspect of space and holds promise as a fundamental facet of qualitative spatial reasoning. Mathematical topology is too abstract to be of relevance to those attempting to formalize common sense spatial reasoning. QSR is concerned with reasoning and not just representation, and this has been paid little attention in mathematics.

One existing approach to topology, which has been espoused by QSR, is the work to be found in philosophical logic (Clarke, 1981; De Laguna, 1922). This work has built axiomatic theories of space which are predominantly topological in nature, and which take regions rather than points as primitive. In particular, the work of Clarke (1981) has led to the development of the *Region Connection Calculus* (Cohn, Bennett, Gooday, & Gotts, 1977; Randell, Cui & Cohn, 1992) and has also been a basis for theory of common sense geometry (Asher & Vieu, 1995).

Mereotopology

Mereology is the theory of parts and whole. Mereology is not sufficient by itself and there are theories in the literature, which have proposed integrating topology and mereology. The notion of *connection*, which is the key topological notion for the qualitative description of space, cannot be defined in terms of the mereological *part-whole* relation alone. Therefore, topological notions have to be added to mereology to provide an adequate qualitative theory of space. Such combination of the disciplines of mereology and topology is referred to as *mereotopology.*

Orientation

Orientation relations describe where objects are placed relative to one another. Of the qualitative orientation calculi to be found in the literature, certain calculi have an explicit triadic relation (Freksa, 1992), while others presuppose an extrinsic frame of reference (Frank, 1992).

Recently Dehak, Bloch, & Maitre (2005) have described a probabilistic method of inferring the position of a point with respect to a reference point knowing their relative spatial position to a third point. They address this problem in the case of incomplete information, where only the angular spatial relationships are known.

Distance and Size

Qualitative representation of distance is based on either some *absolute* scale or some kind of *relative* measurement. De Laguna's *Geometry of Solids* (De Laguna, 1922) is the earliest among the *relative* kind of representations. Distance is closely related to the notion of orientation, for example, distances cannot usually be summed unless they are in the same direction. It is perhaps not surprising that there have been a number of calculi, which are based on *positional information*: a primitive, which combines distance and orientation information.

Shape

Shape is an important characteristic of an object, and particularly difficult to describe qualitatively. Qualitative formalisms for describing shape can either be *constructive representations* or certain *constraining approaches*. Within the constructive representation of qualitative shape, structured combinations of primitive entities describe complex shapes. Approaches that work by describing the boundary of an object include sequence of different types of *curvature extrema* (Leyton, 1988). Meathrel & Galton (2000) present a general theory of qualitative outlines in 2D.

Region-Based Theories of Space

Early Theories

De Laguna's *Geometry of Solids* (De Laguna, 1922) is based on a triadic primitive CanConnect(x,y,z): x can connect y and z. CanConnect(x,y,z)is true if a body x can connect y and z by simple translation i.e., without scaling, rotation or shape change. The primitive is extremely expressive and it is easy to define notions such as *connectedness* and *relative distance* measures. Mereology as understood today is a formulation due to Tarski (1959) and is built on the single primitive relation P(x,y): x is a part of y. Tarski gave a theory of the *Geometry of Solids*, embedded by means of definition into an axiomatization of elementary Euclidean geometry.

Clarke's Calculus of Individuals

Clarke's formalism is based on connectedness (Clarke, 1981). Clarke took as his primitive C(x,y): the notion of two regions x and y being connected. C(x,y)is axiomatized to be reflexive and symmetric. From the C(x,y) relation, Clarke defines the relation of *part to whole* and several other useful spatial relations as enumerated in Table 1 below.

Region Connection Calculus

The Region Connection Calculus (RCC) is a modification and development of Clarke's original theory (Cohn, et al., 1997; Randell, et al., 1992). The basic part of the formal theory assumes a dyadic relation: C(x,y) to mean that region x is connected to region y.

The mereological relation of *parthood*, P(x,y) is defined from the connection relation C(x,y), which together is used to define a number of relations as enumerated in Table 2. DC(x,y) through NTPP(x,y) with the inverses for the last two, that is, $TPP^{-1}(x,y)$ and $NTPP^{-1}(x,y)$ constitute a *Jointly Exhaustive* and *Pair wise Disjoint* (JEPD) set of base relations referred to as RCC-8.

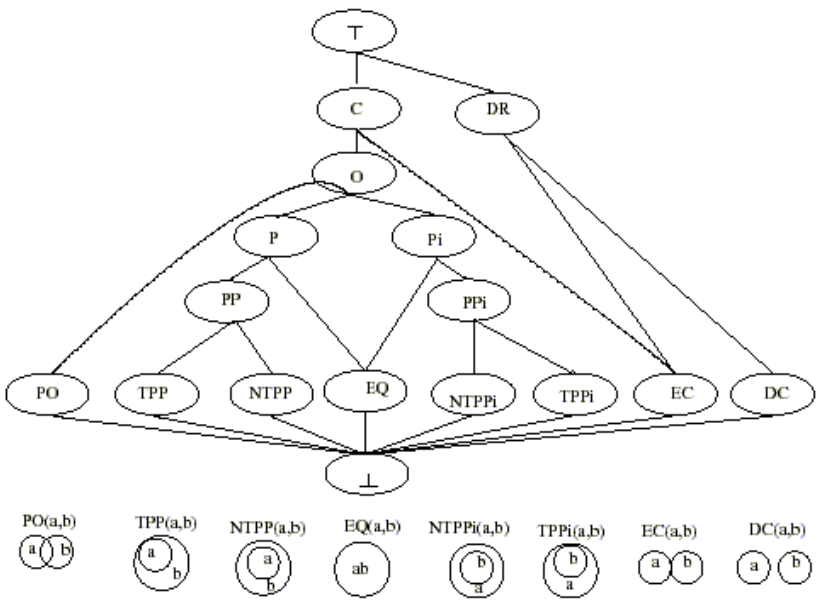
Table 1. Defined relations in Clarke's theory

Relation	Interpretation
DC(x,y)	x is disconnected from y
P(x.y)	x is part of y
PP(x,y)	x is proper-part of y
O(x,y)	x overlaps y
DR(x.y)	x is discrete from y
EC(x,y)	x is externally connected to y
TP(x.y)	x is a tangential part of y
NTP(x,y)	x is a non-tangential part of y

Table 2. Defined relations in Region Connection Calculus

Relation	Interpretation
PP(x,y)	x is proper-part of y
O(x,y)	x overlaps y
DR(x,y)	x is discrete from y
DC(x,y)	x is disconnected from y
EC(x,y)	x is externally connected to y
PO(x,y)	x partially overlaps y
EQ(x,y)	x is equal to y
TPP(x,y)	x is a tangential proper part of y
NTPP(x,y)	x is a non-tangential proper part of y

Figure 1. Lattice defining the subsumption hierarchy of dyadic relations defined in terms of C. The pictorial representation of the eight base relations (referred to as RCC-8) is included below the lattice.



Relations defined in terms of C(x,y) can be embedded in a relational lattice with the top element interpreted as tautology and the bottom element as contradiction. The relational lattice along with the representations of the eight base relations is shown in Figure 1.

Asher & Vieu's Theory

Asher & Vieu (1995) gave a mereotopological system based on Clarke's *Calculus of Individuals*. A significant feature of the theory is the notion of *weak contact* and *strong contact*. They qualify the standard interpretation of connection and make distinction between connection such as "relation between a glass and the table on which it is standing" with that from "relation between the stem of the glass and the cup of the glass" (Asher & Vieu, 1995). The former is an example of weak contact, whilst the latter is of strong contact.

Contrary to the RCC interpretation, Asher & Vieu (1995) argue that differentiating between an individual, its closure, and its interior is cognitively important. Asher

& Vieu 's mereotopological theory incorporated notions of open and closed sets (from point-set topology) to make such distinctions.

Muller's Extension

Muller (2002) has taken over the theory of Asher & Vieu (1995) and extends it to *space-time*. Taking up the idea of Hayes' (1985) spatio-temporal *histories*, Muller presents a mereotopological model in which the primitive entities are spatio-temporal regions, on which spatio-temporal and temporal relations are defined.

The spatio-temporal relations are an extension of spatial relations to space-time. Additional temporal relations are introduced to add further structural specification. Besides a classical *temporal precedence* relation, a primitive *temporal connection* (a connection with almost the same behaviour as C(x,y) but only on a temporal level) is introduced. With these it is possible to distinguish a temporal overlap from a simple temporal contact. Perhaps the most important contribution of Muller's mereotopological theory of space-time was an explicit definition of *qualitative continuity*.

Other Region-Based Theories

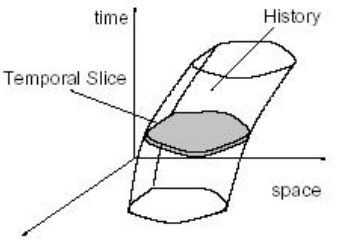
An alternative approach to representing and reasoning about topological relations is Egenhofer's n-intersection Model (Egenhofer & Franzosa, 1991). Three sets of points are associated with every region: its interior, boundary, and complement. A 3x3 matrix called the 9-intersection can characterize the relationship between any two regions[1]. Taking into account the physical reality of 2D space and some specific assumptions about the nature of regions, there are exactly 8 matrices, corresponding to the RCC-8 relations.

Qualitative Spatio-Temporal Reasoning

Spatial *configurations* tend to change. Reasoning about space often involves reasoning about change in spatial configurations. Driven by *cognitive* approaches that characterize the processing of spatial information in QSR, there has been work in other areas within AI such as computer vision, robotics, and so forth. Qualitative representation and reasoning about spatial change (Galton, 2000) and spatial interactions (Hazarika & Cohn, 2002) have been explored. Qualitative Spatio-Temporal Reasoning (QSTR) encompasses all such techniques.

There are two basic approaches to reasoning with qualitative spatial data over time: take a *snapshot* viewpoint and describe dynamic behaviour as a set of temporal states, or view the world as spatio-temporal histories (Hayes, 1985).

Figure 2. A space-time history is a n+1 dimensional volume for n-D space.



Qualitative Space-time Histories

In order to add time to space, an obvious and straightforward choice is to interpret entities in space-time rather than in space alone. In fact, Clarke's intended interpretation of his region-based calculus was spatio-temporal (Clarke, 1981). More recently (Hayes, 1985; Hazarika & Cohn, 2002; Muller, 2002) consider entities to be *histories* as shown in Figure 2.

Qualitative Motion

In spite of a large amount of work in mereotopological theories as a basis for common sense reasoning, very little work has been done on motion in a qualitative framework. Galton (2000) and more recently Muller (2002) and Hazarika & Cohn (2002) have looked at motion in the more cognitive kind of approach characterized by processing spatial information. Muller's (2002) Theory is an enrichment of Asher & Vieu's (1995) theory to achieve a formal theory for reasoning about motion. The expressive power of the theory allows for definition of complex motion classes such as those expressed by motion verbs in natural language.

Other Approaches

Qualitative representation and reasoning over *episodes* in space (El-Geresy, Abdelmolty, & Jones, 2000) is the closest to the spatio-temporal *histories* of a mereotopological theory of space-time. The episode of an object is the consistent behaviour of a spatial object within duration of time when this behavior can be described as being consistent (i.e., described by a single function). The approach is limiting, as only *well behaved* approximations of representation of spatio-temporal relations are possible.

Many qualitative spatial and temporal calculi arise from a set of JEPD relations. Ligozat & Renz (2004) examine the construction of such formalisms in order to make apparent the formal algebraic properties of all formalisms of that type. Malek (2004) propose a logic-based framework for representing and reasoning about qualitative spatial relations over moving agents in space and time. The framework would find applications in intelligent transportation system and mobile autonomous navigation systems.

FUTURE TRENDS

Use of QSR for other areas such as the *semantic web* (Katz & Grau, 2005) and *bio-medical ontologies* (Donnelly, Bittner, & Rosse, 2005) is being explored in a big way. The Web Ontology Language (OWL) has not been designed for representing spatial information. A translation of the RCC-8 calculus into OWL makes it possible to adapt OWL based tools for representing and reasoning on qualitative spatial information. In particular, ontology editors could be equipped with suitable user interfaces for spatial modeling and spatial *knowledge bases* could be published and shared on the Semantic Web.

CONCLUSION

Even though much work has been done in generating spatial representational calculi, there remain a number of theoretical questions. Their inventors have not given a formal semantics for many calculi. The calculus given by Clarke (1981) and all related calculi such as the first order theory of RCC (Randell, et al., 1992) and of Asher & Vieu (1995) are undecidable. The constraint language of RCC-8 has been shown to be decidable. This was achieved by encoding each RCC-8 relation as a set of formulae in *intuitionistic proportional calculus*, which is a decidable calculus.

Renz & Ligozat (2005) show under which conditions algebraic closure can be used to decide consistency in a qualitative calculus, how weak consistency affects different important techniques for analyzing qualitative calculi, and under which conditions these techniques can be applied. All their results are general and can be applied to all existing and future qualitative spatial and temporal calculi. Renz & Ligozat (2005) also gave a road map of how qualitative calculi should be analyzed.

An issue that has not been much addressed yet in the QSR literature is the issue of cognitive validity. Claims are often made that qualitative reasoning is akin to human reasoning, but with little or no empirical justification. More work needs to be done in this direction.

KEY TERMS

Mereology: Mereology is the theory of parts and whole.

Mereotopology: Topological notions have to be added to mereology to provide an adequate qualitative theory of space. Such combination of the disciplines of mereology and topology is referred to as mereotopology.

Qualitative Motion: Description of motion in a more cognitive kind of approach characterized by processing spatial information.

Qualitative Reasoning: Approach for dealing with common-sense knowledge without recourse to complete quantitative knowledge. Representation of knowledge is through a limited repository of qualitative abstractions.

Qualitative Spatial Reasoning: Qualitative Spatial Reasoning is concerned with providing calculus which allow a machine to represent and reason with spatial entities without resort to traditional quantitative techniques. Representation is concerned with different forms of spatial knowledge and reasoning is concerned with methods and techniques for decision-making. The term Qualitative Spatial Reasoning subsumes both the sub-fields of representation and reasoning.

Qualitative Spatio-Temporal Reasoning: Qualitative Spatio-Temporal Reasoning encompasses all techniques of qualitative representation and reasoning about spatial change and spatial interactions.

Region Connection Calculus: RCC is a mereotopological theory of space. The topological primitive of connection is primal from which the mereological primitive of parthood is defined. The theory has a set of eight jointly exhaustive and pair-wise disjoint base relations referred to as RCC-8.

Spatio-Temporal History: Space-time regions traced by objects over time are termed space-time history or spatio-temporal history.

ENDNOTE

[1] A simpler 2x2 matrix known as the 4-intersection featuring just the interior and the boundary is sufficient to describe the eight RCC relations. The 3x3 matrix allows more expressive sets of relations to be defined since it takes into account the relationship between the regions and its embedding space.

Quality Assurance Issues for Online Universities

Floriana Grasso
Liverpool University, UK

Paul Leng
Liverpool University, UK

INTRODUCTION

Online delivery of degree-level programmes is an attractive option, especially for working professionals and others who are unable to contemplate full-time residential university attendance. If such programmes are to be accepted, however, it is essential that they attain the same standards and quality as conventionally delivered degrees. The key challenge is to find ways to ensure that the qualities that make university education attractive are preserved in the context of a new and quite different model of delivery.

Many systems have been developed to support online learning (see, e.g., Anderson & Kanuka, 1997; Davies, 1998; Persico & Manca, 2000; Suthers & Jones, 1997; Yaskin & Everhart, 2002). These systems may or may not mimic conventional lecture-room teaching, but will necessarily involve major differences in the ways in which teaching and student support are organised. Furthermore, the Internet lends itself naturally to an internationalisation of education delivery, but this also poses challenges for universities that have developed their structures within the framework of national education systems. To address these issues, it may be desirable for the university to work in partnership with other agencies, for example to provide local support services for students. This too, however, may introduce new problems of quality control and management. We will discuss here what structures are required to ensure the quality of the education provided and the standards of the degrees offered in this context.

BACKGROUND

The emergence of the Internet as a way of delivering higher education has led to examinations of its implications for education policy in many national and international contexts. A set of benchmarks for quality of online distance education was developed by the (U.S.-based) Institute for Higher Education Policy (2000). This identified a total of 24 benchmarks, in seven categories. In the UK, the Quality Assurance Agency for Higher Education has issued guidelines on the Quality Assurance of Distance Learning (QAA, 2000a), with a similar scope to those of the IHEP. A comparison of the main headings of the two frameworks is illustrated in Table 1. Also relevant, when the delivery model involves partnership with external agencies, is the QAA Code of Practice in relation to Collaborative Provision (QAA, 2000b). Similar issues are examined in an Australian context by Oliver (2001), and from Hong Kong by Yeung (2002). Yorke (1999) discusses quality assurance issues in relation to globalised education, touching especially on collaborative provision. Other perspectives are offered by Pond (2002), Little and Banega (1999), and Davies et al. (2001).

Much of the work in this field reflects "an implicit anxiety that the 'values' of traditional teaching may somehow be eroded" (Curran, 2001). There is consequently, in most prescriptions, a strong emphasis on replicating in an online context the characteristics of quality that we might expect to (but do not always) find in conventional teaching. Thus, one of the precepts of (QAA, 2000a) calls for "…..managing

Table 1. Comparison of U.S. and UK QA frameworks

IHEP (USA)	QAA (UK)
Institutional Support	System Design (i.e., institutional issues)
Course Development	Programme Design (course development and structure)
Course Structure	
Teaching and Learning	Programme Delivery
Student Support	Student Support
Faculty Support	
Evaluation and Assessment	Student Assessment
	Student Communication and Representation

the delivery of each distance learning programme of study in a manner that safeguards the academic standards of the award"; and one of the benchmarks of the IHEP specifies that "Feedback in student assignments is provided in a timely manner". Unexceptionable as they are, these requirements are not peculiar to online distance learning. The key issue is not, therefore, one of defining quality assurance criteria, but rather that of providing structures to ensure their implementation.

QUALITY ASSURANCE FOR ONLINE DEGREES

Pedagogic Issues

Before examining quality assurance as such, we will first consider questions relating directly to the pedagogic approach used in online learning. In this respect, the premise that quality in online learning involves only a replication of on-campus characteristics is, we believe, limiting. We start, instead, from the standpoint that lecture-based teaching, whatever its merits, is not necessarily an ideal which online teaching must emulate. Students all too frequently attend lectures in an entirely passive mode, expecting to listen and receive the information they require while making no positive contribution themselves. Interaction between lecturer and students, and within groups of students is low, especially in the large classes that are typical of modern universities.

Conversely, online teaching makes it possible to recreate, through the medium of moderated online discussion, an atmosphere that is closer to that of a small-group on-campus seminar, and, paradoxically, can be far more involving and interactive than is typically the case in on-campus teaching. Two broad principles inform the approach: *constructivism* (Wilson, 1996), and *collaborative enquiry.* Collaborative enquiry via Internet-mediated communication provides a framework for this mode of learning (Stacey, 1998). The aim is to use the medium to foster the creation of a *learning community* (Hiltz & Wellman, 1997) that will enable dialogue between participants, sharing of information, and collaborative project work.

Moderated discussion (Collins & Berge, 1997) is a key feature of the teaching paradigm here, and serves a number of purposes that are relevant to the question of quality. Most obviously, it provides the means by which students may share information and experience, comment on the course materials and assignments, raise questions, and bring to the class knowledge and expertise that is outside the experience of the course teacher. To a significant extent, the students thus participate actively in the teaching process, augmenting the overall learning experience. Less obviously, there are other issues of quality in which classroom discussion can have a role; we will discuss these next.

Quality Assurance Issues

Key issues of quality assurance in an online degree programme include:

- Academic control
- Academic standards
- Staff appointment and training
- Monitoring of programme delivery
- Assessment procedures
- Student identity and plagiarism
- Student progression and support

Our review of these issues, next, draws on our experience with the online degree programmes at the University of Liverpool (Gruengard, Kalman & Leng, 2000).

Academic Control

The primary requirement of the frameworks defined by the QAA and other bodies is that all academic aspects of an online degree programme should remain the responsibility of the parent university, which should have structures and procedures that are effective in discharging this responsibility. The issue here is that the academic standards and quality of the programme may be threatened by differences between the parties involved in its delivery, especially when there is only an indirect relationship between the university and some of the people involved (for example, regional partner organisations, or locally-based tutors).

In principle, these problems can be resolved by placing online degree programmes firmly within the framework defined by the university for approving and managing its courses. To oversee this, we have at Liverpool established a dedicated organisational unit within the university, the e-Learning Unit.

Academic Standards

A corollary this is that, wherever possible, the quality management of an online programme should follow procedures that are comparable to those established for other degrees of the university, especially in respect to those procedures that define and maintain the academic standards of the degree. These will include course and module approval and review procedures, assessment criteria, and so forth. In most cases, it should be possible to exactly replicate the procedures that apply on campus.

Q

Staff Appointment and Training

In the Liverpool University online programmes, teaching is principally carried out by part-time *instructors* who are based throughout the world. All appointments, however are subject to University approval using the same procedures and criteria that apply for the approval of non-established staff to teach on internal programmes. All instructors are required to first undertake an (online) training programme, over a period of 6 weeks, in which they are instructed on the use of the software platform and the methodology and pedagogic approach used in the programme. Further to this, in the first module they teach, the instructor is overseen by an academic *mentor* whose role is to advise and guide the novice.

Monitoring of Programme Delivery

A key aspect of quality assurance, especially when instructors as well as students are not campus-based, is the monitoring of module delivery. Interestingly, it is easier to do this effectively than is the case for on-campus teaching. In the Liverpool University model, *all* significant communications between staff and students are made electronically, as postings in or through a "virtual classroom". Thus, all are subject to scrutiny by "lurking" in the classroom while the module is being delivered, and/or by examining the recorded history of the class subsequently. In this way the academic staff of the e-Learning Unit monitor the delivery of each module to ensure that the appropriate standards and quality criteria are met. The module monitor is required to complete a report that also incorporates a review of feedback from students and the comments of the instructor. These reports are reviewed routinely by a Board of Studies.

Assessment Procedures

Assessment in this model is readily subject to moderation by the module monitor, who has access to all the relevant information contained in the record of the virtual classroom. Review of assessment outcomes is an explicit part of the end-of-module procedures, and these are finally subject to confirmation by the Board of Examiners, which in the UK framework includes an external examiner from another university. The external examiner also has full access to the virtual classroom and so, in practice, has the opportunity for a more detailed examination of assessment processes and standards than is usually possible in on-ground teaching.

Strict management of the assessment process is in our experience essential when instructors are drawn from a wide variety of cultures. In this case consistency of assessment can only be achieved by defining very clear grading descriptors and criteria, and by insisting that the interpretation of these is moderated firmly within the university's assessment model.

Student Identity and Plagiarism

One of the questions that most exercises organisations considering online learning is that of how to confirm the identity of participants, together with the related question of protecting against plagiarism. In this respect a key role is played by discussion in the virtual classroom. Participation in discussion provides a means of monitoring the effective involvement of each student, and assists in preventing impersonation and plagiarism. Research has shown (Klemm & Snell, 1996; Lai, 1997) that involvement in online discussion is rarely wholly effective unless moderated by external facilitators, and we believe that it is important that it be made a requirement, equivalent to the attendance requirements of on-campus degrees.

The fact that all communications take place online, and are recorded and preserved indefinitely, provides further protection against plagiarism. It is easy to apply programs that perform comparisons of work submitted in the virtual classroom, or use services that perform checks against plagiarism throughout the Web.

Student Progression and Support

The requirement to participate in online discussion also provides a means of monitoring student progress. If a student is failing to keep up with the requirements of the programme, this rapidly becomes apparent as his/her contributions to the discussion falter. At this point the instructor can intervene to investigate and take action if required.

FUTURE TRENDS

A key precept for quality assurance of online degree programmes is that, wherever possible, procedures and structures that are thought to be necessary on campus should have an online equivalent. As the previous discussion reveals, creating equivalent processes is usually possible, but some significant differences emerge, highlighted in Table 2. The comparison of conventional lecture-based teaching with our model of online learning is not, we believe, to the disadvantage of the latter.

Although online degree programmes will not replace campus-based education, we believe there will be a strong future trend towards programmes that will meet particular areas of demand, especially the needs of working adults. Examples of successful online higher education programmes are, so far, relatively few, especially in Europe. We believe firmly that the successful programmes of the future will

Table 2. Comparison of on-campus and online characteristics

	On Campus	Online
Teaching/learning mode	Predominantly lecture-based	Predominantly seminar-based
Interpersonal interactions	Low: via classroom discussions/questions	High: via moderated e-mail dialogue
Verification of student identity	Personal appearance	Textual/linguistic characteristics
Student support	Face-to-face meetings with tutors	E-mail interactions with tutors
Review of standards of attainment	Scrutiny of examination scripts	Inspection of work in online classrooms
Mentoring/monitoring of staff performance	Inspection of selected lectures/classes	"Lurking" in ongoing online classes

be those that focus on pedagogy, and give precedence to academic standards and quality assurance, rather than those that emphasise technological aspects or focus on low-cost delivery.

CONCLUSION

Quality in online degree programmes is often perceived to imply a replication of on-campus characteristics. We believe, conversely, that in some respects online delivery provides an opportunity to enhance the quality of learning opportunities for students. Especially this is so when the learning paradigm encourages a high degree of discussion and interaction between staff and students in the virtual classroom.

In other respects, it is indeed necessary to maintain comparability with on-campus degrees, especially in relation to academic standards. Here, however, the key issues do not relate to the definition of standards and quality criteria, but to the creation of mechanisms to uphold them. We believe it is necessary to establish well-defined and rigorous monitoring procedures for this purpose. Again, a learning environment that emphasises classroom discussion is a help in many aspects of quality management.

KEY TERMS

Constructivism: A form of learning in which students construct their own unique understanding of a subject through a process that includes social interaction, so that the learner can explain understandings, receive feedback from teachers and other students, clarify meanings, and reach a group consensus.

Globalised Education: Educational programmes in which both students and educators may be globally distributed.

Higher Education Programme: The processes, learning materials, and associated procedures and facilities that lead to the completion of a degree or related qualification.

Moderated Discussion: Discussion that is supervised, partly directed, and evaluated by a programme tutor.

Moderation of Assessment: External oversight of an assessment process to ensure that appropriate standards are maintained.

Online Learning: A programme of education that is carried out wholly or primarily through the medium of the Internet.

Quality of Education: Refers to the effectiveness of the programme in promoting student learning and achievement, in relation to its expected outcomes and standards.

Standards (of Education): Refer to the level of attainment achieved by students, in relation to the qualification awarded.

Virtual Classroom: An internet-mediated forum for distribution of learning materials, classroom discussion, and collaborative working.

Quality-of-Service Routing

Sudip Misra
Cornell University, USA

INTRODUCTION

The area of quality-of-service (QoS) routing is concerned with selecting routing paths while meeting strict end-to-end service requirements involving resource constraints, while achieving optimum throughput in the network. The usefulness of QoS routing is not new. QoS routing is quite popular in the telecommunications industry because of the increased demand for satisfying multiple customer demands and obtaining increased utilization of network resources, while satisfying the varied user requirements.

BACKGROUND

Two basic considerations in QoS routing in integrated services packet-switched networks concern: (1) routing traffic with bandwidth guarantees, and (2) routing traffic with delay guarantees. Some of the algorithms proposed traditionally for solving the former class of problems are the widest-shortest path (WSP) (Guerin, Orda, & Williams, 1997), and the shortest-widest path (SWP) (Wang & Crowcroft, 1996) algorithms. More recently, Vasilakos, Saltouros, Atlassis, and Pedrycz, (2003) proposed the stochastic estimator learning automata (SELA) routing algorithm for QoS routing in asynchronous transfer mode (ATM) networks.

Online routing using traffic engineering (TE) principles has recently drawn considerable attention. We mention here a few TE algorithms proposed in the literature (e.g., Iliadis & Bauer, 2002; Kar, Kodialam, & Lakshman, 2000; Suri, Waldvogel, Bauer, & Warkhede, 2003; Szeto, Boutaba, & Iraqi, 2002; Wang, Su, & Chen, 2002). Of all the online TE algorithms, we believe that the one that has attracted the most attention is the minimum interference routing algorithm (MIRA) designed by Kar et al. (2000).

In addition to the MIRA algorithm, there are a few other TE routing algorithms that were proposed by other researchers, some of which are: the profile-based routing (PBR) (Suri et al., 2003); the dynamic online routing algorithm (DORA) (Szeto et al., 2002); Iliadis and Bauer's (2002) algorithm; Wang et al.'s (2002) algorithm; and the random races-based traffic engineering routing algorithm (RRATE) (Oommen, Misra, & Granmo, 2006). Some of these are also described in the sections to follow.

QUALITY-OF-SERVICE ROUTING

A network is said to support QoS (Guerin et al., 1997; Peterson & Davie, 2000), if it has the capability of treating different packets differently. QoS technology has enabled service providers to support different levels of service to different customers, thereby capacitating them with the option to provide better levels of paid services to some customers more than to others. For example, some groups of customers may be concerned with a service that guarantees packet delivery, even if that means paying a higher price for these services, others may just as well be satisfied with relatively less reliable data transfer by paying less for their subscribed services. Networks that transport multimedia traffic, that is, voice, data, and video need differential treatments of different packets—while voice traffic is highly sensitive to time delay and the orderly delivery of packets, data traffic is relatively less sensitive to these, and videoconferencing traffic requires a dedicated connection for a fixed amount of time for the real-time, orderly delivery of packets.

Typical QoS routing-based performance metrics are bandwidth, delay, and throughput. While some applications require bandwidth guarantees, some others mandate the satisfiability of strict end-to-end delays, and others still require a high throughput, or a combination of both of these criteria (Ma, 1998).

Routing protocols in the pre-QoS era did not consider QoS requirements of connections (e.g., delay, bandwidth, and throughput). Furthermore, optimization of resource utilization was not a primary goal. As a result, while there were flow requests that were rejected because of nonavailability of sufficient underlying resources, there were some other resources that remained available. To address such deficiencies with conventional routing protocols, QoS routing algorithms were devised that could locate network paths which satisfy QoS requirements and which made better use of the network. Routing of QoS traffic requires stringent performance guarantees of the QoS metrics (e.g., delay, bandwidth, and throughput) over the paths selected by the routing algorithms. Accordingly, whereas the traditional shortest path algorithms, for example, Dijkstra (1959)'s or Bellman (1958)'s, indeed, have the potential of selecting a feasible path for routing, QoS routing algorithms must consider multiple QoS and resource utilization constraints, typically making the problem intractable. QoS routing is, thus,

different from that of routing in traditional circuit-switched and packet-switched networks.

In ATM networks, for example, a connection is accepted or not by the Connection Admission Control (CAC), depending on whether or not sufficient resources (e.g., bandwidth) are available. The CAC operates by taking into account factors such as the incoming QoS requests and the available resources in the network. The CAC operates the QoS routing algorithms, which identify whether the different possible candidate paths satisfy the QoS requirements or not. The network architects and the engineers want to choose such a routing algorithm that will help the service providers for maximizing the network resources (e.g., the amount of bandwidth to be routed), while satisfying the requirements from the customers. Therefore, the design of any good QoS routing algorithm takes into account factors such as satisfying the QoS requirements, optimizing the consumption of the network resources (e.g., buffer space, link bandwidth), and balancing the traffic load across different paths. In addition to these, a good QoS routing algorithm should characterize itself by its ability to adapt to the periodic dynamic behavior of the network.

Conventional QoS Routing Algorithms

In this section we present an overview of some of the traditional algorithms for QoS Routing.

- **SWP:** The SWP algorithm was proposed by Wang and Crowcroft (1996). They proposed two variants of the algorithm—the *distance-vector-based SWP*, and the *link-state based SWP*—depending on whether the SWP algorithm is governed by *distance-vector-based routing* or by *link-state-based routing*. Essentially, in both variants of the SWP algorithm, the algorithm finds a route with the widest path, that is, the path with the maximum bottleneck bandwidth. When there is more than one choice available, the algorithm chooses the path that has the minimum length, that is, the one that has the shortest propagation delay (Wang & Crowcroft, 1996). If still there is a tie between one or more such path(s), one of the prospective paths is randomly chosen.
- **WSP:** The WSP algorithm was proposed by Guerin et al. (1997). Unlike the SWP algorithm, WSP first attempts to compute the shortest path; if there is more than one alternative, the algorithm chooses the one with the largest residual bandwidth in the bottleneck link (i.e., the widest path). If there is still a tie with one or more such path(s), one of the prospective paths is randomly chosen.
- **SELA:** The SELA routing algorithm was proposed by Vasilakos et al. (2003), and is based on the concept of SELA (Vasilakos & Papadimitriou, 1992). SELA is a QoS-based dynamic source routing algorithm where each source node maintains a database of the topology information between it and its k-shortest path neighbors (to each reachable destination node) (Cormen, Leiserson, & Rivest, 1990). In SELA, a learning automaton is stationed at each node in the network for determining how each call is to be routed between every node to every other reachable node in the network. For establishing a call, the source node selects one of the precomputed shortest path routes that can potentially be accepted by the algorithm based on the QoS requirements and traffic parameters. If no such path can be found, SELA rejects the request. In the heart of the SELA routing algorithm is the design of a function that is used by SELA to estimate the environmental feedback of the path selected by the algorithm. Further details of the algorithm can be found in Vasilakos et al. (2003).

Traffic Engineering Routing

TE mandates to optimize the performance of traffic handling and resource utilization on existing physical network topologies. This is, in principle, engineered by minimizing the over utilization of network capacity and distributing the traffic load on costly network resources such as, links, routers, switches, and gateways (Osborne & Simha, 2002). In the context of routing, TE is of great usefulness because traditional routing techniques are based on greedy shortest path computation techniques that lead to the over utilization of certain network resources, even when other resources remain under utilized.

Multi-protocol Label Switching (MPLS) has recently emerged for many professionals as a de facto standard in TE. MPLS is an Internet Engineering Task Force (IETF) standard which merges the layer 2 information of bandwidth, latency, and utilization of network links, with the control protocols used in layer 3 Internet protocol (IP), in order to simplify the exchange of IP packets. At the heart of the idea is the usage of a *label* (or a *tag*) to calculate shortest paths to all destinations within an autonomous system, thereby expediting the forwarding of packets. A label can be perceived as a simplified representation of an IP packet's header, with the additional advantage of enabling core backbone networks to operate at high speeds because of the exclusion of the need to re-examine each packet's IP header in detail. This, in turn, permits the differentiating between packets on an individual basis and facilitates the support of QoS. The destination of a packet is determined by observing the label and not the IP address it is destined to. MPLS helps network operators manage network route failures and makes the system able to decongest bottleneck links by providing a detour for the incoming traffic. It can also help service providers manage the

provisioning of different kinds of traffic according to different service plans, service, and policies of the customers.

We review the basic MPLS terminologies by using a hypothetical network as shown in Figure 1 and describe hereafter, in brief, how a packet is transmitted. In actuality, the steps involved are much more complex. A Label Switched Router (LSR) is a backbone router in the physical network topology that runs the existing layer 3 IP protocol. The particular cases of LSR, which are the edge routers, are called the label edge routers (LERs). These routers often serve as the *ingress* and *egress routers*, which can be thought of as synonymous to the source and destination routers for packets passing through the MPLS network. Packets are tagged with fixed-length labels at the ingress router and untagged off the labels at the egress routers. The paths (or routes) along which the labeled packets are transmitted are termed as the labeled switched paths (LSPs), and the protocol that monitors the negotiation and the exchange of labels is called the label distribution protocol (LDP). In a typical transmission of a packet through the MPLS network, after the backbone routing protocols, (such as the open shortest path first protocol (OSPF)), ascertains the reachability of a destination node, the LDP protocol establishes a mapping between a label and the destination node; the ingress node then receives a packet and labels it with a fixed length label (as described earlier) and transmits it towards the egress node, which upon receipt of the labeled packet, removes its label and delivers it (Osborne & Simha, 2002).

During the LSP setup phase mentioned previously, the intermediate LSRs between the ingress-egress nodes are specified. During this phase, the paths for a given flow are explicitly specified, thereby bestowing the service providers with a tool for engineering the incoming traffic to be routed and also supporting QoS, optimizing network utilization, and minimizing the number of rejected LSP setup requests, as this is what is typically mandated by the traffic engineers.

The traditional routing algorithms that forward packets based on the information about the destination address are only shortsighted and are, therefore, constrained by the following limitations (as identified by Suri et al., 2003):

- They do not take into consideration the current flows or expected future flow demands in the network. Those algorithms are greedy, in the sense that they would route a request through the default shortest path, the shortest-widest path, or the widest-shortest path, and would reject a demand when the precomputed routes using those algorithms are congested, even when other alternate routes are free to accept more requests.
- They do not take into consideration information about network infrastructure, network topologies, or traffic profiles to avoid loading bottleneck links in a network that might lead to rejection of future demands.
- The previous algorithms will perform negatively when they operate in an online routing situation, where the tunnel setup requests arrive one at a time, and the future demand is unknown. Those algorithms require the knowledge of future demands to operate successfully.
- The previous algorithms are not adaptive to possible link failures. Therefore, in a situation where a link fails, those algorithms will not be able to route requests through alternative routes.

Online TE Routing Algorithms

Kar et al. (2000) identified a set of properties that a "practically useful" TE algorithm (based on MPLS) should have. Some of these properties are

- The algorithm should be based on an *online* routing model, where LSP setup requests arrive one at a time (not all at once), and the future demand is unknown. On the other hand, in an *off-line* model, all LSP setup requests are known a priori, and there are no demands for future LSP setup requests.
- It should be able to use knowledge about the *physical locations* of the ingress-egress router pairs through which an LSP is set up.
- The algorithm should be able to *adapt to possible link failures* in the network. In other words, a good TE algorithm should be able to reroute post-failure requests through alternate routes.
- It should be able to route the requested bandwidth *without splitting the demands* as much as possible through multiple paths. This is necessary because it often occurs that the nature of the traffic does not allow a demand to be split. Splitting traffic is, however, a common practice in scenarios like load balancing and network performance improvement.
- The algorithm should, if possible, support a *distributed implementation*, where instead of performing the route computation in a centralized server, the computations of each LSP's route request is distributed at the local ingress node.
- It is quite desirable that such an algorithm is capable of using different *policy constraints*. For example, service level agreements might impose a restriction that LSPs with less than a threshold value of flow guarantees should not be accepted (Kar et al., 2000; Suri et al., 2003).
- Such an algorithm should operate under strict bounds of computational complexity. The algorithms should be very fast and execute within a fixed time constraint. The amount of computation involved with LSP setup requests should be minimized so that the algorithm

can be implemented on a router or a route-server (Kar et al., 2000; Suri et al., 2003).

The MIRA Algorithm

The most influential and primitive online routing algorithm in TE was the MIRA algorithm of Kar et al. (2000). MIRA is online because it does not require a priori knowledge of the tunnel requests that have to be routed. The algorithm is targeted towards applications such as the setup of LSPs in MPLS networks. The algorithm helps service providers setup bandwidth guaranteed tunnels at ease in their transport networks. The terminology *minimum interference* used in the nomenclature of the algorithm indicates that the tunnel setup request is to be routed through a path (or a path segment) that must not interfere too much with future tunnel setup requests. The algorithm aims to protect the "critical links" in a network from being overloaded and thereby reducing the chances of rejection of future requests. The critical links are identified by the algorithm to be those that if congested because of heavy loading might lead to rejection of requests. Unlike its predecessor algorithms, MIRA uses any available information about ingress-egress nodes for potential future demands. MIRA is based on the core concepts of the *max-flow* and the *min-cut* computations of the area of network flows (Ahuja, Magnanti, & Orlin, 1993).

The RRATE Algorithm

The RRATE algorithm, proposed by Oommen et al. (in press), is perhaps one of the most representative state-of-the-art algorithms. They proposed a new class of solutions by incorporating the family of stochastic random-races (RR) algorithms. The most popular previously proposed TE solutions attempt to find a superior path to route an incoming path setup request. Their algorithm, on the other hand, tries to learn an optimal ordering of the paths through which requests can be routed according to the *rank* of the paths in the order learned by the algorithm. They showed that their algorithm has better performance than the important algorithms in the literature. Their conclusions are based on three important performance criteria: (1) the rejection ratio, (2) the percentage of accepted bandwidth, and (3) the average route computation time per request. While some of the previously proposed algorithms were designed to achieve low rejections and high throughput of route requests, they are unreasonably slow. Their algorithm, on the other hand, in general, attempts to reject the least number of requests, achieves the highest throughput, and computes routes in the fastest possible time, as compared to the algorithms we used as benchmarks for comparison.

FUTURE TRENDS

The future work in this area could involve the investigation of the following issues:

- testing the performance of all the aforementioned algorithms on complex massively sized networks; and
- testing the algorithms on real networks, under real traffic conditions.

Most of the aforementioned algorithms were evaluated on idealistic situations where there were no network link failures. With regard to future work, it would be interesting to consider situations where there are realistic link-ups and downs occurring in a network. It would also be interesting to see how all the algorithms can perform "rerouting" of paths if a desired path fails.

CONCLUSION

This article discussed the concepts of QoS and TE routing in networks and also some of the popular algorithms in this area. QoS and TE are very popular among networking researchers and practitioners because of the increased demand for satisfying multiple customer demands and obtaining increased utilization of network resources, while satisfying the varied user requirements. Different directions of future work for network professionals are also articulated.

KEY TERMS

Algorithm: An algorithm is a set of clear steps that is used to define how a task or a set of tasks can be accomplished.

Label Switched Path (LSP): The paths along which the labeled packets in MPLS networks are transmitted.

Label Switched Router (LSR): An LSR is a backbone router in the physical network topology that runs the existing layer 3 IP protocol.

Multi-Protocol Label Switching: A popular protocol for traffic engineering operating in layer 3, in synchronization with the Internet protocol (IP).

QoS Routing: QoS routing is concerned with selecting routing paths while meeting strict end-to-end service requirements involving resource constraints, while achieving optimum throughput in the network.

Routing: The mechanism by which a path or a set of paths is selected to send information or commodities.

Traffic engineering (TE): An engineering technique or techniques where information and goods can be efficiently transmitted or transported.

Quantum Cryptography Protocols for Information Security

Göran Pulkkis
Arcada Polytechnic, Finland

Kaj J. Grahn
Arcada Polytechnic, Finland

INTRODUCTION

Quantum cryptography will have a severe impact on information security technology. The objective of this article is to present state-of-the-art and future possibilities of two quantum cryptography protocol types. These protocols are for absolutely secure distribution of symmetric encryption/decryption keys and for creating secure digital signatures.

BACKGROUND

In the early 1980s, it was observed that the stochastic parallelism of quantum states cannot be simulated efficiently on a classical computer (Feynman, 1982). This observation started research on using quantum mechanical effects for more efficient information processing than is achievable with classical computers. During the 1980s, the operating principles and implementation possibilities of quantum computing were outlined at Oxford University (Deutsch, 1985). In 1984, a quantum protocol for information transfer with provable confidentiality was proposed (Bennett & Brassard, 1984). This protocol, called the BB84 protocol, uses quantum states implemented by randomly polarized photons.

In the 1990s, efficient algorithms based on the operating principles of quantum computing were proposed. Shor's quantum algorithm for integer factorization (Shor, 1994) has polynomial (cubic) computational complexity and has been experimentally verified in a quantum computer with seven qubits implemented using nuclear magnetic resonance (Vandersypen, Steffen, Breyta, Yannoni, Sherwood, & Chang, 2001). Search with Grover's (1996) quantum algorithm in an unsorted database has only square root computational complexity. The BB84 protocol has been used for secure distribution of symmetric encryption/decryption keys (Quantum Key Distribution, QKD) in research networks (BBN Technologies, 2005; Elliot, 2004; Quellette, 2005;). For some years also commercial QKD technology has been available (id Quantique Portal, 2005; MagiQ, 2005).

The RSA algorithm is often used to create digital signatures. RSA is secure because the best known factorization method for large integers has superpolynomial computational complexity in a classical computer. False signed messages could however be created with a sufficiently large quantum computer since the private signing key could easily be computed with Shor's algorithm from the corresponding public key. On the other hand, secure digital signatures could be created by manipulation and measurements of quantum states (Gottesman & Chuang, 2001; Lu & Feng, 2005).

INFORMATION REPRESENTATION WITH QUANTUM STATES

Quantum states are energy levels of molecules, atoms, and photons. Two quantum states for which a state transition exists can be used to represent an information bit, if the energy levels of both states can be measured. A bit defined by quantum states is called a quantum bit or qubit. However, quantum states are probabilistic. When the energy level of a molecule, an atom, or a photon is measured, the outcome is one of all possible energy levels, and each possible outcome is associated with a probability. The sum of the probabilities of all possible measurement outcomes is, of course, 1. A qubit is thus also probabilistic. The binary values 0 and 1 are represented by two possible quantum states of a qubit. If the measurement probabilities of these two quantum states are p_0 and p_1, then $p_0+p_1=1$.

Properties of Quantum Bits (Qubits)

A qubit can be treated mathematically by linear algebra as a 2-dimensional vector. The orthogonal base vectors $(1,0)^T$ and $(0,1)^T$ represent the quantum states associated with the binary values 0 and 1, respectively. Usually the **Dirac Notation** is used for qubits as well as for these two orthogonal base vectors, thus $(1,0)^T = |0\rangle$ and $(0,1)^T = |1\rangle$.

A qubit is a superposition of $|0\rangle$ and $|1\rangle$ and both values are simultaneously present. A measured qubit is set to the measured value, which is $|0\rangle$ or $|1\rangle$. Let $|\psi\rangle$ be a qubit in Dirac Notation. Then

$$|\psi\rangle = a\cdot|0\rangle + b\cdot|1\rangle \quad (1)$$

where a and b are complex numbers for which

$$\langle\psi||\psi\rangle = (a^*,b^*)\cdot(a,b)^T = a^*\cdot a + b^*\cdot b = |a|^2 + |b|^2 = 1, \quad (2)$$

{a*,b*} are complex conjugates of {a,b}, and $\{|a|^2,|b|^2\}$are the probabilities to measure the values 0,1, respectively. A qubit has thus three dimensions because complex numbers have two dimensions. From this follows further, that a qubit can be presented geometrically as a point on a 3-dimensional unit sphere.

A fundamental qubit property is the No Cloning Property, according to which it is impossible to clone an unknown quantum state (Nielsen & Chuan, 2002).

Multiple Qubits

The quantum state of **2 qubits** is a column vector with 2^2 = 4 components. For the qubits

$$|\psi_1\rangle = a\cdot|0\rangle + b\cdot|1\rangle \text{ and } |\psi_2\rangle = c\cdot|0\rangle + d\cdot|1\rangle \quad (3)$$

the quantum state is

$$|y_1y_2\rangle = |\psi_1\rangle \otimes |\psi_2\rangle = a\cdot c\cdot|00\rangle + a\cdot d\cdot|01\rangle + b\cdot c\cdot|10\rangle + b\cdot d\cdot|11\rangle \quad (4)$$

where $\otimes$ is the **tensor product** of two column vectors. In such a product, the result vector is obtained by multiplying the latter vector with each component in the first vector, see the following examples: $|00\rangle = |0\rangle\otimes|0\rangle = (1,0,0,0)^T$, $|01\rangle = |0\rangle\otimes|1\rangle = (0,1,0,0)^T$, $|10\rangle = |1\rangle\otimes|0\rangle = (0,0,1,0)^T$, and $|11\rangle = |1\rangle\otimes|1\rangle = (0,0,0,1)^T$ are called the **base vectors** of the 2 qubit state.

An **N qubit** quantum state $|\psi_1\psi_2\ldots\psi_N\rangle$ is a superposition of 2^N base vectors. For a three qubit quantum state $|\psi_1\psi_2\psi_3\rangle$ the 2^3 base vectors are {|000>,|001>,|010>,|011>, |100>,|101>, |110>,|111>}, where $|001\rangle = |0\rangle\otimes|0\rangle\otimes|1\rangle = (0,1,0,0,0,0,0,0)^T$, and so forth.

The qubit state $|\psi_1\psi_2\ldots\psi_N\rangle$ is an **entangled state** if there exists no $|\psi_1\rangle,|\psi_2\rangle,\ldots,|\psi_N\rangle$ for which $|\psi_1\psi_2\ldots\psi_N\rangle = |\psi_1\rangle\otimes|\psi_1\rangle\otimes\ldots\otimes|\psi_N\rangle$.

Example: The 2 qubit state $2^{-½}$ (|00> + |11>) is entangled.

Proof: $(a\cdot|0\rangle+b\cdot|1\rangle)\otimes(c\cdot|0\rangle+d\cdot|1\rangle) = a\cdot c\cdot|00\rangle+a\cdot d\cdot|01\rangle +b\cdot c\cdot|10\rangle+b\cdot d\cdot|11\rangle \neq 2^{-½}\cdot(|00\rangle + |11\rangle)$, since one of {a,d} and one of {b,c} must be 0.

Physical Implementation of Qubits

Qubits have been implemented by ion traps, by cavity quantum electrodynamics (QED), by nuclear magnetic resonance (NMR), and by quantum dots (Nielsen & Chuang, 2002).

A qubit is implemented by the **polarization state** of a photon in practical quantum cryptography. A polarization state consists of all planes in which the electromagnetic wave of a photon propagates. The polarization of a randomly polarized photon is a superposition of any pair of orthogonal states. Examples of orthogonal polarization state pairs are:

- horizontal and vertical polarization;
- +45° and -45° diagonal polarization.

The polarization of a photon can thus be modeled by a qubit $|\psi\rangle$ for which

$$|\psi\rangle = a\cdot|\text{horis}\rangle + b\cdot|\text{vert}\rangle = c\cdot|+45°\rangle + d\cdot|-45°\rangle \quad (5)$$

where a,b,c,d are complex numbers and $|a|^2 + |b|^2 = |c|^2 + |d|^2 = 1$. One polarization state must be interpreted as |0> and the other state as |1> for a chosen orthogonal state pair. For example,

- $|\text{horis}\rangle = |0\rangle$ and $|\text{vert}\rangle = |1\rangle$
- $|+45°\rangle = |0\rangle$ and $|-45°\rangle = |1\rangle$.

Notice also that (c,d) can be calculated from (a,b) and vice versa since

$$|+45°\rangle = 2^{-½}(|\text{horis}\rangle + |\text{vert}\rangle),\ |-45°\rangle = 2^{-½}(|\text{horis}\rangle - |\text{vert}\rangle). \quad (6)$$

The polarization of a photon is measured with a filter. After measurement, only the component defined by the filter can pass through. For example, the polarization will change to $|\psi\rangle = |\text{horis}\rangle$ when a photon with polarization $|\psi\rangle = a\cdot|\text{horis}\rangle + b\cdot|\text{vert}\rangle$ passes through a horizontal filter. If a=0 and b=1, then the photon is absorbed by a horizontal filter.

A consequence of the No Cloning Property of a qubit is that an unknown polarization state of a photon cannot be copied to any other photon.

QUANTUM INFORMATION PROCESSING

Quantum Gates and Circuits

Qubit states are changed with quantum gates. Basic single qubit quantum gates are:

- Identity Gate I, defined as $I\cdot|\psi\rangle = |\psi\rangle$ for a qubit state $|ø\rangle$
- Negation Gate X, defined as $X\cdot|0\rangle = |1\rangle$ and $X\cdot|1\rangle = |0\rangle$
- Phase Shift Gate Z defined as $Z\cdot|0\rangle = |0\rangle$ and $Z\cdot|1\rangle = -1\cdot|1\rangle$
- Hadamard Gate, H defined as $H\cdot|0\rangle = 2^{-½}\cdot(|0\rangle + |1\rangle)$ and $H\cdot|1\rangle = 2^{-½}\cdot(|0\rangle - |1\rangle)$.

Basic 2 qubit quantum gates are:

- Identity Gate I, defined as $I\cdot|\psi_1\psi_2\rangle = |\psi_1\psi_2\rangle$ for a two qubit state $|\psi_1\psi_2\rangle$
- Controlled-NOT C_{not}, defined as $C_{not}\cdot|0\psi\rangle = |0\psi\rangle$ and $C_{not}\cdot|1\psi\rangle = |1\rangle\otimes X\cdot|\psi\rangle$ for a qubit state $|\psi\rangle$ where $\otimes$ is the tensor product.

Also N qubit gates for N>2 can be defined, for example an N qubit Identity Gate. An N qubit gate has a $2^N * 2^N$ matrix representation G for which $G\cdot G^* = I$ where G^* is the complex conjugate matrix of G.

A quantum circuit is an interconnection of quantum gates. In Figure 1, a quantum circuit for teleportation of an unknown qubit state is shown. The state of the qubit $|\psi\rangle = a\cdot|0\rangle + b\cdot|1\rangle$ is teleported to the qubit $|\theta\rangle$. The upper qubit is the control bit in both C_{not} gates. m1 and m2 are measured qubit values. $X^{m2} = I$ for m2 = 0, $X^{m2} = X$ for m2 = 1, $Z^{m1} = I$ for m1 = 0, and $Z^{m1} = Z$ for m1 = 1. Notice that teleportation is not in contradiction with the No Cloning Property of a qubit, since the original state of the qubit $|\psi\rangle$ is lost in the measurement m1 and the measurement result m1 is needed in the teleportation.

Quantum Algorithms

An algorithm in quantum information processing is based on qubit state modifications with quantum gates and qubit measurements. Any algorithm in quantum information processing can be implemented by:

- quantum circuits of interconnected single qubit and Controlled-NOT quantum gates;
- qubit state measurements.

QUANTUM CRYPTOGRAPHY

Quantum cryptography means development and application of cryptographic protocols based on measurement and manipulation of quantum states. Technology for absolutely secure distribution of session and transaction keys to cryptographic network software with quantum protocols has been available for some years. Quantum protocols for signing both classical bit strings and quantum states have been proposed and thoroughly examined for future technology solutions (Gottesman & Chuang, 2001; Lu & Feng, 2004).

Quantum Key Distribution (QKD)

In this section, proposed QKD protocols are surveyed and integration of these protocols in the TCP/IP network protocol stack is outlined. Available QKD technology and present QKD applications are described. Security threats to QKD applications are also discussed.

QKD Protocols

The communication architecture and the phases of the BB84 protocol are shown in Figure 2.

1. Alice sends over an optical channel a sequence of polarized photons to Bob. Each photon is randomly polarized to a state in the set {|horis>, |vert>, |+45°>, |-45°>}. Bob guesses the polarization base (horizontal/vertical or diagonal) of each photon and measures the polarization in the guessed base. Polarization is correctly measured only for a correctly guessed polarization base, since measurement outcome is with equal probability one of the two orthogonal states of a wrongly guessed polarization base.

Figure 1. A quantum circuit for teleportation of the unknown qubit state $|\psi\rangle$ to the qubit $|\theta\rangle$

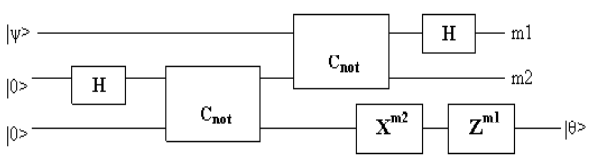

Figure 2. Principle of the BB84 QKD protocol

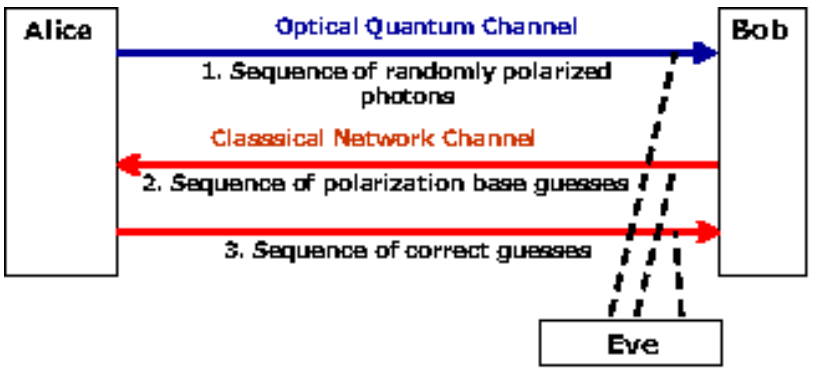

2. Bob sends over a classical network channel the sequence of polarization base guesses to Alice.
3. Alice returns to Bob the sequence of correct guesses.

Now Alice and Bob can use Bob's correctly measured polarizations as a shared secret (key), which consists of the polarization states of about 50% of the photons sent by Alice.

For the notation

- **u** is horizontal/vertical polarization base with **h** = |horis> as 0 and **v** = |vert> as 1
- **d** is diagonal polarization base with + = |+45°> as 0 and - = |-45°> as 1
- **r** is measurement of 0 or 1 with equal probability, **t** is true and **f** is false.

Assume, that

- Alice sends +hv++h-vvhv+—vh-v-
- Bob guesses and sends uuuuuudduuududddduud
- Bob measures r01rr01r1010r11rrr11
- Alice sends fttffttfttttfttfffft.

Then Alice and Bob share the secret 010110101111, since these bit values are correctly measured and they have not been revealed in the communication between Alice and Bob.

Assume that Eve (eavesdropper) measures the polarization of each photon in Alice's sequence in a guessed basis and forwards the measured photons to Bob. This means that a random choice of 0 or 1 is forwarded when Eve's polarization basis guess is incorrect. Since the probability of an incorrect guess is 50 %, about half of the bits are randomized in the bit sequence, which Alice and Bob think is a shared secret. Let **e** be an incorrect guess of Eve:

- Alice sends +hv++h-vvhv+—vh-v-
- Eve guesses dudddduudduduuuudddd
- Eve sends +he++eeveev+eeeve-e-
- Bob guesses and sends uuuuuudduuududddduud
- Bob measures r0erreeree10reerrre1
- Alice sends fttffttfttttfttfffft.

Now Alice thinks that she shares the secret 010110101111 with Bob, but Bob thinks that he shares the secret 0eeeee10eee1 with Alice. Here e is 0 or 1 with equal probability because of the intervention of Eve. About four of the eight e bits are probably correct but the eavesdropper Eve also knows these 4 bits.

The original BB84 protocol is presently the Sifting Phase of a QKD protocol for production of the raw keys of Alice and Bob. Sifting means that photons, which fail to reach the receiver, are omitted from the raw keys. Practical use of the BB84 protocol must include a Key Distillation process, which consists of Error Correction and Privacy Amplification. The shared secret will then include the bits extracted from the raw keys in the Key Distillation process. Error Correction means that the bits, which are different in the two raw keys, are detected and removed. Privacy Amplification means that as many as possible of the correct bits known by a possible eavesdropper are dropped from both raw keys. If both raw keys are equal, then any same bit subset of the required shared secret key size can be taken from both raw keys. The reason is that the probability for an eavesdropper to correctly guess the polarization basis of all photons corresponding to the bits in the raw keys is $O(2^{-N/2})$. Here, N is the length of the sequence of randomly polarized photons (Elliott, Pearson & Troxel, 2003).

Since the BB84 protocol is based on random choice from four different polarization states, it has been called a 4-state QKD protocol. It can be proved that only two non-orthogonal polarization states are actually needed to implement a perfectly secret QKD protocol (Bennett, 1992). Also,

perfectly secret 6-state QKD protocols have been proposed and analyzed (Bruss, 1998).

QKD Protocol Integration

Quantum Repeaters

With optical communication technology, one can transmit polarized photons with reasonable error rates over distances up to about 70…100 km (MagiQ, 2005; Stucki, Gisin, Guinnard, Ribordy, & Zbinden, 2002). For longer distances the current QKD protocols would need quantum repeaters (see Figure 1 for functional principle) on the physical layer of the network protocol stack. However, technology for optical quantum repeaters has still not been developed. Research efforts to implement a quantum repeater are presented in (Curcic et. al, 2004).

QKD Key Agreement

Secure network communication protocols for TCP/IP networks like IPSec, TLS/SSL, and SSH presently use the Diffie-Hellman protocol or RSA key transport for session key agreement. The use of a QKD protocol in these client/server communication protocols may require additional optical network links with own Ethernet interfaces.

QKD protocol integration in the IKE Deamon of the IPSec protocol is described in Elliott, Pearson, and Troxel (2003). Protocol phases are Sifting, Error Correction, Privacy Amplification, and Authentication before a session key can be included in a new Security Association (SA).

New cipher suites defining key exchange are prerequisites for QKD protocol integration in the TLS/SSL Handshake Protocol. New ServerKeyExchange and ClientKeyExchange messages must also be defined. The same phases as for QKD protocol integration in IPSec are needed before a shared secret is available in the SSL client and server. This shared secret could be used as Premaster Secret in the TLS/SSL handshake protocol.

Attacks Against QKD Systems

Security of quantum cryptography has been proven for any eavesdropping attack limits of security have been established for the case of a noisy environment and imperfect detection as well as of using non-ideal light sources. In all these cases, Eve performs her measurements on the quantum states transmitted from Alice to Bob (Vakhitov, Makanov, & Hjelme, 2001).

The real security of a quantum cryptography system will also be determined by technological implementations, technical measures, and by loopholes in the optical system. Attacks do not deal with quantum states but use loopholes and imperfections in implementations (Gisin, Ribordy, Tittel, & Zbinden, 2002). Optical loophole attacks are:

- **Large Pulse Attack:** A strong light pulse launched into a QKD system may be partly reflected. Measuring characteristics of pulses reflected via internal modulators of the system may allow the intruder to detect transmitted quantum states unambiguously (Bethune & Risk, 2000).
- **High-power destruction of optical components:** Damaging an optical component by using high-power external pulses could, for instance, make beam splitting and other quantum attacks more efficient.
- **Light emission from avalanche photodiodes (APDs, see Key Terms):** During an avalanche, an APD emits light over a broad spectrum and a part of this light leaks back into the system. An intruder may detect this leak.
- **Faked States Attack:** A faked states attack is an intercept-and-resend attack. Imperfections in Bob's scheme are utilized by Eve to generate light pulses not discovered by any alarm and legitimate parties are fooled.

QKD Technology and Applications

QKD works through optical telecommunication fibers or through the atmosphere. Data is transmitted faster in free space systems, but the distance is a limiting factor. Key data rates close to 5,000 bits/s have been reached at distances of up to 50 km through optical fiber and 10 to 20 km through atmosphere (Elliott, 2004). Single photons allow only slow real-time data transmission because of the limited detection rate of single photons.

The first commercial quantum cryptography products, for example single photon detectors and random-number generators, were introduced in 2002. Encoding was based on the phase of the photon not on the polarization state. In 2005, a new quantum cryptography Link Encryptor was presented, which combines QKD with AES (Advanced Encryption Standard) and securely bridges two Fast Ethernet networks. Key refresh rates up to 100 times per second and a transmission distance of 100 km in an optical fiber are supported (id Quantique Portal, 2005).

A quantum cryptography based solution called QPN™ Security Gateway adds layers of VPN security and classical data encryption to QKD. Protocols like BB84, IPSec, and 256 bit AES are implemented. A key refresh rate up to 100 keys/second, a transmission distance of 100 km, and full-duplex 10/100 Ethernet ports are supported (MagiQ, 2005).

The world's first quantum cryptographic network interconnects BBN Technologies, Harvard, and Boston University. This network has 10 nodes and uses different QKD protocols with a bandwidth up to 5 Mbit/s (BBN Technologies, 2005).

Quantum Digital Signature

Classical digital signatures can be created from any one-way function. A sender (Alice) chooses two binary private keys {***k0, k1***} and publicly announces ***f***, {***0,f(k0)***}, {***1,f(k1)***}, where f is the used one-way function. To sign a single bit ***b***, Alice sends {***b,kb***} to receivers, who can compare ***f(kb)*** with the earlier announcement. The signature is verified if ***f(kb)=f(k0)*** or ***f(kb)=f(k1)***, since only Alice can send a correct ***kb***. The public keys can, however, only be used once (Lamport, 1979).

A secure quantum digital signature scheme based on the use of quantum one-way functions is proposed in Gottesman and Chuang, (200)1. Alice

1. chooses a one-way quantum circuit ***f***, which maps a classical bit string ***k*** of length ***L*** to an ***n*** qubit state $|f_k\rangle$.
2. chooses ***M*** different pairs of private bit strings {***k0,k1***}. ***M*** depends on the application environment.
3. announces the structure of the quantum circuit ***f*** and ***M*** different $\{(0,|f_{k0}\rangle),(1,|f_{k1}\rangle)\}$ pairs to ***T*** recipients.

To sign a single bit message ***b***

1. Alice sends ***b*** in combination with ***M kb*** values over an insecure classical communication channel to all ***T*** recipients and thus reveals half of her private bit strings. Each recipient checks all ***M kb*** values with a swap quantum circuit (Buhrman, Cleve, Watrous, & De Wolf, 2001) to find out for each ***kb*** if the qubit state $|f_{kb}\rangle$ is identical with $|f_{k0}\rangle$ or with $|f_{k1}\rangle$. The check fails if $|f_{kb}\rangle$ is different from both $|f_{k0}\rangle$ and $|f_{k1}\rangle$.
2. Each recipient counts the number ***s*** of failed checks.
3. All ***T*** recipients must also know two numbers, c_1 and c_2, thresholds for acceptance and rejection. Both threshold values depend on the application environment. Each recipient
   - accepts the message ***b*** as valid and transferable (***result 1-ACC***) if $s<c_1 \cdot M$.
   - rejects message ***b*** as invalid (***result REJ***) if $s>c_2 \cdot M$.
   - otherwise concludes the message b to be valid but not necessarily transferable to other recipients (***result 0-ACC***).
4. All used and unused keys are discarded.

The number of recipients ***T*** must be less than ***L/n***, since measurements of the public state $|f_k\rangle$ can reveal up to ***n*** bit values in ***k***. When ***s*** is large, the message has been heavily tampered and may be invalid. c_1 can be zero in the absence of noise. When ***s*** is small, the message cannot have been changed very much from what Alice sent. ***s*** is similar for all recipients, but ***s*** values must not be identical. Forgery is prevented by c_2, and cheating by Alice is prevented by the difference between c_2 and c_1. The results ***1-ACC*** and ***0-ACC*** verify that Alice has sent the message. ***1-ACC*** means verification to the recipient that any other recipient will also find the message valid. Thus, the message is "transferable". ***0-ACC*** means, that a second recipient might find the message invalid. Result ***REJ*** means that the recipient cannot safely reach any conclusion about the authenticity of the message. It should be required that any recipient who receives a correct (message, signature) pair always reaches conclusion ***1-ACC***.

The quantum digital signature scheme (Gottesman & Chuang, 2001) is for signing only classical bit strings. Another quantum digital signature scheme based on quantum one-way functions for signing general quantum states is proposed in (Lu & Feng, 2004). Authentication of quantum messages can be based on schemes for signing quantum states. Quantum message authentication issues are examined in (Barnum, Crepequ, Gottesman, Smith, and Tapp, 2002).

FUTURE TRENDS

Today, the maximum guaranteed transmission distance is short because optical fibers are not perfectly transparent. Random noise degrades the photon stream. Therefore, continued research and development in the field of quantum repeaters is necessary. Researchers are also looking beyond optical fibers as the medium to distribute quantum keys. By optimizing free-space technology, it might be possible to build systems that transmit and receive signals reaching satellites in low earth orbit.

A major factor limiting the development of QKD systems is the lack of fast photon detectors. New detectors based on cryogenic niobium nitride superconductors may be a solution (Quellette, 2005).

The work on ideal single-photon sources continues. If more than one photon is emitted, the system will be vulnerable. An intruder will have the possibility to discover the used polarization and then send the rest of the photons further onto the receiver.

The ongoing EU Sixth Framework Programme, including research on Information Society Technologies, has a strong focus on Quantum Information Processing and Communications in Future and Emerging Technologies (CORDIS ISTweb Future, 2005). An example is the SECOQC ("Development of a Global Network for Secure Communication based on Quantum Cryptography") project, see (CORDIS ISTweb Network, 2005).

CONCLUSION

Quantum cryptography is an emerging information security technology, which is presently already available but still

neither fully integrated in current network technology nor standardized. Technological obstacles regarding quantum transmission distance and quantum device technology must be removed. Two potential information security areas are quantum key distribution and quantum digital signatures. Needed innovations will renew the classical information security technology.

KEY TERMS

Avalanche Photodiode: A photodetector which can be regarded as the semiconductor analog to a photomultiplier.

Photon: A discrete packet of electromagnetic energy.

Polarization: The plane in which an electromagnetic wave propagates.

QPN: A registered abbreviation for Quantum Private Network, which is a VPN link where session key agreement is based on a QKD protocol.

Quantum Gate: A device for changing the state of one or of multiple qubits.

Raw Key: Two parties agree on a shared binary secret from a sequence of randomly polarized photons.

Teleportation: Transfer of an unknown qubit state.

Real Options Analysis in Strategic Information Technology Adoption

Xiaotong Li
University of Alabama in Huntsville, USA

INTRODUCTION

Many information resource managers have learned to be proactive in today's highly competitive business environment. However, limited financial resources and many uncertainties require them to maximize their shareholders' equity while controlling the risks incurred at an acceptable level. As the unprecedented development in information technology continuously produces great opportunities that are usually associated with significant uncertainties, technology adoption and planning become more and more crucial to companies in the information era. In this study, we attempt to evaluate IT investment opportunities from a new perspective, namely, the real options theory. Its advantage over other capital budgeting methods like static discounted cash flow analysis has been widely recognized in analyzing the strategic investment decision under uncertainties (Amram & Kulatilaka, 1999; Luehrman, 1998a, 1998b). Smith and McCardle (1998, 1999) further show that option pricing approach can be integrated into standard decision analysis framework to get the best of the both worlds. In fact, some previous IS researches have recognized the fact that many IT investment projects in the uncertain world possess some option-like characteristics (Clemsons, 1991; Dos Santos, 1991; Kumar, 1996). Recently, Benaroth and Kauffman (1999) and Taudes, Feurstein and Mild (2000) have applied the real options theory to real-world business cases and evaluated this approach's merits as a tool for IT investment planning.

As all real options models inevitably depend on some specific assumptions, their appropriateness should be scrutinized under different scenarios. This study aims to provide a framework that will help IS researchers to better understand the real options models and to apply them more rigorously in IT investment evaluation. As the technology changes, the basic economic principles underlying the real options theory do not change. We do need to integrate the IT dimension into the real options based investment decision-making process. Using electronic brokerage's investment decision in wireless technology as a real-world example, we show the importance of adopting appropriate real options models in IT investment planning. By specifically focusing on the uncertainties caused by IT innovation and competition, our study also gives some intriguing results about the dynamics between IT adoption and the technology standard setting process.

REAL OPTIONS THEORY

It is generally believed that the real options approach will play a more important role in the highly uncertain and technology driven digital economy. Before reviewing the real options literature body that is growing very rapidly, we use an example to give readers an intuitive illustration of the values of real options and their significance in financial capital budgeting.

Pioneer Venture: The Value of a Growth Option

In this example, the management of a large pharmaceutical company wants to decide whether to acquire a young biomedical lab. If they decide to acquire it, they should provide $100,000 funding to cover the initial costs for the pioneer venture. Five years after the initial funding, the management will decide whether to stop the pioneer venture or to expand it significantly according to the market situation at that time. If they choose to expand it, additional $1,000,000 is needed. The cost of capital is assumed to be 15%. Five years after acquisition of the lab, the management will face two scenarios. The good scenario will occur with 60% likelihood, while the bad one will have 40% likelihood of happening. All expected future cash flows during the next 10 years are given in Table 1. Using standard capital budgeting method, we can find that the NPV for the pioneer venture is -$15,215. For the period of large-scale production, the NPV is -$71,873. As the NPVs for both periods are negative, it seems that the management should give up the acquisition. However, the acquisition will be a good investment if we consider the growth option associated with it. By acquiring the lab, the company also buys a growth option that enables it to expand the lab when the conditions are favorable 5 years later. In this case, the good scenario will occur with 60% likelihood. After simple calculation, it is easy to find that the growth option has a value of $28,965. Combining

Table 1. Projected cash flows in the example of pioneer venture project

Year	Pioneer Stage	Larger Scale Stage	Total Cash Flows	Discount Rate
0	-$100,000		-$100,000	15%
1	$10,000		$10,000

Value of the Option	$28,965.40

its value with the negative NPV during the pioneer venture period, the adjusted NPV of the acquisition is $13,750, which means this investment is strategically plausible.

Many researchers recognized the potential of this options pricing theory in capital budgeting because traditional DCF (discounted cash flows) technique has its inherent limitation in valuing investments with strategic options and many uncertainties. Table 2 gives a comparison between an American call option on a stock and a real option on an investment project. Despite the close analogy, some people may still question the applicability of option pricing theory on real options that are usually not traded in a market. However, Cox, Ingersoll and Ross (1985) and McDonald and Siegel (1984) suggest that a contingent claim on a non-traded asset can be priced by subtracting a dividend like risk premium from its growth rate.

Recent development in real option theory focuses on the valuation of more complicated real options like shared options, compounded options and strategic growth options. Dixit and Pindyck (1994) examine the dynamic equilibrium in a competitive industry. Their model suggests that a firm's option to wait is valuable when uncertainty is firm-specific. For industry-wide uncertainty, there is no value to wait because of the asymmetric effects of uncertainty.

FOUR CATEGORIES OF IT INVESTMENT OPPORTUNITIES

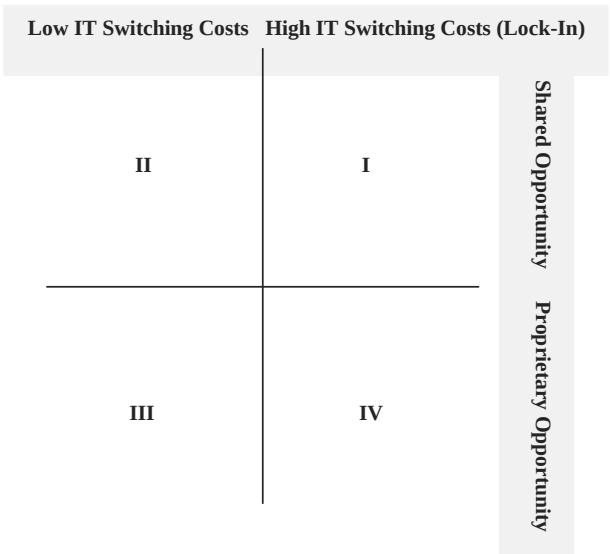
As shown in Figure 1, we have four types of IT investment opportunities based on the two criteria: (i). Shared opportunities with high IT switching costs; (ii). Shared opportunities with low IT switching costs; (iii). Proprietary opportunities with low IT switching costs; (iv). Proprietary opportunities with high IT switching costs. It is worth noting that each category has distinctive requirements on the application of real options models. We use the continuous-time model developed in McDonald and Siegel (1986) as a benchmark to show why we differentiate IT investment opportunities based on the two criteria. It basically suggests that the option to defer uncertain investment is very valuable and should be taken into account when a company makes investment decisions. A major assumption of this model is that there is no competitive erosion; in other words, the investment

Table 2. Comparison between an American call option and a real option on a project

AMERICAN CALL OPTION ON STOCK	REAL OPTION ON A PROJECT
Current Stock Price	Present Value of Expected Cash Flows
Option Exercise Price	Investment Cost of a Project
Right to Exercise the Option Earlier	Right to Invest in the Project at any time before the Opportunity Disappears
Stock Price Uncertainty	Project Value Uncertainties
Option Price	Value of Managerial Flexibility Associated with the Project
Expiration Time	Time Window of the Investment Opportunity
Traded in Financial Market	Usually not Traded
Easy to Find a Replicating Portfolio	Hard to Find a Replicating Portfolio

project is a proprietary opportunity. Without this assumption, the value of the project should not follow the symmetric geometric Brownian motion described in their model. The reason is simple: the existence of potential competition makes the distribution of future project value asymmetric, with high project value less likely to occur. It is worth noting that the well-known Black-Scholes option pricing formula is also based on the assumption that the underlying asset price follows the geometric Brownian motion. In the real business world, most investment opportunities are shared or at least partially shared. Especially in the IT business sector where intensive competition is pervasive, those real options models assuming symmetric uncertainty in investment opportunity value are generally inappropriate. Intuitively, competition pressure will decrease the value of the option to defer an investment. There are usually two approaches to deal with this issue. One approach is to model the competitive entries as exogenous shocks. For examples, Dixit and Pindyck (1994) and Trigeorgis (1991) use a Poisson Jump process to describe the competitive arrivals. Their studies show that the effect of the competitive erosion can be expressed as the following equation

Figure 1. Four categories of IT investment opportunities



Strategic NPV= NPV+ (Value of Option to Wait - Competitive Loss).

In other words, strong competition will restrict managerial flexibility if the investment opportunity is shared. We need to evaluate the investment opportunity in the context of the real options theory by considering the growth option and the waiting option simultaneously. Alternatively, we can incorporate the preemptive effect into the standard real options models. For example, Li (2001) proposes a real options model with strategic consideration based on the model in McDonald and Siegel (1986).

The other criterion we used to categorize different IT investment opportunities is the IT switching cost. We all know that future uncertainty makes the options embedded in an investment opportunity valuable. Theoretically, there is no need to single out technology uncertainty from all other uncertainties in the real options model. All these uncertainties have the same effect: they make the future

payoff of an investment project less predictable. However, we will concentrate on the technology uncertainty in this study because it plays a pivotal role in affecting IT investment payoff. Perhaps the most important question that management faces before committing an IT investment is whether the technology adopted is the right choice. More specifically, will the adopted technology be the best solution to maximize the expected investment payoff? Clearly there is not a simple answer to this question because there are so many uncertainties involved. Some very promising or popular IT solutions may become obsolete in a few years. In some other cases, some neglected IT solutions may evolve to be the standard solution. Nevertheless, most technology uncertainties can be resolved as the process of technology competition goes forward. A typical process of technology competition includes:

- Problem identification: An important problem is identified and new technology is sought to solve it.
- Technology solutions proposition: Several technology developers/vendors propose different solutions to solve the problem.
- Solution testing and comparison: Different technology solutions are competing in the market and their effectiveness is tested and compared.
- Technology standardization: The best solution will flourish over time. Based on it, the technology to solve the problem will be standardized.

For many IT investment projects, decision makers face an uncertain technology environment where several IT solutions are competing in the market. Obviously, the future successes of these projects will to some extent depend on whether the IT solutions adopted will win the technology competition. Consequently, decision makers do have an incentive to use the deferring option to let more technology uncertainties be resolved. Under this scenario, many option-to-wait models can be easily extended to find the optimal investment strategy. However, to apply these real options models we must presume that there are significant technology switching costs once an IT solution is adopted. Otherwise, the uncertainties in technology competition will not make the option to wait valuable because the decision makers can easily switch to other IT solutions after they implement the investment project. As pointed out by Shapiro and Varian (1998), the IT switching costs are very significant in many cases. They use the term "technology lock-in" to describe the situation where management has little flexibility to switch to other technology solutions once they have adopted one IT solution.

Now it should be clear why we use IT switching cost as the second criterion to classify different IT investment opportunities. When the IT switching cost is significant (technology lock-in), the option to wait is valuable. Therefore, real options analysis should concentrate on the managerial flexibility in deferring an IT investment to let more technology uncertainties be resolved. When the switching cost is low, high IT uncertainties cannot be used to justify the wait-and-see policy. On the contrary, we should use real options analysis to quantify the value of the option to switch that usually makes an investment opportunity more appealing to the management.

To summarize our discussion, let us look at the four categories of IT investment opportunities based on the two criteria.

- Category I: Shared investment opportunity with high IT switching cost. For this type of IT investment opportunity, we must consider both the strategic benefit of early preemptive investment and the valuable option to wait. Potential competitive pressure forces investors to be proactive. However, preemptive investment will incur the loss of the valuable option to wait. So for this type of IT investment opportunity, the key in the real options analysis is to consider the strategic growth option and the option to wait at the same time. By balancing the two contradictory effects, we can find the optimal investment point at which the expected investment payoff will be maximized.
- Category II: Shared investment opportunity with low IT switching cost. For this type of IT investment opportunity, early preemptive investment is usually the best strategy. As we discussed before, it is beneficial to invest early to preempt potential competitors. Moreover, IT uncertainties will not make the wait-and-see strategy more appealing because the IT switching cost is low. Therefore, real options models should be used to quantify the values of the growth option and the switching option embedded in the IT investment opportunity.
- Category III: Proprietary investment opportunity with low IT switching cost. It is worth noting that the option to wait is a very valuable component of a proprietary investment opportunity. However, technology uncertainty will not contribute a lot to the value of the option to wait because the IT switching cost is low for investment opportunities in this category. So in the real options analysis we should pay attention to other business uncertainties that may increase the value of the option to wait.
- Category IV: Proprietary investment opportunity with high IT switching cost. Wait-and-see is the dominant strategy for this type of IT investment opportunity. So real options analysis should concentrate on the option to defer an investment. With the presence of technology lock-in, decision makers should be more patient before they commit a proprietary investment.

In the real business world, an IT investment opportunity may dynamically evolve from one category to other ones. So decision makers should be very cautious when they conduct real options analysis. In the next section, we use a real-world case to show the importance of adopting appropriate real options models as the IT investment opportunity evolves.

CONCLUSION

Although some recent studies recognized the potential of real options theory in evaluating strategic IT investment opportunities, we believe that the applicability of various real options models should be scrutinized under different scenarios. Standard real options models assuming symmetric uncertainty in future investment payoffs cannot be directly applied to the shared opportunities because of the competitive erosion. With the presence of potential competitive entry, real options analysis should balance the strategic benefit of preemptive investment and the value of the option to wait. IT switching cost is another important factor we must consider when we conduct real option analysis. As high IT switching cost or technology lock-in is very common in the digital economy, decision-makers should pay more attention to the technology uncertainties before committing early investment to preempt their competitors.

KEY TERMS

Black-Scholes Option Pricing Model: A model that is used to calculate the value of an option by taking into account the stock price, strike price and expiration date, the risk-free return, and the standard deviation of the stock's return.

Deferred Option: Option to defer a project or an investment gives a firm an opportunity to make an investment at a later point in time.

Managerial Investment Flexibility: Flexibility in the timing and the scale of an investment provided by a real investment option.

Net Present Value (NPV): The present value of an investment's future net cash flows minus the initial investment.

Option: The right, but not the obligation, to buy or sell an asset by a pre-specified price on before a specified date.

Real Options Theory: Financial valuation tool that helps in calculating the value of managerial flexibility under uncertainties.

Switching Costs: Switching costs refer to the hidden costs consumers face when switching from one product or technology to another in the marketplace.

Real Time Interface for Fluidized Bed Reactor Simulator

Luis Alfredo Harriss Maranesi
University of Campinas, Brazil

Katia Tannous
University of Campinas, Brazil

INTRODUCTION

Nowadays, the world witnesses a large technological revolution which has brought new information distribution forms, interpretation and storage. With that, computational tools can be used to sustain the education, as with the learning objects case. A learning object is any digital product that could be re-used for knowledge acquisition, with significant economy and reduction of computer time.

Learning objects have led to new solutions, which resulted in good structured and safe programs. Hereby, they rend possible creations of simple units, and the objects, which are associated with each other, can produce large units. Some of them are distinguished among the presence or absence of simulation functions.

The software SEREA has been developed to reach undergraduate and graduate chemical engineering for studies about fluid dynamics of fluidized bed reactors motivating students in order to acquire a successful learning process. Motivating students is certainly a stimulating and challenging problem, and is always present in teaching methodologies (Tannous, 2007). This article will present a comparison between two methodologies for interface creations, to sustain the chemical engineering learning and other correlated fields.

BACKGROUND

Since 2002, the Laboratory of Particle Technology and Multiphase Flow at State University of Campinas have developed new learning objects, mainly simulator modules, to evaluate their limitations as educational software.

Several denominations are found in the literature about the concepts of learning objects such as: instructional object, educational object, knowledge object, intelligent object and data object (Gibbons, Nelson, & Richards, 2000). Nevertheless, it does not matter what denomination has been improved, as the object can be practically the same.

The IEEE Learning Technology Standard Committee (2002) defines learning objects "*as any entity, digital or non-digital, which can be used, re-used, or referenced during technology supported learning.*" Chronological and instructional texts, class activities, books and revision aids are some examples of nondigital learning objects.

However, concerning digital learning objects, the main idea is to break the contents in small pieces that can be re-used in different learning environments, following the "spirits" of oriented-objects programming (Wiley, n.d., Verbert & Duval, 2004). According to Downes (2001), the idea of object-oriented tends toward the development of real pattern that, once defined, are copied and used in a part of the software. In this way, the simulators associated with the object-oriented programming can be classified in this definition.

According to Logmire (2001), for designing and developing material to be reused as learning objects, it should consist of features such as flexibility, easy to update, search and management, customization, interoperability, facilitation of competency-based learning, and increased value of content. All these characteristics show that the learning object models can make an easier and enhanced quality of learning, providing several facility tools for professors, students and administrators.

The simulation is a learning resource that allows the students to observe the different system behaviors through mathematical graphics or symbolical modeling of the phenomenon. In this context, the simulations have an important role to minimize the problems due missing equipment and laboratories for undergraduate students.

Tannous (2005) and Rimoli, Assis, and Tannous (2006) described some of the strategies and methodologies applied to develop learning objects (simulators with or without instructional program). It is important to remark that, in general a few works are applied to chemical engineering.

DEVELOPMENT OF LEARNING OBJECTS

General Information

SEREA (Fluidized bed reactors modules) is simulator software for undergraduate chemical engineering students. It was developed to simulate the fluid dynamics parameters

of different fluidized bed reactors, being divided by behavior of particles and project of distributors. As SEREA expanded, it was split in one real time process named "slipping controls."

The following sections cover two modules for basic parameters that consist of the determination of minimum fluidization velocity and porosity, and bed expansion. The fluidization engineering concepts are based upon Geldart (1986), Kunii and Levenspiel (1991) and Martin (1998), and are also covered in other texts (Tannous, 1993).

Required Hardware

For an educational tool to be effective, it must be readily accessible to students. SEREA has been developed on personal computers sufficiently supplied with the necessary amount of memory and processing of operational systems. The exact hardware chosen was processor Intel Pentium 4 1.6 GHz, 768 MB of RAM memory, CD recorder, Monitor of 15," video board Nvidia Riva TNT 2, mouse and keyboard.

Software and Operating System

Nowadays, several technologies can be used to build the learning objects, including Java applets, flash, Modellus, Javascript and those more powerful and innovative resources as Java and C++ languages. Also, we found the most popular object-oriented programming languages to be Visual basic and Delphi. Each language has their own advantages and disadvantages depending upon the developers requirements. For our case a feasibility analysis was constructed identifying our problem and indicating available resources within the department to assist with our costs/benefits analysis. Justifiably, Borland Delphi 2005 IDE was chosen to develop the SEREA simulator. It has been successfully run in Windows XP.

The integration of this programming language with **graphics** resources causes easier and faster creation of software, with better results. Some of these characteristics are: elements repository, automatic inclusion of declarations of variables and classes upon the insertion of an element using the graphic mode, list of properties that allow modification of the parameters for each object easily and quickly, compilation and execution of codes with automatic syntax and verification of semantic error and integration with the Paradox 7.0 database, that allows for easy interaction between different modules of the software (Rimoli et al., 2006).

Other software employed in the development of SEREA was the open source application package OpenOffice.org which includes text, presentations, diagrams, mathematical equations and spreadsheet editors. The equation editor (OpenOffice.org Math) creates complex mathematical equations with only one line of code and OpenOffice.org Writer elaborates explanation texts for each field in the software.

Methodology Applied

The methodology adopted for creating the software modules followed the software engineering steps (Schaerer & Schauer, 1991; Rimoli et al., 2006): Analysis, Design, Coding, Testing, Production and Maintenance.

Analysis: it is the process of defining the problem. The requests are evaluated, selecting which factors are limited for the development and viability of the software. The factors are: cost, time, in and out data format, and concepts of the problem. If the software is practicable, we have a product of this process and the project specifications will be made for the next step.

Design: it starts with a known basic model to determinate an outline without details of product and a plan for the development of the software, making appropriate choices concerning the graph design, mathematical methods, languages and tools (e.g., IDE). The decision making in this process defines the final characteristics of the software, and can guarantee the success or failure of the whole project. However, it may be necessary after advancing to the next phase to return to this step within the software development cycle, in order to succeed in codification and to solve possible problems identified by the developer.

Implementation and final product: codification, function tests and others structures created, satisfying all requirements demanded in previous steps without execution errors, composes the program process. As a final product, the software is completed once it meets the initial requirements and solves the question in a satisfactory way. The project is then ready to be integrated into the rest of the system. In due course the final product will require continual maintenance.

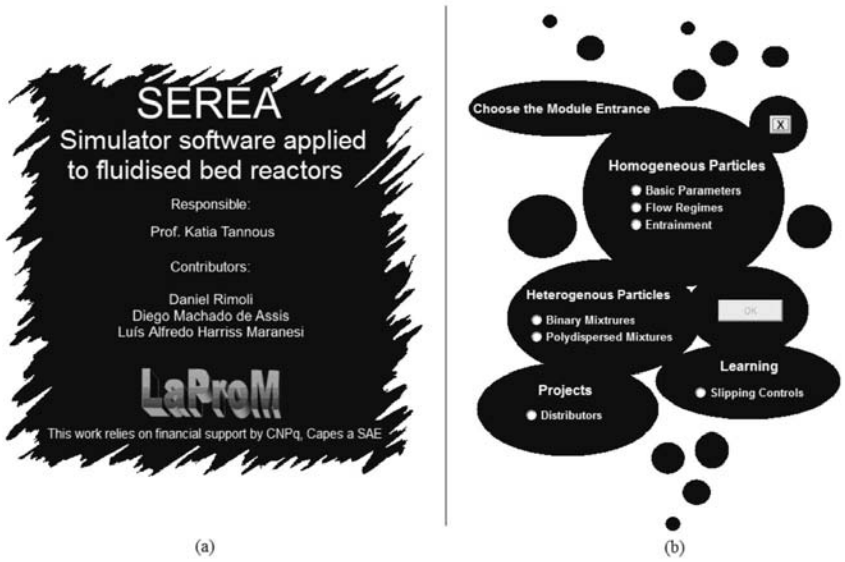
User Interface

Users interface with SEREA using a mouse to activate objects and request information about parameters and identify the equations. Each result can be saved for the next module, keeping all data introduced or only one individual module in different order.

Getting Started

The simulator modules were developed to be objective and intuitive aiding the students to achieve better results in a complex mathematical analysis. The program SEREA is composed of five modules (traditional) with the same structure but with differences in the entrance variables, correlations and results: the module of basic parameters of fluidized beds (minimum fluidization velocity and porosity, bed expansion), the module of fluidisation regimes (transition velocities of different regimes), and entrainment of particles. All of them were applied for the hydrodynamic of homogeneous particles. For heterogeneous particles, until now, we developed

Figure 1. Software simulator: (a) initial screen (b) menu



minor modules considering the mixtures and segregation parameters and basic parameters. Distributors are essential for sustaining the particles on the bed. So, we propose two distributor designs: perforated plate and tuyere.

A special module was developed defined as "real time simulator-slipping controls" to compare with the first module of homogeneous particles and understand how the knowledge can reach the students.

Figure 1 shows the open screen of the software SEREA marking the (a) project collaborators and sponsorships and (b) the simulator module menu. The latter shows modules for fluid dynamics behaviour of fluidized bed reactors: three modules for homogeneous particles, two modules for heterogeneous particles and one module for distributors. All of them present the same structure but with differences in the entrance variables, correlations and results.

Besides that, we have also developed one alternative module, called "learning." In this article, we will compare the latter and the first module, concerning the basic parameters for fluidized bed rectors, to calculate the minimum fluidization velocity and bed expansion.

The comparison is related concerning the purpose of interface using practically the same programming developed for the simulator.

RESULTS AND DISCUSSION

The learning objects developed until now are disposable in the Laboratory of Particle Technology and multiphase Flow and in the intranet of the School of Chemical Engineering at State University of Campinas. For each module concluded, the learning objects are applied in different courses as Operation Units I (practical and theoretical) and Fluidization Technology. In this article, we will present a comparison between two different styles of interfaces to reach the students during the chemical engineering courses.

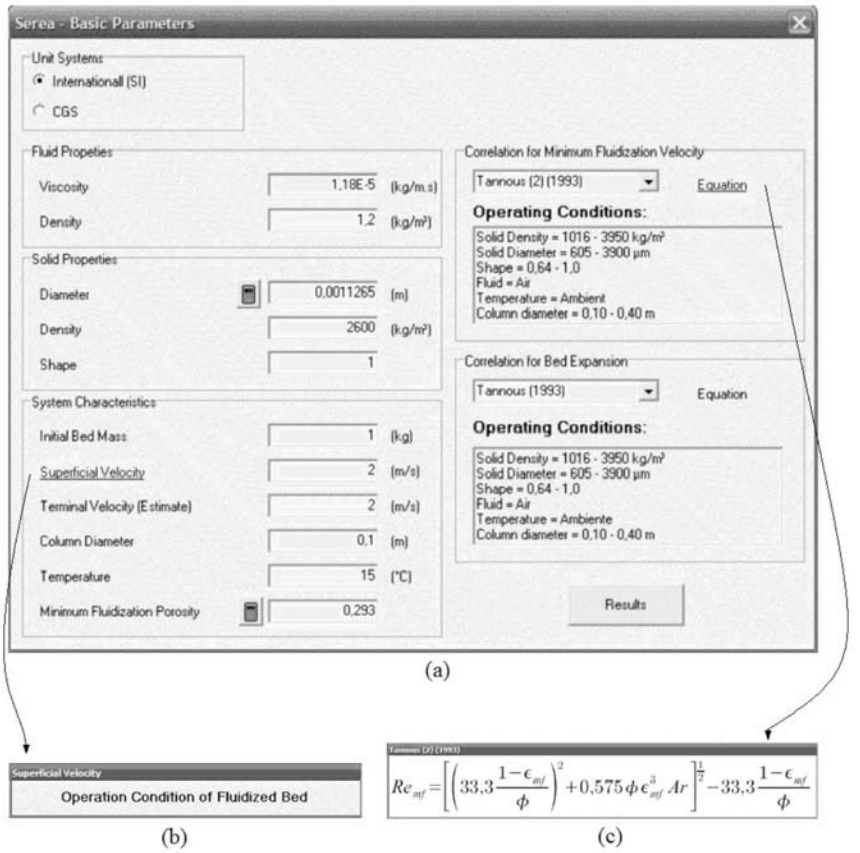
Traditional Module

The first module of the SEREA software (Figure 2a) intends to give users the immediate results of these parameters, allowing to diagnose and to change the variables of process interferences (Assis & Tannous, 2006; Rimoli et al., 2006). For example, in the laboratory experiments, it will allow the user to compare the experimental and theoretical results in the same time and to verify the mistakes during the runs. The users have total control regarding the data and no limitation for applying the models. They are responsible for right or wrong results.

The interface proposed concerning the seven focal areas: four areas in the right side and two in the left side. In the right side, it presents the unit systems (top), fluid and solid properties (middle) and characteristic system (bottom). In the right side, it shows the correlations about minimum fluidization velocity and bed expansion, and at the bottom, the results button.

For each variable present in the screen (Figure 2a), there is a space besides its name where the value can be inserted manually in the International System (IS) or Centimeter-

Figure 2. Screens of basic parameters module of homogeneous particles: (a) simulator interface (b) variable definition (c) minimum reynolds number equation (Tannous, 1993)



gram-second system (CGS) of Units. Passing the mouse under the name of solid and fluid physical properties, and the characteristics of the system, a new window with a small explicative text will appear, as shown in Figure 2b (e.g., superficial velocity).

The variables, mean particle diameter and minimum fluidisation porosity, with a calculator icon besides, can be calculated through an auxiliary window choosing correlations and introducing experimental data (Rimoli et al., 2006).

The minimum fluidisation velocity is obtained from the solid and fluid properties, but in some cases it needs specific variables such as minimum fluidisation porosity and particle sphericity. There is a correlations list in a selection box. Each correlation has an operational range that can be seen in the box below the drop-down menu. By moving the mouse over the word "equation" the formulas can be seen in Figure 2c.

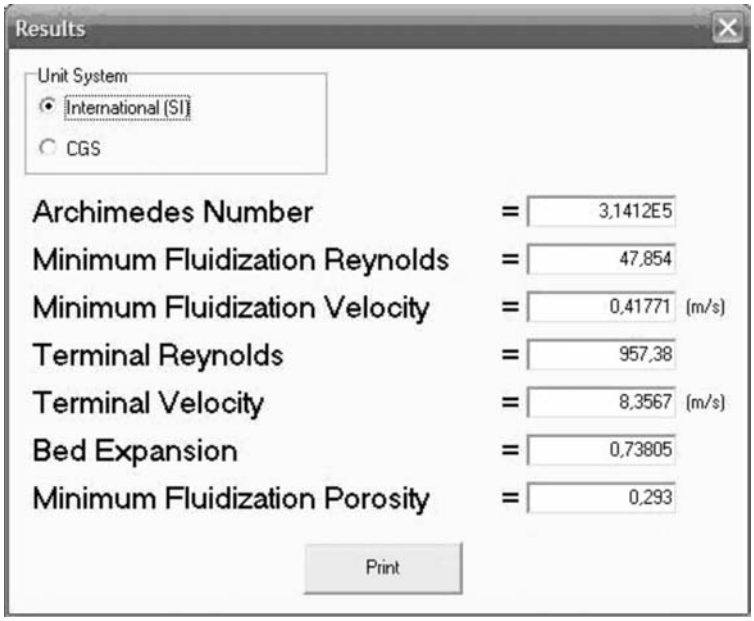
To calculate bed expansion, the user can again choose between several correlations. There is no standard form in these correlations, so one or more extra functions are required in each case to get the results.

If the users choose incompatible system units between the correlations, an error message appears and allows amending of the problem before obtainment of wrong results.

When the button "results" is put into action, the program verifies if the entrance values comply with the restrictions, producing an error message when necessary. Otherwise, the values are copied as internal variables that follow a sequence to calculate the results exhibited on the screen shown in Figure 3: the Archimedes number, the Reynolds number and velocity at minimum fluidisation, the Reynolds number and terminal velocity, bed expansion, and minimum fluidization porosity.

All results are saved in a database to be accessed by other program modules or just finally results. The screen shows a printer button that allows one to print a page containing a table with all the entrance data and graphs produced in the calculation of the mean diameter (Rimoli et al., 2006).

Figure 3. Final results screen of basic parameters



After that, the user is responsible for the interpretation of results.

Real Time – Slipping Controls

The development of a new module, on real time, comparative of traditional software emerged in relation to the difficulties of students in understanding the magnitudes in the elaboration and execution of projects in fluidized beds. The use of the calculator in the engineering courses does not contribute to comprehension of phenomena as well as the knowledge of empirical or semi-empirical models.

In general, the students rarely find additional information about the physical meaning of results leading to excessive mistakes. Then, to solve this problem, we have adopted the use of slipping controls simultaneously with results presentation (Figure 4). The interface proposed looks like a control panel used in chemical industries located in special rooms, controlling the operational conditions of equipments connected in the processes.

The interface was built considering the same structure of focal areas cited in the traditional module. Six focal areas are considered: the correlations about minimum fluidization velocity and bed expansion (top), fluid and solid properties and characteristic system (middle), the results and storage (bottom).

The help functionalities were maintained once the mouse was passed upon the text of the exhibited equations and on the variables (entrance fields).

The main difference between the two modules is the method in which data entry is made into the form and the presentation of the result. The entrance of data is filled by adjustment of slipping controls or introducing the specific place of a variable. We remark that each correlation has it own range conditions.

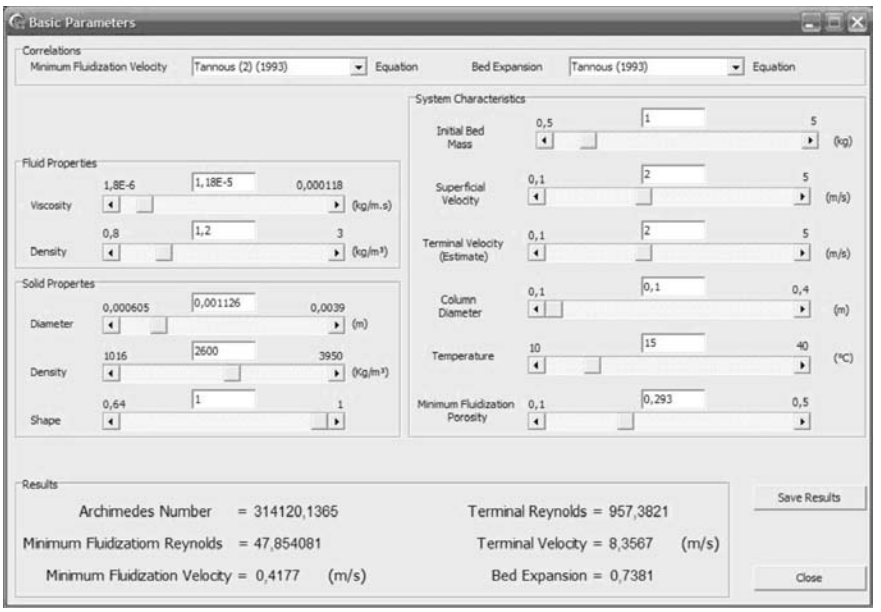
This solution allows the user to examine with details the influence of each data entry upon the final results, obtaining more sensibility about the phenomena inside of reactors.

In the case of disagreement between parameter ranges, for example, the density and the column diameter ranges, a new screen shows the incompatibly of that for users. The methodology applied guarantees that the user will acquire right decisions at the end of simulations.

The option "save results," located in the left bottom of the window (Figure 4), offer the user the possibility of saving the results obtained during the simulations. For each press of a button, the program stores in its memory the values tested and finally a spreadsheet file (MS-Excel) organizes these values, as shown in Figures 5a and 5b. Saving the results make possible to analyze all simulations together and make a correct opinion about the process and data chosen.

In this way, the software can apply in different courses to understand the fluidized bed processes and assist the students for elaboration of general reports.

Figure 4. Module interface of basic parameters on real time



FUTURE TRENDS

For future works, the software should keep the objects created and follow the same characteristics of interfaces known, constructing easily the development of new modules. Moreover, the software has been prepared for effective application of deterministic modeling representatives of solid-fluid systems. The integration between Object Pascal programming language and other languages, for example, C++ language, can create new auxiliary components for simulations.

CONCLUSION

A learning object can be present in different features stimulating students through texts, videos, tutorials, graphs, simulators and educative programs where they are distributed electronically and applied for the learning process. In this way, the information distribution makes it easily accessible, far reaching and economically more feasible for a higher number of people. The objects are found in the literature distinguished by presence or absence of simulation functionalities, and may perhaps be used individually or complementary of conventional learning.

The learning object, SEREA, allows easy simulation of the main parameters of different processes applied to fluidized bed reactors. In general, the software demonstrates that the decisions adopted and the implementation process was appropriate. The whole decision was in agreement with the literature and also provided adequate results applied in chemical engineering courses.

The module "Learning" with sliding controls allows the users to manipulate the data immediately after operation, gaining the sensibility of measurements and results involved in the fluidized bed processes.

ACKNOWLEDGMENT

The authors gratefully acknowledge the contribution of many students who were involved in this project. The authors also wish to thank CAPES and SAE/UNICAMP for their sponsorship.

KEY TERMS

Chemical Engineering: The branch of engineering that deals with the application of physical science (e.g., chemistry and physics), with mathematics, to the process of converting raw materials or chemicals into more useful or valuable forms.

Fluidization: The operation by which the fine and large solids are transformed into a fluid-like state through contact with a gas or liquid.

Fluidized bed reactor: Consists of a particle-laden vessel, with the particle bed kept fluidized by feeding a gas flow through it. It is widely used in the chemical, petrochemical, and pharmaceutical industries, and also for desulphurization of flue gases, calcinations, gasification and combustion of waste/biomass.

Interface: Defines the communication boundary between two entities, such as a piece of software, a hardware device, or a user. The interface between a human and a computer is called a user interface.

Learning Object: Digital product that could be re-used for the knowledge acquisition

Object-Oriented Programming: A programming paradigm that uses "objects" and their interaction to design applications and computer programs.

Object Pascal: An object-oriented derivative of Pascal mostly known as the primary programming language of Borland Delphi.

Database: A structured collection of data that can be used to answer queries and retrieve previously stored data.

Simulator: The mathematical representation of the interaction of real-world objects.

Slipping Controls: Artifacts used in software interface to implement controls that look like real life machine controls.

Really Simple Syndication (RSS)

Kevin Curran
University of Ulster, UK

Sheila McCarthy
University of Ulster, UK

INTRODUCTION

E-mail has been one of the major reasons for the broad acceptance of the Internet, and although e-mail is still a vitally important communication tool, it suffers from an increasing number of problems as a medium for delivering information to the correct audience in a timely manner. The increasing volume of spam and viruses means that e-mail users are forced into adopting new tools, such as spam-blocking and e-mail-filtering software, that attempt to prevent the tirade of unwanted e-mails. Many users are also becoming increasingly reticent to divulge their e-mail address for fear of an impending spam influx. Further to this, recent studies suggest that up to 38% of bona fide e-mail messages are being erroneously blocked by filtering software. In reality, this means that more than a third of e-mails, newsletters, special offers, and event announcements are not reaching their intended audience (Patch & McKinlay-Key, 2004). Therefore, the combination of e-mail issues, such as the increasing difficulties associated with multimedia downloads, such as delays, compression, and data integrity maintenance, could be seen as creating a demand for an alternate, effective, and secure communication methodology. One such alternative technology is Really Simple Syndication (RSS), previously known as Rich Site Summary. RSS allows some elements of Web sites, such as headlines, to be transmitted in unembellished form. When devoid of all elaborate graphics and layouts, such minimalist headlines are quite easily incorporated into other Web sites. In other words, third-party Web sites can insert this content on their site through embedded RSS news readers and thus, provide active news feeds quite easily to their clientele. RSS, termed a lightweight content syndication technology, offers many advantages over streaming and e-mail, and for the consumer, no more difficult to access as the RSS readers are akin to e-mail clients (Byrne, 2003). There is no question that the media is keen to adopt a new communications option, and RSS most certainly can comply.

RSS solves a myriad of problems Web masters commonly face, such as increasing traffic, and gathering and distributing news (BBC, 2008). RSS can also be the basis for additional content distribution services (Kerner, 2004). The real benefit of RSS, apart from the added benefit of receiving news feeds from multiple sites, simultaneously, in the viewer, is that all the news feeds (i.e., news items) are chosen by the user. With thousands of sites now RSS-enabled and more on the way, RSS has become perhaps one of the most visible Xtensible Mark-up Language (XML) success stories to date. RSS formats are specified using XML, a generic specification for the creation of data formats. Although RSS formats have evolved since March 1999, the RSS icon ("") first gained widespread use in 2005/2006. RSS democratizes news distribution by making everyone a potential news provider. It leverages the Web's most valuable asset, content, and makes displaying high-quality relevant news on a site relatively easy (King, 2004). It must be recognized, however, that RSS cannot entirely replace the primary function of e-mail, which is to provide person-to-person asynchronous communications, but it does compliment it in some interesting ways.

BACKGROUND

RSS can be found as an acronym for, *Rich Site Summary*, *Resource Description Framework (RDF) Site Summary,* or indeed *Really Simple Syndication*, the latter is used here (Oasis-open, 2004). The RSS format was created to facilitate "channels" on Netscape Netcenter (Netscape, 2005), and was made available to the general public in March of 1999. Channels were a "pull" type mechanism where users requested certain information from various channels. The original RSS, version 9.0, was created by Netscape as a method of building portals to major news sites for news headlines. Portals are Web sites dedicated to specific topics. It was, however, soon replaced by the 0.91 version that stripped out many of the less important features, as Netscape believed 0.90 proved simply too intricate for this undemanding task. The newly established 0.91 itself was promptly dropped by Netscape as their interest in the portal-making business declined. The now obsolete 0.91 was swiftly adopted by the competition, UserLand Software, and employed as the foundation for all its Web-based concepts. Shortly after this, RSS version 1.0, a new version based on Resource Description Framework (RDF), was developed by a third-party spin-off, a group of designers who built their version modeled closely on the concepts and framework of the initial, original 9.0 (prior to its

simplification into version 0.91). The Resource Description Framework (RDF) integrates a variety of applications from library catalogs and worldwide directories to syndication and aggregation of news, software, and content to personal collections of music, photos, and events, using XML as an interchange syntax. The RDF specifications provide a lightweight ontology system to support the exchange of knowledge on the Web (Nilsson, 2001; Van der Vlist, 2001). As a result of this, Userland, indignant at being omitted from the latest increment, ignored version 1.0 and continued to advance their own brand of RSS, developing versions 0.92, 0.93, 0.94 through to their current 2.0. In reality, this means there are seven different formats to contend with. A feed aggregator, also known as a feed reader, news reader, or simply as an aggregator, is client software or a Web application that aggregates syndicated Web content, such as news headlines, blogs, podcasts, and vlogs in a single location for easy viewing (Wikipedia, 2008). Aggregators must be flexible and comprehensive, and must be able to recognise and deal with all versions. RSS version 2.0 is currently offered by the Berkman Centre for Internet and Society, at Harvard Law School.

REALLY SIMPLE SYNDICATION (RSS)

RSS has rapidly developed into a prevalent means of sharing content between Web sites. Many sites already use RSS, and as word spreads, new sites incorporate this feature into their sites daily. RSS looks set to become a dominant force. Numerous news sites, including BBC, Yahoo! and Wired, currently use RSS to provide their subscribers with the latest headlines. Indeed the Web sites of many mainstream "giants" also incorporate RSS in a bid to keep their subscribers notified of announcements, events, and advertisements. As yet, only sites that currently offer news in RSS format may be read using a news aggregator. To ascertain if a site utilizes RSS is generally simple. Sites make no secret of the fact and proudly display RSS feed pictograms, such as ("  ") throughout their pages, indicating which sections are available in RSS format. Right clicking on such an icon, copying the shortcut (URL), and adding it to an aggregator, creates a feed. This establishes a subscription to that particular Web site for the desired information. Channels to numerous sites can be created, maintained, and removed, if desired, using most aggregators with minimal effort.

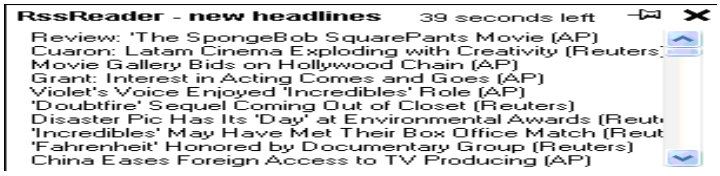
An RSS text file contains both static and dynamic information. At a high level, an RSS document is an rss element, with an obligatory attribute called version, this attribute specifies the version of RSS that the document conforms to. Here an element is a piece of data within a document that may contain either text or other subelements describing the RSS data. Succeeding the rss element is a single channel element that contains information about the channel (metadata) and its contents. Metadata is commonly defined as "data about data" or data describing context, content, and structure of records and their management through time. A channel may, in turn, contain any number of items. Items are subelements that are enclosed in matching XML start and end tags, and appear as subelements of channel, listed before the closing/channel tag. Each item is identified with an opening item tag, and concluded with a closing/item tag. All child elements of an item are optional, however, at least one element must be present, either title or description. An item may be a snippet of information that represents a larger article, much in the same way as a headline represents a newspaper article. If this is the case, the item's description is a synopsis of the story, and the link points to the full story. An item may also be complete in itself; if so, the description contains the full text, and the link and title may be omitted. In this way, an RSS channel can contain many items that, in turn, may incorporate many differing subelements. When design and coding is complete, the validated RSS file can be registered with various aggregators, allowing the feed to be "sucked up" by discerning subscribers. Any amendments or updates made to the RSS file will automatically be relayed to all subscribing clients.

RSS Enclosures

RSS version 2.0 encompasses a powerful feature; it allows an item to have an enclosure. This can, in simplistic terms, be likened to an e-mail having an attachment. In reality, enclosures hold huge potential, and represent another step in the evolution of content syndication (Kerner, 2004). By incorporating an enclosure subelement into an item, any RSS element can then describe a video or audio file. The enclosure feature has three attributes, the first, "url," says where the multimedia file is located, the second "length" determines the size of the file in bytes, and the last "type" describes the Multipurpose Internet Mail Extension (MIME) type of the multimedia file. In this way, an aggregator can determine the payload attributes prior to any communication, and can then apply the appropriate scheduling and filtering rules.

Primarily, the most attractive feature of RSS is that it enables information from numerous Web sites to be viewed simultaneously, all on one page; consequently, numerous sites can be scrutinized in seconds rather than having to be tediously downloaded independently. A free newsreader is *RssReader*. Like other aggregators, the RssReader aggregator can sustain numerous channels, scouring each of the user's designated Web sites for updated feeds at regular intervals. When RssReader gathers updated headlines from the various sites, it displays an amalgamation of such in a list box positioned in the bottom right of the user's desktop (see Figure 1; which displays headlines from Yahoo's entertainment news feed).

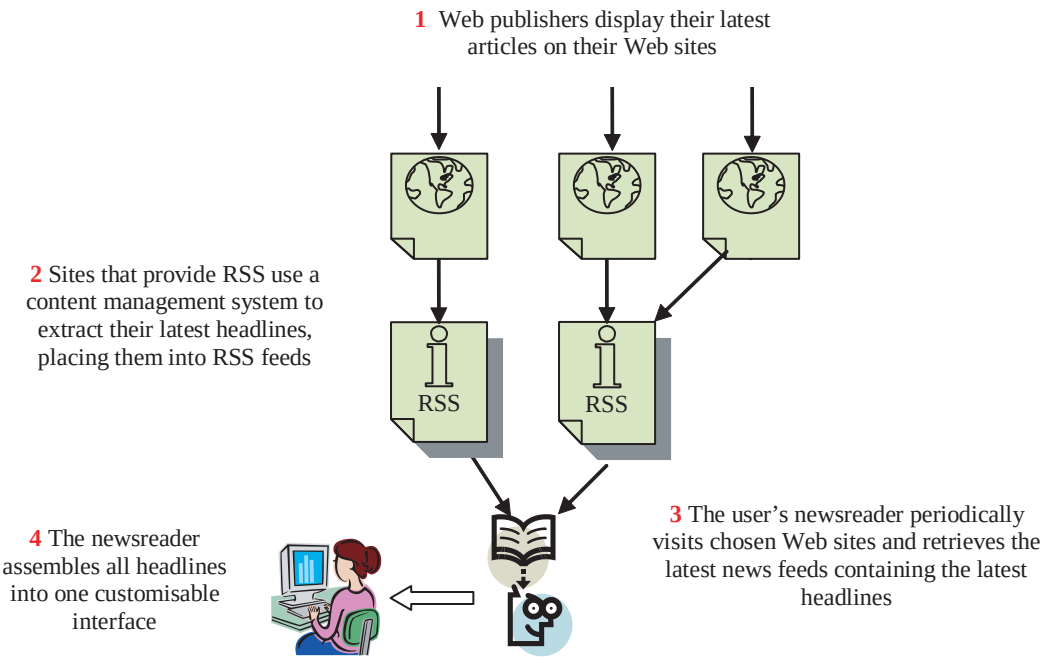
Figure 1. RssReader's "headline alert" screen



If a user wishes to select a headline from the list, aggregators will provides features to open and provide a synopsis of each news article, if the user wishes to read further on any given topic a link is provided to the specific article on each of the initiating Web sites. This way, Web publishers are able to channel tremendous traffic towards their sites. No longer having to wait for passing traffic, RSS bestows a means of advertising ware on a much wider stage indeed. This way, by employing a news aggregator, a client can subscribe to any sites of their choosing that provide RSS feeds. The Web sites that do not offer this facility may be disadvantaged, and must wait for the client to visit their page directly, if at all, see Figure 2.

Perhaps the most compelling feature of RSS feeds is the ability to keep track of changes on the Web. It is not difficult to ascertain what Web sites are available today, what is difficult is to ascertain when such sites make crucial changes. RSS feeds provide us with the necessary aptitude to overcome such problems.

Figure 2. How RSS feeds work



Podcasting

Podcasting is a term derived from Apple's portable MP3 player,that is, the iPod. Podcasting is the preparation and distribution of predominately audio for download to digital music players, such as the iPod player. A podcast is created from a digital audio file that must be saved in an MP3 format and then uploaded to the Web site of a service provider. The MP3 file then receives its own URL, which is inserted into an RSS XML document as an enclosure within an XML item tag. Once a podcast has been created, it is usually registered with content aggregators, such as podcasting.net or ipodder.org, for inclusion in podcast directories. Interested parties can then browse through these categories, or subscribe to specific podcast RSS feeds that will, in turn, download to their audio players automatically when they next connect. Although podcasts are generally audio files created for digital music players, the same technology can be used to prepare and transmit images, text, and video to any capable device, this is the approach taken for this project. Podcasting could be described as the first application based on RSS enclosures to capture the imagination of users and developers. Podcasting allows users to listen to selected podcasts whenever they like, similar to the way time shifting allows viewers to watch television programs when it suits them. The cultural milieu supporting podcasting is sometimes referred to as the podosphere, just as the cultural environment surrounding the blog is called the blogosphere. Anyone using RSS to distribute information can potentially make use of enclosures, for example, a company currently distributing a newsletter using an RSS feed could upgrade this completely with the inclusion of a promotional video clip as an enclosure in the feed.

COMMERCIAL RSS SYSTEMS

There are an increasing number of Web sites that offer RSS format producing software. Two of the more popular are Nooked and Radio Userland.

Nooked (Nooked, 2008) is an online service that enables users to create, publish, and maintain their own RSS channels, with the minimal amount of effort and at low costs. Nooked makes RSS potentially available to users of all abilities by shielding the technical intricacies of how RSS is configured. They have a FeedWizard on their site that is Web based. It allows a feed to be created quite quickly and support podcasting and flashcasting similar to the system described here.

Radio UserLand is one of the most popular Web logging tools. Radio supports the publication of Web logs that can optionally include enclosures, and also allow customers use of its own built-in news aggregator. Users can subscribe via this aggregator to feeds, allowing Radio users to achieve more than is possible with similar services that offer only Web log hosting. Radio comprises features such as the "category" feature that supports blogging on varied topics, and an "author Web log tool" that permits multiple authors to contribute to a community Web log.

FUTURE TRENDS

It should not be forgotten that one of the main objectives of all RSS modules is to extend the basic XML schema that was established for more robust content syndication allowing for wider–ranging, yet standardized, transactions without modifying the core RSS specification. This can be achieved with an XML namespace that give names to concepts and relationships between those concepts. We can expect to see an increasing number of RSS 2.0 modules with established namespaces appearing in the near future, such as Media RSS Module - RSS 2.0 Module (MRSS, 2007).

Really Simple Syndication is central to some of the leading companies such as Google, Yahoo, and Microsoft (Rubel, 2006). Yahoo has stated in the past that almost 3 out of 10 Internet users consume RSS-syndicated content on personalized start pages without knowing that RSS is the enabling technology (Hrastnik, 2005). We expect that feed reading will become even easier than it is now, and should be incorporated into all kinds of connected devices especially mobile phones and home media units.

We can expect to see it become more embedded into bit-torrent-based peer-to-peer applications where even now, feeds (also known as *Torrent/RSS-es* or *Torrentcasts*) allow client applications to download files automatically from the moment the RSS reader detects them. The term for this currently is Broadcatching.

News site, such as the Guardian (http://www.guardian.co.uk), will continue to increasingly provide RSS feeds for a selection of news services and sites, automatically updating as stories are added across the network, flagging up what's new as it breaks (Guardian, 2008) .

We also expect to see diverse uses of RSS, such as the encoding of location in RSS, as performed by georss.org. Here, location is described in an interoperable manner so that applications can **request, aggregate, share,** and **map** geographically tagged feeds. This site was created to promote a relatively small number of encodings that meet the needs of a wide range of communities in the hope that building these encodings on a common information model would result in an "upwards-compatibility" across encodings.

CONCLUSIONS

E-mail suffers from an increasing number of problems as a medium for delivering information to the correct audience in a timely manner due to the volume of spam and viruses arriving in our in-boxes on an hourly basis. RSS is a way of receiving constantly updated links to selected Web sites. Once a connection is setup to a Web site, then a list of all the stories currently shown on a certain page or section of that site can be retrieved. There are several ways of receiving RSS feeds, but a common method is to download a program called a "News Reader," which can then be setup to receive RSS information from Web sites offering it, and browse headlines and story summaries that link through to the full story on the Web site. Alternatively, newer Web browsers offer similar functionality already built-in that will detect whether the Web site one is currently browsing offers an RSS feed, and will then let you create a constantly-updated list of links in the "bookmarks" menu. Perhaps the most compelling feature of RSS feeds is the ability to keep track of changes on the Web, as it can be difficult to ascertain when sites make crucial changes. RSS feeds, however, provide us with the necessary aptitude to overcome such problems.

KEY TERMS

E-Mail: The term electronic mail shortened itself to E-mail, e-mail, and now email as it became an everyday process. E-mail is a cheap, fast text message delivered electronically over the Internet, or indeed local area networks.

Podcasting: The preparation and distribution of predominately audio for download to digital music players, such as the iPod player. A podcast is easily created from a digital audio file that must be saved in an MP3 format and then uploaded to the Web site of a service provider. The MP3 file then receives its own URL, which is inserted into an RSS XML document as an enclosure within an XML item tag. Once a podcast has been created, it is usually registered with content aggregators, such as podcasting.net or ipodder.org, for inclusion in podcast directories. Interested parties can then browse through these categories, or subscribe to specific podcast RSS feeds that will, in turn, download to their audio players automatically when they next connect

Resource Description Framework (RDF): RDF integrates a variety of applications from library catalogs and worldwide directories to syndication and aggregation of news, software, and content to personal collections of music, photos, and events using XML as an interchange syntax. The RDF specifications provide a lightweight ontology system to support the exchange of knowledge on the Web**.**

RSS: An acronym for, *Really Simple Syndication*. Also known in parts by the terms *Resource Description Framework (RDF) Site Summary,* or *Rich Site Summary*. RSS has rapidly developed into a prevalent means of sharing content between Web sites.

RSS Enclosures: RSS version 2.0 encompasses a powerful feature; it allows an <item> to have an enclosure, this can, in simplistic terms, be likened to an e-mail having an attachment. In reality, enclosures hold huge potential and represent another step in the evolution of content syndication. By incorporating an <enclosure> subelement into an <item>, any RSS element can then describe a video or audio file.

RSS Readers: RSS aggregators can scour designated Web sites for updated feeds at regular intervals. An aggregator can gather updated headlines from the various sites and display them in a variety of ways for users.

Real–Time Thinking in the Digital Era

Yoram Eshet-Alkalai
The Open University of Israel, Israel

INTRODUCTION

In 2004, Eshet-Alkalai published a 5-skill holistic conceptual model for digital literacy, arguing that it covers most of the cognitive skills that users and scholars employ in digital environments, and therefore providing scholars, researchers, and designers with a powerful framework and design guidelines. This model was later reinforced by task-based empirical research (Eshet-Alkalai & Amichai-Hamburger, 2004). Until today, it is considered one of the most complete and coherent models for digital literacy (Akers, 2005); it is used as the conceptual design infrastructure in a variety of educational multimedia companies and was also described in the *Encyclopedia of Distance Learning* (Eshet-Alkalai, 2005). The conceptual model of Eshet-Alkalai consists of the following five digital literacy thinking skills:

1. **Photo-Visual Digital Thinking Skill:** Modern graphic-based digital environments require scholars to employ cognitive skills of "using vision to think" in order to create photo-visual communication with the environment. This unique form of digital thinking skill helps users to intuitively "read" and understand instructions and messages that are presented in a visual-graphical form, as in user interfaces and in children's computer games.
2. **Reproduction Digital Thinking Skill:** Modern digital technologies provide users with opportunities to create visual art and written works by reproducing and manipulating texts, visuals, and audio pieces. This requires the utilization of a digital reproduction thinking skill, defined as the ability to create new meanings or new interpretations by combining preexisting, independent shreds of digital information as text, graphic, and sound.
3. **Branching Digital Thinking Skill:** In hypermedia environments, users navigate in a branching, nonlinear way through knowledge domains. This form of navigation confronts them with problems that involve the need to construct knowledge from independent shreds of information that were accessed in a nonorderly and nonlinear way. The terms *branching* or *hypermedia thinking* are used to describe the cognitive skills that users of such digital environments employ.
4. **Information Digital Thinking Skill:** Today, with the exponential growth in available information, consumers' ability to assess information by sorting out subjective, biased, or even false information has become a key issue in training people to become smart information consumers. The ability of information consumers to make educated assessments requires the utilization of a special kind of digital thinking skill, termed *information skill*.
5. **Socio-Emotional Digital Thinking Skill:** The expansion of digital communication in recent years has opened new dimensions and opportunities for collaborative learning through environments such as knowledge communities, discussion groups, and chat rooms. In these environments, users face challenges that require them to employ sociological and emotional skills in order to *survive* the hurdles that await them in the mass communication of cyberspace. Such challenges include not only the ability to share formal knowledge, but also to share emotions in digital communication, to identify pretentious people in chat rooms, and to avoid Internet traps such as hoaxes and malicious Internet viruses. These require users to acquire a relatively new kind of digital thinking skill, termed *socio-emotional*, because it primarily involves sociological and emotional aspects of working in cyberspace.

The publication of Eshet-Alkalai's (2004) model of digital thinking skills has led to an extensive debate within the community of instructional technology designers, researchers, and educators, as to its validity and completeness, and a special panel in *ED MEDIA2005 Conference* (Montreal) was dedicated to it. This discussion (Aviram & Eshet-Alkalai, 2006) confirmed the validity and value of the model, but indicated that it lacked a sixth thinking skill: the *real-time thinking skill*, which relates to the ability of users to perform effectively in advanced digital environments, mainly high-tech machines, multimedia games, and multimedia training environments that require the user to process simultaneously large volumes of stimuli which appear in real time and at high speed. In the present article, real-time thinking is introduced as the sixth digital thinking skill, which completes the conceptual model of digital thinking skills.

BACKGROUND

The rapid development in digital technologies in recent decades confronts users with situations that require them to master a variety of technical, sociological, and cognitive skills, collectively termed *digital literacy* (Hargittai, 2002; Lanham, 1995), that are necessary to perform effectively in digital environments. Digital literacy is more than just the technical ability to operate digital devices properly; it comprises a variety of cognitive skills that are utilized in executing tasks in digital environments, such as surfing the Web, deciphering user interfaces, and chatting in chat rooms. Digital literacy has become a "survival skill" in the technological era—a key that helps users to work intuitively and effectively in executing complex digital tasks (Lazar, Bessiere, Ceaparu, Robinson, & Shneiderman, 2003).

In recent years, extensive efforts have been made to establish models that describe the cognitive skills that users employ in digital environments (e.g., Hargittai, 2002; Wegerif, 2004; Zins, 2000). Unfortunately, these efforts are usually local, focusing on a selected and limited variety of skills, mainly information-seeking skills (Zins, 2000) and, therefore, they do not cover the full scope of digital literacy. The present article presents real-time thinking, as an additional, sixth skill, in Eshet-Alkalai's (2004) holistic conceptual model of thinking skills in the digital era.

WORKING IN REAL-TIME ENVIRONMENTS

Imagine a pilot flying a jet, a driver driving a car, or a child playing a video game. In all these situations the users are exposed to a large flux of stimuli that *bombard* their cognition in real time, at very high speed, and in random temporal and spatial distribution. In all these situations the key to the users' successful performance is their ability to manage and synchronize these stimuli effectively. When operating such environments, users need to split their attention, reacting to various kinds of stimuli that appear simultaneously in different places on the monitor; they have to be able to execute different tasks simultaneously (multitasking); they need to be able to rapidly change their angle of view and perspective of the environment; and they have to respond to feedback that appears in real time. And above all—they have to quickly and effectively synchronize the chaotic multimedia stimuli into one coherent body of knowledge.

Today, situations that require real-time and high-speed processing of simultaneous large fluxes of information have become common in our lives, mainly in operating multimedia computer programs and advanced machines. This requires that users of today's digital environments master a special kind of thinking skill, here termed *real-time thinking*. Of course, real-time thinking is not new; it has been utilized ever since humans began to think and to synchronize information simultaneously in order to create knowledge. But in the digital era, with the central role of fast computers, multimedia environments, and devices that can process and present information in real time and at high speed, real-time thinking has become a critical skill. Real-time thinking situations usually require the utilization of split-attention skills in order to manage simultaneously large volumes of stimuli (text, sound, and images) that appear in real time and at a very high speed.

Today, most studies of real-time situations are conducted by researchers in the field of operations research, who explore human performance in aircrafts (Hamblin, Naidu, & Miller, 2006; Roessingh, 2005), cars (Casimir & Gilchrist, 2002) and other real-time working environments. Very little research has been done on the "soft" pedagogic aspects of real-time learning, such as digital games and language acquisition in real-time environments (Eshet-Alkalai, & Chajut, 2006; Pemberton, Fallahkhair, & Masthoff, 2004).

DIMENSIONS OF REAL-TIME THINKING

Simultaneous Synchronization

According to the *dual channel model* (Mayer, 2001), in multimedia environments, real-time stimuli are processed in parallel, independent channels (auditory-verbal and visual-pictorial), and the users' ability to synchronize them effectively is a major factor in their performance (Gopher, Weil, & Bareket, 2004). This model is useful for describing information processing in most multimedia environments such as microworld simulations (e.g., flight or driving simulations, in which the users operate a simulated aircraft or car). In the operation of these simulations, the users employ real-time thinking as they process large volumes of digital information simultaneously. Studies show that practicing real-time thinking in such real-time simulations is useful for improving synchronization ability, and therefore performance, of pilots (Gopher et al., 2004) and drivers (Barkan, Zohar, & Erev, 2003). However, information processing is not limited to these two channels only; in real-life situations, people utilize additional channels for processing real-time information, such as emotions and tactile information, which makes real-time thinking much more complex. Leuchter and Urbas (2002) showed that effective real-time thinkers are capable of synchronizing many channels of information processing simultaneously. One of the common applications of real-time synchronization is the case of language acquisition from subtitled films and from *living books*—computer-based storytelling multimedia programs (http://www.livingbooks.com). In living books, children simultaneously hear a story and watch its text on the monitor. Studies have shown that

children acquired a foreign language by synchronizing subtitles with narration in both living books (Eshet-Alkalai & Chajut, 2006) and interactive television (Pemberton et al., 2004).

High Speed

In addition to the simultaneous synchronization of information, modern, real-time digital environments are characterized by the fact that information passes through the information processing channels at very high speed. In car racing, fighting video games, or in flight simulations, users are *bombarded* with a large variety of high-speed moving stimuli (e.g., enemies, snipers, and road obstacles) as they move quickly from place to place and from scene to scene in the game environment. This requires that users not only master simultaneous synchronization skills, but also be able to respond quickly to obstacles. The response rate aspect of real-time thinking was investigated in a variety of real-time situations such as games (e.g., Erev, Luria, & Erev, 2006), simulations that require real-time thinking (Seagull, Wickens, & Loeb, 2001) and real-time situations drawn from daily life such as car driving (Barkan et al., 2003). These studies showed that the best performers were those who were able to process information quickly, indicating the crucial role of high-speed information processing in real-time situations. Roessingh (2005) found that flight simulators were useful in increasing the response rate of pilots and their ability to manage fast-moving stimuli. Eshet-Alkalai, and Chajut (2005) investigated the performance of gamers in shooting and car racing, real-time game environments, in which the users' success depends on their ability to respond in real time to fast-moving obstacles and stimuli. They found that the younger participants were the best real-time performers in their response rate and their ability to retain a high level of performance over a long period.

Attention Management and Multi-Tasking

In most real-time environments, users are required to be able to split their attention and respond simultaneously to stimuli that appear in different areas on the screen, and at the same time to conduct multitasking, physical activities such as operating the keyboard and the mouse simultaneously. For example, in *FIFA*—a real-time soccer-playing environment (http://fifa06.ea.com/) multiple events take place simultaneously on the screen: One player leads the ball, another runs after him, and on the other end of the yard, the gatekeeper is away from the gate. In such an environment, gamers must be able to split their attention among independent events in order to analyze the situation and adopt the most appropriate playing strategy. Gopher (1982) and Gopher et al. (2004) studied attention management and multitasking problems that relate to the management of real-time environments such as flight and basketball training simulations. Participants were tested on their ability to simultaneously split attention and relate to different types of stimuli such as sound, pictures, and text. Split attention and multitasking management—the ability of users to turn their attention simultaneously to different stimuli and to conduct different simultaneous tasks, was found to be the most significant factor in determining the level of performance and real-time thinking, and the best predictor of success in a flight course (Gopher, 1982). The combination of constant attention shifting and multitasking in real-time environments requires that real-time thinkers have a high degree of cognitive flexibility that helps them in shifting perspectives effectively. Erev and Gopher (1999) summarized the major aspects of selective attention strategies and showed that the ability to perform effectively in real-time environments is closely related to a high level of the user's selective attention management.

Multiple Perspectives

Many real-time environments, especially multimedia games and simulations, provide users with the ability to shift their perspectives, angles of view, and degree of resolution, as they work. For example, in FIFA, the user can shift constantly between different views: the single-player view; the gatekeeper view, and the entire system view; in Flight Simulator, the user can shift between the interior in-plane view and exterior view. The flexible shifting of perspectives in real-time environments may improve users' performance (Erev & Gopher, 1999) but it also requires them to be able to synthesize these multiple perspectives, accessed in real time, into a coherent decision or body of knowledge. For example, in Flight Simulator, the multiple perspectives that the users gain help them to select the flight route and make appropriate combat decisions. These situations require the utilization of a high level of real-time thinking. Roessingh (2005) found that pilots' ability to employ multiple perspectives in real-time flight simulations is closely related to their ability to successfully create mental models of the flight route and the interior of the plane.

Real-Time Feedback

Just-on-time feedback is an integral part of most real-time environments. These environments provide users with constant feedback that helps to improve their performance. For example, in typist training programs (e.g., http://www.21stsoftware.com/SS_Typing.htm), in car racing, multimedia simulations, or sport games, the system provides vocal and visual feedback on users' mistakes and achievements. This enables gradual improvement in performance through a process of successive approximation. Such a pro-

cess requires that users be able to manage a steady flow of real-time feedback of a different nature, in order to perform effectively. The positive impact of real-time feedback on the performance of users was illustrated in recent years by various empirical studies (e.g. Barron & Erev, 2004; Erev et al., 2006).

FUTURE TRENDS

Real-time digital thinking is a skill that evolves side by side with present-day technological developments. In the future, with the rapid evolution of technologies, mainly multimedia and game technologies, we will face increasingly more complex real-time environments, in which more stimuli occur much faster and users are required to manage more multiple-perspective and multitasking situations. This will open new frontiers for users, but at the same time, confront them with an ever-growing assortment of problems and challenges that must be addressed in order to perform effectively.

CONCLUSION

Real-time digital thinking is a cognitive skill that helps users of present-day digital environments to work effectively and to create knowledge from large volumes of information that are introduced simultaneously and at high speed. It is a pivotal skill for users of many present-day digital environments such as multimedia environments, digital games, and advanced machines (e.g., aircraft and cars). Studies from the field of operations research show that a high level of real-time digital thinking is critical for successfully operating real-time environments.

In the present article, real-time thinking is presented as a sixth digital thinking skill that completes Eshet-Alkalai's (2004) holistic conceptual mode of digital thinking skills, in which an attempt was made to represent digital literacy and human thinking skills in the digital era with five digital thinking skills.

Effective real-time thinkers are able to successfully process simultaneous stimuli in real time, manage stimuli that appear at very high speed, split their attention effectively, conduct multitasking jobs, simultaneously manage the multi-perspective representations of the environment, and utilize effectively the just-on-time feedback provided by the system.

KEY TERMS

Channel Model: A model which suggests that in multimedia environments information is processed in parallel independent channels: verbal and visual-pictorial.

Digital Era: A term used to describe today's era, in which digital technologies are used in almost every aspect of life.

Digital Literacy: A term used to describe the ability of users to perform in digital environments.

Digital Thinking Skills: A refinement of the term *digital literacy*, describing the variety of thinking skills that comprise digital literacy.

Real-Time Digital Thinking: A term used to describe the thinking skill that is employed in many of today's digital environments. In such environments, the user needs to manage large volumes of information, perspectives, and tasks that are introduced in real time and very high speed.

Real-Time Digital Environment: A term used to describe digital environments in which users need to manage in real-time simultaneous stimuli, multiple perspectives, and multitasking.

Synchronous Stimuli: Stimuli that are emitted simultaneously by the environments. For example, simultaneous sound, text, and images to which users of digital environments are exposed.

Recent Progress in Image and Video Segmentation for CBVIR

Yu-Jin Zhang
Tsinghua University, Beijing, China

INTRODUCTION

A simple search from EI Compendex by using the term "image segmentation" only in title field could produce around 5000 records (Zhang, 2006). However, as no general theory for image segmentation for different application domains, particular algorithms have been developed. The domain of Content-Based Image Retrieval (CBIR) is such a typical example, where many specific techniques have been proposed. An introduction focused on research works before 2004 can be found in Zhang (2005). This paper is an up-to-date and extended version from CBIR to CBVIR (Content-Based Visual Information Retrieval) by including CBVR (Content-Based Video Retrieval), which focused on the progress in last 3 years, and especially on video segmentation.

BACKGROUND

A Formal Definition of Image Segmentation

Image segmentation is the first step and also one of the most critical tasks of image analysis. It is often described as the process that subdivides an image into its constituent parts and extracts those parts of interest (objects).

A formal definition of image segmentation, supposing the whole image is represented by $f(x, y)$, and $f_i(x, y)$, $i = 1, 2, \ldots, n$ are disjoint non-empty regions of $f(x, y)$, consists of the following conditions (Fu, 1981):

1. $\bigcup_{i=1}^{n} f_i(x, y) = f(x, y)$;
2. For all i and j, $i \neq j$, there exits $f_i(x, y) \cap f_j(x, y) = \varnothing$;
3. For $i = 1, 2, \ldots, n$, it must have $P[f_i(x, y)] = TRUE$;
4. For all $i \neq j$, there exits $P[f_i(x, y) \cup f_j(x, y)] = FALSE$; where $P[f_i(x, y)]$ is a uniformity predicate for all elements in $f_i(x, y)$ and $\varnothing$ represents an empty set. Considering the real situation in practice, the following condition can be added:
5. For all $i = 1, 2, \ldots, n$, $f_i(x, y)$ is a connected component.

In the above conditions, condition (1) points out that the summation of segmented regions could include all pixels in an image; condition (2) points out that different segmented regions could not overlap each other; condition (3) points out that the pixels in the same segmented regions should have some similar properties; condition (4) points out that the pixel belonging to different segmented regions should have some different properties; and, finally, condition (5) points out that the pixels in the same segmented region are connected.

Definition Extension to Video Segmentation

If a 2-D still gray level image is represented by $f(x, y)$, then its extension to 3-D moving images or sequences of images (video) can be represented by $f(x, y) \Rightarrow f(x, y, t)$. In video domain, two kinds of segmentation can be distinguished: *spatial segmentation* and *temporal segmentation*. In *spatial segmentation*, each frame of $f(x, y, t)$ can be denoted as $f_t(x, y)$, which is a 2-D still image and the above formal definition for image segmentation can still be used.

The *temporal segmentation* of video can be defined as follows. Given a video sequence $f(x, y, t) = \{f_1(x, y), f_2(x, y), \ldots, f_i(x, y), \ldots, f_n(x, y)\}$, the k-th partition of $f(x, y, t)$ can be denoted as $g_k(x, y) = \{f_i(x, y), f_{i+1}(x, y), \ldots, f_{i+ik-1}(x, y)\}$, where i_k is the number of frames in the k-th partition, and $\sum_{k=1}^{m} i_k = n$. The formal definition of temporal video segmentation consists of the following conditions:

1. $\bigcup_{k=1}^{m} g_k(x, y) = g(x, y)$;
2. For all k and l, $k \neq l$, there exits $g_k(x, y) \cap g_l(x, y) = \varnothing$;
3. For $k = 1, 2, \ldots, m$, it must have $P[g_k(x, y)] = TRUE$;
4. For all $k \neq l$, there exits $P[g_k(x, y) \cup g_l(x, y)] = FALSE$.

Compared with the definition of image segmentation, the corresponding condition (5) has already been included in the definition of $g_k(x, y)$. In other words, the frames in the same shot are connected in time.

MAIN THRUST

In recent years, many researches on image and video segmentation for CBVIR are carried out. Two of them are described with some detail in the following, some others are just briefly indicated.

Color Image Segmentation in Feature and Image Spaces

In CBVIR, color information plays an important role. Early retrieval algorithms for CBVIR are often based on the color information of image or object. Many current retrieval algorithms are still using color information to derive semantic description. Therefore, efficient color segmentation techniques are critical for CBVIR.

One color segmentation technique based on *watershed* and feature space analysis is described below. This technique made the combination of *watershed* transform and feature space analysis.

In most cases, the *watershed* algorithm is applied on image domain (usually on the edge image). It focuses on local color feature instead of global color distribution. In edge image, the local minima exist in the interior of objects and high altitude appears on the boundary of objects. After a flooding process, dams (*watershed* lines) will be constructed on object boundary and different objects are separated. In this way, it captures only information of local color feature instead of global color distribution.

In feature space, one obstacle of segmentation is the difficulty relies on color clustering. Researchers have noticed (Park, 1998; Pauwels, 1999) that color distribution in 3-D color space cannot be well approximated by the traditional parameter based clustering algorithm (such as *K*-mean model or Gaussian mixture model). For example, *K*-mean is unable to handle unbalanced or elongated clusters. Gaussian mixture model is not appropriate for cluster with irregular shape. One example is shown in Fig. 1. The original image PEPPERS is in Fig. 1(a), its pixel distribution in color RGB space is projected onto 2-D plane as in Fig. 1(b) and its pixel distribution in color $L^*a^*b^*$ space is projected onto 2-D plane as in Fig.1(c). In Fig. 1(b), the distribution has irregular shapes, some clusters are sharp and compact, and some are flat. In Fig. 1(c), the clusters seem more salient, but it is still hard to get the boundary between clusters with parametric models.

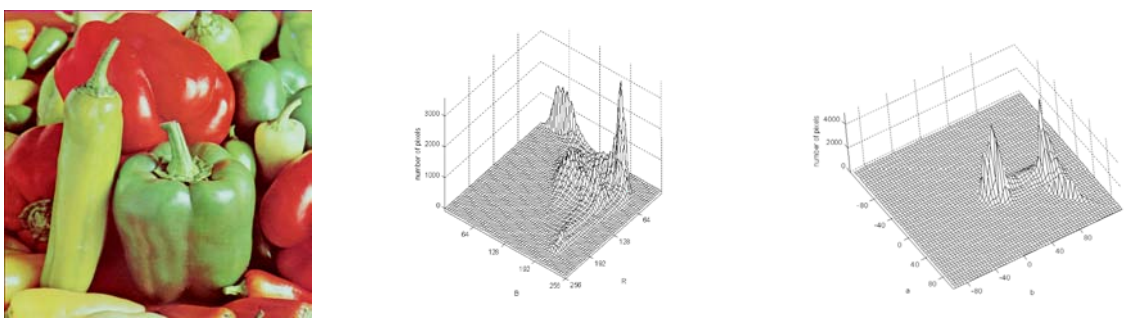
To solve the problem, the *watershed* algorithm is applied on a 3-D $L^*a^*b^*$ histogram $H(x, y, z)$ to capture the feature space information. A labeling process with the following steps is used to cluster the color histogram (Dai, 2006):

1. Get the reverse histogram $H'(x, y, z) = -H(x, y, z)$ $(0 \le x < u, 0 \le y < v, 0 \le z < w)$.
2. Get all local minimum of the reverse histogram H', label them as 1, 2, 3, …, m.
3. Find the unlabeled bin in H' with minimum value and label it according to its neighbors:
   i. If more than one label appears in its neighborhood, it is a "dam" bin, and it will be labeled as 0.
   ii. If else, label it the same as its labeled neighbor.
4. Go to step (3) until all non-zero bins are labeled.

After obtaining the *watershed* in the color histogram, the results can be brought back to the image space. The following post-process steps are used to get continuous homogeneous regions with meaningful size.

1. Get all pixels with corresponding color bins labeled

Figure 1. Pixel distribution of image PEPPERS in color space



(a) *(b)* *(c)*

Figure 2. Examples of segmentation result

(a)

(b)

as 0, and label them as 0 in image domain.

2. Get all continuous (4-neighborhood) regions, and label them the same value in image domain.
3. Label all pixels in regions with size smaller than a predefined threshold as 0.
4. (i) Label the left regions as 1, 2, …, *m*, and all pixels in the labeled regions are labeled the same as their correspondent regions. (ii) Label the rest pixels the same as the label of their correspondent histogram.

The initial segmentation result is thus obtained (see Fig. 2(a)). It is composed of two parts: some continuous homogeneous regions with meaningful size, and some scattered pixels labeled as zero, which are called uncommitted pixels. A Markov Random Field algorithm is followed to refine the initial result. Two efficient energy minimization techniques are applied to get sub-optimal results. One is Highest Confidence First (HCF), which can enforce continuity properties. Another is Graph Cuts, which can efficiently avoid the problem of over-smoothness. The final result obtained by HCF is shown in Fig. 2(b).

Video Segmentation with Parametric Model

In CBVR, a preliminary step is shot boundary detection that partitions video data into fundamental units called shots that are composed of a sequence of frames taken by one camera without interruption. Recently, a parametric model for shot boundary detection (and key frame extraction) is proposed (Chen, 2008). The *autoregressive* (AR) modeling is used to model the frame feature sequence over time and to make the future analysis in the AR parametric space.

Autoregressive model is a simple time-series model widely used for prediction and modeling. An AR model with order p (4 ~ 24) can be expressed as follows (Martin, 2000):

$$\boldsymbol{x}_n = \sum_{j=1}^{p} \boldsymbol{a}_j \boldsymbol{x}_{n-j} + \eta_n \tag{1}$$

where η_n is the uncorrelated noise with variance σ.

The parameters in AR model can be estimated by using the direct-form of recursive least squares (RLS) FIR adaptive filter as follows:

- Initial: $\boldsymbol{a}(0) = 0$, $\boldsymbol{P}(0) = \delta^{-1}\boldsymbol{I}$, where δ is a small positive number (usually 0.01), $\boldsymbol{I}$ is an identity matrix.
- Update: for $n = 1, 2, \ldots$

$$\boldsymbol{e}(n) = \boldsymbol{d}(n) - \boldsymbol{a}^T(n-1)\boldsymbol{u}(n) \tag{2}$$

$$\boldsymbol{k}(n) = \frac{\boldsymbol{P}(n-1)\boldsymbol{u}(n)}{\lambda + \boldsymbol{u}^{\mathrm{T}}(n)\boldsymbol{P}(n-1)\boldsymbol{u}(n)} \tag{3}$$

$$\boldsymbol{P}(n) = \frac{1}{\lambda}\left[\boldsymbol{P}(n-1) - \boldsymbol{k}(u)\boldsymbol{u}^T(n)\boldsymbol{P}(n-1)\right] \tag{4}$$

$$\boldsymbol{a}(n) = \boldsymbol{a}(n-1) + \boldsymbol{k}(n)\boldsymbol{e}(n) \tag{5}$$

where λ is a forgetting factor (can be selected from 0.92 to 0.98), $\boldsymbol{a}(n)$ is the AR coefficient vector, $\boldsymbol{u}(n)$ is the input vector, $\boldsymbol{d}(n)$ is the output vector, $\boldsymbol{k}(n)$ is the gain for the recursive procedure, $\boldsymbol{e}(n)$ is the model prediction error, $\boldsymbol{P}(n)$ is the inverse of the input covariance matrix.

The problem of shot boundary detection can be viewed as an estimation of the on-line *autoregressive* system parameters. It is believed that there would be a shot boundary

at the place where the system structure changes. This can be shown by focusing on the AR prediction errors (APE) in the recursive parameter estimation procedure. In the AR model, APE can measure the accumulated errors as long as the orders of the model. When the APE grows big, it means the present model's parameter cannot fit the current frame well, and a shot change may happen. The transition between two adjacent shots can be divided into two classes: abrupt shot boundary where the change takes place over a single frame, and gradual shot boundary where the change of video content occurs over a sequence of frames gradually. Both of them can be detected with this method.

In order to detect possible abrupt shot boundary, an adaptive threshold on that parameter should be selected:

$$T_b = km \tag{6}$$

where m is the local APE mean values on a 1-D temporal window of size p, and k is suggested to be 2 to 3 according to some empirical studies.

For the gradual transitions, the frame sequences change progressively, causing the correspondent evolvement of the APE among consecutive frames. Such a change can be detected by combining the twin-comparison method (Furht, 1995) with APE.

The proposed method has been tested by using a variety of test videos, as listed in Table1. Among the test videos, the movie (V1) is from the film "Star Wars: The Phantom Menace". The cartoon (V2) is from an episode of "The Incredible". The news (V3) and the advertisement (V4) are from the CCTV-9, and the sports video (V5) is a table tennis game in Olympic Games. The movie and the cartoon are characterized by significant camera parameter changes like zoom-in/out, pans, abrupt camera movement, as well as significant object motion, but the shot change patterns are mostly abrupt ones. The news and the advertisement have nearly all kinds of shot boundaries, including cut, fade in/out, and dissolves.

Two measures: recall (R) and precision (P), are used to evaluate the performance of detection algorithm.

$$R = \frac{\#\text{ of hits}}{\#\text{ of hits} + \#\text{ of misses}} \times \% \tag{9}$$

$$P = \frac{\#\text{ of hits}}{\#\text{ of hits} + \#\text{ of false alarms}} \times \% \tag{10}$$

The detection performance obtained for all test videos are shown in Table 1, too. The proposed method is based on color histogram which is robust to camera motion as well as object motion, and not sensitive to the transition and rotation of the view axis. This intrinsic property of the color histogram and the robust of the RLS to the white noise make the proposed method not sensitive to the motion interruption. In the meanwhile, the parametric model can distinguish motion from some shot changes by the long sequence modeling. Therefore, the performance of this method is in general satisfactory. On the other side, histograms are sensitive to illumination changes, so the scenes with explodes in the movies were falsely detected as shot boundaries.

More Technique Examples

The current research works on CBVIR are toward Semantic-Based Visual Information Retrieval (SBVIR), see (Zhang, 2007). One important stage in SBVIR consists of extracting objects from image and video. An algorithm has been devised for fast, fully automatic, and reliable object segmentation from live video for scenario with static camera (Ong, 2006). It adaptively determine the threshold for change detection; generates robust stationary background reference frame; select the reference frame to improve segmentation results; and refine the spatial change detection mask by incorporating information from edges, gradients, and motion.

Shot boundary detection is the first step for video analysis. After shots are obtained, related shots can be further grouped into scenes with some help of spatial and/or temporal constraints. This process is called shot grouping or

Table 1. Experiments and results on test videos

Video	Frame	Shot #	Cut			Fade in/out			Dissolve		
			#	R(%)	P(%)	#	R(%)	P(%)	#	R(%)	P(%)
V1	10000	188	188	90.5	94.5	0	—	—	0	—	—
V2	7000	130	130	85.0	96.6	0	—	—	0	—	—
V3	10500	54	27	92.6	96.2	15	93.3	100	12	83	100
V4	8000	199	191	96.3	94.4	2	100	100	6	83	83
V5	7500	48	42	97.6	97.6	0	—	—	6	100	100

scene segmentation. Both shot boundary detection and shot grouping are inherently similar tasks. One method has been proposed to formulate both shot boundary detection and shot grouping as the problem of sequential change detection (Lu, 2006). The difference is that in shot boundary detection the feature sequence is extracted from video frame (e.g.,, using frame color histogram as features) while in shot grouping the feature sequence is extracted from shots (e.g., using shot color histograms as features).

Image semantics can be represented more accurately by keywords than by low-level visual features. In this regard, automated image classification and annotation are considered to be promising. Besides obtaining text annotation, a successful image categorization will significantly enhance the performance of the content-based image retrieval system by filtering out images from irrelevant classes during matching.

Recent progresses in object recognition and image annotation have shown that local salient features are more informative in describing image content than global features (Csurka, 2004; Fergus, 2003). In the process of image classification, features are required to be common for the same class and discriminative for different classes. In the object semantic concept learning, the model should emphasize the object in an image category.

Two approaches have been proposed for detecting local salient features (Xu, 2007), which are capable of selecting the most informative features based on the detected salient patches. One approach detects the salient patches by the local salient feature detector proposed in (Kadir, 2001). This detector finds regions that are salient over both location and scale. For each point in an input image, a number of intensity histograms are calculated in circular regions of different radiuses (scales). The entropy of each histogram is then calculated and the local maximum is selected as a candidate region. The regions with highest saliency over the image provide the features. In practice, this method gives stable identification of features over a variety of sizes and copes well with intra-class variability. Only intensity information is used to detect and represent features. Another approach transforms image data into scale-invariant coordinates relative to local features by SIFT (Scale Invariant Feature Transform; Lowe, 1999). SIFT is built by selecting key locations at maxima and minima of a difference of Gaussian function applied in scale space. Maxima and minima of this scale-space function are determined by comparing each pixel in the pyramid to its neighbors.

FUTURE TRENDS

The following research directions should be considered in the future:

1. Both spatial and temporal information are included in video, how to combine them or fuse them in segmentation is an interesting topic.
2. The domain of content-based visual information retrieval has particular requirements for extracting useful information; specific segmentation techniques should be developed.
3. With the trends of more research focused on *SBVIR* (Zhang, 2007), semantic image and video segmentation will play an even significant role.

CONCLUSION

Some recent progress in image and video segmentation for *CBVIR* are reported. Compared to other application areas of segmentation, CBVIR has certain particularities. Further development of image and video segmentation techniques should take them into consideration.

It is expected that the techniques of image and video segmentation will evolve with the advancement of CBVIR and it will also push CBVIR to an even high level.

R

KEY TERMS

AR Model Order: It characterizes how close the relation is for the frame subsequence in the visual content.

Clustering: A process to group, based on some defined criteria, two or more terms together to form a large collection. In the context of image segmentation, clustering is to gather several pixels or groups of pixels with similar property to form a region.

Feature Space Analysis: Image analysis performed in the feature space, in which each point corresponds to a feature value extracted from image.

Gaussian Mixture Model: A traditional parameter-based clustering model. All samples are assumed to belong to one of several Gaussian distributions, the ensemble can be described by the sum of several Gaussian distribution.

Graph Cuts: A widely used technique in energy minimization and clustering. When there are only two labels, the energy minimization problem can be reduced directly to a problem of computing the max-flow (or min-cut) of a graph.

Highest Confidence First: An efficient technique for energy minimization. It is a deterministic minimization algorithm, which is suitable for assigning label to pixels with unknown label, because it introduces an uncommitted label.

***K*-mean Model: A** traditional parameter-based clustering model. *K* initial classes are represented by their mean values, the following iterations try to minimize the distance between the samples with their respect means.

Watershed: A transform or an algorithm for image segmentation. It is traditionally classified as a region-based segmentation approach. The idea underlying watershed transform comes from geography.

Reconciling the Perceptions and Aspirations of Stakeholders in a Technology Based Profession

Monash University, Australia

INTRODUCTION

Information systems professionals help to achieve business and organizational goals through the use of information technology.[a] The information systems (IS) profession is team-oriented and project-based. It involves a blend of business knowledge and understanding, technical skills, and working relationships with business and technical professionals. The skills and knowledge involved range from traditional computing, wide ranging business related studies, to "soft" skills useful in working with individuals and teams to achieve organizational objectives.

IS students are first and foremost concerned with future employability. Employers, on the other hand, often indicate that they want new graduates who can be immediately productive in their environment.

Are the aspirations of students and employers fundamentally incompatible? How can IS educators help to find a workable and satisfying balance? How can information systems educators achieve a better fit between the workplace and the university "studyplace"?

BACKGROUND

The past decades have been characterized by a rapidly and constantly changing business environment. Lee, Trauth, and Farwell (1995) argued that technological and sociological developments facilitated by evolving information technology and changing business needs has made it necessary for IS professionals to develop a wider range of nontechnical skills than was previously the case. Similar views have been expressed by many others, including Burn, Ng, and Ma (1995), Cafasso (1996); Lowry, Morgan, and FitzGerald, (1996); Morgan, Lowry, and FitzGerald (1998). Beise, Niederman, Quan, and Moody (2005) saw a need for the reform of undergraduate IS programs to specifically target the global IT environment by adding a global business perspective to existing curricula or by developing new curricula focusing on globalized information management. The perpetual global competition for skilled information systems professionals continues unabated (Florida, 2005; Schwarzkopf, Saunders, Jasperson & Croes, 2004).

The preparation of IS professionals must encompass a body of knowledge and a repertoire of technical skills identified by various professional bodies (ACM-AIS, 2002; Cheney, Hale, & Kasper, 1990; Cohen, 2000; Davis, Gorgone, Feinstein & Longenecker, 1997; Gorgone & Gray, 1999; Lidtke, Stokes, Haines & Mulder, 1999; Lyytinen & King, 2004; Mulder & van Weert, 2000; Underwood, 1997). IS curricula must take cognizance of the greater diversity within the IT labour force as a result of globalization (Trauth, Huang, Morgan, Quesenberry & Yeo, 2006).

The persistent research finding that employers want graduates who possess better business skills has often been interpreted by academics to mean that more traditional, formal business subjects such as accounting, economics, business finance, and marketing should be taught alongside traditional technical or "hard" skill subjects such as systems analysis & design and programming in particular languages. (Amarego, 2005; Gardiner, 2005; Holt, MacKay & Smith, 2004; Lee, 2005; Leong & Tan, 2004; Litecky, Arnett & Prabhakar, 2004; Medlin, 2004; Trauth, Farwell, & Lee, 1993; Van Slyke, Kittner, & Cheney, 1997). Beachboard and Parker (2003) observed that course requirements in model curricula likely contain more technical material than can be covered in an undergraduate course. On the other hand, "soft" areas such as teamwork, communication skills, ability to accept direction, and others are expected to be somehow "picked up" along the way by students through an unspecified, osmotic process and not addressed as part of a curriculum. Unfortunately, anecdotal evidence continues to suggest that at least some new graduates continue to lack "soft skills" (Maiden, 2004). Berghel and Sallach (2004) maintain that a curriculum must take account of developments in technologies, business models, and applications to enable students to build the necessary competencies.

The work presented here is part of an ongoing research program that investigates the views of major IS curriculum stakeholders including employers, IS practitioners, currently

enrolled students, recent graduates, and academics. The data were gathered from surveys of IS practitioners and IS decision makers in Australia and covered all industry sectors as well as business unit sizes. We argue that IS practitioners, employers, and students see little value in some of the more formal business subject areas that often form the core of an IS degree offered in business or commerce faculties. These stakeholder groups see more value in the development of "soft skills" useful in client interaction, often through cooperative education in which students are placed in real-world roles as novice business analysts (Dressler & Keeling, 2004; Fincher, Clear, Petrova, Hoskyn, Birch & Claxton, 2004; Gallivan Truex & Kvasny, 2004). The findings have serious implications for IS educators and IS curriculum design (Turner & Lowry, 1999a; 1999b; 2000; 2001; 2002; 2003; Turner, Fisher & Lowry, 2004a; 2004b; 2005a; 2005b; Lowry & Turner, 2005a; 2005b; Turner, Lowry & Fisher, 2005; Turner, Fisher & Lowry, 2005a; 2005b; Lowry, Turner & Fisher, 2006).

IS CURRICULUM CONTENT AND DELIVERY IN THE FIRST DECADE OF THE 21ST CENTURY

In a 1999 study, the authors began to suspect that the "other business skills" desired of new IS graduates were not syn-

onymous with traditional business curriculum subjects. Study results indicated that, of nine business subjects that are typically included in IS curricula, only three, Accounting, Business Ethics, and Management were judged to be important by students and employers alike. Follow-up studies were conducted in 2001 and 2002 to further explore the "other business skills" aspect of the IS curriculum (Turner & Lowry, 1999b; 2001; 2002; 2003). Tables 1 and 2 show comparative ratings of "hard" or traditional IS and business subjects and of "soft" skills by information systems and technology professionals and employers.

Comparative Ratings of Academic Subjects by IS Practitioners and Employers

Table 1 shows the mean and standard deviations of ratings of academic subjects and soft skills by (IS/IT) Professionals and IS/IT Employees.

The research instruments contained two sections pertaining to the academic preparation of graduates. These sections separately covered the technical areas of an IS business degree and the other academic areas that are not specific to IS. Subjects responded to each question using a seven point Likert scale.

Of the 14 subjects/skills that achieved a mean rating of 5.0 or more, the highest rating by both practitioners and employers was achieved by Communications & Report Writing—a soft skill. 11 technical subjects and 2 "other business subjects", management and business ethics, achieved mean ratings of 5.0 or more, consistent with earlier findings by the authors (Turner & Lowry, 1999b).

Comparative Importance of Soft Skills by IS/IT Professionals and Employers

A third section in the survey solicited rankings of the importance of a range of so-called "soft skills". The results are presented in Table 2, which shows the ratings by IS/IT Professionals and IS/IT Employees for soft business skills.

Table 2 shows a marked similarity between practitioners and employers in their ratings of the importance of soft business skills. Only the ability to prepare multimedia presentations failed to achieve a mean rating of 5.0. All other soft business skills were highly rated by both IS practitioners and employers.

hard3	soft skills development subjects
hard4	more valued non-IS academic subjects
hard5	less valued non-IS academic subjects
hard6	IT networking and operations subjects
hard7	applied planning and modelling subjects
hard8	fundamental systems development subjects

Differences

Eight hard academic subject factors and four soft skills factors were identified through factor analysis. The academic subject factors accounted for 66% of the variance. The soft factors accounted for 58% of the variance extracted. These factors were used to establish composite variables and these composite variables were then used in comparing the two groups. Table 3 shows the academic subject factors.

The focus of each of the hard factors shown in Table 3 is characterised in Table 4.

Table 5 shows subject factors for the soft skills rated by IS/IT Professionals and Employers in Table 2.

The focus of each of the soft skill factors shown in Table 5 is characterized in Table 6.

Table 6. Focus of Soft Skills Factors

Factor	Focus
soft1	intellectual skills
soft2	work environment skills
soft3	communication and public persona
soft4	effectiveness across disciplines and cultures

Ranking of Soft Skills by IS/IT Employers and Professionals

Table 8 shows the rankings of soft skills by IS/IT Employers and Professionals.

IS/IT Employers ranked the **soft4** factor, *effectiveness across disciplines and cultures* highest, followed by **soft2,** *work environment skills* and **soft1**, *intellectual skills*, rating **soft3**, *communication and public persona* last.

IS/IT Professionals ranked all factors higher than IS/IT employers. This group ranked factor **soft3**, *communication and public persona***,** first. Factor **soft1,** *intellectual skills*, was next, followed by **soft2,** *work environment skills*. The **soft4** factor, *effectiveness across disciplines and cultures*, received the lowest rating by this group.

IS/IT Employers and IS/IT Professionals ranked all four of the soft factors differently. Both groups ranked factor **soft4,** *effectiveness across disciplines and cultures* around the same, middle level, but whilst **soft4** was ranked **highest** by IS/IT Employers, it was ranked **lowest** by IS/IT Professionals. The inverse order of soft skills rankings by the two groups is cause for concern by all stakeholder groups.

Table 8. Ranking of soft skills by IS/IT employers and professionals

a.

Ranking of Hard Skills by IS/IT Employers and Professionals

Once again, IS/IT Employers and IS/IT Professionals ranked all four of the "hard" factors differently. Table 9 shows the rankings of hard skills by IS/IT Employers and Professionals.

Employers ranked **hard4,** *more valued non-is academic subjects*, first. This appears to be consistent with the value placed by employers on the **soft4** factor, *effectiveness across disciplines and cultures***.** As with soft skills, rankings of hard skill factors by employers and professionals are inverse images of one another throughout.

IS/IT Employers ranked the **hard6** factor, *IT networking and operations* ***subjects***, second. This was followed by

hard1, *enterprise software development and management subjects*, **hard3,** *soft skills development subjects*, **hard7**, *applied planning and modelling subjects*, **hard5**, *less valued non-is academic subjects*, **hard8**, *fundamental systems development subjects*, with **hard2**, *software engineering and programming subjects*, rated last.

IS/IT Professionals ranked the **hard2,** *software engineering and programming* subjects factor first, followed by **hard8**, *fundamental systems development subjects*, **hard5**, *less valued non-is academic subjects*, **hard7**, *applied planning and modelling subjects*, **hard3**, *soft skills development subjects*, **hard1**, *enterprise software development and management subjects*, **hard6**, *IT networking and operations subjects*, and **hard4**, *more valued non-IS academic subjects*, rated lowest by this group. As with the soft skills ratings, the inverse order of hard skills rankings by the two

Table 11. Issues and Recommendations for IS Curriculum Refinement

Issue	Recommendation
Confusion: Research results that call for more "business skills" have handily and traditionally been interpreted as meaning exposure of students to additional, formal business subjects. While an IS student may well gain knowledge and skill in marketing, economic analysis, or international business in that way, our findings suggest that it is the "soft" skills, rather than formal academic skill, wanted by IS/IT practitioners and employers.	**Reducing confusion:** Local course advisory and professional bodies can provide invaluable insight into the mix of technical and non-technical formal courses and "soft" skills appropriate for a given institution's service area. Focus groups and local replication of available studies should provide targeted, timely, and authoritative guidance for ongoing curriculum evolution.
Tradition and inertia - Content: It is easy and tempting to offer traditional business subjects as they are already being taught anyway. In many institutions, the existing IS academic staff would have to acquire the additional academic background and skills needed to introduce a substantive "soft skills" emphasis into the IS curriculum. In most instances, there may be insufficient time or interest to do so. **Tradition and inertia – Delivery Method:** Many, if not most, subjects are taught in a familiar lecture / practical mode. As a project and team-oriented profession, information systems programs may well achieve a better match between the workplace through the "study place" through the adoption of active-learning, student-centered delivery methods such as Problem-Based Learning (PBL) and Work-Integrated Learning (WIL). (Bentley, Sandy, & Lowry, 2002)	**Overcoming tradition and inertia:** To some extent, prospective students have taken matters into their own hands by opting in larger numbers to bypass traditional university courses in favour of industry-sponsored/sanctioned entry gateways such as those offered by Microsoft, Oracle, SAP, amongst others. It is possible that students electing the non-academic alternative see more value in industry-focused training than in academic education, which they may see as irrelevant to their career aspirations. A large number of traditional business subjects were rated low in importance by IS practitioners and employers in the tables above. Tertiary educators need to reconsider the value of these traditional business subjects and will have to develop and deliver revitalised curricula that squarely address the expressed desire for "soft" skills that have been identified in a number of studies.
Resources: If a substantial portion of an undergraduate degree program was shifted from traditional business subjects to the acquisition and development of "soft skills", who would develop, teach, and assess the new "soft skills" curriculum component?	**Finding resources:** Resources are easier to obtain from a body of satisfied clients, such as the firms who employ our graduates. If we are seen to consult with, listen to, and serve the interests of those firms, they will follow their self-interest and become rich sources of guidance in curriculum planning and development, work experience for students, consultancies for academics, equipment, money, political weight in our own institution.
We must learn to master what we teach about building client ownership to enlist influential industry partners.	
Vested interest: Some academic institutions supplement the enrolment in less relevant or popular subjects through inclusion of those subjects in a popular curriculum such as Information Systems. In many institutions, economic incentives exist for students to be enrolled in subjects within a single administrative unit, such as a business or IT faculty.	**Neutralising vested interests:** University senior managers may oppose substantive IS curriculum reform such as that discussed in this chapter for a number of reasons, including loss of revenue if students enroll in "soft" skill courses provided by another administrative unit. It is up to IS educators to develop strategies to address the turf issues that preoccupy some administrators. Building effective partnerships with the right industries and accrediting bodies in our service area can provide a powerful voice to speak on our behalf to senior management.

groups is cause for concern by all stakeholder groups. These findings are consistent with findings from an earlier study by the authors (Turner & Lowry, 1999b).

Analysis of the differences in ratings between the two groups, shown in **Table 10**, indicates significant differences between four factors, **soft3,** *communication and public persona***, hard2,** *software engineering and programming subjects,* **hard4,** *more valued non-IS academic subjects* and **hard8**, *fundamental systems development subjects*. Professionals rated **soft3** highest whilst Employers rated **soft3** lowest. Employers rated **hard2** eighth, whilst Professionals rated **hard2** first**.** The **rankings** were reversed for **hard4** and Employers rated **hard8** seventh and Professionals rated this second. As no other differences between groups were significant, stakeholders may more productively focus on understanding and reducing the gaps in rankings between stakeholder groups.

FUTURE TRENDS

Barriers to meaningful reform and evolution of the IS curriculum include confusion, tradition and inertia, scarcity of resources, and vested interests. Table 11 summarizes these issues and offers recommendations, in increasing order of difficulty.

CONCLUSION

There has long been agreement that the IS curriculum should be comprised of some combination of technical subjects and nontechnical business subjects, and that graduates also need soft business skills. There is far less agreement about what the mix between these should be and how best to prepare students in some areas, notably in the development of soft business skills.

While we agree with the general view that soft skills have become increasingly important, we argue that the traditional business subjects are *not* the business skills primarily sought in studies of the IS marketplace. Does the study of traditional business subjects such as marketing, business law, or economics directly help the students to develop a repertoire of soft business skills? The findings suggest that in reality it is not more core business subjects that are needed but an appreciation of business processes and activities that are not always covered in IS degree programs.

Some formidable barriers exist to substantive revision of IS curricula to emphasise acquisition and development of soft business skills. In increasing order of difficulty, Table 11 summarizes some of the issues and barriers to meaningful reform and evolution of the IS curriculum might be surmounted over time and with sufficient dedication. There are, of course, no easy solutions to resolve these issues.

While study after study has called for soft skills acquisition and development by IS students, some IS programs have a clearer and better-developed vision than others of what those skills are and how they may be introduced and cultivated. The growing emphasis on soft skills in IS education is an indication that what began as a fundamentally technology-oriented discipline is, indeed, evolving into a technology-based profession. We can watch someone else claim that knowledge and the opportunities that it offers or we can embrace it ourselves, hoping that there is still time.

KEY TERMS

Hard Skills: Measurable capabilities and academic knowledge acquired through traditional tertiary study. Current MIS curriculum examples such communications and report writing, systems analysis and design, client/server applications, and business applications, are shown in rank-order in Table 1**.**

Inquiry-Based Learning: A student-centered, active learning approach focusing on questioning, critical thinking, and problem-solving. IBL is expressed by the idea "involve me and I understand". The IBL approach is more focused on using and learning content as a means to develop information-processing and problem-solving skills. The system is more student-centered, with the teacher as a facilitator of learning. There is more emphasis on "how we come to know" and less on "what we know". Students are involved in the construction of knowledge through active involvement. The more interested and engaged students are by a subject or project, the easier it will be for them to construct in-depth knowledge of it. Learning becomes easier when reflects their interests and goals and piques their natural curiosity.

Problem-Based Learning: Is an active learning strategy that may be suitable for better preparing information systems students for professional practice. In the problem-based approach, complex, real world problems or cases are used to motivate students to identify and research concepts and principles they need to know in order to progress through the problems. Students work in small learning teams, bringing together collective skill at acquiring, communicating, and integrating information in a process that resembles that of inquiry.

Project-Based Learning: An active learning approach that focuses on developing a product or creation. The project may or may not be student-centered, problem-based, or inquiry-based. Project-based learning uses open-ended assignments that provides students with a degree of choice, and extends over a considerable period of time. Teachers act as facilitator, designing activities and providing resources and advice to students. Instruction and facilitation are guided by a broad range of teaching goals. Students collect and analyze information, make discoveries, and report their results. Projects are often interdisciplinary.

Soft Skills: Cultivated elements of professionalism that derive from example, reflection, imitation, and refinement of attitudes, personal capabilities, work habits, and interpersonal skills and are expressed in consistent and superior performance, characterized by a customer service and team orientation. Current MIS curriculum examples such as ability to work as a member of a team, well-developed oral and written presentation skills, and the ability to work independently, are shown in rank-order in Table 2.

Student-Centered/Active Learning: Places the student into active, self-directed learning, learning by enquiry and ownership of the learning goals. Active-learning strategies include Problem-Based Learning (PBL), Project-Based Learning; and Inquiry-Based Learning, and Work-Integrated Learning.

Teacher-Centered Learning: Is characterized by didactic teaching, passive learning, and the teacher as the "expert". Control of learning rests with the instructor. The learning of the students is directed by the instructor and is often based on what the instructor believes the student needs to learn. This approach can lead to students focusing on determining what knowledge they require to pass the subject rather than the instructional objectives of the program, a phenomenon well known to educators.

Work-Integrated Learning: WIL is a hybrid approach that achieves learning outcomes through a combination of alternating periods of traditional academic pedagogy with extended periods of practical experience in the professional workplace. Work-Integrated Learning is a mature pedagogical strategy that is often referred to as "sandwich" and "end-on" courses.

ENDNOTE

[a] The term "information systems" will be used to mean "business information systems", "management information systems", "informatics", and similar variations throughout this entry.

Reconfigurable Computing Technologies Overview

Kai-Jung Shih
National Chung Cheng University, ROC

Pao-Ann Hsiung
National Chung Cheng University, ROC

INTRODUCTION

Reconfigurable computing is breaking down the barrier between hardware and software design technologies. The segregation between the two has become more and more fuzzy because reconfigurable computing has now made it possible for hardware to be programmed and software to be synthesized. Reconfigurable computing can also be viewed as a trade-off between general-purpose computing and application specific design. Given the architecture and design flexibility, reconfigurable computing has catalyzed the progress in hardware-software codesign technology and a vast number of application areas such as scientific computing, biological computing, artificial intelligence, signal processing, security computing, and control-oriented design, to name a few.

In this article, we briefly introduce why and what is reconfigurable computing in the introduction section. Then, the resulting enhancements of hardware-software codesign methods and the techniques, tools, platforms, design and verification methodologies of reconfigurable computing will be introduced in the background section. Furthermore, we will introduce and compare some reconfigurable computing architectures. Finally, the future trends and conclusions will also be given. This article is aimed at widespread audiences, including both a person not particularly well grounded in computer architecture and a technical person.

Why Reconfigurable Computing?

With the popularization of the use of computers, computer-aided computing can be roughly divided into two technical areas, one of which is general-purpose computing and the other is application-specific integrated circuit (ASIC) computing.

On one extreme, general-purpose computing was accomplished by the world's first fully operational electronic general-purpose computer, called *Electronic Numerical Integrator and Calculator* (ENIAC), built by J. Presper Eckert and John Mauchly. But it is well-known as *von Neumann computer* because ENIAC was improved by John von Neumann (Hennessy & Patterson, 2007). A general-purpose computer is a single common piece of silicon, called a *microprocessor*, that could be programmed to solve any computing task. This means many applications could share commodity economics for the production of a single integrated circuit (IC). This computing architecture has the flexibility and superiority that the original builders of the IC never conceived (Tanner Research, 2007).

On the other extreme, an ASIC is an IC specifically designed to provide unique functions. ASIC chips can replace general-purpose commercial logic chips, and integrate several functions or logic control blocks into one single chip, lowering manufacturing cost and simplifying circuit board design. Although the ASIC has the high performance and low power advantages, its fixed resource and algorithm architecture result in drawbacks such as high cost and poor flexibility.

As a tradeoff between the two extreme characteristics, reconfigurable computing has combined the advantages of both general-purpose computing and ASIC computing. A comparison among the different architecture characteristics is illustrated in Table 1 (Tredennick, 1996; Tessier & Burleson, 2001).

From Table 1, we observe that reconfigurable computing has the advantage of programmable or configurable computing resources, called configware (TU Kaiserslautern, 2007a), as well as configurable algorithms, called flowware (Hartenstein, 2006; TU Kaiserslautern, 2007b). Further, the performance of reconfigurable systems is better than general-purpose systems and the cost is smaller than that of ASICs. The main advantage of reconfigurable system is its high flexibility, while its main disadvantage is its high power consumption. The design effort in terms of nonrecurring engineering (NRE) cost is between that of general-purpose processor and ASICs.

Because reconfigurations of underlying resources help achieve the goals of balance among performance, cost, power, flexibility, and design effort. The reconfigurable computing architecture has enhanced the performances of large variety of applications, including embedded systems, SoCs, digital signal processing, image processing, network

Table 1. Comparison of representative computing architecture

Computing Architecture	Programming source		Advantage				
	Resources	**Algorithms**	**Performance**	**Cost**	**Power**	**Flexibility**	**Design effort (NRE)**
General-purpose	Fixed	Software	Low	Low	Medium	High	Low
ASIC	Fixed	Fixed	High	High	Low	Low	High
Reconfigurable	Configware	Flowware	Medium	Medium	High	High	Medium

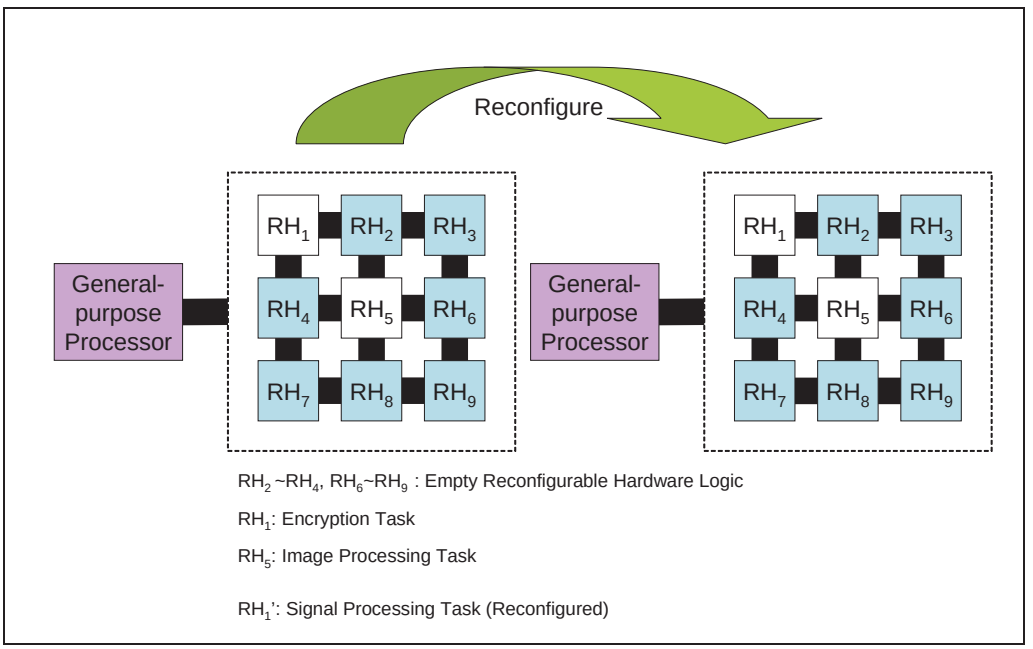
security, bioinformatics, supercomputing, boolean SATisfiability (SAT), spacecrafts, and military applications. We can say that reconfigurable computing will widely, pervasively, and gradually impact human lives.

What is Reconfigurable Computing?

In 1960, Estrin (1960) first proposed the term "reconfigurable computing." The reconfigurable computing architecture is composed of a general-purpose processor and reconfigurable hardware logic. The reconfigurable computing architecture can be concisely defined as *Hardware-On-Demand* ™ (Schewel, 1998), *general purpose custom hardware* (Goldstein et al., 2000) or a *hybrid approach between ASICs and general-purpose processors* (Singh et al. 2000).

We illustrate a general reconfigurable computing architecture in Figure 1. In this architecture, the reconfigurable hardware logic executes application-specific computation intensive task, such as encryption (RH_1) and image processing (RH_5) as shown in Figure 1. The processor is used to

Figure 1. Reconfigurable computing



control the behavior of the task running in the reconfigurable hardware and some other functions such as external communications. When a reconfigurable hardware has finished its computation, such as the encryption task in RH_1, the processor reconfigures the hardware to execute another task such as the signal processing task. During this reconfiguration process, the image processing task continues to execute in RH_5 without interruption.

From the above illustration, we can also define reconfigurable computing as a discipline in which system or application functions can be changed by configuring a fixed set of logic resources through memory settings (Hsiung & Santambrogio, 2008). Functions may be transforms, filters, codec, and protocol, the fixed set of logic resources may be logic block, I/O block, routing block, memory block, and application-specific block, and the memory settings mean configuration bits.

BACKGROUND

Materials science and technology progress has resulted in the maturity and development of reconfigurable computing. To understand the development of reconfigurable computing, an important perspective is to view it from the transition of hardware-software (HW-SW) codesign technology to reconfigurable computing. In the following, we will first introduce reconfiguration techniques and the *Field-Programmable Gate Arrays* (FPGA) (Gokhale & Graham, 2005). Furthermore, we will introduce some reconfiguration tools and platforms used in the academia and the industry. Finally, the design and verification methodologies will also be introduced.

From Codesign to Reconfiguration

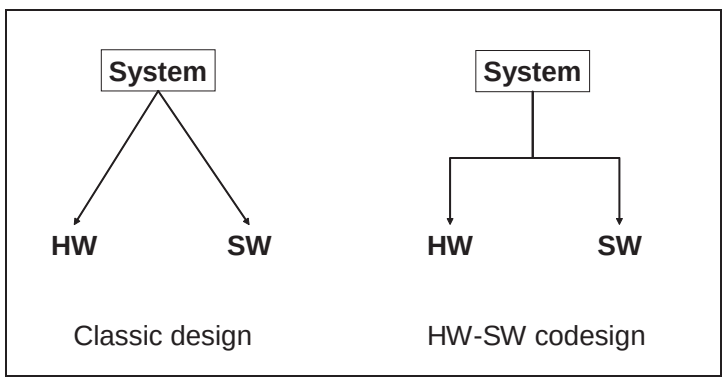
HW-SW *codesign* is an emerging topic that highlights a unified view of hardware and software (Vahid & Givargis, 2002). It is a system design methodology different from *classic design,* as illustrated in Figure 2.

The classic design partitions a system into hardware and software. Because a software designer may not know the final hardware architecture design and the hardware designer may also be unacquainted with the software design flow, hardware and software and are often implemented independently and then integrated toward the end of the design flow. If problems crop up during integration, changing either the hardware or the software could both be quite difficult. This will increase the maintenance difficulty and also delay the marketing time.

To address the problems mentioned above, a system design methodology called HW-SW codesign was proposed, which emphasizes the consistency and the integration between hardware and software. It is based on a system-level view, and thus eases both software verification and hardware error detection. The HW-SW codesign methodology reduces the cost of design and also shortens the time-to-market.

Nevertheless, the high cost in hardware design is a major issue of the HW-SW codesign flow because hardware must go through a time-consuming flow including design, debug, manufacturing, and test. The inconvenient hardware manufacturing forces designers to search for alternate ways. One way is to use modeling languages such as SystemC (Black & Donovan, 2004) to simulate hardware and software. Another method is to use concurrent process models to simulate hardware and software tasks. However, simulation speed is a major bottleneck (Schewel, 1998). To overcome the drawback, prototyping using reconfigurable architectures has

Figure 2. Classic design and HW-SW codesign



become the most appropriate choice for HW-SW codesign. In contrast to ASIC design, reconfigurable hardware can be much easily used to design hardware prototypes that can be integrated with software to obtain performance and functional analysis results much more efficiently and accurately. We can thus say that reconfigurable computing has accelerated and enhanced the HW-SW codesign flow.

Reconfiguration Techniques

From the mid 1980s, reconfigurable computing has become a popular field due to the FPGA technology progress. An FPGA is a semiconductor device containing programmable logic components and programmable interconnects (Compton & Hauck, 2002) but no instruction fetch at run time, that is, FPGA do not have a program counter (Hartenstein, 2006). In most FPGAs, the logic components can be programmed to duplicate the functionality of basic logic gates or functional intellectual properties (IPs) and also include memory elements composed of simple flip-flops or more complete blocks of memories (Barr, 1998).

Besides FPGA, the *reconfigurable data-path array* (rDPA) is another reconfiguration technique. In contrast to FPGA having single bit programmable logic blocks, rDPAs have *multiple* bits wide (e.g., 32 bit path width) reconfigurable data-path units (rDPUs). An rDPA is structurally programmed from configware sources, compiled into pipe networks to be mapped onto the rDPA. The term *reconfigurable data-path array*, or rDPA, had been proposed by Rainer Kress in 1993 at TU Kaiserslautern (Hartenstein, 2006). For further details on the comparison between FPGA and rDPA, readers can refer to the section on "Fine-grained vs. Coarse-grained Reconfiguration."

The main part of a reconfigurable system is the configware such as FPGA or rDPA. Besides configware, the software is another essential part that can control and thus incorporate the configware into a reconfigurable system. Although configware can provide resources for high performance computation, complex control must be implemented in software. Reconfiguring hardware implies software must also be appropriately reconfigured, and thus we need reconfigurable software design too (Compton & Hauck, 2002; Voros & Masselos, 2005).

Reconfiguration Tools and Platforms

To construct a reconfigurable computing system, designers need computer-aided design (CAD) tools for system design and implementation, such as a design analysis tool for architecture design, a synthesis tool for hardware construction, a simulator for hardware behavior simulation, and a placement and routing tool for circuit layout. We may build these tools ourselves or we can also use commercial tools and platforms for reconfigurable system design, such as the *Embedded Development Kit* (EDK) from Xilinx, which is a common development tool. The EDK integrates both the software and

Table 2. Commercial reconfiguration tools

Functionality	Tool Name	FPGA/EDA Company

the hardware components of a design to develop complete systems (Donato et al., 2005). In fact, EDK provides developers with a rich set of design tools, such as Xilinx Platform Studio (XPS), gcc, and Xilinx Synthesizer (XST). It also provides a wide selection of standard peripherals required to build systems with embedded processors, like MicroBlaze or IBM PowerPC (Xilinx, 2007). Besides Xilinx EDK, we list commonly used commercial FPGA and electronic design automation (EDA) tools in Table 2.

After designers build a reconfigurable system, a platform for operating and testing is needed. We can use the platforms developed in the industry or in the academia, such as the Caronte Architecture (Donato et al., 2005) and the Kress-Kung Machine (Hartenstein, 2006). The Caronte Architecuture is entirely implemented in the FPGA device and constituted by several elements such as a processor, memories, a set of reconfigurable devices and a reconfiguring device. It implements a module-based system approach based on an EDK system description and provides a low cost approach to the dynamic reconfiguration problem. The Kress-Kung is a data-stream-based machine. Instead of rDPAs, it has no *Central Processing Unit* (CPU) or program counter.

Design and Verification Methodologies

To design reconfigurable computing systems, we need some appreciation of the different costs and opportunities inherent in reconfigurable architectures. Currently, most systems are designed based on our past experiences. We can use the design patterns identified and cataloged by DeHone et al. (DeHon et al., 2004). Each pattern description has a name, intent, motivation, applicability, participants, consequences, implementation, known uses, and related patterns. They also cataloged the design patterns into several classification types, such as patterns for area-time tradeoffs and patterns for expressing parallelism. This classification is a good start for constructing reconfigurable systems. In the following, we present a typical design methodology and a typical verification methodology for illustration purpose.

Tseng and Hsiung (2005) proposed a UML-based design flow for *Dynamically Reconfigurable Computing Systems* (DRCS). This design flow is targeted at the execution speedup of functional algorithms in DRCS and at the reduction of the complexity and time-consuming efforts in designing DRCS. The most notable feature of the design flow is a HW-SW partitioning methodology based on the UML 2.0 sequence diagram, called *Dynamic Bitstream Partitioning on Sequence Diagram* (DBPSD). In DBPSD, partitioning guidelines are also included to help designers make prudent partitioning decisions at the class method granularity. The enhanced sequence diagram in UML 2.0 is capable of modeling complex control flows, and thus the partitioning can be done efficiently on the sequence diagrams.

After design and implementation, we need to verify that the system design is correct and complete. Correctness means that the design implements its specification accurately. Completeness means that our specification described appropriate output responses to all relevant input sequences (Vahid & Givargis, 2002).

Hsiung, Huang, and Liao (2006) proposed a SystemC-based performance evaluation framework, called *Perfecto*, for dynamically partially reconfigurable systems, which is an easy-to-use system-level framework. Perfecto is able to perform rapid explorations of different reconfiguration alternatives and to detect system performance bottlenecks. In their framework, a system designer can detect performance bottlenecks, functional errors, architecture defects, and other system faults at a very early design phase.

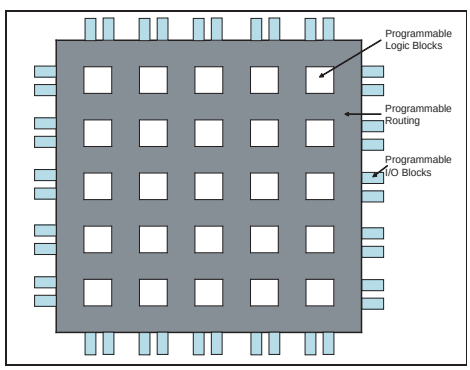
RECONFIGURATION ARCHITECTURES

As illustrated in Figure 3, FPGA is constructed from a large number of programmable logic structures, called programmable logic blocks, which can be interconnected to each other through programmable routing resources. If we want to connect the programmable logic blocks to the external, we can also interconnect them to the programmable I/O blocks through the programmable routing resources (Gokhale & Graham, 2005).

The programmable logic block can be configured as the desired circuit functionality and the programmable I/O blocks can be configured for communicating with outer devices. Between programmable logic blocks or between programmable logic blocks and I/O blocks, programmable routing can be configured for interconnection (Gokhale & Graham, 2005).

In this section, we will go through different classification schemes of reconfigurable architectures. In terms of reconfiguration granularity, we have fine-grained and

Figure 3. A generic FPGA architecture



coarse-grained reconfiguration. If we consider the time when reconfigurations are performed, we have static and dynamic reconfigurations. Considering the amount of logic resources that can be reconfigured, we have full and partial reconfigurations. Considering the model of reconfiguration supported, we will introduce column-based and tile-based reconfiguration. Finally, we give a comparison among different reconfiguration architectures.

Fine-Grained vs. Coarse-Grained Reconfiguration

To understand what fine-grained and coarse-grained mean, we can refer to Table 3 as formulated in Hartenstein (2006). In Table 3, the data path width indicates the granularity of the configware, that is, fine-grained or coarse-grained. The data path of FPGA is about 1 bit wide and rDPA is about 32 bits, so we call FPGA fine-grained and rDPA coarse-grained.

Besides the difference in data path width, the reconfigurable unit is also different. Fine-grained reconfiguration uses look-up table (LUT) as the typical reconfigurable unit and coarse-grained uses ALU-like unit. LUT is the most common implementation method for combinational logic. The characteristic of LUT is to use a multiplexer to select the input data. For example, a four inputs and one output multiplexer, denoted as a 4x1 multiplexer, is used as an LUT, which is shown in Figure 4.

In Figure 4, the selector will select which input will be connected to the output. For example, if the A=1 and B=0, the output port will be connected to input port I_{10} and output data is 0. For the example in Figure 4, the LUT represents a logic AND gate. When AB = "00", "01", "10", "11", the output will be connected to corresponded input I_{00}, I_{01}, I_{10}, I_{11}, respectively, and result in "0", "0", "0", "1". These are the values in a logic AND truth table. Based on this characteristic, a LUT can reserve, that is, reconfigure, the input to obtain any logic circuit.

The rDPA is an array of reconfigurable data unit (rDPU) and can be illustrated as in Figure 5. A typical example of rDPU is an arithmetic-logic unit (ALU) which is found in a von Neumann computer. The ALU is a digital circuit that calculates arithmetic and logic operations. The rDPUs constitute the set of coarse-grained programmable logic blocks.

Figure 4. A two-input look-up table

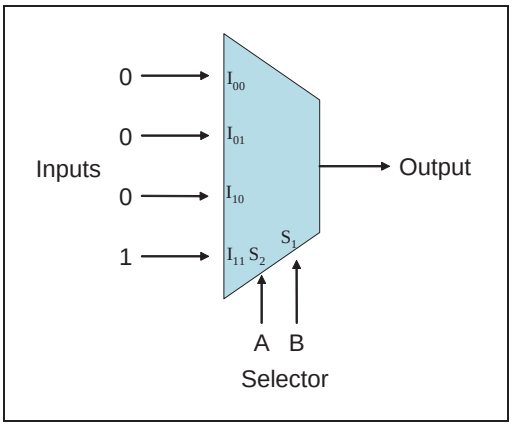


Table 3. Comparison of reconfiguration granularities

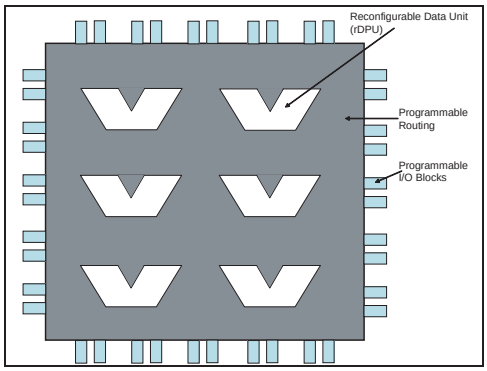
	Fine-grained	**Coarse-grained**
Configware	Field-programmable gate array (FPGA)	Reconfigurable data-path array (rDPA)
Data path width	~ 1 bit	~ 32 bits
Physical level of basic reconfigurable units	Gate level	RT level
Typical reconfigurable units examples	LUT (look-up table)	ALU-like
Configuration time	Milliseconds	Microseconds
Clock cycle time	~ 0.5 GHz	~1 - 3 GHz

Figure 5. Reconfigurable data array



Static vs. Dynamic Reconfiguration

As we mentioned earlier, traditional configwares can be configured for a hardware design as required. If we want to replace a new hardware design in the configware, the configware needs to be sent the RESET signal for reconfiguration use. Because the reset action usually consumes a lot of time, we would want to reduce the number of times this action is taken. In other words, we can say that traditional configwares are reconfigurable, but not run-time reconfigurable (Barr, 1998). We can classify these configwares as *static reconfiguration* unit.

Besides static reconfiguration, dynamic reconfiguration has also resulted from progress in new reconfiguration technologies. Run-time reconfiguration has added another dimension of flexibility in such systems. When we want to place a hardware design into a dynamically reconfigurable configware, we can just stop the clock of the region we need, reset the hardware resources in that region, and then configure the desired the hardware design and start the clock for this region. The other regions on this configware will still work unrestrictedly. Thus, it is called *dynamic* or *run-time reconfiguration*. Dynamic reconfiguration technique reduces the response time and the configuration overhead compared to static reconfiguration. Nowadays, industry products, such as Xilinx Virtex-II, Virtex-II Pro, Virtex-4, and later versions of the Virtex series all support dynamic reconfiguration.

Full vs. Partial Reconfiguration

In traditional reconfiguration, we integrate a set of one or more hardware design and configure them using a single reconfiguration action into a configware. We can call this type of reconfiguration as *full reconfiguration*. If a hardware design uses much fewer resources than that available in the configware, full reconfiguration will result in low resource utilization.

If the configware can be configured partially, resource utilization can be increased and portions of the chip can be reconfigured while other parts can still continue running and computing.

Partial reconfiguration is illustrated in Figure 6, where the resource usage of hardware design A is smaller than that available in the configware. The configware is partially configured with the bitstream of design A. When another hardware design B is required, the configware will again be partially configured with hardware design B. During the configuration of B, A will run without any glitches. Thus, the partial reconfiguration technology results in better configware resource utilization than that in full reconfiguration.

Currently, the dynamically reconfigurable architectures also support partial reconfiguration, including Xilinx Virtex-II, Virtex-II Pro, Virtex-4, and the later versions of the Virtex series.

Column-Based vs. Tile-Based Reconfiguration

Traditionally, configware was designed for column-based reconfiguration, that is, the basic unit of configuration is a *column* that crosses the chip. Thus, in implementing a partially reconfigurable system, the configware is modeled as a one-dimensional area of resources in which hardware designs can be configured. A typical example of configware with column-based reconfiguration is the Xilinx Virtex II series

Figure 6. An example of partial reconfiguration

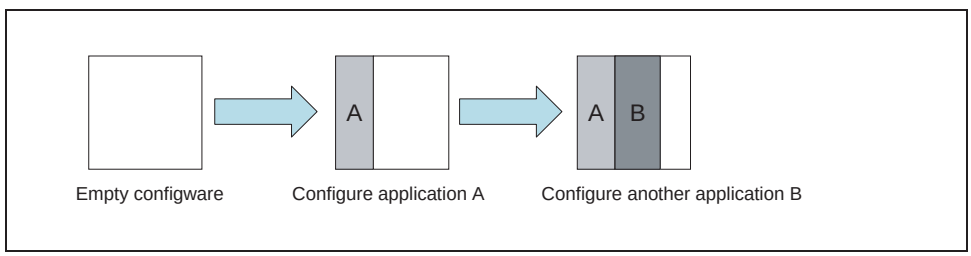


Figure 7. Column-based vs. tile-based reconfiguration

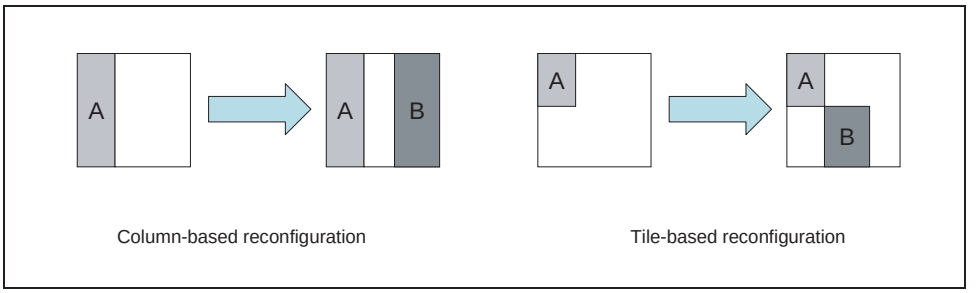

of FPGA chips. Tile-based reconfiguration is another more flexible architecture that can be found in the Xilinx Virtex 4 series of FPGA chips. These two types of reconfiguration are illustrated in Figure 7.

A *tile* is the area smaller than a column. In the Xilinx Virtex 4 series of FPGA chips, each column is partitioned into two tiles. Thus, designers can have the two-dimensional vision of their reconfigurable system. As shown in Figure 7, if the sizes of hardware designs A and B are the same in the column-based and the tile-based instances, then they can be configured with more flexibility with the tile-based one. The resource utilization of the configware is also increased with tile-based reconfiguration.

Reconfiguration Architecture Comparisons

Summarizing and analyzing the discussions from above, we can compare the reconfiguration architectures as in Table 4, where the traditional reconfiguration architecture supports static and full reconfiguration, while the modern architecture supports dynamic and partial reconfiguration. When the resource requirements of a hardware design can be met by a configware, the performance and power will be the same for both traditional and modern reconfiguration architectures because dynamic and partial reconfiguration techniques are not needed. However, when a hardware design cannot fit in a configware, these modern techniques will be required, resulting in higher performance and power.

The cost, flexibility, and design effort are all quite high for the modern architecture because the dynamic and partial reconfiguration techniques require additional hardware support, tool support, scheduling support, and user expertise, while providing greater flexibility in system design.

FUTURE TRENDS

With technology progress, not only has the gate count capacity of FPGA increased rapidly, but chip reconfiguration can now be performed at *run-time* and *partially*. On one hand, the large gate capacity enables several hardware tasks to run concurrently in a single FPGA chip, which could also interact with software tasks running on a microprocessor. On the other

Table 4. Comparison of configuration

Reconfiguration Architecture	Reconfiguration Classification		Advantage				
	Temporal	Spatial	Performance	Cost	Power	Flexibility	Design effort
Traditional	Static	Full	Low	Low	Low	Low	Low
Modern	Dynamic	Partial	High/Low	High	High/Low	High	High

hand, the partial run-time reconfigurability allows a system to dynamically change some of its hardware functionalities such as in mobile networking, wearable computing, and networked embedded systems. The complexity in designing such systems drives the need for an *operating system* that not only manages software tasks and resources, but also manages hardware tasks and related FPGA resources.

As an important feature trend, in the design and implementation an *operating system for reconfigurable systems* (OS4RS), we need to complete the following tasks.

1. OS4RS architecture design, including services, components, abstractions, performance, and hardware support mechanism
2. OS4RS kernel design, including the main kernel, system call interfaces, device drivers, loader, partitioner, scheduler, process manager, memory manager, placer, and router
3. OS4RS loadable modules design, including power manager, virtual memory manager, and other drivers
4. Set up the experiment platform and related software and *computer-aided design* (CAD) toolchains.

CONCLUSION

Reconfigurable computing has become an important field of research in the academia and the industry. Reconfigurable architecture requires changes in both computer architectures and software systems leading to many research topics. A reconfigurable system is composed of a standard processor and a set of reconfigurable hardware. The reconfigurable hardware executes application-specific computing intensive task and is reconfigured by the standard processor. Reconfigurable computing combines the advantages of both general-purpose and ASIC computing, including performance, cost, power, flexibility and design effort. Due to its reconfigurable hardware characteristics, reconfigurable computing has accelerated and enhanced the HW-SW codesign flow.

Reconfigurable computing architecture can be classified according to the granularity of configware. One is fine-grained and the other is coarse-grained. The most representative of fine-grained configware is FPGA and rDPA is the representative of coarse-grained configware. To increase flexibility of reconfiguration, configwares have been enhanced from static/full reconfiguration to dynamic/partial reconfiguration.

To develop a reconfigurable system, we can use the design patterns collected by DeHone et al. (2004) as an initial solution. Several tools and platforms developed in the academia and in the industry support reconfigurable computing and thus will help us to implement reconfigurable systems easily and rapidly. When the reconfigurable system is implemented, we can use the verification methodologies to verify the system.

With technology progress, not only has the gate count capacity of FPGA increased rapidly, but chip reconfiguration can now be performed at *run-time* and *partially*. To design and implement an *operating system for reconfigurable systems* (OS4RS) will be an important future trend in reconfigurable computing.

KEY TERMS

Codesign: The meeting of objectives by exploiting the trade-offs between hardware and software in a system through their concurrent design.

Configware: Source programs for configuration like field-programmable gate arrays (FPGA) or reconfigurable data path array (rDPA).

Dynamic/Static Reconfiguration: A reconfiguration technology that allows resources in a configware to be programmed without/with resetting the configware.

Field-Programmable Gate Arrays (FPGA): A programmable integrated circuit and contains a set of gate array that is programmed in the field.

Flowware: A data-stream-based software. It is the counterpart of the traditional instruction-stream-based software.

Full/Partial Reconfiguration: A traditional/modern reconfiguration technology which forces all/partial resources of a configware to be programmed during each configuration.

Reconfigurable Data Path Array (rDPA): A programmable integrated circuit with coarse-grained granularity.

Reconfiguration: The process of physically altering the location or functionality of configwares with new ones.

System on Chip/SoC: A chip which is complete to constitute an entire system or major subsystem.

Wearable Computing: A small portable computer that is designed to be worn on the body during use.

Referential Constraints

INTRODUCTION

Inclusion dependencies support essential semantic aspects of the standard relational data model. An inclusion dependency is defined as the existence of attributes in a table whose values must be a subset of the values of the corresponding attributes in another table (Codd, 1990; Abiteboul, Hull, & Vianu, 1995; Connolly & Begg, 2004). Formally, it can be expressed as $R[X] \subseteq S[Z]$. R and S are relation names. With X and Z as compatible attributes, R[X] and S[Z] are the inclusion dependency's left and right sides respectively. When Z is the primary key of S or it is restricted by a unique clause, the inclusion dependency is key-based (also named referential integrity restriction, *rir*). In this case, X is a foreign key (FK) for R. On the contrary, if Z does not constitute the key of the relation, the inclusion dependency is non-key-based (simply, an inclusion dependency, *id*). Both *rir*s and *id*s are referential constraints.

*Rir*s are important because they contain basic local semantic characteristics, which have been elicited from the Universe of Discourse (UofD). They are sufficient to symbolize many natural semantic links such as the relationships and hierarchies that are captured by semantic models (Abiteboul et al., 1995). Conversely, *id*s do not appear as a product of the translation 'conceptual schema→logical schema', but because of ad-hoc changes made in the phase of detail design, some denormalization degree, or the presence of complex n-ary relationship constructs. In this scenario, *id*s frequently misrepresent objects and their corresponding inter-object relationships.

*Rir*s can be declaratively defined via the SQL foreign key clause (SQL:1999-2, 1999) and are enforced by most current database systems:

FOREIGN KEY (<referencing column list>) REFERENCES <referenced table name> [(<referenced column list>)]

[MATCH <match type>]
[ON UPDATE <update referential action>]
[ON DELETE <delete referential action>]

If <referenced column list> is omitted, the foreign key refers to the primary key of <referenced table name>.

The *rir*s can be specified with respect to different match types: SIMPLE (implicit if no match option is declared), PARTIAL, and FULL. As stated in the SQL:1999 standard document: If <match type> is not specified, then for each row in the referencing table, either the referencing column has at least one null value or its value matches the value of a corresponding row in the referenced table. If PARTIAL is specified, then for each row in the referencing table the value of each foreign key column is null, or it has at least one non-null value that equals the corresponding referenced column value. Finally, FULL means that, for each row in the referencing table, either all foreign key values are null or they equal the value of the corresponding referenced column (Türker & Gertz, 2001; SQL:1999-2).

When an integrity restriction is violated, the usual response of the system is the *rollback* of the data manipulation intended by the user. In the case of *rir*s, some other alternative actions are possible. These actions, named referential actions or referential rules, specify the behavior of the left and right relations under the deletion or the updating of a referenced row (a row in the right table), or the insertion of a row in the referencing (left) table. Possible actions are: *cascade*, *restrict*, *no action*, *set null*, *set default* (Markowitz, 1994; SQL:1999_2, 1999; Türker & Gertz, 2001). With the *cascade* option, the referencing rows will be deleted (updated) together with the referenced row. With the *set null* (*set default*) option, all references to the deleted (updated) row will be set to null (default) values. The deletion (update) of a referenced row is disallowed by *restrict* and *no action* rules, whenever at least a row in the left table is pointing to it. The unique referential rule for insertions is *restrict*: inserting a row into the referencing table is possible only if the referenced tuple already exists in the right term.

*Id*s may be defined with general CHECK statements having the semantics of assertions or triggers. Erroneously *id*s are frequently specified by means of an attribute-based CHECK constraint associated to the referencing table, requiring the existence of the referred-to value.

CHECK (<referencing column> IN (SELECT <referenced column>
FROM <referenced table>))

Since these constraints are checked whenever any tuple changes the value for that attribute, an update of the referred-to value in the referenced table would result in the attribute-based CHECK constraint becoming violated.

Triggers are a widespread way of implementation, although they usually complicate the development of ap-

plication programs and make the integrity maintenance quite difficult (Date & Darwen, 1997; Elmasri & Navathe, 2000; Connolly & Begg, 2004).

BACKGROUND

The comprehension of the semantic issues related to referential constraints is facilitated by the study of the syntactic structure of their terms.

Structure

Considering a relation shape, there are five possible placements of a non-empty set of attributes with regard to the key placement. With W as such a set of attributes and K the primary key of R, the five placements are depicted in the Figure 1: (I) $W \equiv K$ (W coincides with K); (II) $W \equiv Z$, where Z is a subset of non-key attributes; (III) $W \equiv K^1$, where K_1 is a proper subset of K, $K_1 \neq \varnothing$; (IV) $W \equiv K \cup Z$; and finally (V) $W \equiv K_1 \cup Z$, $K_1 \neq \varnothing$ (W and K partially overlap). In all cases, $Z \neq \varnothing$.

As a consequence, 25 possible configurations of $R[W_R] \subseteq S[W_S]$ can be derived (see Table 1). The five cases having $S[W_S]$ as the primary key for S (numbered 1 to 5 in Table 1) correspond to *rir*s.

Semantic Perspective

*Rir*s of types I, II, and III represent typical relationships in semantic models (Abiteboul et al., 1995). Type I depicts subtype relationships; type II corresponds to designative relationships such as 1:1, N:1, or n-ary relationships with at least one 1 cardinality; and type III appears in associative relationships such as N:N, n-ary relationships, and weak entities (Elmasri & Navathe, 2000; Teorey, 1990). *Rir*s of types IV, V, and *id*s deserve a different analysis, as they cannot be derived from a conceptual model. They appear as the specification of well-typified business rules with the semantics of an inclusion in latter stages of the logical design (Rivero, Doorn, & Ferraggine, 2001, 2004).

(II) Non Key (Z_l)	**2.** $Z_l << K_r$	**7.** $Z_l \subseteq Z_r$	**12.** $Z_l \subseteq K_r^1$	**17.** $Z_l \subseteq K_r \cup Z_r$	**22.** $Z_l \subseteq K_r^1 \cup Z_r$
(III) Part of a Key (K_l^1)	**3.** $K_l^1 << K_r$	**8.** $K_l^1 \subseteq Z_r$	**13.** $K_l^1 \subseteq K_r^1$	**18.** $K_l^1 \subseteq K_r \cup Z_r$	**23.** $K_l^1 \subseteq K_r^1 \cup Z_r$
(IV) Key + Non Key ($K_l \cup Z_l$)	**4.** $K_l \cup Z_l << K_r$	**9.** $K_l \cup Z_l \subseteq Z_r$	**14.** $K_l \cup Z_l \subseteq K_r^1$	**19.** $K_l \cup Z_l \subseteq K_r \cup Z_r$	**14.** $K_l \cup Z_l \subseteq K_r^1 \cup Z_r$
(V) Part of a Key + Non Key ($K_l^1 \cup Z_l$)	**5.** $K_l^1 \cup Z_l << K_r$	**10.** $K_l^1 \cup Z_l \subseteq Z_r$	**15.** $K_l^1 \cup Z_l \subseteq K_r^1$	**20.** $K_l^1 \cup Z_l \subseteq K_r \cup Z_r$	**25.** $K_l^1 \cup Z_l \subseteq K_r^1 \cup Z_r$

CHARACTERISTICS AND APPLICATIONS OF REFERENTIAL CONSTRAINTS

A description of main issues about referential constraints and relevant applications of this concept follows.

Referential Actions and Global Semantics

Update operations promote the execution of specialized triggers—the referential actions—for the programmed maintaining of *rir*s. As mentioned, the standard actions are: *cascade, restrict, no action, set null, set default* (Markowitz, 1994; SQL:1999_2, 1999; Türker & Gertz, 2001).

Despite the fact that the local effect of such rules is precisely defined, when update operations are executed on the database state, the global effects of those interacting actions may show ambiguities (Markowitz, 1994; Reinert, 1996; May & Lüdascher, 2002). This problem has been—and currently is—a matter of profuse research from the beginning of the relational databases era. Markowitz (1994) described the anomalies caused by the use of referential actions (in some cases interacting with null constraints) and presented some solutions for its treatment. In addition, Reinert (1996) revised this study and showed that the problem of deciding if a relational schema may or may not have an instance leading to ambiguities is undecidable. The whole understanding of the global behavior of referential actions based on the local characterization of the rules was formalized in May and Ludäscher (2002).

Referential actions for *id*s have not been defined, but they can be inferred from those corresponding to *rir*s. All standard local actions can be directly applied when the deleted (updated) tuple is the one that contains the last instance of a referred value. Naturally, the global effect of these extended referential actions and the interaction with other restrictions must be studied in the context of the coexistence of triggers and declarative restrictions. In other words, it depends on the adherence of each product to the SQL:1999 execution model (Türker & Gertz, 2001).

Inclusion Dependencies and Functional Dependencies: Interaction, Inference Rules, and the Implication Problem

Levene and Loizou (1999) affirm that "the interaction between functional and inclusion dependencies is a complex problem, and there is not a complete and sound system of axioms for functional and inclusion dependencies at all." While some interactions may result in a new (functional or inclusion) dependency being obtained, other cases derive in redundant attributes. Pullback, Collection, and Attribute-Introduction rules capture significant interactions between such restrictions (Levene & Vincent, 2000; Levene & Loizou, 1999). Levene and Loizou (1999) discuss the relational database theory needed to understand the inference rules and the implication problem for *id*s. The axiom systems for *id*s and the interaction between *id*s and functional dependencies were originally introduced in Mitchell (1983) and Casanova, Fagin, and Papadimitriou (1984). Particularly, the pullback rule is one of the mechanisms useful to solve specific schema reengineering cases.

Use of Inclusion Dependencies as Domain Constraints

Some relationships have the semantics of *id*s or *rir*s symbolizing, essentially, domain restrictions that indicate the legal values for an attribute. UofD business rules associated to specific domain restrictions over dynamic and voluminous sets of values are frequently written as *id*s or *rir*s. The right term may be a table containing only the valid values for an attribute or an arbitrary set of columns of another table. For example, CHECK (LeftAttrList IN (SELECT RightAttrList FROM R)) indicates that the set of allowable values for LeftAttrList is conformed by the current set of instances of RightAttrList in R (Rivero et al., 2001, 2004). Naturally, as the specification of this constraint involves a subquery, under certain circumstances it could be violated. This problem was addressed in the Introduction.

Equality Constraint

Like other constraints, equality restrictions embody an important portion of the UofD business logic. An equality constraint between two sets of values is shorthand for two inclusion dependencies, one in either direction. Such a constraint indicates that the population of one column (simple or composite) in a table must always be equal to the values of the corresponding column (simple or composite, respectively) in another table. They would have to be modeled at the conceptual phase, but its specification is often deferred to late stages of the logical design. However, the analysis of the syntactic structures of the equality constraints terms, similar to the one made for the inclusion dependencies, allows the designers to find adequate forms of specification during the conceptual design. In addition, the study of inclusion dependencies helps to comprehend relevant issues of the equality constraints as they express comparability of domains for two different sets of attributes (Halpin, 1998; Rivero et al., 2004).

Basis for the Database Reengineering

This application is strongly related to the previous two issues, as inclusion dependencies and equality constraints enable different kinds of schema transformations. The structure of the left and right terms of *id*s is a key concept for the reengineering of relational database schemas. *Rir*s of types IV and V, and all cases of *id*s reveal specific business logic specified as inclusion relationships. A careful examination of the structure of these constraints allows the transformation of a subject schema into an enhanced one by applying the pullback rule, specific heuristic methods, and/or refinements of the final product (Tari, Buhkres, Stokes, & Hammoudi, 1998; Rivero et al., 2001, 2004). With respect to the equality constraints, the reiterated application of such restructuring mechanisms helps finding design patterns that can be captured with the standard facilities provided by any CASE tool for the relational conceptual design.

Referential Integrity in Object-Oriented and Object-Relational Databases

From its beginnings, relational technology has experienced a fantastic process of evolution to finally become a mature environment. Main commercial and open source software offer referential constraints and triggers to maintain referential integrity, even though support for SQL:1999 characteristics for referential integrity varies by product.

Referential integrity is a concept that also applies to post-relational environments. Object-oriented (OO) literature typically uses the term "relationship" to mean relationships supported by foreign keys in a relational system. This implementation may be used in an object-relational DBMS (ORDBMS) as well (Stonebraker, 1999). Object-relational (OR) systems, in compliance with the current standard—SQL:1999—provide the *reference* as a natural surrogate for primary key-foreign key relationships. In these systems, a column in a table may contain a value that is a *reference* to an instance of a type stored in another table. This implementation is supported by the unique object identifier (*oid*) of rows (SQL:1999-2).

This is a pragmatic implementation since the user has no way to update or generate unintentionally *oid*s. In this way, the system can guarantee the referential integrity since a reference is valid when it is created. On the other hand, being able to perform delete operations raises the problem of the integrity of the references. Referential actions, defined in the relational context, must be efficiently implemented in the OR and OO context. Different strategies suggest implementing integrity rules following the principles of the relational side of ORDBMS. Others, coming from the OO technology, recommend the implementation following the business logic—that is, within the objects.

There are three standard maintenance strategies: (a) the reference can be deleted, by placing null in the reference pointer; (b) the deletion of the object could be rejected if it is referenced by other objects, or (c) the referencing object could be deleted as well. Other solutions could be implemented to cope with the problem of dangling references: to allow delete operations freely (causing exceptions whenever the deleted object is being referenced) or a reference count (an object could not be deleted unless its reference count is zero).

As mentioned, programming code (triggers) for referential integrity is an alternative to the use of foreign key constraints, even though these ones are preferable to explicit triggers since they are declarative, more concise, and then more productive (Blaha, 2005). The decision about the choice of the best strategy taking into account the structure of relations, their variability, and other performance issues pose a challenging research area.

FUTURE TRENDS

Referential integrity concepts have usually been associated to implementation issues in databases. However, referential integrity has a deeper meaning related to dependencies among objects (Blaha, 2005) and makes this concept applicable to modeling methodologies. Moreover, modern software development works with languages that implement classes and their relationships; as a consequence, application programs must deal with referential integrity as well.

While OO programming and semantic models are now the standard for best developers and programmers, OO databases constitute just a small portion of the market, albeit they have gained popularity in the last few years. One of the reasons why the OO paradigm has been adopted to extend the relational technology is because it allows developers to cope with the growing capacity of current software development. Consequently, the OO paradigm has been the basis for current research on models that integrate the relational data model and SQL query languages with features coming from the object-oriented world. The result of this integration is the current generation of OR database systems (ORDBMS), which emerged in the last decade (Stonebraker, 1999). As mentioned, this evolution has posed new challenges related to the referential integrity maintenance.

The degree of distribution and heterogeneity of the DBMS and the variety of data that current DBMSs can manage are two of the current directions of developments and advances in DBMS technology. With respect to the first issue, the definition and implementation of a consistency checking service is particularly difficult whenever data is stored in a heterogeneous collection that is not controlled by a single DBMS (Hamidah, 2005).

On the other hand, multimedia databases (Dunckley, 2002), spatio/temporal databases (Rodríguez-Tastets, 2005),

XML databases (Graves, 2001), and active databases (Zaniolo et al., 1997; Paton & Diaz, 1999) are recent examples that illustrate the variety of data information that a DBMS should be able to manage. Efficient implementation of integrity issues and mainly referential integrity constraints to deal with heterogeneous data sources in centralized or distributed environments represent a challenge and a promising research area.

The World Wide Web, lacking specific guidelines to enforce referential integrity (Aldana, Yagüé, & Gómez, 2002), and newer multilevel security strategies posing a different scenario to the integrity maintenance (Lee, Kim, & Kim, 2004); digital libraries (Martínez-González, 2005) and the recent development of applications and DBMSs for mobile databases (Pitoura & Samaras, 1998)—all have given rise to interesting challenges and research opportunities in the area of database management and particularly in the area of data consistency.

CONCLUSION

This work presents an overview of main issues and applications of inclusion dependencies and the particular case of referential integrity restrictions. Some topics related to its structure and semantics have been sketched. Relevant results related to both inclusion dependencies interacting with functional dependencies and the application of these concepts in the context of database reengineering have been outlined.

Atypical behaviors promoted by design flaws should encourage users to consider referential constraints not only as merely integrity constraints but also as the basis for a good practice on database design. With respect to this problem, recent findings in the context of object-oriented applications, reengineering patterns, and modern software development theory were briefly explained.

Finally, current and future directions of database evolution are succinctly mentioned to describe the scenarios in which the integrity issues must mature.

KEY TERMS

Axiom System for Inclusion Dependencies: Set of inference rules that axiomatize *id*s. Let **ID** be a set of *id*s over a database schema $\mathbf{R} = \{R_1, R_2, \ldots, R_k\}$, **FD** a set of functional dependencies over **R**, and $sch(R_i)$ the set of attributes of R_i:

(id-1) Reflexivity: If $X \subseteq sch(R_i)$, then $R_i[X] \subseteq R_i[X] \in \mathbf{ID}$.

(id-2) Projection and Permutation: if $R_1[X] \subseteq R_2[Y] \in \mathbf{ID}$, with $X = < A_1, A_2, ..., A_m > \subseteq sch(R_1)$, $Y = < B_1, B_2, ..., B_m > \subseteq sch(R_2)$, and $i_1, i_2, ..., i_k$ is a sequence of distinct natural numbers over {1, ..., m}, then $R_1[A_{i_1}, A_{i_2}, ..., A_{i_k}] \subseteq R_2[B_{i_1}, B_{i_2}, ..., B_{i_k}] \in \mathbf{ID}$.

(id-3) Transitivity: If $R_1[X] \subseteq R_2[Y]$; $R_2[Y] \subseteq R_3[Z] \in \mathbf{ID}$, then $R_1[X] \subseteq R_3[Z] \in \mathbf{ID}$.

Axiom System for the Interaction Between Inclusion and Functional Dependencies: Comprises the following three inference rules:

(if-1) Pullback: If $R_1[X,Y] \subseteq R_2[U,V]$; $R_2: U \rightarrow V \in \mathbf{FD} \cup \mathbf{ID}$, with $X,Y \subseteq sch(R_1)$ and $U,V \subseteq sch(R_2)$, then $R_1: X \rightarrow Y \in \mathbf{FD} \cup \mathbf{ID}$, where $|X|=|U|$.

(if-2) Collection: If $R_1[X,Y] \subseteq R_2[U,V]$; $R_1[X,Z] \subseteq R_2[U,W]$; $R_2: U \rightarrow V \in \mathbf{FD} \cup \mathbf{ID}$, then $R_1[X,Y,Z] \subseteq R_2[U,V,W] \in \mathbf{FD} \cup \mathbf{ID}$, where $|X|=|U|$.

(if-3) Attribute Introduction: If $R_1[X] \subseteq R_2[U]$; $R_2: U \rightarrow W \in \mathbf{FD} \cup \mathbf{ID}$, then $R_1[X,Z] \subseteq R_2[U,W] \in \mathbf{FD} \cup \mathbf{ID}$, with Z an attribute newly added to $sch(R_1)$.

Business Rules: Statements that model the reaction to events that occur in the real world, having tangible side effects on the database content.

Database Schema Reengineering: The process of analyzing a subject database schema to recover its components and their relationships. It guides the reconstitution of such a system into one with a higher level of abstraction and semantically closer to the Universe of Discourse.

Equality Constraint: Shorthand for two inverse inclusion dependencies, $R[X] \subseteq S[Z]$ and $S[Z] \subseteq R[X]$. It can be specified as $R[X]=S[Z]$ (the populations of the attributes R.X and S.Z must always be equal).

Inclusion Dependency (*id*): The existence of attributes in a relation whose values must be a subset of the values of the corresponding (compatible) attributes in another (or the same) relation: $R[X] \subseteq S[Z]$. R and S are relation names (possibly the same); R[X] and S[Z] are the left and right sides, respectively.

Referential Action: Specific reactions to compensate referential integrity violations. SQL:1999 standard defines *Cascade*, *Restrict*, *No Action*, *Set Default*, and *Set* Null actions explicitly for referential integrity restrictions.

Referential Integrity Restriction (*rir*): Particular case of an inclusion dependency, when Z is the primary key K of S: R[FK]<<S[K]. X constitutes a foreign key FK for R.

Relating Cognitive Problem–Solving Style to User Resistance

Michael J. Mullany
Northland Polytechnic, New Zealand

INTRODUCTION

This chapter explores cognitive problem-solving style and its impact on user resistance, based on the premise that the greater the *cognitive difference* (*cognitive gap*) between users and developers, the greater the user resistance is likely to be. Mullany (1989, 2003) conducted an empirical study demonstrating this. This study contradicts the findings of Huber (1983) and supports Carey (1991) in her conclusion that cognitive style theory, as applied to IS, should not be abandoned. Mullany's findings, in fact, are the opposite. Kirton (1999, 2004) supported Mullany's results. In particular, Mullany made use of Kirton's (2004) adaption–innovation theory. The emergent instrument, called the Kirton adaption–innovation inventory (KAI; Kirton, 1999, 2004), was used by Mullany as his measure of cognitive style.

Mullany's study also investigated the relationship between user resistance and user ages and lengths of service in the organisation. It failed to show any relationship between these factors and user resistance. This countermands the findings of Bruwer (1984) and dismisses any intimation that older or longer-serving employees are necessarily more resistant to change as myths.

BACKGROUND

Ever since the early 1980s, experts have identified user resistance to new systems as an expensive time overhead (see studies by Hirschheim & Newman, 1988, and Markus, 1983). Some authors suggest the greater importance of age and length of service. Bruwer (1984), for instance, claimed to have demonstrated that the older or longer-serving an employee, the more resistant he or she is likely to be to a new computer system. Clarification of issues surrounding user resistance has also highlighted *cognitive style theory* as potentially important, but to date, its impacts have only been sparsely researched in relation to user resistance, many of the prior studies being open to question. This research, on the other hand, proposes that a system will fail when the developer and user differ significantly in their problem-solving approaches. To reduce user resistance, it thus makes sense to recommend system designs that suit the user's approach to problem solving.

This issue appears only to have been studied empirically by Mullany (1989, 2003). He formulated the research question, "Is there a relationship between user resistance to a given information system and the difference in cognitive style between the user and the developer?" With the aid of his own instrument for measuring user resistance and the Kirton adaption–innovation instrument (Kirton, 1999) to measure the cognitive styles of users and associated system developers, he found a highly significant relationship between developer–user cognitive style differences and the level of user resistance to systems.

Why no other studies along similar lines have been reported in credible current research is difficult to explain. One possibility is that the literature contains speculative studies, such as that by Huber (1983), that discredit cognitive-style theory as a tool in understanding system success. Other studies, such as that by Carey (1991), while encouraging the continued use of cognitive-style theory in studying system phenomena, do not demonstrate its predictive success in information systems (IS). The remainder of this chapter thus examines the meaning and measure of cognitive style, the measure of user resistance, the specific findings of Mullany (1989, 2003), and outlooks for the future in this area of research.

THE MEANING AND MEASURE OF COGNITIVE PROBLEM-SOLVING STYLE

Liu and Ginther (1999) defined *cognitive style* as, "An individual's consistent and characteristic predispositions of perceiving, remembering, organizing, processing, thinking and problem-solving." Schroder, Driver, and Streufert (1967), in a discussion of human information processing, suggested that organisms "either inherit or develop characteristic modes of thinking, adapting or responding and go on to focus upon adaptation in terms of information processing." In short, an individual exhibits characteristic ways of processing information (and, hence, solving problems), known as his or her "cognitive style." Table 1 gives an historic summary of key experts over the years who have endeavoured to name and measure the construct of cognitive style. Of these, the MBTI (Myers–Briggs type indicator) is the most used in current, credible research literature, followed by the KAI

Table 1. Cognitive-style constructs: Key studies

Reference	Cognitive-Style Construct	Instrument
Kelly (1955)	Cognitive complexity or simplicity	**RepGrid** (Repertory grid)
Jung (1960)	Jungian typology	**MBTI** (Myers–Briggs type indicator)
Witkin et al. (1967)	Field dependence or independence	**EFT** (Embedded figures test)
Hudson (1966)	Converger or diverger	None
Schroder et al. (1967)	Cognitive complexity	**DDSE** (Driver's decision-style exercise)
Ornstein (1973)	Hemispherical lateralisation	Brain scan
Kirton (1976)	Adaptor–innovator continuum	**KAI** (Kirton adaption–innovation inventory)
Taggart (1988)	Whole-brain human information processing	**HIP** (Human information-processing instrument)

(Kirton, 1976, 1984). As previously stated, the only evident effort made to relate cognitive style to user resistance was carried out by Mullany (1989) using the KAI. The reason for his preferred use of the KAI stemmed from its ability to provide a near-continuous, bipolar scale, convenient for finding correlations and associations. The MBTI, by contrast, yields only certain cognitive classifications, where no mutual order is evident. The correlation with other factors would then have been more difficult to show statistically.

Turning to the theory behind the KAI, Kirton (1999) identified two extremes of cognitive style; namely, the *adaptor* and the *innovator*. The adaptor tends to follow traditional methods of problem solving, while the innovator seeks new, often unexpected, and frequently less-accepted methods. The adaptor tends to "do well" within a given paradigm, where the innovator tends to "do differently," thus transcending accepted paradigms. The adapter is prepared to be wedded to systems, solving problems "in the right way," but is often seen as "stuck in a groove." The innovator has little regard for traditions, is often seen as creating dissonance, and elicits comments such as, "He wants to do it his own way, not the 'right' way." All humans, Kirton proposed, can be located on a continuum between the extremes of these two cognitive styles.

Both cognitive extremes can be highly creative, can resist change, and can act as agents for change. Adaptors support changes to the conservative, back to the "good old ways," and resist changes to novel methodologies. Innovators support changes toward unprecedented systems and technologies and resist changes to the traditional.

Kirton's instrument, the KAI, has been widely demonstrated to be a successful measure of his construct of cognitive problem-solving style. The instrument takes the form of a questionnaire, on which the respondent has to rate himself or herself against 33 character traits. KAI scores can range from 32 to 160, with a mean of 96 and a standard deviation of about 16. A person scoring above the mean of 96 is considered to be an innovator; conversely, a person scoring below 96 is rated as an adaptor. However, in the range of 80 to 112 (that is, within one standard deviation of the mean), a third cognitive style can be identified—the mid-scorer. Such persons tend to have human rather than technical problem-solving preferences and can relate better to the extreme scorers than either can to the other.

A DESCRIPTION AND MEASURE OF USER RESISTANCE

Mullany (1989) measured user resistance at personal interviews with the key user of each system selected for investigation. The user was asked to list the problems that he or she recalled had occurred during the system's development and implementation. They were asked, in effect, to make complaints, in confidence, against the system and its manner of implementation. Then they were requested to rate the severity of each complaint on a seven-point scale (with seven representing the most severe weighting). The sum of severities of all the complaints measured the respondent's

resistance score or *R-score*. Obvious criticisms of the R-score method are as follows:

1. It may be highly influenced by the cognitive style of the interviewer.
2. At an interview, the user might forget certain crucial problems that had been experienced.

Mullany refuted (1) on the grounds that the same person (himself) did all the interviewing in his study. He assumed (2) to be of limited impact, because the object of the R-score method is to observe the user in the process of complaining. Consequently, the resistant user is capable of exaggerating or even inventing complaints, making the issue of those forgetten less relevant. However, he conceded the limitation that there are covert forms of resistance, such as absenteeism and withdrawal, that are not necessarily related to overt complaints.

To investigate a relationship between cognitive-style differences and user resistance, Mullany (1989) set out to collect data from a suitable sample of computer system developers and users. Bivariate data were to be collected, namely, the analyst–user KAI difference and the R-score for each user. The association between these was then to be measured. For his association measure, he used both the Kendall-*t* and the more traditional Spearman-*r*, which are equally reliable for significance testing (Liebetrau & Kendall, 1970). According to Kendall (1970; who invented the Kendall-*t* measure of association) and as confirmed by Liebetrau (1983), sample sizes of 10 to 20 are sufficient for such tests. The author thus selected a much larger sample size of 34 systems in 10 South African organizations. However, the following further criticisms were identified and addressed:

1. The sample size is small compared with some other studies in IS.
2. A user who champions a system may point out deficiencies in the hopes of improving that system.

Referring to the first of these criticisms, one should be alerted to the fact that sample representivity is more important than size in obtaining reliable results. In fact, the larger the sample, the less the researcher is likely to be able to guarantee a lack of significant bias. For example, suppose that with the aid of a suitable instrument, one sets out to measure the diligence of some human population. If a large sample size is sought through a postal, Web-based, or e-mail survey (the only practicable methods for really large samples), only the most diligent respondents are likely to respond, giving a bias to the more diligent and, thus, casting serious doubt on the results. To reduce this effect, Mullany (1989) collected all the data at personal interviews with the analysts and users. Furthermore, organisations he approached were requested to provide a fair spread of systems in use. He thus used legitimate power lent to him by the organisations to interview those as he required.

The second criticism was addressed by obtaining approval to keep all employees' responses confidential and to make this clear at each interview. This meant that a user would be unlikely to complain to Mullany in the hopes of achieving some system improvement, as he or she knew that no information would be relayed to the rest of the organisation. Every effort was made to preserve standard interviewing conditions: these being freedom from pressure or interruption and complete assurance of confidentiality. In short, interviewing conditions similar to those of face-to-face counselling were achieved. Furthermore this technique of measuring user resistance has been confirmed by respected researchers. First, both Markus (1983) and Hersheim et al. (1988) identified complaint as an overt symptom of, if not even a form of, resistance. Kirton (2004), in a discussion of Mullany's study, confirmed the technique as valid.

THE RELATIONSHIP BETWEEN USER RESISTANCE AND THE DIFFERENCES IN COGNITIVE STYLES BETWEEN THE USER AND THE DEVELOPER

The key developer and key user of each were interviewed. In each case, measures were obtained for the developer KAI score, user KAI score, and user R-score. At the same time, demographic data were collected; most particularly, the ages and lengths of service of the respondents, in order to test the findings of Bruwer (1984). A relationship as an association was found for the user R-scores versus the absolute differences between developer and user KAI scores. The association (with $p < 0.005$) proved to be strong, suggesting that user resistance can be minimized by matching a user with a developer of similar cognitive style. However, no significant associations were found between the ages and lengths of service of users and their R-scores, in contradiction of Bruwer's (1984) results. Rosen and Jerdee's (1976) study, which sought a similar result for occupational groups in general, agrees with Mullany's findings in this respect.

An interpretation of the R-score was demonstrated based on a near-perfect direct proportion that proved to exist between the weighted and nonweighted numbers of the users' complaints. In this relationship, the constant of proportionality was found to be 3.913 (that is, nearly 4). The R-score can thus be described as approximately four times the number of complaints a user will make retrospectively, in private, concerning a system and its manner of implementation.

FUTURE TRENDS

This study reignites the issue of cognitive style as an important issue in IS and completely countermands the conclusions of Huber (1983). It substantially strengthens the case made by Carey (1991) that cognitive-style issues in IS research should not be abandoned. Further, it suggests that user resistance and the related constructs of user dissatisfaction and system success can be predicted from cognitive-style measures (that is, KAI scores) prior to system development.

Areas for further research centre upon the main limitation of this study. For instance, there is little known regarding how the developer-user cognitive gap influences the system development life cycle (SDLC) over a significant passage of time, and neither this study nor any other found in the literature has achieved this. In fact, the literature is devoid of any attempts to conduct such research. A longitudinal study where SDLC curves are compared with the developer-user cognitive gap would be of immense importance and interest. New rules for system development based on cognitive-style testing would be expected to emerge.

CONCLUSION

It is clear that cognitive problem-solving style, as defined by Kirton and measured using the KAI, impacts user resistance. The greater the cognitive gap between users and developers, the greater the user resistance is likely to be. This contradicts the findings of Huber (1983) and supports Carey (1991) in her conclusion that cognitive-style theory, as applied to IS, should not be abandoned. Mullany's findings, in fact, are the opposite.

The failure to show any relationship between users' ages and lengths of service, and their resistance ratings, countermand the findings of Bruwer (1984) and suggest that organisations should be alerted to the danger of discriminating against older or longer-serving users or dispensing with their services on such grounds.

As mentioned above, areas for further research centre upon the main limitation of this study. A longitudinal study where SDLC curves are compared with the developer–user cognitive gap would be of great importance and interest.

KEY TERMS

Adaptor: An adaptor tends to follow traditional methods of problem solving, tending to "do well." He or she is often seen as "stuck in a groove" (Kirton, 1999).

Association: A relationship between two statistical variables. Unlike a *correlation*, an association does not yield a quantitative result but is contingent upon the ranking of the bivariate data values only.

Cognitive Gap: The difference in cognitive problem-solving style between two people, especially two people who are obliged to interact as members of a group or team.

Cognitive Problem-Solving Style: The position an individual occupies between two extremes of cognitive problem-solving style personality; namely, *the adaptor* and *the innovator*.

Cognitive Style: An individual exhibits characteristic ways of processing information and, hence, solving problems, known as his or her "cognitive style."

Innovator: The innovator seeks new, often unexpected, and frequently less acceptable methods. He or she has little regard for traditions, is often seen as creating dissonance, and elicits comments such as, "He wants to do it his own way, not the 'right' way" (Kirton, 1999).

KAI (Kirton Adaption-Innovation Inventory): An instrument that measures cognitive problem-solving style. It takes the form of a questionnaire, on which the respondent is asked to rate himself or herself against 32 character traits.

R-Score (Resistance Score): A method of measuring user resistance where, at personal interviews with the key user of a given system, the user is asked to list system problems and then to rate the severity of each on a seven-point scale. The sum of severities of all the complaints measures his or her *R-score* (Mullany, 1989).

User Resistance: Any user behaviour, action, or lack of action that inhibits the development, installation, or use of an information system.

Reliability Growth Models for Defect Prediction

Norman Schneidewind
Naval Postgraduate School, USA

INTRODUCTION

In order to continue to make progress in software measurement as it pertains to reliability, there must be a shift in emphasis from design and code metrics to metrics that characterize the risk of making requirements changes. By doing so, the quality of delivered software can be improved because defects related to problems in requirements specifications will be identified early in the life cycle. An approach is described for identifying requirements change risk factors as predictors of reliability problems. This approach can be generalized to other applications with numerical results that would vary according to application.

BACKGROUND

Several projects have demonstrated the validity and applicability of applying metrics to identify fault prone software at the code level (Khoshgoftaar & Allen, 1998; Khoshgoftaar, Allen, Halstead, & Trio, 1996a; Khoshgoftaar, Allen, Kalaichelvan, & Goel, 1996b; Schneidewind, 2000). This approach is applied at the requirements level to allow for early detection of reliability and maintainability problems. Once high-risk areas of the software have been identified, they would be subject to detailed tracking throughout the development and maintenance process (Schneidewind, 1999).

Much of the research and literature in software metrics concerns the measurement of code characteristics (Nikora, Schneidewind, & Munson, 1998). This is satisfactory for evaluating product quality and process effectiveness once the code is written. However, if organizations use measurement plans that are limited to measuring code, the plans will be deficient in the following ways: incomplete, lack coverage (e.g., no requirements analysis and design), and start too late in the process. For a measurement plan to be effective, it must start with requirements and continue through to operation and maintenance. Since requirements characteristics directly affect code characteristics and hence reliability, it is important to assess their impact on reliability when requirements are specified. As will be shown, it is feasible to quantify the risks to reliability of requirements changes—either new requirements or changes to existing requirements.

Once requirements attribute that portend high risk for the operational reliability of the software are identified, it is possible to suggest changes in the development process of the organization. To illustrate, a possible recommendation is that any requirements change to mission critical software—either new requirements or changes to existing requirements--would be subjected to a *quantitative* risk analysis. In addition to stating that a risk analysis would be performed, the policy would specify the risk factors to be analyzed (e.g., number of modifications of a requirement or *mod level*) and their threshold or critical values. The validity and applicability of identifying critical values of metrics to identify fault prone software at the code level have been demonstrated (Schneidewind, 2000). For example, on the space shuttle, rigorous inspections of requirements, design documentation, and code have contributed more to achieving high reliability than any other process factor. The objective of these policy changes is to prevent the propagation of high-risk requirements through the various phases of software development and maintenance. The payoff to the organization would be to reduce the risk of mission critical software *not* meeting its reliability goals during operation.

Definitions

- **D_{ir}:** *Cumulative* defects (e.g., discrepancy reports: program executes incorrect path due to excessive requirements conflicts), corresponding to risk variable r during operating time interval i.
- **r_i:** Requirements risk (e.g., risk of excessive size, excessive conflicting issues)
- **rmin:** Minimum value of r_i
- **rmax:** maximum value of r_i

Risk Variables:

- **Sloc:** *Cumulative* source lines of code (sloc): number of source lines of code written for a Shuttle release.
- **Issues:** *Cumulative* number of possible conflicts among requirements (e.g., an aggregation of requirements to provide greater Shuttle thrust conflicts with the fact that more thrust requires more engine weight). An aggregation of conflicting requirements issues causes reliability risk.
- **t:** Operating time (e.g., execution, wall clock, calendar time)

- **t_c:** Critical value of t = maximum value of t
- **i:** Operating time interval
- **a and b:** Coefficients of D_{ir} obtained through regression analysis
- **Decision maker:** Software quality control manager

Research Ideas on Models

Models are representations of states, objects, and events. They are less complicated than reality, hence easier to use. This is due to the fact that only relevant properties are included in the model, as explained by Ackoff, Gupta, & Minas, 1962).

Models of Problem Situations (Ackoff et al., 1962)

$V = f(X_i, Y_j)$, where

V = measure of the value of the decision that is made (i.e., action that is taken)

Example: Probability that software will survive for an operational time > t (i.e., reliability R (t))

X_i = the variables that are subject to control by the decision. The decision variables define alternative courses of action.

Example: amount of time T allocated to testing software

Discrete or continuous decision variables

Example: $D_{ri} = a\ r_i^b$ has the continuous variable defect count D_{ri}

Y_j: the factors (variable or constant) that affect performance, which may or may not, be subject to control by the decision maker. These are called parameters.

Example: Failure rate parameters α and β in reliability model

f = functional relationship between independent variables and parameters X_i and Y_j and dependent variable V.

Example: $D_{ri} = a\ r_i^b$

A model has two essential characteristics: At least one of the decision variables X_i is subject to control by the decision maker.

Example: Amount of time T allocated to testing software Second, the value V must be a measure of alternative courses of action.

Example: Probability that software will survive for an operational time > t (i.e., reliability R (t)). The decision maker sets the value of t, and, hence, the value of R (t).

Models with the above properties are called decision models.

Some models contain constraints:

Example: R (t) > R* (t), where R* (t) is the minimum allowable reliability.

Models as approximations of the real world

Therefore, we start with a small and simple defect prediction model and build upon this to achieve more complex and accurate models.

Churchman, Ackoff, and Arnoff, (1957) offers the following advice concerning how to view models:

Viewed generically, a model is a representation of some subject of inquiry such as a process, like the software defect reduction process. The model is used for prediction (e.g., predict defect count as a function of risk variables) and control (i.e., control software quality by managing defect occurrence). The primary purpose is explanatory rather than descriptive. For example, we could want to show how defect count varies as a function of risk variables and operating time interval. A great advantage of such models is the ability to manipulate the model without having the change the system that is being modeled. Thus, we would not want to change the software quality control system just to experiment with how defects vary with requirements risk! Rather, we might change the system depending on the results of our model experiments.

Box, Hunter, and Hunter (1978) states the following with respect to experimental model building:

1. The experimenter must construct a flexible model, subject to change, in case the model assumptions turn out to be erroneous. For example, we may find that defect count does not vary exponentially with requirements risk variables. With this outcome, we want a model that could be changed easily, for example, to a linear model.
2. Frequently, the mechanism underlying the model is not completely understood, or is too complicated, to allow an exact model to be postulated from theory. In this case, a simplified model with a response over a limited range of the variables is appropriate.

The manner in which defects occur is a complicated process involving the complexity of software requirements, quality of personnel, the quality of the software development process, and the nature of the application and its operating environment. Therefore, obviously, a simple model like $D_{ri} = a\, r_i^{b}$, which is only a function of requirements risk, cannot possibly capture all of the foregoing attributes. However, before we rush to judgment about simple models, we must be cognizant of the fact that if a model is too complex, it will be difficult to use and understand. Furthermore, there is the principle of *surrogate* variables that can substitute for the variables of interest. This principle is illustrated by requirements risk substituting for complexity of requirements in our model.

Hillier and Lieberman (2001) state the following principles for model development:

1. It is important to validate the model before it is put into practice. One check is to ensure that the variables and parameters have consistent dimensions, as recommended by For example, in the defect count model, Dri = a rib, where Dri has the dimension of defects and ri has the dimension, for example, of sloc, a must have the dimension of defects per sloc and b must be a dimensionless parameter.
2. Additionally, the model builder should try extreme values of the variables on the model—outside the range of the collected data—to test the reaction of the model to these outliers.

An example would be to try extremely large values of the risk variables *sloc* and *issues* and see whether the predictions of D_{ri} are plausible. The most important validation method is to compare model predictions against *future* actual values. For example, we would want to compare predictions produced by $D_{ri} = a\, r_i^{b}$ with *actual defect count* in time interval greater than the range of *i* for estimating the parameters a and b. This is not to suggest that *retrospective* testing is not valuable. It is only to urge that model builders not assume that because they obtain a good fit with historical data that the model is valid. Unfortunately, such "validation" will only be legitimate to the extent that the future is like the past!

Objective of Research

We have several objectives in this research. One is to suggest a methodology for software reliability development using templates designed by researchers in the field operations research and statistical modeling, as described in the foregoing section.

Another objective is to develop and demonstrate a new model for predicting risk (i.e., probability that defect counts exist on a release), as a function of risk variables. To develop and evaluate this model, we use defect and risk data from the NASA Space Shuttle Flight Software. We build upon our previous research, Schneidewind (2005), to develop predictors of risk (e.g., discrepancy report counts on a release), as a function of risk variables (sloc and issues). These predictors are significant because, with them, the risk to reliability of making requirements changes can be predicted early, when the cost and effort of correcting problems is low.

Desirable Properties of Model

Application of Ackoff et al. (1962) to the Defect Modeling Problem

Models are representations of states, objects, and events. They are less complicated than reality, hence easier to use. This is due to the fact that only relevant properties are included in the model.

$V = f(X_i, Y_j)$, where

V = measure of the value of the decision that is made (i.e., action that is taken)

An example of V is defect count D that is a measure of the quality of the software that would result from reduction D.

X_i = the variables that are subject to control by the decision maker. The decision variables define alternative courses of action.

Continuing the example, X_i could represent the controllable variable r_i, the risk variable i, which could be, for example, requirements risk such as Sloc: *cumulative* source lines of code and issues: *cumulative* number of possible conflicts among requirements. In this example, the r_i are continuous decision variables.

Now, consider the Y_j factors, which in our case, are the parameters a_i and b_i. These are under the control of the decision maker because their values would be obtained from regression analysis, using the r_i risk variables (i.e., X_i variables).

f = functional relationship between independent variables and parameters X_i and Y_j and dependent variable V.

Example: $D_{ri} = a\, r_i^{b}$, which expresses the dependence of defect count D_{ri} on the risk variables r_i.

Objective of Defect Count Metric

The defect count metric $D_{ri} = a\, r_i^{b}$ should be able to predict D_{ri} within the confidence intervals, as given by equation, with a specified α (.01):

$$(\bar{D}_{ri} - Z_\alpha S) \le D_{ri} \le (\bar{D}_{ri} + Z_\alpha S)$$

$$S = \sqrt{\sum_{i=1}^{N} \frac{(D_{ri} - \bar{D}_{ri})^2}{N-1}} \qquad (0.1)$$

Looking at Figure 1, it can be seen that this objective is satisfied.

Constraint of Defect Count Metric

There is a constraint levied on D_{ri}:

The objective $(\bar{D}_{ri} - Z_\alpha S) \le D_{ri} \le (\bar{D}_{ri} + Z_\alpha S)$ must be achieved in an operating time $t < t_c$

Figure 1 shows that constraint 1) is satisfied.

FUTURE TRENDS

Reliability predictions that are made in the test phase, when failure data are available, are useful, but it would be more useful to predict at an earlier phase--preferably during requirements analysis—when the cost of error correction is relatively low. Thus, there is great interest in the software reliability and metrics field in using static attributes of software in reliability modeling and prediction. Presently, the software engineering field does not have the capability to make early predictions of reliability problems. Early predictions would allow errors to be discovered and corrected when the cost of correction is relatively low. In addition, early detection would prevent poor quality software from getting into the hands of the user. As a future trend, the focus in research and practice will be to identify the attributes of software requirements that cause the software to be unreliable.

CONCLUSION

Risk factors that are statistically significant can be used to make decisions about the risk of making changes. These changes affect the reliability of the software. Risk factors that are not statistically significant should not be used; they do not provide useful information for decision-making and cost money and time to collect and process. This methodology can be generalized to other risk assessment domains, but the specific risk factors, their numerical values, and statistical results may vary.

KEY TERMS

Failure: The inability of a system or component to perform its required functions within specified performance requirements.

Metric: A quantitative measure of the degree to which a system, component, or process possesses a given attribute.

Quality: The degree to which a system, component, or process meets specified requirements.

Reliability: The ability of a system or component to perform its required functions under stated conditions for a specified period of time.

Requirement: A condition or capability needed by a user to solve a problem or achieve an objective.

Risk: The chance of injury, damage, or loss.

Representational Decision Support Systems Success Surrogates

Roger McHaney
Kansas State University, USA

INTRODUCTION

Rapid and frequent organizational change has been a hallmark of business environments in the past two decades. Frequently, technology and new software development are embraced as aspects of complex strategies and tactical plans. Without sufficient analysis, the unforeseen consequences of change can result in unexpected disruptions and the loss of productivity. In order to better control these contingencies, modern managers often employ a variety of decision support aids. One such aid, classified as a representational decision support system, is discrete event simulation (DES).

BACKGROUND

In its purest form, DES is considered to be a branch of applied mathematics. Its considerable popularity is due in part to the availability of computers and improvements in simulation languages and simulator software packages. DES is often the technique of choice when standard analytical or mathematical methodologies become too difficult to develop. Using a computer to imitate the operations of a real-world process requires a set of assumptions taking the form of logical relationships that are shaped into a model. These models assess the impact of randomly occurring events. Experimental designs are developed and the model manipulated to enable the analyst to understand the dynamics of the system. The model is evaluated numerically over a period of time, and output data are gathered to estimate the true characteristics of the actual system. The collected data are interpreted with statistics allowing formulation of inferences as to the true characteristics of the system. Table 1 lists primary features of a DES application.

While the value of DES in organizational settings has been accepted and is evidenced by the varied and growing market of related products, not every DES application is suited for every problem domain. For this reason, information systems researchers have worked to identify salient characteristics of DES and its usage, and then measure the relationship between its application and successful organizational outcomes. These studies have been conducted in different ways with focuses on independent and dependent variables.

INDEPENDENT VARIABLE RESEARCH

Much DES research has focused on identifying and evaluating software and project characteristics (independent variables) and then producing recommendations that suggest either how a project can be successfully implemented or how failure can be avoided. A variety of useful practitioner-focused articles have been published in this area (Hlupic & de Vreede, 2005; Swain, 2003). These studies provide recommendations, based in part on first hand experience, of consultants and simulation analysts. In many cases, these recommendations list the packages currently available and focus on the pros and cons of each.

Academic studies of independent variables have also been conducted. In one of the first studies using information systems as a basis for DES, McHaney and Cronan (2000) extended a framework of general decision support system (DSS) success factors identified by Guimaraes, Igbaria, and Lu (1992). The developed contingency model was theoreti-

Table 1. DES features

Feature	Description
Statistics Collection	Tools that gather data for purposes of inferential statistics about the model
Resource Modeling	A means for the representation of a constrained resource in the model
Transaction	A means for representation of the participants in the simulation model
Simulation Clock	Tools for analysis and step processing of the coded model
Random Number Generators	A means for producing random number streams for randomization of events within the simulation model
Model Frameworks	Generalized frameworks for the rapid development of a model

Table 2. List of DES success factors

Factor 1: Software Characteristics
Factor 2: Operational Cost Characteristics
Factor 3: Software Environment Characteristics
Factor 4: Simulation Software Output Characteristics
Factor 5: Organizational Support Characteristics
Factor 6: Initial Investment Cost Characteristics
Factor 7: Task Characteristics

cally derived from the simulation literature and empirically tested. The results indicated a seven-factor model that was structured as shown in Table 2.

Academic research by Robinson (1999) approached the problem from the opposite perspective and identified sources of simulation inaccuracy that may result in project failure. Other studies, such as one by McHaney and White (1998), developed a DES software selection framework that matched salient DES characteristics with software package features. The importance of evaluation and selection of appropriate DES packages were determined in relation to the success of simulation implementation. As might be expected, the choice of the wrong simulation package often correlated with simulation system failure. This study provided a set of criteria to be systematically considered when evaluating DES software. The taxonomy for simulation evaluation together with importance ratings provided by the collective expertise of a large number of DES users were used as guidelines in deciding the relative weighting to give various software package capabilities.

Other research (McHaney, White, & Heilman, 2002) attempted to develop an understanding of DES project success by determining which characteristics of a simulation project were more likely to be present in a successful simulation effort. Potential success factors were derived from the simulation literature and used to develop a questionnaire. Based on the findings, projects perceived as failing were often characterized by high costs, model size constraints, and slow software. Successful projects were characterized by teamwork, cooperation, mentoring, effective communication of outputs, high quality vendor documentation, easily understood software syntax, higher levels of analyst experience, and structured approaches to model development. By understanding the simulation process and characteristics of successful simulations, practitioners will find it easier to avoid common mistakes that can ruin a modeling effort.

DEPENDENT VARIABLE RESEARCH

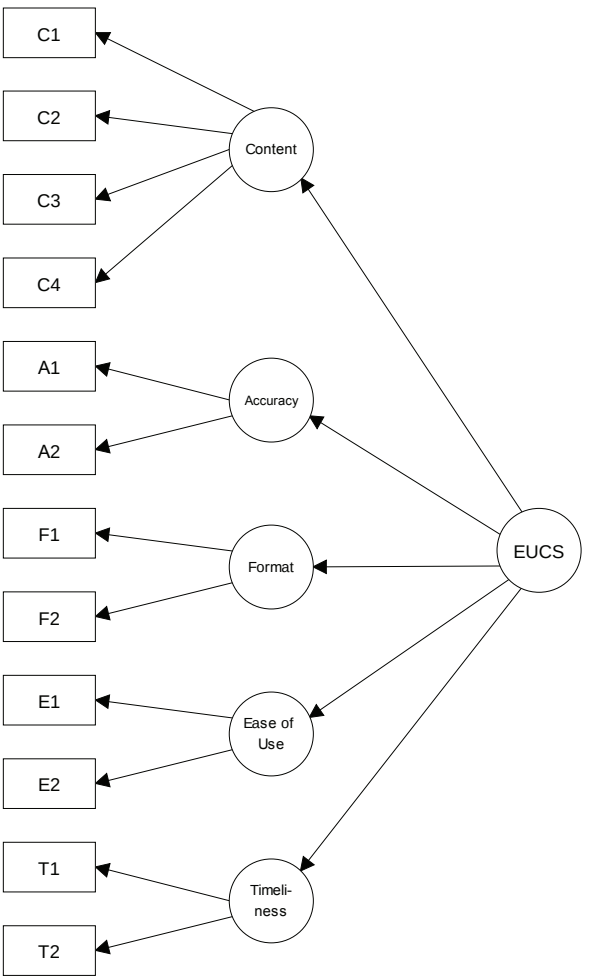
The studies mentioned in the previous section focused on understanding independent variables defining successful representational decision support system applications. A problem with research that considers only the independent side of the equation is the lack of objective measures of whether suggested recommendations correlate with desired outcomes. This dilemma has been problematic throughout information systems research in general and has been the subject of academic debate (Delone & McLean, 1992). DES researchers recognize that the identification of a meaningful, reliable, and robust dependent variable is central to being able to conduct accurate comparisons between competing tools, techniques, software implementations, project approaches, and modeling perspectives.

A wide variety of dependent variables have been investigated in the broader fields of information systems (Delone & McLean, 1992) and decision support systems. Among these, DES researchers have focused on success surrogates and investigated the possibility of assessing DES success or failure. Representational DSS researchers have extended the use of these surrogates.

The first information system success surrogate validated in the context of DES was the end-user computing satisfaction instrument (Doll, Deng, Raghunathan, Torkzadeh, & Xia, 2004; Doll & Torkzadeh, 1988). The EUCS instrument, shown in Figure 1, is of particular interest because most applications of discrete event computer simulation can be categorized as end-user computing. McHaney and Cronan (1998) collected data from 411 participants using a variety of discrete event computer simulation software packages. The analysis indicated the instrument retained its psychometric properties and provided a valid success surrogate for end users beyond the introductory stages of using representational DSSs. The study established the use of information systems surrogate success measures for applied instruments. The results suggest EUCS can reliably and confidently be used in the investigation of competing tools, features, and technologies in the area of DES. Later, EUCS was the subject of a test-retest reliability study that was distributed to users of DES through a mail survey. One month later, follow-up surveys were administered. The original respondents were asked to again evaluate the same system. The two data sets were compared, and the results supported the instrument's internal consistency and stability (McHaney, Hightower, & White, 1999).

Another success surrogate, the technology acceptance model (TAM), was also investigated within the context of representational decision support systems. TAM was developed by Davis (1989) to provide a theoretical explanation of factors influencing technology usage. Davis' theory is derived from the theory of reasoned action (TRA) model (Fishbein & Ajzen, 1975). The TRA model explains actions by identifying connections between various psychological constructs such as attitudes, beliefs, intentions, and behaviors. TRA posits that an individual's attitude toward a given behavior is determined by the belief that this behavior will result in a particular outcome. TAM expands upon this framework

Figure 1. EUCS instrument



C1: Does the simulation system provide the precise information you need?
C2: Does the simulation output information content meet your needs?
C3: Does the simulation provide reports that seem to be just about exactly what you need?
C4: Does the simulation system provide sufficient information?
A1: Is the simulation system accurate?
A2: Are you satisfied with the accuracy of the simulation system?

F1: Do you think simulation output is presented in a useful format?
F2: Is the simulation output information clear?

E1: Is the simulation system user friendly?
E2: Is the simulation system easy to use?

T1: Do you get the output information you need in time?
T2: Does the simulation system provide up-to-date information?

to provide a theoretical explanation of factors influencing technology usage. However, instead of relying on purely attitudinal determinants, TAM hypothesizes that perceived ease of use and perceived usefulness influence a person's intention, which in turn determines actual technology usage. In essence, Davis' research identifies the external variables that influence attitude toward voluntary use of technology. TAM has been validated and tested in a variety of technology-related studies (Adams, Nelson, & Todd, 1992; Davis, Bagozzi, & Warshaw, 1989; Mathieson, 1991). Figure 2 illustrates the Davis Instrument and TAM. McHaney and Cronan (2001) focused on external validity aspects of TAM when applied to users of DES. The findings suggested that TAM provided a reasonable surrogate measure for success within this domain. An updated version of this study was developed into a book chapter (McHaney & Cronan, 2002).

FUTURE TRENDS

Representational decision support systems will continue to become more important to managers, particularly as computing power increases and costs decrease. Web-enabled DES, applications embedded in enterprise computing systems, visualization, and use of DES to fine-tune manufacturing operations and supply chain operations on the fly will become more commonplace. Although questions have been raised concerning the direction and relevance of DSS research in general (Arnott & Pervan, 2005), representational decision support system research should grow in importance. Areas requiring additional work include the search for better dependent variables and related surrogates that enable competing tools and techniques to be evaluated and compared. User interface design and development environments will also

U3: Using simulation in my job would increase my productivity.
U4: Using simulation would enhance my effectiveness on the job.
U5: Using simulation would make it easier to do my job.
U6: I would find simulation useful in my job.

be important. Mainstream DSS and information system research will continue to contribute methodologies and techniques that can be adopted for use in this growing field, and representational DSS systems will find wider user bases as the capabilities offered by simulation are integrated with popular spreadsheets and ERP systems software.

CONCLUSION

Representational decision support systems, particularly as manifested in DES, have become an important tool in a modern manager's decision-making arsenal. In order to determine the effectiveness of these applications, researchers have investigated characteristics of the technology and determined the suitability of various success surrogates to enable comparisons between competing packages, approaches, and methodologies. Future research in this field may determine whether other surrogates are suitable for use with DES and will provide managers with quantitative comparisons to aid in their software selection processes.

KEY TERMS

Dependent Variable: A value representing the presumed effect or consequence of various states of related independent variables. In other words, a dependent variable is the condition for which an explanation is sought.

Discrete Event Simulation (DES): Use of a computer to mimic the behavior of a complicated system and thereby gain insight into the performance of that system under a variety of circumstances. Generally the system under investigation is viewed in terms of instantaneous changes due to certain sudden events or occurrences.

End-User Computing Satisfaction: A widely accepted information systems success surrogate that measures the degree to which a technology provides the user with a sense of satisfaction that meaningful usage has been affected.

Independent Variable: A value representing a presumed cause of a particular outcome.

Representational Decision Support System: Computer-based information system that combines models with data in a fashion that closely resembles the system that is being studied. Computer simulation is a form of representational decision support system.

Success Surrogate: A proxy for information systems success that takes the form of measurable values. A success surrogate is a dependent variable.

Technology Acceptance Model: A theoretical explanation of factors influencing technology usage that hypothesizes perceived ease of use and perceived usefulness influence a person's intention, which in turn determine actual technology usage.

Theory of Reasoned Action (TRA): This theoretical model explains actions by identifying connections between various psychological constructs such as attitudes, beliefs, intentions, and behaviors, then posits that an individual's attitude toward a given behavior is determined by the belief that this behavior will result in particular outcome.

A Requirement Elicitation Methodology for Global Software Development Teams

INTRODUCTION

Failures during the elicitation process have been usually attributed to the difficulty of the development team in working on a cooperative basis (Togneri, Falbo, & de Menezes, 2002), but today there are other points that have to be considered. In order to save costs, modern software organizations tend to have their software development team geographically distributed, so distance between members becomes one of the most important issues added to the traditional problems of the requirement elicitation process (Brooks, 1987; Loucopoulos & Karakostas, 1995).

So far, literature has widely analysed real life Global Software Development (GSD) projects and pointed out the main problems that affect such environments, especially related to communication. As a complementary view, we have focused our research on analysing how cognitive characteristics can affect people interaction in GSD projects, especially during the requirement elicitation process, where communication becomes crucial.

In this article, we present the main characteristics of requirements elicitation in GSD projects and introduce a cognitive-based requirement elicitation methodology for such environments.

BACKGROUND

Advantages and challenges of GSD have been widely analyzed in literature. As part of the advantages, the most cited are:

- Taking advantage of time difference to extend productive hours (Herbsleb & Moitra, 2001);
- Minimizing development costs (Lloyd, Rosson, & Arthur, 2002);
- Locating developers closer to the customers (Damian & Moitra, 2006); and
- Taking advantage of diversity of stakeholders' knowledge and experiences (Ebert & De Neve, 2001).

On the other hand, the challenges that GSD must face are (Damian & Zowghi, 2002):

- the loss of communicative richness, affected by the lack of face-to-face interaction;
- the time difference between sites, that introduce delays in the project;
- cultural diversity, as a source of misunderstandings; and
- knowledge management, because of the need of maintaining information from many distributed sources.

Looking for solutions to improve communication in GSD, concepts from CSCW (Computer-Supported Cooperative Work) become important because this research area concerns the development of software for enabling communication between cooperating people (*groupware*), that can be simple systems (like e-mail or plain-text chat), more complex ones (like videoconferencing), or the combination of more than one of them. To be more specific, when talking about groupware we follow a convention: We refer to every simple communication technology (e-mail, chat, videoconference) as groupware tools, and to the systems that combine them as groupware packages (Gralla, 1996). Doing so, the most common groupware tools used during multisite developments are e-mails, newsgroups, mailing lists, forums, electronic notice boards, shared whiteboards, document sharing, chat,

instant messaging, and videoconferencing (Damian & Zowghi, 2002; Gralla, 1996).

Another research area related to the distributed requirements elicitation process is Cognitive Informatics (CI), a transdisciplinary research area that encompasses informatics, computer science, software engineering, mathematics, cognition science, neurobiology, psychology and philosophy, and knowledge engineering (Chiew & Wang, 2003). In CI, there is a bidirectional relationship between cognitive sciences and informatics (Wang, 2002):

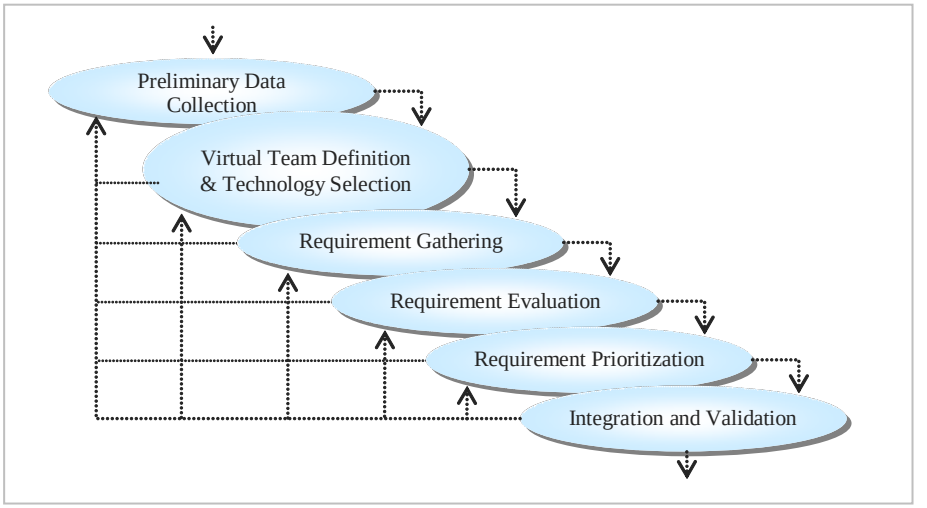
1) using computing techniques to investigate cognitive science problems like memory, learning, and thinking; and
2) using cognitive theories to investigate informatics, computing, and software engineering problems.

In our research, we have followed the second point of view, using concepts from cognitive psychology to improve the requirement elicitation process. Doing so, our research focused on learning styles models (LSMs), a cognitive psychology theory based on Jung's theory of psychological types published in 1921 (Miller & Yin, 2004), that classify people according to the ways they perceive and process information. These models have been discussed in the context of analyzing relationships between instructors and students, but we propose applying them to a virtual team that deals with a distributed requirement elicitation process, considering an analogy between stakeholders and roles in LSM, because during the elicitation process everybody "learns" from others (Martin, Martinez, Martinez, Aranda, & Cechich, 2003), and stakeholders play the role of students or instructors alternatively, depending on the moment or the task they are carrying out.

After analyzing five LSM in Martin et al. (2003), we found out that every item in the other models was included in the model proposed by Felder-Silverman (Felder & Silverman, 1988), so that we may build a complete reference framework choosing this as a foundation. The Felder and Silverman (F-S) model classifies people into four categories, each of them further decomposed into two subcategories (*Sensing – Intuitive*; *Visual – Verbal; Active – Reflective; Sequential – Global*). To know their cognitive profile, people must fill in a multiple-choice test (available at http://www.engr.ncsu.edu/learningstyles/ ilsweb.html), that returns a rank for each category. Depending on the circumstances people may fit into one category or the other, being, for instance, "sometimes" active and "sometimes" reflective, so preference for each category is measured as *strong*, *moderate*, or *mild*.

Most of related works use learning and psychological style models with educational purposes, while few works use them to solve problems in software engineering. One work which uses cognitive styles as a mechanism for software inspection team construction is described in Miller and Yin (2004). They use the MBTI method, an instrument similar to the F-S model. Their intent is different from ours because they use the cognitive styles to set which people seem to be more suitable to work together, while we try to give the best solution (concerning technology) for an already chosen group of people.

Figure 1. RE-GSD methodology



OUR METHODOLOGY: RE-GSD

In order to define the basis for a methodology for requirement elicitation in GSD projects, we have analyzed methodologies used in colocated development and proposed extending them from a cognitive point of view, using the F-S model as a basis for defining a model for technology selection.

We have called our methodology RE-GSD (Requirement Elicitation for Global Software Development projects) and, as a starting point for it, we have selected the models proposed by Christel and Kang (1992) and Hickey and Davis (2003). This selection is due to the fact that both models share a generic view of the selection of requirement elicitation techniques, which fits our intention of defining what to use according to stakeholders' personalities. Both models have been extended and adapted to a distributed environment, so that our methodology can be expressed as follows (see Figure 1):

1. Preliminary data collection: Further decomposed into two categories: (1) about the stakeholders, and (2) about the system and the domain.
2. Virtual team definition & Technology selection: Before starting the requirement gathering, it is important to determine who is going to participate in that stage, because not all the stakeholders in the project are required to participate in every iteration of the elicitation process. Then, the selection of appropriate technology should be carried out, that means, choosing the most appropriate set of requirement elicitation techniques and groupware tools for a given group of people, by taking into account their personal characteristics.
3. Requirement gathering: Once technology has been defined, it is time to apply the requirement elicitation techniques (which are combined with appropriate groupware tools) to obtain a new list of requirements, trying to answer "*what*" is to be built (Christel & Kang, 1992).
4. Requirement evaluation: In this stage, requirements lists must be analyzed in order to determine consistency between different statements.
5. Requirement prioritization: Once requirements are defined, it is important to give them an order of relative importance so as to know when they should be addressed in relation to other requirements (Christel & Kang, 1992). Specially designed tools for distributed requirement inspection (Lanubile, Mallardo, & Calefato, 2003), which allow synchronous and asynchronous discussion, voting, and so forth, can be used to address both this step and the previous one.
6. Requirement integration and validation: In this step, the new requirement list must be integrated to the requirements collected in the previous iterations, looking for inconsistencies also with the system's goals and organizational factors initially defined.

The following sections present the first two phases of our model that are related to our proposal of technology selection according to the stakeholders' cognitive styles.

PHASE 1: PRELIMINARY DATA COLLECTION

a) About the stakeholders
   1) Identify people whose participation is important for the requirement elicitation process, including people from different levels of the organization.
   2) Get personal information about stakeholders, using the form shown in Figure 2. Some important points for distributed environments are, for instance, distinguishing which is the given name and the family name, because different cultures use different order (for instance, in China the family name goes first, while in most of occidental countries, the family name is the last one). Also, recording information about the country of origin and the country of residence is important to identify their mother language and possible differences in cultural background, as well as the foreign languages stakeholders know to choose a second language.
   3) Get information about stakeholders' job, roles, responsibilities and schedules. And because they are distributed, obtaining information about each team member's location (time difference with other sites, work hours, lunch time, etc.) is relevant for other members to know how to contact each other. The form is shown in Figure 3.

b) Get information about the structure, culture, and internal politics of the organization (SWEBOK, 2004), to answer the following questions:
   4) *About the groupware tools*: Which groupware tools are commonly used in the organization? Have stakeholders received training in the use of groupware tools? Which ones do they know better? Which ones have they not used before? Is there any policy that limits the use of groupware tools? Are stakeholders willing to learn how to use other groupware?
   5) *About the requirements elicitation techniques*: Which requirement elicitation techniques are commonly used in the organization? Have stakeholders received training in the use of

requirement elicitation techniques? Which ones do they know better? Which ones have they not used before? Are stakeholders willing to learn new techniques?

6) *About the organizational culture*: Do organizational policies allow stakeholders to communicate with others in the virtual team freely, or is there a person that must act as a mediator?

c) About the system and the domain
   7) Get information about the domain and the system in construction.
   8) Determine the system goals.
   9) Identify similar systems

PHASE 2: VIRTUAL TEAM DEFINITION AND TECHNOLOGY SELECTION

As we have mentioned before, we aim at defining strategies that analyze the personal characteristics of stakeholders with the objective of selecting the best groupware tools and requirement elicitation techniques for them. For that reason, selecting appropriate groupware tools is related to our goal of providing the stakeholders with the possibility of communicating with others in a manner closer to the way in which they perceive and process information. That means giving them the chance to feel comfortable with the way in which they interact (synchronously or asynchronously) and the kind of information they interchange (based on words, based on diagrams, etc.).

Even when the technology selection is done for a given virtual team before the elicitation process, obtaining the preference rules is a previous step. Preference rules are obtained from a generic set of people that works on GSD projects, and then the resulting sets can be used in many different GSD projects as well as different virtual teams, at the same time that new information can be added to improve the source of knowledge of the fuzzy logic system.

Obtaining Preference Rules

In order to support personal preferences toward groupware tools, in Aranda, Cechich, Vizcaíno, and Castro-Schez (2004) a model based on fuzzy logic and fuzzy sets to obtain rules from a set of representative examples has been proposed. The obtained rules represent patterns of behavior that indicate the preferences of stakeholders in their daily use of groupware tools and requirements elicitation techniques, according to their classification in the F-S model. To do so, we have collected examples of people preferences and applied a machine learning algorithm. The algorithm we chose (Castro, Castro-Schez, & Zurita, 1999) finds a finite set of fuzzy rules to reproduce the input-output system's behavior. Using this machine learning algorithm over a set of examples that represent the preferences of many stakeholders, we obtained a set of rules (Aranda, Vizcaíno, Cechich, Piattini, & Castro-Schez, 2006). The resulting set of preference rules can be applied to choose the best suite of groupware tools for a group of people by analyzing the results and combine them appropriately, as we will explain in the next section.

The Technology Selection Strategies

According to the analysis of real life projects, analysts are those who choose the techniques for requirement elicitation

Figure 4. Requirement technique selection according to analyst's preferences (π)

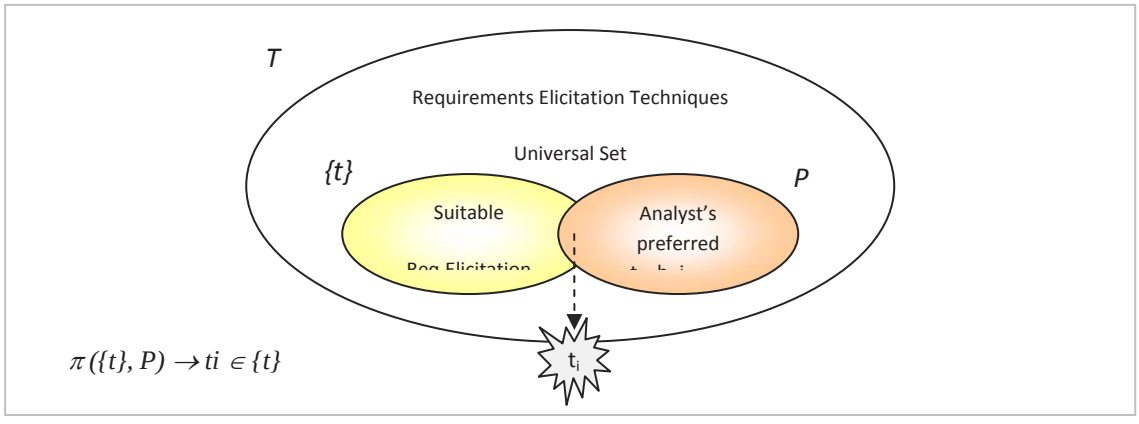

Figure 5. Requirement technique selection according to the most common preference (π^*)

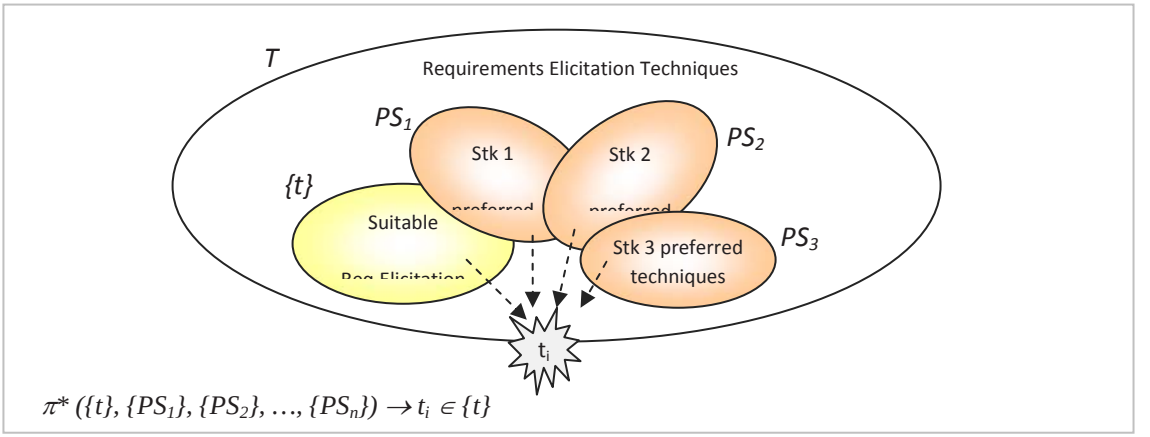

Figure 6. Requirement technique selection according to the strongest preferences in the group (π^{**})

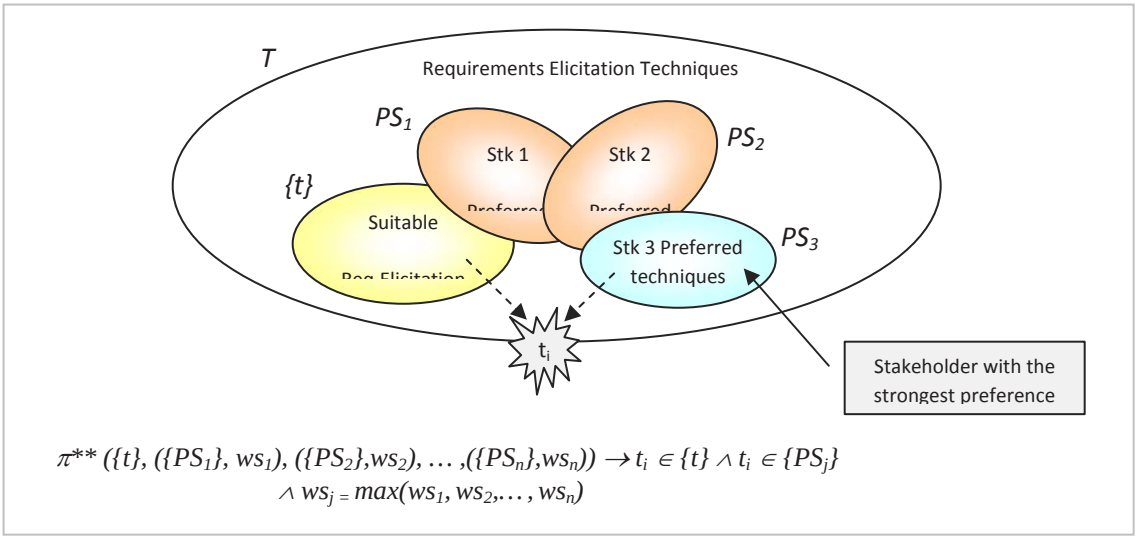
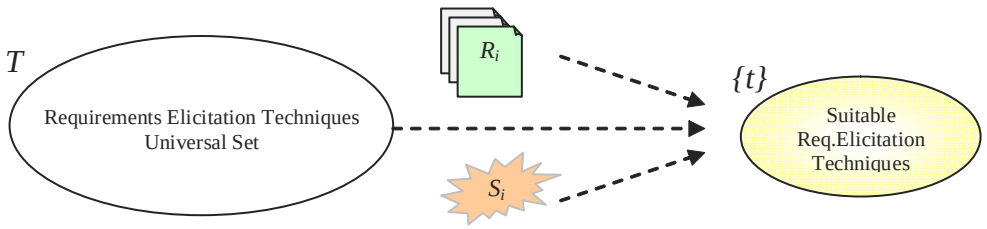


(Hickey & Davis, 2003). To model such a selection, Hickey and Davis' model considers a personal selector function π that returns a technique t_i, from a given a set of techniques *{t}* and a set *P* that represents the personal preferences of the analyst. That means only the analyst's preferences are taken into account, as it is shown in Figure 4.

A first attempt to adapt the previous generic model to our cognitive point of view analyzes the preferences of all the stakeholders and chooses the technique that has more adherents (Aranda, Vizcaíno, Cechich, & Piattini, 2005). This extension of the π function, called π*, is shown in Figure 5. In this formula PS_i represents a set of techniques that fit the *i-th* stakeholder's preferences (defined by the mechanisms based on fuzzy logic and fuzzy sets we have described previously), and $t_i \in \{t\}$ is the technique that appears in most of the PS_i. In this case, analysts are considered without any priority over the rest of the stakeholders.

A later improvement of π* considers the relative importance of stakeholders' preferences by means of weighting them. Its purpose is that, if some stakeholders' preferences are stronger than the rest, the preferences that should be primarily considered are those of the first group of stakeholders. Also, the different weights might be used to prioritize preferences according to stakeholders' roles. The resulting function, called π**, is shown in Figure 6. In this case, ws_i represents the weight (how strong the preferences are), and the resulting t_i is a technique that is appropriate for the current

Figure 7. Definition of the requirements elicitation techniques most suitable for a given situation in a collocated environment (σ)



$\sigma(R_i, S_i, \chi(T)) \rightarrow \{t \in T \mid t \text{ is applicable in situation } S_i \text{ when the current state of requirements is } R_i\}$

situation and is also appropriate for the stakeholder whose personal preferences are the strongest.

PHASE 3: REQUIREMENT GATHERING

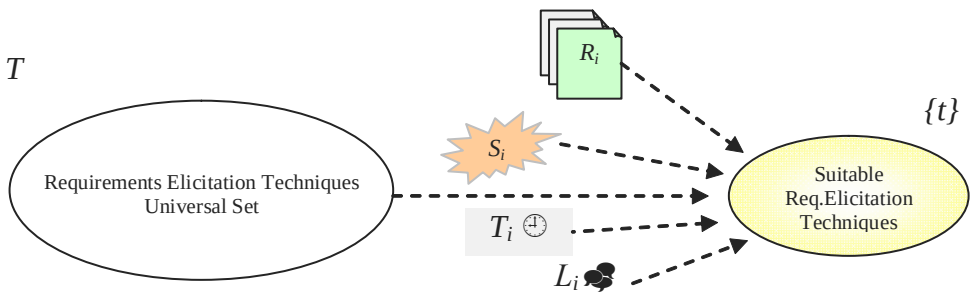
At the moment of deciding how to conduct the requirement gathering, the first step is deciding which of the possible techniques is best, given a current state of knowledge and a particular situation. To do so, the Hickey and Davis model defines the selector function σ (shown in Figure 7).

In a scenario where stakeholders are distributed along many geographically distanced sites, the selector function σ must also consider other aspects. The most important are time difference and the level of knowledge of a common language.

Time difference is important because when timetable does not overlap, or overlaps for a very short period of time, synchronic communication is not possible, then the selection process should prioritize those techniques that work better on asynchronous basis. Similarly, when stakeholders do not share the same language, some of them would need more time to read, think quietly, look for some vocabulary in the dictionary, and so forth.

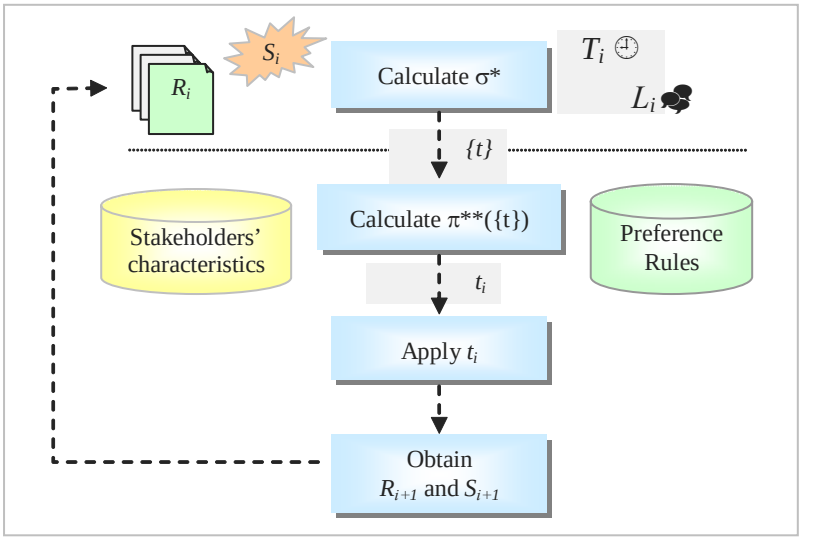
With those considerations in mind, we extended the selector function σ as it is shown in Figure 8, where T_i (time difference) indicates in which degree synchronous communication is possible between the sites that need to interact; and L_i (degree of knowledge of a common language) indicates the level of fluency of communication.

Figure 8. Definition of the requirements elicitation techniques most suitable for a given situation in a distributed environment (σ)*



$\sigma^*(R_i, S_i, \chi(T), T_i, L_i) \rightarrow \{t \in T \mid t \text{ is applicable in situation } S_i \text{ when the current state of requirements is } R_i, \text{ according to restrictions } T_i \text{ and } L_i\}$

Figure 9. Requirement elicitation in GSD, as an iterative process of technique selection and application



Finally, a graphical representation of the requirement elicitation process in a distributed environment is shown in Figure 9.

FUTURE TRENDS

For many years, research on GSD has focused on improving technology as a supporting media for spreading global communication. Those technology topics are really necessary indeed, but not enough for a society challenged by cultural diversity and worldwide-located working teams. Currently, research efforts are looking at GSD as a human-intensive process, where new strategies to deal with socio-cultural differences and distance are bringing psychological and cognitive aspects into the arena. Human factors seem more complex than technological ones, so probably we will see many strategies in the future trying to find the most effective way people understand, choose, and communicate during GSD. Certainly, cognitive informatics will be one of them.

CONCLUSION

GSD projects are a common way of work these days. Looking for solutions to improve communication in virtual environments has led us to analyse human interaction and how to apply well-known techniques from the field of cognitive psychology (called learning style models) as a base for technology selection.

Based on a cognitive-based technology selection approach, we propose a methodology for requirement elicitation in GSD projects, which focuses on improving communication between distant stakeholders. Considering cognitive aspects of stakeholders is significant because the selection of requirement elicitation techniques according to personal characteristics of all the members of a virtual team (instead of just the analyst) might affect positively the quality of the information gathered during the requirement elicitation process. In addition, as stakeholders might feel more comfortable expressing themselves when using a groupware tool closer to the way they perceive and reason about the world, communication in virtual teams is expected to be more fluid and personal satisfaction higher.

In this article, we show the first three phases of such a methodology, called RE-GSD, which are the most clearly different from traditional requirement elicitation methodologies. Current work is focused on defining experiments, in academic and industrial scenarios, to analyze its performance.

KEY TERMS

Cognitive Informatics: It is an interdisciplinary area that applies concepts from psychology and other cognitive sciences to improving processes in engineering disciplines, such as informatics, computing, and software engineering.

CSCW (Computer-supported Cooperative Work): It is a research area that focuses on how people work together and the design and development of software (groupware) that may help their work as a group.

Distributed Software Development: It is a way of developing software that allows the stakeholders to be distributed in geographically distanced sites.

Global Software Development: When the distribution of the members of a distributed software development team exceeds the frontiers of a country.

Groupware: Software that supports and improves group work. It can be a simple text-based technology like e-mail or more sophisticated like videoconferencing.

Learning Style Model: It is a cognitive psychology theory that classifies people according to a set of behavioural characteristics pertaining to the ways they perceive and process information. They can be used to improve the way people learn a given task.

Requirements Elicitation: It is the first stage in the process of understanding the problem the software has to solve. It is crucially based on human communication between the development team and the customer. Other terms that are used as synonyms are "requirements capture," "requirements discovery" and "requirements acquisition."

Stakeholders: They are all the actors that have some interest on a system. They can be the people that pay for it, work on its development or people whose task will be affected by the system, among others.

Requirements Prioritization Techniques

INTRODUCTION

As part of Requirements Engineering, "Elicitation" is the phase where an analyst collects information from the stakeholders, clarifies the problems and the needs of the customers and users, tries to find the best solutions, and makes its planning on what software system will be developed. During elicitation, to get well-defined requirements, a consensus among the different stakeholders is needed. There are several elicitation techniques in the literature; however every technique faces the same problem: each stakeholder has different requirements and priorities, which potentially produces conflicting situations. Therefore, this situation points out Requirements Prioritization as a relevant research area to define the requirements' level of importance.

Nevertheless, often the strategies implemented to solve conflicts among stakeholders are inadequate; for example, weighting requirements can be problematic because sometimes weights are inconsistent and lead to confusion about which are the most essential customer requirements. The prioritizing process must hold stakeholder satisfaction considering high-priority requirements first. However, practical experience shows that prioritizing requirements is not as straightforward task as the Literature suggests. In any case, clearly defining a way of balancing preferences on requirements is essential to the elicitation process.

The remainder of this chapter is structured as follows. Section 2 describes a conceptual framework to describe several prioritization proposals, which are characterized in Section 3. Future trends are presented afterwards.

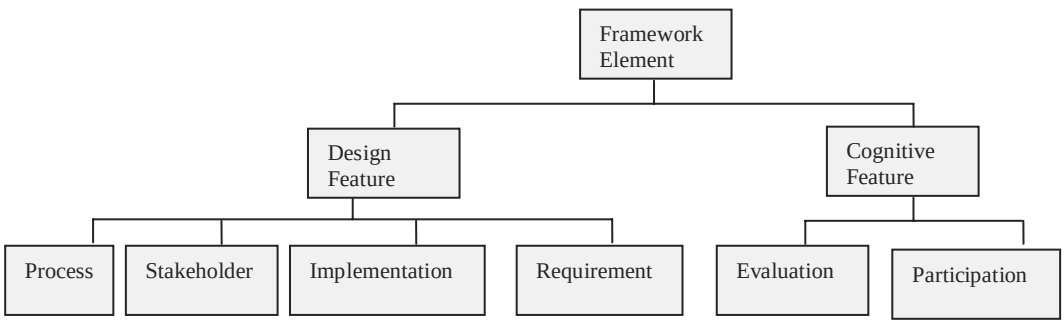
BACKGROUND

Some comparisons of elicitation methods have clarified common features. Firstly, the comparative study by Thomas and Oliveros (2003) is centralized in properties and limitations of five of the most significant methods for eliciting requirements in goal-oriented requirements engineering. This comparison is organized from the viewpoint of goal acquisition with especial emphasis in goal elicitation. Secondly, based on an evaluation framework and influenced by an industrial application (Karlsson & Ryan, 1997), characterizes six different methods for prioritizing software requirements. The objective of Karlsson's evaluation is outlining the methods' behavior for a particular experience, thus the results obtained are not supposed to be generalized by any environment for any application. This evaluation framework is based on inherent characteristics, objective measures and subjective measures.

Our classification framework (Figure 1) is structured into two building blocks – *design features* and *cognitive features*.

The *Design category* is composed of four elements that consider different aspects: *Process, Stakeholders, Implementation* and *Requirements*. The specific features of each

Figure 1. A conceptual framework for comparison



prioritization method are categorized by the *Process* element. It considers answering some questions, such as: Does the process detect inconsistency? Is the process referred to as a systematic or a rigorous process? How we address the problem of dealing with different priorities? Conceptually, is it based on goal decomposition? Does it use a priority or an importance order? The framework also characterizes how prioritizing methods consider *stakeholders*. There are two parameters to be analyzed here: the former refers to the kind of information the method provides with respect to stakeholders. Does the method analyze which stakeholder prioritized a goal, and which priority degree was assigned? The second parameter considers stakeholders geographically distributed.

The *implementation category* depends on the method's scalability and dynamism, that is, usability. It is influenced by how many and which calculus the method uses, and by the performance of the method with a huge number of requirements. It is considerably important whether tools, as well as a reference to spread projects, were applied to support the method. The framework considers information that can demonstrate the method's success in pilot studies. *Requirements* analyze functional (FR) and nonfunctional requirements (NFR) as well as interactions among requirements – *interdependency* represents requirements interaction. Some methods calculate cost and benefit figures for individual requirements, but if there are significant interactions among requirements, the situation becomes more complex. As an example, if two requirements in a method can be achieved by sharing the same solutions to subproblems, then the cost of attaining both of them may be significantly less than the sum of their individual costs. Therefore, the main key is whether the method can handle requirements' interdependencies. The *requirement category* also analyses if the methods deal with functional—FR—and nonfunctional requirements—NFR.

Cognitive aspects cover the evaluation of cognitive features as participation and negotiation among stakeholders during the whole process (Chiew & Wang, 2003). *Evaluation* studies what personal characteristics serve to establish priorities. *Participation* includes defining how priorities were assigned (subjective or objective) from personal experiences and interviews to ensure the success of the developed method. The cognitive aspects no cover the cognitive techniques for knowledge acquisition of knowledge based system.

FEATURES FOR COMPARISON

We can identify two kinds of features: those present in any strategy, and those that may be present or not. Although the first group of features is present in any method, the way these characteristics are maintained is specific of each method. Our appreciation focuses on the second group, which makes the comparison more interesting. By taking into account these concerns, we established three levels of increasing importance to analyze the features: desirable "D", highly desirable "HD" and mandatory "M".

Simple Features

The simple features we considered to analyze processes are:

Consistency: Many times two stakeholders agree on requirements with opposite meanings, which turns impossible the implementation of those requirements. These requirements inconsistencies arise as a result of conflicts between requirements. We consider the action of *detect inconsistencies mandatory* because it is the key of a successful project.

R*igorous:* If a method is *rigorous* and *systematic* it provides robust and comprehensive steps and handling requirements consistently and effectively, which became this feature *highly desirable*. It aids in the validity and verification and it is related intimately to the consistency of requirements.

Goal decomposition: The process based on *goal decomposition* is *desirable* in a prioritization process. The reason is that goals help do not assure successfulness. Clarifying conflicting terms can reduce conflicts, even if the technique does not support goal decomposition.

Priority: Discussion of requirements priorities improves communication between the customer and the developer and helps resolve conflicts. Therefore, we consider *mandatory* the process of deriving an order relation on a given set of requirements, in order to assign a *priority order*, with the ultimate goal of obtaining a shared rationale for partitioning them into subsequent product releases.

Requirements Interdependence: The different occurrences of requirements changes throughout the life cycle points out some dependencies among functional requirements. Understanding these dependencies may improve the requirements process. An approach assumption implies that if two functions are modified due to the same fault report, then there are some *requirements interdependencies* between them. Thus an analysis of such identified fault reports is *desirable* as it may give additional information about requirements.

Objective: One disadvantage detected is that in many methods only one stakeholder has the responsibility of estimating the relative requirements value, which becomes the process subjective. We suppose as *desirable* that the process considers the search of solutions to be as *objective* as possible because the quality requirements always are influenced by analysts' opinions.

Table 1. Characterization in terms of simple features

	Consistency (M)	Rigorous/ Systematic (HD)	Goal Decomposition (D)	Priority (M)		Objectivity (D)
AGORA	By attaching attribute values as preference matrices.	Rigorous process	It uses AND-decomposition and OR-decomposition	Priorities are based on conflicting goals	Only in goal	Attribute values are attached subjectively. But techniques as AHP can be used to obtain more objective values
AHP	By redundancy of pair-wise comparison	Systematic and rigorous method	No	Compares requirements in three hierarchical levels	No	Objective because it represents each term respect to other term.
Cost-Value	By redundancy of pair-wise comparison	Systematic and rigorous method	No	Idem as AHP	No	Idem as AHP
Win-Win	By analyzing the priorities with a Conflict Consultant tool.	Not rigorous or systematic	No	Detects priorities between the requirements	No	Objective because it must reach consensus among the stakeholders
QW-W	Between pairs of requirements (AHP process), eliminating some of them and checking the resulting set.	Systematic process	No	Detects priorities between the requirements	No	It is more objective than Win-Win because it adds a quantitative analysis
ReqInt	Although it detects inconsistencies, it does not have an explicit methodology to correct them.	Not rigorous or systematic	No	Requirement precedence can be given	The process is based on requirements	It is subjective

	Consistency	Rigorous/ Systematic	Goal Decomp.	Priority	Req. Dependence	Objective
QFD	It does not detect inconsistencies.	Not rigorous	No	Precedence can be given because it is based on assigning a numeric value to each requirement	No	Priorities are given subjectively
MPARN	It does not detect inconsistencies.	Systematically negotiated agreements using the multi-criteria preference analysis techniques	No	It considers a precedence for each option through the preference function	No	Although the priorities occur in subjective form they return unfailingly objective

continued on the following page

Table 1. continued

VI	It does not detect inconsistencies.	Nor systematic or rigorous	No	It considers a precedence that can be shared by one or several requirements	No	Priorities are given subjectively
GSP	It does not detect inconsistencies.	Nor systematic or rigorous	Each goal is a node in a goal graph, and is decomposed in OR/AND relationships into sub goals	It considers a precedence when evaluating the alternatives	No	It is subjective. The first part of the process (identification of objectives) can be made by using any elicitation technique
Psy. SR	Although it detects divergence between the stakeholders, it does not detect inconsistencies.	Nor rigorous or systematic	No	The precedence is subjective and is not well defined	No	It is subjective

Table 2. Characterization in terms of compound features

	Traceability (M)	**Distributed Stk (HD)**	**Tools (D)**	**Experience (D)**	**Cognitive aspects (HD)**	**Human experience (D)**	**NFR (D)**
AGORA	It allows to maintain information of objectives prioritized by each stakeholder, using the preference matrix, but not why	No	It is still not supported by computational tools	It has not been used in spread projects. The example proposed is a user accounting system on the Web	None	Although it requires little experience, also requires many interviews	It considers only functional require-ments
AHP	The process involves almost all the stakeholders, so it does not maintain information of who considered each priority or why.	No	An extensive bibliography of reference and several computational tools has been generated	It is applied by main companies and world-wide institutions	None	Although it does not need much experience, it needs several interviews to coordinate the relative values between the stakeholders	Although it is usually used for functional require-ments, it could also be used for non-functional ones.
Cost-Value	It does not maintain information of whom considered each priority or why	No	The second phase of the method is supported by a program written in language C	It was used in several industrial projects	None	Interviews are necessary to coordinate the relative values between the stakeholders and to review the results of the cost-value diagrams	It is adapted for both types of require-ments

continued on the following page

Table 2. continued

	Traceability	Distributed Stakeholders	Tools	Experience	Cognitive aspects	Human experience	NFR
QWW	It is possible to obtain which participants prioritized certain objectives, but not why	No, this method is fed up on the co-participation of the stakeholders to consider new require-ments	Some specific tools not widely used such as. Boehm also created a prototype for his Win-Win spiral model	It was used in spread projects. It is widely used in industry, independently from the domain	None	Although it does not require too much experience, it requires too many interviews	It can be adapted to both types of require-ments
ReqInt	It does not maintain information of who assigned each priority or why	Yes, since stakeholders choose products independently	Parts of the method are supported by tools, nevertheless it does not exist a general software that fully support this methodology	It was used in spread projects, usually in industry	It considers the political status of the stake-holders	It needs experience to make the process successful	It can be adapted to both types of require-ements
QFD	It does not maintain any type of information from the stakeholders	The geometric nature of the process allows working better with isolated groups	This technique is partially supported by tools.	It has been applied successfully from 1991 in the industry of health	It considers the political status of the stake-holders	It needs experience to make the process successful.	It can be adapted to both types of requirements
MPARN	Yes, as in the Win-Win method, it is possible to obtain which participants prioritized certain objectives, but not why. Preference analysis can be a useful tool	No	The MPARN offers supports for generation and negotiation planning, for criteria exploration and assessment of scores and criteria	It does not mention any spread project	None	Similar to the Win-Win method. It does not require too much experience	It can be adapted to both types of requirements
VI	Although the different priorities assigned from each requirement are known, it is not possible to know who assigns each priority or why	Yes, authors are even working to improve this item	Currently working on the elabo-ration of supporting tools, inspired by (DCPT)	It has not been used in real-world projects for case studies	None	Although it does not need much experience, it needs several interviews to negotiate priorities	It is thought for functional requirements

continued on the following page

Table 2. continued

	Traceability	Distrib Stk	Tools	Experience	Cognit. Aspects	Human experience	NFR
GSP	No. As the criteria of all the participants are joined together, it does not register who prioritized each requirement	No	There is no tool yet. It is an on-going project.	It is applied to a case study involving traumatic brain injury patients	Yes, but it does not use it as a weight to mediate.	It needs much experience and many interviews to determine, for each user, goals, skills and preferences	It is developed only for functional require-ments
PsySR	No. As the criteria of all the participants are joined together, it does not register who prioritized each requirement	No.	It does not make calcula-tions of any type. It is not supported by tools	It is used in many small projects, but it is not used in great projects.	It does not consider cognitive characteristics of any of the partici-pants	It does not need much experience, which is obtained in two or three days of training	It can be adapted to both types of require-ments

Compound Features

Our specific set of compound features is:

Traceability: It involves providing techniques and tools for controlling the impact of changes in different parts of the project. Typical changes in requirements specifications include adding or deleting requirements. The process for dealing with requirements changes, as the environments that support this process, is considered *mandatory* because it helps to scope the possible impact of changes.

Distributed stakeholders: Many organizations have adopted a decentralized, team-based, distributed structure, whose members communicate and coordinate their work through information technology. As the groups are several and heterogeneous, the process which support distributed stakeholders, allowing powerful ways of communication and allowing groups to develop distributed software engineering activities, is highly desirable.

Computational tools: Is our intention that computational tools support the prioritization process; the argument for that is that sometimes this feature avoids paralyzing the process or making the process not too hard.

Experience: The process must be proved in real projects, which implies practical experience. At least this is a *desirable* item since many processes are good theoretically but they are practically impossible to be implemented.

Cognitive aspects: Cognitive techniques may be satisfactory used in personal requirements evaluation. Therefore, we consider *highly desirable* the evaluation of *cognitive aspects* to establish priorities weights in order to solve requirements conflicts.

Human experience: Requirements specialists are generally more familiar than other development staff with recent technology advances and also can help eliciting real customer needs and expectations. Sometimes developers have not enough experience, (or the ones which have enough experience are too expensive for specific projects). Anyway, it would be *desirable* to have methods or processes, which imply less *human experience*.

NFR: The software requirements specification serves as a container for both the functional requirements and the nonfunctional requirements. It is *desirable* that quality attributes – *nonfunctional requirements* such as usability, efficiency, portability, and maintainability – can be elicited from users during the prioritization process.

Characterizing Approaches

Nowadays, a broad spectrum of elicitation techniques are practiced in different software development projects (Hickey & Davis, 2003; Leoucopoulos & Karakostas, 1995; Young, 2002). To reduce conflicting situations, methods as (Boehm, Grünbacher & Briggs, 2001; Grüenbacher, 2000; Ruhe, Eberlein & Pfahl, 2002) must negotiate the "right requirements".

Systematic methods, such as the AHP, and the Cost-Value (Karlsson & Ryan, 1997; Saaty, 1990), have received some interest in the application of elicitation procedures, and simpler decision-making techniques (In, Olson & Rodgers, 2001), or visualization techniques (In & Roy, 2001) have

been found out to be appropriate to resolve disagreements promoting a cost-effective use.

On the other hand, the requirements elicitation techniques have widely used a family of goal-oriented requirements analysis (GORA) methods (Antón, 1996; Dardenne, van Lamsweerde & Fickas, 1993; GRL homepage, I* homepage, KAOS homepage) as approaches to refine and decompose the needs of customers into more concrete goals that should be achieved. Particularly, a proposal called AGORA (Kaiya, Horai & Saeki, 2002) extends a version of a Goal-Oriented Requirements Analysis Method by considering detecting and resolving conflicts on goals; the work considers greater priority when there exists a dependency between requirements, and these interdependencies can be identified before they are negotiated More recently, the Goals-Skills-Preferences Framework (Hui, Lisakos & Mylopoulos, 2003) is used to generate a customizable software design; or techniques from Cognitive Informatics try to find solutions to communication problems during all stages of software engineering.

Table 1 characterizes the following proposals in terms of the framework's simple features we have introduced in section 2: Attributed Goal-Oriented Requirements Analysis Method –*AGORA*- (Kaiya et al., 2002), Analytical Hierarchy Process –*AHP*- (Saaty, 1990), *Cost-Value Approach* (Karlsson & Ryan, 1997), *Win-Win* (Grüenbacher, 2000), Quantitative Win-Win –*QWW*- (Ruhe et al., 2002), Requirements Interdependencies –*ReqInt*- (Giesen & Völker, 2002), Quality Function Deployment method –*QFD*- (Dean, 1992), Multi-Criteria Preference Analysis Requirements Negotiation –*MPARN*- (In et al., 2001), Visualization technique –*VT*- (In & Roy, 2001), Goals-Skills-Preference –*GSP*- (Hui et al., 2003), Psychotherapy for System Requirements -*PsySR*- (Goetz & Rupp, 2003; Rupp, 2002)

Table 2 characterizes the same proposals in terms of the framework's compound features we have introduced in section 2.

FUTURE TRENDS

Nowadays, requirements prioritization techniques give much importance to minimize personal efforts maintaining an agreement between stakeholders. However, we have identified a number of interesting issues that can be the basis for more targeted research projects. The tendency is to systematize as much as possible, with computational tools, the activities implied in each technique. The goal is obtain a set of requirements strong and consistent enough to avoid future pitfalls. Currently, some of the proposals are improving to work well in a distributed setting. Generally, the approaches use cognitive aspects only during the negotiation phase, where the analyst must reach mutual consensus, but the assignment of cognitive weights to each stakeholder may help assess a candidate group to be involved in prioritizing a set of requirements. Some research efforts on this line have introduced learning style models to improve communication and perception of goals (Martinez Carod & Cechich 2007), showing promissory results.

CONCLUSION

From *Table 1* and *Table 2* we can observe there is not a complete, simple, fast and reliable prioritizing approach. Neither of them provides specific tools to solve conflicts. Some approaches as Goals-Skill and Preferences (GSP) and AGORA are based on goals, others such as the Win-Win, Quantitative Win-Win and Visualization Issue technique, on negotiation processes, and some others such as QDF and MPARN are based on industrial and decision-making techniques. On the other hand, AHP and Cost-Value are based on pair wise comparison, and the Psychotherapy for System Requirements method is based on human interaction using natural language and is the only method that cannot establish priorities between requirements. AGORA, as the methods based on negotiation processes, can detect such inconsistencies. In these methods, we can see both win conditions and candidate requirements as initial goals. Considering this aspect, only the GSP and AGORA approaches allow decomposition from needs of the customers into subgoals. Although both AHP as Quantitative Win-Win are reliable, they require a large number of mathematical calculations to prioritize few requirements. Only the Psychotherapy from System Requirements takes cognitive aspects into account allowing people specify what they really mean. However, it is not a formal or systematic method.

Now, we focus our attention on both mandatory and highly desirable features. Even *consistency checking* is considered the most important feature, only few of them (those based on negotiation, AGORA and ReqInt) provide support to it. Besides, only systematic methods (such as AGORA, AHP, and MPARN) and Win Win, ReqInt and GSP have the ability to define priorities among requirements. Analyzing *traceability,* AGORA, Win Win, MPARN, VT have the property of knowing whose participants prioritized certain objectives, but neither of them maintains the information about requirements changes. Respect of *distributed Stakeholders,* AGORA, AHP, MPARN, GSP and PsySR do not provide this characteristic; in particular there are some proposals to incorporate geographically distributed participants to AGORA. Only the PsySR takes *cognitive aspects* into account allowing people specify what they really mean, not from the viewpoint of assigning cognitive weights to each stakeholder, but for knowledge acquisition. Only AHP and MPARN are essentially systematic and rigorous.

The comparison framework introduced in this chapter allowed us to analyze interesting features of most representative requirements prioritization techniques, revealing their strengths and weaknesses. Hope our work will help clarify the field and identify opportunities for improvement.

KEY TERMS

Candidate Requirements: A set of requirements which probably requirements engineer would decide to be implemented first.

Cognitive Features: The use of cognitive sciences such cognitive psychology and cognitive informatics to characterize people according to some personal characteristics or cognitive profiles.

Conflicts Between Requirements: Are conflicts between stakeholders on satisfactory level of a requirement, imprecise requirements or opposite candidate requirements.

Distributed Stakeholders: Participants geographically situated in distant places that are involved in a software

development project.

Goal Decomposition: When a goal can be expressed in terms of logical combinations of subgoals.

Negotiation Process: When at least two people groups interchange opinions in order to resolve conflicts between stakeholders with satisfaction for each group.

Nonfunctional Requirements: There are quality attribute describing systems needs, such as performance, safety, security, traceability.

Requirements Interdependencies: When one requirement depends in a big percentage on the implementation of others requirements.

Requirements Traceability: The ability of manage all concern about a requirement. The reason for its existence, which constraints has the implementation of it, which dependent requirement has, the person who has defended it and so on.

Rigorous Method: A method which has consistent and well defined steps to follow.

Researching Technological Innovation in Small Business

Arthur Tatnall
Victoria University, Australia

INTRODUCTION

The introduction of a new information system into a small business, or upgrading an existing system, should be seen as an innovation and considered through the lens of innovation theory. The most widely accepted theories of how technological innovation takes place are provided by innovation diffusion (Rogers, 1995) and the technology acceptance model (Davis, 1986), but most of the research based on these models involves studies of large organizations or societal groups. This article argues that another approach, innovation translation, has more to offer in the case of innovations that take place in smaller organizations (Burgess, Tatnall, & Darbyshire, 1999; Tatnall, 2002; Tatnall & Burgess, 2004).

BACKGROUND

There are important differences in the processes by which small and large enterprises choose to adopt or reject computers (Tatnall, 2002, 2005a), and this article concerns itself only with issues related to small business. To begin, however, it is important to distinguish between invention and innovation. Whereas invention can be seen in the discovery or creation of new ideas, innovation involves putting these ideas into commercial or organizational practice (Maguire, Kazlauskas, & Weir, 1994). Invention does not necessarily invoke innovation, and it fallacious to think that invention is necessary and sufficient for innovation to occur (Tatnall, 2005b).

Changing the way things are done is a complex affair (Machiavelli, 1515) and one that is difficult to achieve successfully. The dominant paradigm, by far, in innovation research is that of *innovation diffusion*, and no discussion would be complete without consideration of this approach. Innovation diffusion has had success in describing how innovations diffuse through large populations (Rogers, 1995). There are occasions, however, when diffusion does not occur, and the diffusion model finds these difficult to explain (Latour, 1996). Another common approach is to use the technology acceptance model proposed by Davis, Bagozzi, & Warshaw (1989) that looks at user perceptions of technology as a basis for adoption or non-adoption. The approach offered in *innovation translation*, informed by actor-network theory (ANT), is also worthy of consideration. In the translation model the key to innovation is creating a powerful enough consortium of actors to carry it through, and when an innovation fails, this can be considered to reflect on the inability of those involved to construct the necessary network of alliances amongst the other actors. This article will compare these models of technological innovation.

INNOVATION DIFFUSION

Rogers (1995), perhaps its most influential advocate, approaches the topic of innovation diffusion by considering a variety of case studies, the prime concern of which is the identification of factors that affect the speed with which an innovation is adopted, or that cause it not to be adopted at all.

In diffusion theory the existence of an innovation is seen to cause uncertainty in the minds of potential adopters causing a lack of predictability and of information. Rogers (1995) asserts that a technological innovation embodies information and that this has the potential to reduce uncertainty. Diffusion is thus considered to be an information exchange process amongst members of a communicating social network driven by the need to reduce uncertainty (Lepa & Tatnall, 2002). There are four main elements of the theory of innovation diffusion (Rogers, 1995):

Characteristics of the Innovation Itself

Rogers argues that the attributes and characteristics of the innovation are important in determining the manner of its diffusion and the rate of its adoption and outlines five important characteristics of an innovation that affect its diffusion: relative advantage, compatibility, complexity, trialability, and observability. The attributes of the potential adopter are also seen as an important consideration, and Rogers maintains that these include social status, level of education, degree of cosmopolitanism, and amount of innovativeness.

Nature of the Communications Channels

Acts of communication are a necessary part of any change process, and to reach a potential adopter the innovation must be diffused through some communications channel. Channels

involving mass media are the most rapid and efficient means of spreading awareness of an innovation, but interpersonal channels are generally more effective in persuading someone to accept a new idea.

The Passage of Time

In common with earlier researchers, Rogers found that different individuals in a social system do not necessarily adopt an innovation at the same time. Borrowing from work by Deutschmann and Fals Borda (1962), he proposes that adopters can be classified by their degree of "innovativeness" into five categories—innovators, early adopters, early majority, late majority, and laggards—and that if the number of individuals adopting a new idea is plotted over time, it usually follows a normal curve.

The Social System

Diffusion occurs within a social system in which the structure constitutes a boundary inside which this diffuses. Rogers argues that the system's social structure affects diffusion through the action of social norms, the roles taken by opinion leaders and change agents, the types of innovation decisions that are taken, and the social consequences of the innovation.

TECHNOLOGY ACCEPTANCE MODEL (TAM)

The main goal of TAM is "to provide an explanation of the determinants of computer acceptance that is general, and capable of explaining user behavior across a broad range of end-user computing technologies and user populations, while at the same time being both parsimonious and theoretically justified" (Davis et al., 1989, p. 985). Davis's (1986) conceptual framework proposed that a user's motivational factors are related to actual technology usage and hence act as a bridge between technology design (e.g., system features and capabilities) and actual technology usage. In his conceptual framework, Davis (1986) assumes that stimulus variables (e.g., system features and capabilities) trigger organism factors (e.g., user motivation to use the technology), and in turn users respond by actually using the technology. Davis identifies the following major determinants of technology acceptance:

- Perceived usefulness
- Perceived ease of use

INNOVATION TRANSLATION

An alternative view is that of innovation translation, which draws on the sociology of translations, more commonly known as actor-network theory (ANT). The core of the actor-network approach is translation (Law, 1992), which can be defined as "... the means by which one entity gives a role to others" (Singleton & Michael, 1993, p. 229).

Essentialism

Diffusion theory asserts that a technological innovation embodies "information": some essential capacity or "essence" instrumental in determining its rate of adoption. A significant problem with an essentialist paradigm like this arises if a researcher tries to reconcile the views of all parties involved in the innovation on what *particular* essences are significant. The difficulty is that people often see *different* "essential attributes" in any specific technological or human entity, making it hard to identify and settle on the ones that allegedly were responsible for the diffusion.

To illustrate this difficulty, consider the case of a small business deciding whether to purchase their first computer. Researchers using an innovation diffusion model would begin by looking for innate characteristics of the PC that would make a potential adopter more likely to accept it. They would consider the relative advantages of a PC over alternatives like a filing-cabinet. An examination of the compatibility, trialability, and observability of a PC with this older office technology would show good reasons for acceptance. An examination of the PC's complexity would, however, bring out some reasons for reluctance in its adoption. The researchers would then investigate characteristics of the potential adopters, considering factors like their educational background, innovativeness, and how they heard about the innovation. If, however, you *ask* small business people why they purchased their first PC, the answers often do not match with this view.

Actor-Network Theory: The Sociology of Translations

Rather than recognizing in advance the essences of humans and of social organizations and distinguishing their actions from the inanimate behavior of technological and natural objects, ANT adopts an anti-essentialist position in which it rejects there being some difference in essence between humans and non-humans. ANT considers both social and technical determinism to be flawed and proposes instead a socio-technical account (Latour, 1986) in which neither social nor technical positions are privileged. To address the need

to properly consider the contributions of both human and non-human actors, actor-network theory attempts impartiality toward all actors in consideration, whether human or non-human, and makes no distinction in approach between the social, the natural, and the technological (Callon, 1986).

Mechanisms of Translation

The process of translation has four aspects or "moments" (Callon, 1986), the first of which is known as *problematization*. In this stage, a group of one or more key actors attempts to define the nature of the problem and the roles of other actors so that these key actors are seen as having the answer and being indispensable to the solution of the problem. In other words, the problem is re-defined (translated) in terms of solutions offered by these actors (Bloomfield & Best, 1992). The second moment is *interessement* and is a series of processes that attempt to impose the identities and roles defined in the problematization on the other actors. It means interesting and attracting an entity by coming between it and some other entity. Here the enrollers attempt to lock the other actors into the roles proposed for them (Callon, 1986) and to gradually dissolve existing networks, replacing them with a network created by the enrollers themselves.

If the interessement is successful, then the third moment, *enrollment*, will follow through a process of coercion, seduction, or consent (Grint & Woolgar, 1997), leading to the establishment of a solid, stable network of alliances. Enrollment, however, involves more than just one set of actors imposing their will on others; it also requires these others to yield (Singleton & Michael, 1993). Finally, *mobilization* occurs as the proposed solution gains wider acceptance and an even larger network of absent entities is created (Grint & Woolgar, 1997) through some actors acting as spokespersons for others.

An Example: Adoption of a Slide Scanner by a Small Publishing Company

To illustrate the use of the two innovation models, consider the case of DP Pty Ltd—a small publishing company where four people work on the publication of information systems textbooks. DP is a very small business with a well established market. Members of the company do much of the writing and all of the work involved in publication of their books but send the work off for printing and binding. Most of DP's print runs are small. All those involved in the work of the company are computer literate and make good use of IT. None of them, however, has much knowledge of computer graphics.

Several years ago the company decided it needed to improve the appearance of the covers on its textbooks. Several options were considered until someone thought of using a photograph. The brother of one of the directors is a landscape photographer who was able to provide a suitable color photograph. This was supplied in print form, and a problem arose in how to convert it (or its negative) into a suitable format to print on the cover along with the cover text. A digital image seemed to be the answer. The photograph was scanned (using a flat-bed scanner) and the digital image inserted into Microsoft Word so that text could easily be added. The final result was then converted into an Acrobat file and sent off to the printer. This process, however, proved to be quite a bother. Today the company makes use of a Nikon slide and negative scanner, considerably improving the quality of the covers, but also making the process of producing them much simpler. This device is capable of producing digital images of slides and negatives at various resolutions. The question is: why did DP decide to adopt this *particular* item of technology?

Consider first the application of a diffusion model. Here the company would have been mainly influenced by attributes and characteristics of the technology itself. The directors would have considered the relative advantage, compatibility, complexity, trialability, and observability of this technology compared with the alternatives. Two of the directors of the company certainly did see some relative advantage in using the slide scanner, particularly as they both had large numbers of color slides that they had taken over the years. There was, however, one major disadvantage of this technology, and that was its high cost: the slide scanner was around four times as expensive as a good flat-bed scanner. The slide scanner did not come out well on compatibility or complexity, as it was quite different and difficult to use. The company arranged trial use of the scanner, which was lucky as it proved difficult to find anyone else using one—its observability was low. On this basis it is difficult to see why DP would have adopted the slide scanner at all.

When a translation model is applied, the situation is seen quite differently. The socio-technical network consisting of the publishing company personnel, their computers, and their books was destabilized by the need to find a new way of producing book covers. The addition of a new actor, the landscape photographer, introduced new possibilities that worked to further destabilize this network. The slide scanner (also seen as an actor seeking to enter the network) offered new possibilities in which existing (and future) slides and negatives could easily be turned into digital images. This included *any* of the directors' old slides, not just those required for book covers. As well as the main application of producing book covers, both directors quickly saw advantages in a device that could also easily convert the old slides and negatives they had each taken of their children and of their holidays into digital format. It was thus a combination of factors, some business-related and others rather more personal, that the translation modes suggests could be seen as leading to the adoption of this technology.

Table 1. Innovation diffusion versus innovation translation (Adapted from McMaster, Vidgen, & Wastell, 1997)

	Innovation Diffusion	**Innovation Translation**
Innovation	A technology perceived to be new by the potential adopter.	A technology that has yet to be "black-boxed."
Communication	Communication channels can be categorized as cosmopolite or localite, and mass media or interpersonal. Innovations are transferred through these channels.	Translations are made by actors in enrolling the innovation.
Time	Speed of decision to innovate, earliness of adoption, and rate of adoption are important.	Network dynamics in enrollment, control, and dissemination are what matter.
The Social System	Homophily vs. heterophily. Sharing of interests of human actors.	Interessement between actants, both human and non-human, and goals. Black boxes form when interests move in the same direction.
The Technology	Changes are made to the form and content of the technology as a result of experiences during implementation (re-invention).	The technology is translated through being enrolled, regardless of whether its form or content is modified.
Socio-Technical Stance	The social system and the technology are separate. Diffusion is the adoption of technology by a social system. Technology transfer requires the bringing together of social and technical elements.	The social system and the technology are inseparable. Successful innovation and technology transfer give the appearance of separation, but this is merely evidence that the actor-network has stabilized.

It should also be pointed out that a significant translation occurred from the slide scanner advertised by Nikon in the magazine article and on their Web page to the device adopted by the publishing company. DP was not interested in using the scanner in all the ways that Nikon offered. They wanted a device to digitize slides and negatives for two reasons: the easy creation of attractive book covers and the conversion of their own color slides into a format that could easily be displayed on a video monitor. They did not adopt the scanner advertised by Nikon, but a device for creating book covers and formatting their slides for video display.

FUTURE DIRECTIONS: TRANSLATION VS. DIFFUSION

Many small businesses are family-related concerns with several members working in the business. Investigations (Tatnall, 2002; Tatnall & Burgess, 2002; Tatnall & Pliaskin, 2005) suggest that a common reason why a small business first acquired a PC is that it was, at least partly, intended for family use. In this regard, one reason that the PC was obtained was in the belief that it would assist with their children's education. Once obtained, other uses are almost always also found for the technology, but the question remains: would the characteristics of the PC and of the people involved in its adoption have been identified by a diffusion model? Table 1 summarizes differences in approaches between the diffusion and translation frameworks.

CONCLUSION

The translation approach to innovation details the construction of networks and alliances to support and embed changes in order to make them durable. Innovation diffusion and innovation translation are based on quite different philosophies, one stressing the properties of the innovation and the change agent and routed in essentialism, and the other emphasizing negotiations and network formation.

Innovation translation is more attuned to the human and political issues involved in small business decision making, and so offers a useful approach to modelling innovation in small business. Most current writings on technology uptake and innovation employ either no theoretical model at all, or else use a diffusion model. The author suggests that future research should further investigate the use of a translation model to explain the adoption of information technology in small business and encourages future researchers to consider this approach.

KEY TERMS

Actor-Network Theory (ANT): An approach to research in which networks' associations and interactions between actors (both human and non-human) are the basis for investigation.

Innovation: The application, in any organization, of ideas new to it, whether they are embodied in products, processes, or services.

Invention: The discovery or creation of new ideas.

Innovation Diffusion: A theory of innovation in which the main elements are characteristics of the innovation itself, the nature of the communication channels, the passage of time, and the social system through which the innovation diffuses.

Innovation Translation: A theory of innovation in which, instead of using an innovation in the form it is pro-

posed, potential adopters *translate* it into a form that suits their needs.

Small Business: For the purpose of this article, small businesses are considered to be those businesses that have from 1-20 employees.

Socio-Technical Research: Involving both social and technical interactions, occurring in such a way that it is not easily possible to disentangle them.

Sociology of Translations: Another term used to refer to actor-network theory.

Technological Innovation: The introduction or alteration of some form of technology (often information technology) into an organization.

Risk Management in the Digital Economy

Bob Ritchie
University of Central Lancashire, UK

Clare Brindley
Nottingham Trent University, UK

INTRODUCTION

Digital Economy and Risk: A Two-Edged Sword

Business processes have been transformed by radical changes predicated on the digital economy. Every business sector has witnessed changes in the competitive structure of the marketplace, consumer preferences, buying habits, marketing and promotional strategies, production operations, internal administration systems, supply chain arrangements, and the opening up of the global economy. These changes provide an array of risks for managers. A study of 500 financial executives in Europe and America (FM Global, 2007) concluded that they expected an increase in overall business risks in the foreseeable future. Similarly, Harland, Brenchley, and Walker (2003) concluded that the risk exposure of organizations will heighten due to increased complexity, turbulence, and the dynamic and changing supply chain context. However, the digital economy is a two-edged sword in the sense that the information and communication technologies (ICTs) generating the additional uncertainties and risks also provide the means to enable decision makers to manage them more effectively. The key to survival in the digital economy depends on the abilities of managers to utilize ICTs effectively to manage uncertainties and risks.

ICTs have largely been seen as helping to enhance database access, analytical powers, and the communications capacity of managers. The justification for these efforts has been based on the premise that more and better quality information will result in reduced uncertainty and improved risk perceptions in decision situations. In short, the outcome would be reflected in "better quality" decisions in terms of risk assessment and resolution.

Key topic areas presented in this article include:

- primary elements of the digital economy
- overview of risk and risk management,
- risk and uncertainty,
- individual/organizational response to resolving risk,
- role of information search and corporate intelligence,
- contribution of the digital economy to risk resolution,
- individual characteristics and risk perceptiveness,
- management of risks,
- risk perception,
- information processing and risk resolution, and
- risk management within the digital economy.

BACKGROUND

The Digital Economy

The term "digital economy" reflected in the title of this article may be viewed from a variety of perspectives:

1. *Technology* developments, especially those relating to the digital communication of data and information, are usually considered the primary driver in the creation of the digital economy. Increases in speed, improvements in capacity, accuracy, reliability, general quality, and ease of use are all features that have enabled the widespread adoption and development of digital technologies. The developments in audiovisual communication technologies and wireless technologies have opened up further opportunities for the transmission and exchange of business intelligence. Bluetooth technology /WiFi capabilities are now features of most hotels, gyms, educational centers, and other social spaces.
2. *Socio-economic* changes have been equally influential in the rapid adoption of the new technologies. Individuals of all ages, and educational and social backgrounds are prepared to regularly use mobile communications, access the Internet, and engage in interactive video communications, often with friends and family in different parts of the globe. The impact that these changes in individual and group social behaviors have had on the rate of adoption of new technologies should be fully appreciated. This is evidenced by the growth in social networking sites, such as MySpace and Facebook, and the ubiquitiness of MP3 technologies. The reasons underlying such changes are multifaceted, complex, and

beyond the scope of our present discussion, although they have been broadly influenced by individual social and economic needs.

3. *Micro-economic* factors at the level of the individual organization have been responsible for "pulling" and "pushing" organizations and their management towards increased attention and adoption of the digital economy. Significant "pull" factors include demands from end users of the product or service (e.g., requests for more detailed information on the product/service prior to and subsequent to the purchase, in terms of performance, maintenance, modifications, upgrades). The "push" factors are typically associated with the business organization seeking to maintain its competitive position by offering services equivalent to those of its main competitors, especially if these may be viewed as providing a distinctive competitive advantage (e.g., providing detailed product information via the Web and enabling customers to order directly). Some of the issues involved will be discussed further in later sections of the article.
4. *Macro-economic* factors are particularly significant in enabling the development of the digital economy, although they are often less evident when exploring individual product/market developments. Changes in legislation affecting consumer rights, guarantees of financial transactions, security of information held on computer systems, and commercial contracts negotiated via the Internet are all examples of the changes in the macro-economic environment needed to facilitate and support the development of the digital economy. Without such changes, individual organizations and customers might consider the risks of such commercial transactions to be too high. In essence, the responsiveness of governments and other similar institutions have lagged behind many of the demands placed on them by the rate of change in the digital economy. However, the introduction of the 2007 Gambling Act by the UK government illustrates how legislation is beginning to take into account digital developments, such as the growth in online gambling.

It may be argued that defining the term "digital economy" remains problematic due to the number of perspectives from which this term may be viewed and due to the number and interactive nature of the variables involved.

Overview of Risk and Risk Management

The key dimensions of risk and its management are:

- risk and uncertainty,
- risk resolution,
- role of information search and corporate intelligence,
- contribution of the digital economy,
- individual characteristics,
- management of risk, and
- risk perception.

Risk and Uncertainty

This seemingly simple term "risk" has proved somewhat problematic in arriving at an agreed definition. Most academic fields and researchers (e.g., Dowling & Staelin, 1994; Knight, 1921) provide variations on the theme, though most would agree that risk relates to two dimensions: the *likelihood* of a particular event occurring (i.e., probability), and the *consequences* should this event occur.

In the case of the consequences, it has been common to assume that these are generally undesirable, for example, financial loss or even loss of life. Sitkin and Pablo (1992, p. 9) define risk as "the extent to which there is uncertainty about whether potentially significant and/or disappointing outcomes of decisions will be realised." Similarly, MacCrimmon and Wehrung (1986) identified three components of risk: the magnitude of loss, the chance of loss, and the potential exposure to loss. However, it is important to recognize that there would be no point in taking risks unless there were some benefits to compensate for the possible negative outcomes (Blume, 1971). An associated feature is that of differing risk perceptions. Different individuals, groups of individuals, and organizations may view or perceive the risks (i.e., the likelihood of occurrence, nature and scale of negative consequences, and the potential rewards) differently (e.g., Forlani & Mullins, 2000; March & Shapira, 1987).

Uncertainty is viewed by many authors as a special case of the risk construct (Paulsson, 2004). The term "uncertainty" typically reflects the ambiguity surrounding the decision situation in terms of the precise nature of the situation, its causes, possible solutions, and the reaction of others to possible actions taken. Rowe (1977) has defined uncertainty as the absence of information concerning the decision situation and the need to exercise judgment in determining or evaluating the situation.

Risk Resolution

A natural reaction by decision makers facing uncertainty and risk is to seek to resolve the uncertainty and risk inherent in the decision situation. There are several actions that may be taken:

- seek to understand the parameters of the "problem" or situation,
- assess the predictability of the parameters,

- consider the possibility of eliminating or ameliorating the risks, and
- assess the attitudes of the decision makers towards the risks.

These elements represent the process that individuals and organizations develop to manage the risk, to position the organization, and to develop appropriate strategies to manage the impact of such events (Bettis, 1982). Brindley (2004) suggests that global competition, the continuous search for competitive advantage, and the multi-faceted relationships that have evolved are the primary motives behind organizations turning towards risk management approaches. Giannakis, Croom, and Slack (2004) also evidenced the emergence of risk management as an important contributor to most fields of management decision and control.

Role of Information Search and Corporate Intelligence

The decision maker confronted with a risky decision situation naturally follows a process of gathering more information, processing this in different ways, and evaluating this in relation to the risks faced. This information is then used—maybe consciously or unconsciously—by the decision maker to assess to what extent the risk has been removed, reduced, or resolved. If the decision maker is not satisfied that he or she has achieved sufficient resolution of the risks involved, then further information searches, analysis, and processing will occur. However, this intelligence-gathering process need not necessarily result in improved understanding and risk resolution. Uncovering more information may reveal more influencing variables, causing perceptions of greater uncertainty, both as a consequence of uncovering new influencing variables and an increasing sense of complexity. Ritchie and Marshall (1993) argued that the quality and sufficiency of the information available will influence the perception of risk by those involved in the decision-making process. Ritchie and Brindley (1999) argued that risk perception is both the consequence of information search and analysis as well as its determinant.

Contribution of the Digital Economy

Information can be considered as a risk-reduction or risk-insulating tool, on the basis that more and better information would result in improved decision making and more effective risk management. The rapid pace of ICT developments (Lumpkin & Dess, 2004; Kalakota & Robinson, 2000; Rycroft & Kash, 1999) and the emerging digital economy (Brindley & Ritchie, 2001) demonstrate that both individuals and organizations have easier access to more information that is more immediate and arguably more relevant. The decision makers can therefore access internal data, external market reports, competitor information, and so forth through their own desktops. Swash (1998) recognized that it is essential to overcome the problem of information overload by ensuring the Internet is used frequently, thus improving the users' surfing proficiency and their knowledge of "useful" sites. Improvements in the voluntary exchange of information may produce better knowledge of the situations surrounding the dynamics of a business or commercial relationship. This provides greater potential for detecting, averting, and managing risks. Indeed, organizations believe that the best approach is to accept that they will be exposed to risks, and the best strategy is to become more aware and proactive of the risks and better prepared to respond more quickly should such risks materialize (Kovoor-Misra, Zammato, & Mitroff, 2000).

Individual Characteristics and Risk

It is generally accepted that there are differences in individual risk perception, information-processing styles, and decision-making attributes (e.g., Chung, 1998). There is perhaps less agreement on the nature and consequences of such individual differences. For example, differences in gender have been posited as the reason for women being more meticulous in information search, more responsive to decision cues, and more risk averse than men (e.g., Chung, 1998). Others have failed to establish significant differences (e.g., Masters & Meier, 1988), suggesting that other contextual variables (e.g., social, educational, and experiential background) may be more relevant to any differences in behavior. For example, the decision to start a business may generate differences in risk-taking behavior that is not gender, culture or age related (Busenitz, 1999; Shapira, 1995). A number of authors (see Forlani & Mullins, 2000; Ghosh & Ray, 1997; Kahneman & Lovallo, 1993) have suggested that the provision of structured decision approaches and information search frameworks can provide the appropriate mechanism to overcome any biases and improve the quality of decisions. Ritchie and Brindley (2007) have posited a framework for managing risks within the supply chain.

Management of Risk

The strands of risk together with business intelligence in the digital economy may be captured in the three dimensions of individual/group/organizational behavior when confronted with risk in given decision situations:

- willingness to seek further resolution of the decision situation faced, both in terms of the context and the decision-specific variables;
- desire to identify and measure the risks in some way, either objectively or subjectively; and

- information search and processing to support the decision.

These three dimensions are closely inter-related and are employed to modify the risk perceptions of the decision makers. In addition to these decision-making activities is the range of activities associated with risk management. Some risk management activities may be undertaken prior to the decision itself (e.g., insuring against certain risks) or after the decision (e.g., effective management of relationships with customers to reduce the likely incidence of disputes). While activities of this type may be employed fairly readily with local markets, many managers may find it more difficult to avoid the risks resulting from increased global competition in their home or local markets, consequential of the digital economy.

Risk Perception

Throughout the decision process, an individual is seeking information to remove the uncertainties and to resolve the risks involved in the decision. The factors that contribute to the perceptions of uncertainty and risk experienced by the individual may be represented as (Brindley & Ritchie, 2001):

- direct implications in terms of costs and benefits and the scale of these;
- other decision outcomes, known with less certainty (e.g., reactions of peers and colleagues);
- time available in which to take the decision, typically constrained;
- funding available to undertake the research, analysis, and evaluation processes involved;

Figure 1. Information processing and risk resolution (adapted from Ritchie & Marshall, 1993)

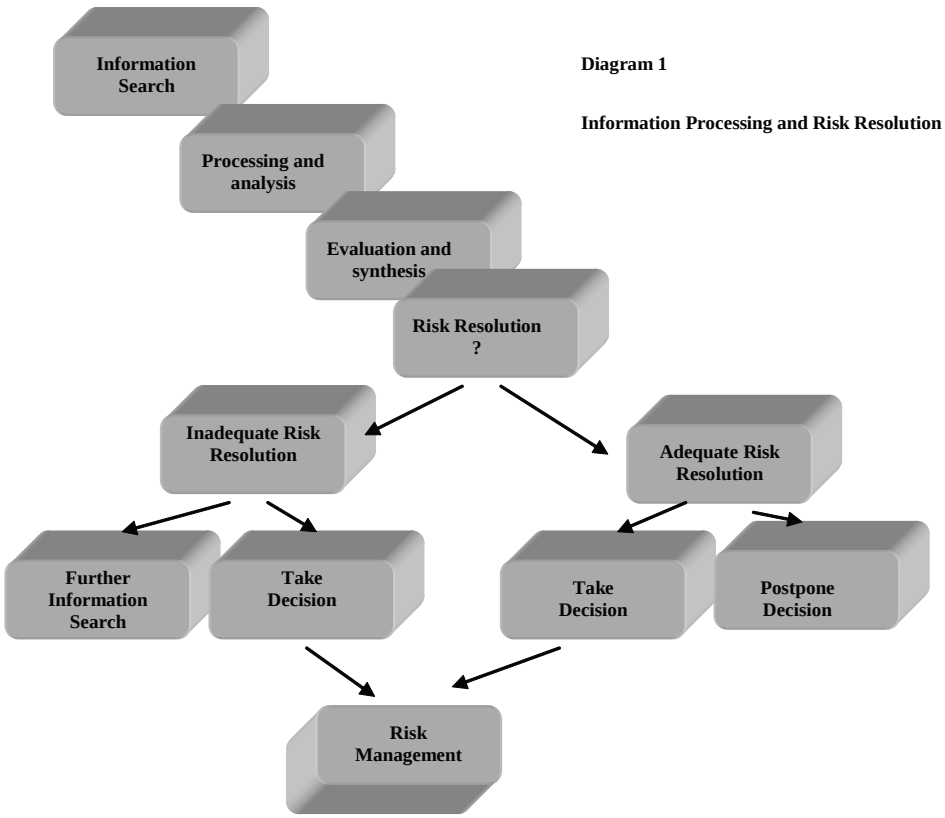

Diagram 1

Information Processing and Risk Resolution

- achievement of personal goals that decision maker(s) seek to satisfy; and
- data quality, which may significantly influence the nature of the risks perceived.

The integration and interaction of many of these components increases the complexity of understanding both risk perception and decision behavior. For example, although funding may be available to undertake intensive research, the pressures of time to respond to a given situation may preclude such activities even though they may be considered desirable.

Information Processing and Risk Resolution

The information-processing behavior of the individual may be presented in terms of the process described in Figure 1. The decision maker seeking to resolve the risks perceived will search for appropriate information, process, analyze, evaluate, and synthesize this with other information relating to the situation. The contribution of the digital economy is evident not only in providing the initial intelligence, but in assisting the decision maker in the processing and manipulation of the data prior to the decision-making stage. It is suggested that the decision maker either consciously or subconsciously assess whether the risks have been sufficiently resolved or not. In many respects, this may be posing the question concerning one's own degree of confidence in proceeding with the decision, though it may also be influenced by the factors identified.

An assessment that the risks had not been adequately resolved would normally result in further information search, analysis, synthesis, and so forth, repeating this cycle until the individual believed the risks had been sufficiently resolved to proceed. It is unlikely that the decision maker would achieve the situation where he or she was fully confident concerning risk resolution. The probable outcome, even after seeking further risk resolution, is that of having to make the decision even though the risks are not fully resolved, as a consequence of pressure of time, lack of resources to pursue further information, or the feeling that further search is unlikely to prove cost effective. This is probably a very common outcome reflected in the statements of many decision makers that "there are many other angles that we ought to explore but we no longer have the time to do so."

In situations where the decision maker considers that the risks have been adequately resolved, one might conclude that the normal procedure would be to proceed with the decision. Another possible outcome could be suggested where the decision maker decides to delay the decision. This may be simply a reluctance to commit oneself even if one is fairly clear and confident of the decision to be made. Alternatively, it may reflect a more deliberate tactic of delay to await changes in the decision situation, to assess the likely responses of other participants in the competitive situation, or perhaps in the hope that someone else may take the responsibility. The making of the decision is no longer viewed as the concluding stage in the process. Attention is increasingly being directed to the post-decision activities that seek to ensure that the opportunity is taken to avoid potential risks anticipated in the decision process, to avoid risks seen as less likely to impact on the situation, and to minimize the likelihood and consequences of those risks seen as more likely to occur. A generic term for these activities is *risk management.* Examples include:

- insuring against the financial consequences of particular outcomes;
- developing formal contractual arrangements with trading partners to limit scope for non-predicted behavior;
- training and staff development;
- communication of intentions within the appropriate internal and external networks to ensure involvement and commitment (e.g., relationship marketing);
- detailed planning, monitoring, and control at all stages;
- building close relationships with key partners to generate a sense of common purpose and trust (e.g., partnering); and
- developing more effective risk management strategies through more effective communications at all levels, both within the organization and with external partners.

FUTURE TRENDS

Risk Management Within the Digital Economy

The digital economy is impacting on organizations irrespective of their size, geographic location, or sector, a trend that is set to continue (Ritchie & Brindley, 2005) While such developments will engender greater uncertainty and risks, they will also facilitate solutions and opportunities for organizations to resolve and manage the new risks. Specific challenges for the organizations in the digital economy are:

1. Fundamental changes occur in the marketplace as a consequence of providing more direct communications with the consumer, greater heterogeneity in the market in terms of consumer needs and behavior, and a movement in the balance of power towards the consumer as opposed to the manufacturer or service provider.
2. Individuals and organizations are unlikely to behave in a rational and structured manner to resolve risks.

The previous emphasis on predictable patterns of information search, corporate business intelligence, and evaluation of information is likely to be replaced by less predictable demands as the nature of the problems encountered are less predictable. This will have significant implications for the development and design of business intelligence systems.

3. Predictions that the digital economy—by providing improved access to information and processing capabilities—will lead to improved decisions is unlikely to be sustainable.
4. The modus operandi of competitive and business relationships within the digital economy will evolve as the nature and extent of risks faced change, both in terms of novel risk situations encountered and the rate at which these occur. This is evident in the changing nature of supply chains (Brindley, 2004).
5. The development and training of the individual in terms of the appropriate knowledge, skills, and behavior patterns provides an important requirement to utilize the information available effectively.
6. The nature of what constitutes "effective" risk management is changing in the digital economy (Ritchie & Brindley, 2007).

CONCLUSION

The digital economy has produced a fundamental change in the nature of the risks faced and increased the likelihood that the marketplace will remain turbulent, unstable, and risk prone. Managers now need to have the capability—through improved knowledge, skills, and understanding—to identify, analyze, and manage these competitive developments and the associated risks. Associated with the improved capability to manage the risks is the ability to implement a wider range of risk management strategies to ameliorate the consequences of the incidence of risks and their consequences. The digital economy and the associated ICTs improve the opportunities to ensure effective risk management.

KEY TERMS

Decision Support: The tools, techniques, and information resources that can provide support to the decision maker in improving the efficiency and effectiveness of his or her decisions. Many of these decision support tools may employ ICTs and be part of the management information system itself.

Digital Economy: Accepts as its foundation the ICT developments and represents the impact that these have had on the conduct of business and commercial activities. Changes in markets and supply chains as well as increasing global competition all represent what is encapsulated within the term 'digital economy'.

Information and Communication Technologies (ICTs): A generic term used to encapsulate the diverse range of technological developments (e.g., computer storage and retrieval, computing capacity, wired communications, wireless communications, portable technologies) that have enhanced the internal and external activities of organizations. Especially important is the manner in which these strands of technological development have been integrated to provide greater synergy.

Management Information: A term that covers a wide variety of sources and types of information that may provide valuable to the decision making, management, and control of an organization. This term would include quantitative and qualitative information types, internal and externally sourced information, as well as classifying the information in terms of its quality (e.g., accuracy, detail, relevance, timeliness).

Risk: In a limited manner, the decision situation in which the full range of possible outcomes are known with certainty and the probability of their occurrence can be assessed accurately, usually by some objective means (e.g., rolling the dice is a classic risk decision situation). More usually, the probabilities must be assessed subjectively, often based on previous experiences or intuition, and the outcomes themselves may not be fully identifiable. The term "risk" is used commonly to generally define decision situations that are really a combination of classical risk and uncertainty – that is, the more normal decision situation in organizations.

Risk Management: The range of activities that may be taken to avoid the occurrence of an undesirable event or to modify, minimize, or eliminate the consequences should the event occur (e.g., an insurance policy against particular risks would not prevent the occurrence, but would compensate for the financial and other consequences of the outcome).

Risk Perception: The term used to express how a situation is viewed or seen by the decision maker(s). Individual characteristics, experiences, and beliefs may influence the way in which we might view a given situation as being either more or less risky. Usually this is measured on a subjective and relative scale (i.e., Situation A is perceived as riskier than B) rather than on an objectively measurable scale.

Uncertainty: The situation where less-than-perfect knowledge exists about a particular problem or decision requirement. There exists a wide variation in terms of degrees of uncertainty from extreme uncertainty (i.e., very limited knowledge of outcomes or likelihood of their occurrence)

to near certainty (i.e., almost complete knowledge of the outcomes and the likelihood of occurrence). Generally, an uncertain decision situation refers to one containing ambiguity about part or all of the decision parameters.

A Road Map for the Validation, Verification and Testing of Discrete Event Simulation

INTRODUCTION

The aim of this chapter is to give an elaborate reasoning for the motivation for Validation, Verification, and Testing (VV&T) in Simulation. Thereby, defining Simulation in its broadest aspect as embodying a certain model to represent the behavior of a system, whether that may be an economic or an engineering one, with which conducting experiments is attainable. Such a technique enables the management, when studying models currently used, to take appropriate measures and make fitting decisions that would further complement today's growth sustainability efforts, apart from cost decrease, as well as service delivery assurance. As such, the Computer Simulation technique contributed in cost decline; depicting the "cause and effect," pinpointing task-oriented needs or service delivery assurance, exploring possible alternatives, identifying problems, as well as proposing streamlined, measurable, deliverable, solutions, providing the platform for change strategy introduction, introducing potential prudent investment opportunities, and finally, providing a safety net when conducting training courses. Yet, the simulation development process is hindered due to many reasons.

Like a rose, Computer Simulation technique, does not exist without thorns, of which the length, as well as the communication during the development life cycle. Simulation reflects real-life problems; hence, it addresses numerous scenarios with handful of variables. Not only is it costly, as well as liable for human judgment, but also, the results are complicated and can be misinterpreted.

BACKGROUND

There are four characteristics, which distinguish simulation from any other software intensive work, that also makes

Table 1. Published research of V & V in WSC adapted from (Abu-Taieh & ElSheikh, 2006)

Year	V & V Papers	Total Published Papers	Percentage
1997	15	280	**5%**
1998	22	236	**9%**
1999	26	244	**11%**
2000	19	280	**7%**
2001	15	224	**7%**
2002	1	119	**1%**
2003	12	263	**5%**
2004	6	280	**2%**
2005	11	412	**3%**
2006	10	412	**2%**
Total	**137**	**2750**	**5%**
Average	**13.7**	**275**	**5%**

distinction VV&T for simulation from VV& T for other software. The four characteristics were discussed by Page and Nance (1997): *time*, *correctness*, *computational intensive*, and *the uses of simulation*. In simulation there is an indexing variable, called *TIME,* that "establishes an ordering of behavioral events" (p. 91). The objective of *correctness* is very special to simulation software for this simple reason: how useful is simulation program "if questions remain concerning its validity" (p.91). Simulation is *computational intensiveness;* therefore, the execution efficiency is essential due to the repetitive sample generation for statistical analysis and testing alternatives. *Uses of simulation*: the uses of simulation are not typical; in fact there is "No typical use for simulation can be described" (p.91).

Accordingly, validation and verification methods and techniques that relate to simulation have been thoroughly discussed by 137 research papers in the Winter Simulation Conference (WSC) over the years 1997 through 2006, as seen in Table 1 and Figure 1, highlighting the fact that such numbers clearly indicate the importance, inimitable, and unique case of validation, verification, and testing of simulation software.

In this context, it is worth noting that validation, verification, testing, as well as experimentations, execution, and design are so important that Shannon (1998) suggested giving 40% of the project time for these steps.

Why Do Simulation Projects Fail?

The arising issue of simulation projects falling short of being labeled as successful can be attributed to many reasons. An answer by Robinson (1999) has been put forth, as he listed three main reasons: the first being "poor salesmanship when introducing the idea to an organization," (p. 1702) which includes too much hope in too little time, while identifying the second reason as "lack of knowledge and skills particularly in statistics, experimental design, the system being modeled and the ability to think logically" (p. 1702), and pinpointing the third reason as "lack of time to perform a study properly" (p. 1702). Nevertheless, simulation inaccuracy has become a recurrent condition that instigated a thorough query into its sources.

Sources of Simulation Inaccuracy

There are three sources of inaccuracy the simulation project might be developing during the three major steps that are in the simulation life cycle, namely; modeling, data extraction, and experimentation (see Figure 2).

In this regard, the modeling process includes a subordinate set of steps, namely, the modeler understanding the problem, then developing a mental/conceptual model, and finally the coding. Note that, from these steps, some problems might mitigate themselves, such as (i) the model could misunderstand the problem, (ii) the mental/conceptual model could be erroneous, and (iii) the conversion from mental/conceptual model to coding could be off beam.

Furthermore, during the modeling process, the data collection/analysis is a key process element, particularly since the data collected is really the input of the simulation program. If the data is collected inaccurately, then the principle of *Garbage In Garbage Out* is clearly implemented; likewise, the data analysis, while using the wrong input model/distribution (see Leemis, 2003) is also a problem.

Figure 1. V & V research papers in WSC adapted from (Abu-Taieh & ElSheikh, 2007)

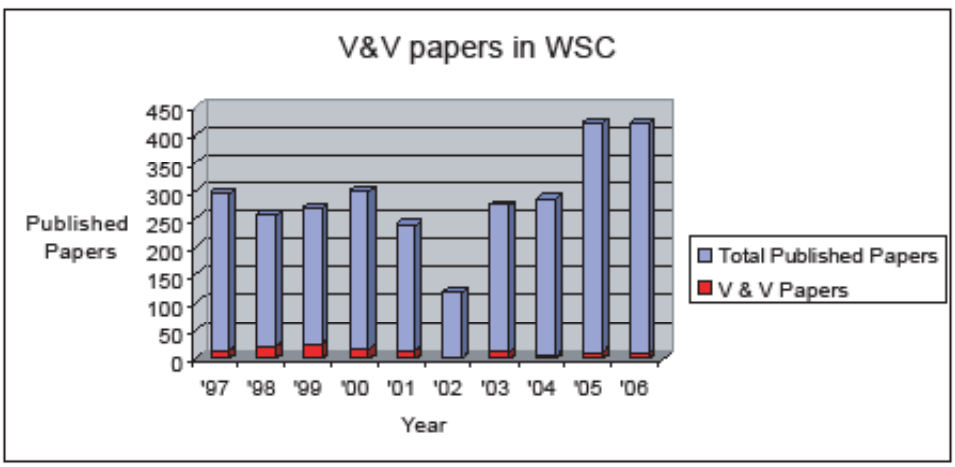

Figure 2. The simulation modeling process (simple outline) (Robinson, 1999, p. 1702)

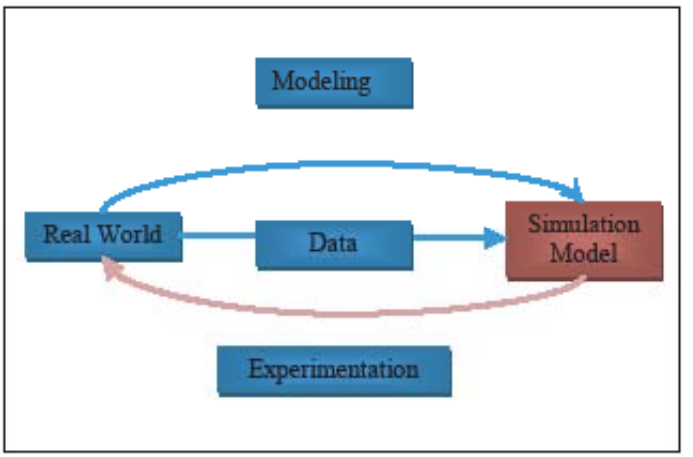


Last, but not least, the third source of inaccuracies is experimentation, which is using the collected data used in the simulation system and comparing the end result to the real world, given that experimentation inaccuracies can result from ignoring the initial transient period, insufficient run-length or replications, insufficient searching of the solution space, not testing the sensitivity of the results.

Within this context, ignoring the initial transient period, labeled as the first inaccuracy source during experimentation process, has been identified by Robinson (1999), when stating that "Many simulation models pass through an initial transient period before reaching steady-state" (p. 1705). The modeler, suggests Robinson, can either take into account such period or set the simulation system so that the system has no transient period. Moreover, insufficient run-length or replications, particularly as running the simulation system requires long enough is essential, in order to reach the results that reflect real life, therefore, Robinson suggests two remedies; (i) run the simulation system long enough, or (ii) do many reruns (replications). In addition, insufficient searching of the solution space is the third and last source, which in turn would incite the modeler to "only gain a partial understanding of the model's behavior" (Robinson, 1999, p. 1702), such inaccuracy, obviously leads to erroneous conclusion.

Acknowledging that, clearly, errors in the simulation world do not originate only from one source, therefore, validation, verification, and testing are not only considered a necessity, but also considered to be imperative and crucial, as Osman Balci, the well-known simulation scientist declared 15 principles, see (Balci, 1995, p. 149-151), demonstrating the fundamentality and inevitability of conducting VV&T to the simulation world.

VV&T Definition and Distinction (Main Focus)

In order to be able to discuss the VV&T, first, they must be defined, based on their original definition, fully comprehending the true denotation of VV&T, as related to simulation systems. Sommerville, (2001) defines validation by raising the question "are we building the right product?"(p. 420), while defining verification by raising another question, "are we building the product right?" (p. 420), as a pure software engineering point of view, noting that the simulation perspective on the definitions of V & V as similar yet not the same. On another note, Pidd (1988) defines Validation as "a process whereby we asses the degree to which the lumped model input: output relation map onto those real systems" (p. 157).

Likewise, Pidd (1998) distinguishes validation from verification by referring to verification as "a process by which we try to assure ourselves that the lumped model is properly released in the computer program. The lumped model is defined as an explicit and simplified version of the base model and is the one that will be used in management science" (p. 157). While Smith (1998) paraphrases validation as answering the question "Are we building the right product?" (p. 806) and verification as answering the question, "Are we building the product right?"(p. 806). (Balci, 1994, 1995 , 2003,) and (Kleijnen, Bettonvil, & Gmenendahl

1996) define *model validation* as follows:" *Model validation* is substantiating that the model, within its domain of applicability, behaves with satisfactory accuracy consistent with the study objectives" (Balci, 1995, p. 147).

Defining validation as true simulation scientist when stressing the words domain and satisfactory. Also, Balci (1995) defines *model verification* as in the following": *"Model verification* is substantiating that the model is transformed from one form into another, as intended, with sufficient accuracy" (p. 147). Again, Balci's (1995) definition is stressing here sufficient accuracy. Then Balci defines *model testing* as follows: "*Model testing* is demonstrating that inaccuracies exist or revealing the existence of errors in the model" (p. 147).

As such, the mere distinction between verification and validation is minute, yet substantive, acknowledging that validation ensures that the product caters to the needs, whereas, verification ensures the correctness and aptness of the product. Within this context, the word *testing* would be the tool to examine these two aspects.

Validation, Verification and Testing (VV&T) Taxonomy

Back in 1994, Balci (1994) categorized 45 VV&T techniques to informal, static, dynamic, symbolic, constraint, and formal (Balci, 1994), later he categorized 115 VV&T techniques to three families: conventional, adaptive, and specific VV&T (Balci, 1997), of which, 77 VV&T techniques for conventional simulation was again categorized to informal, static, dynamic, and formal, the remaining 38 VV&T techniques for adaptive and specific VV&T to be used in object-oriented simulation. Nevertheless, others, like Pressman (2005) and Hoffer (Hoffer, George, & Valacich, 2005) categorized the VV&T techniques based on the life-cycle phase. Within this context, following is a thorough discussion of both Balci's categorization.

On one hand, the conventional VV&T, in Figure 3 of Balci, had been before the object-oriented simulation idea in which the 45 VV&T techniques were categorized: informal, static, dynamic, symbolic. Within this context, the *informal VV&T technique* includes tools and approaches that "relay heavily on human reasoning" (Balci, 1994, p.217) rather than "mathematical formalism" (Balci, 1994, p.217), this category includes audit, desk checking, inspection, reviews, Turing test, walkthroughs (Freedman & Weinberg, 2000; Hoffer et al., 2005; Zammit, 2005), given the fact that the word *informal* should not reflect lack of structure or formal guidelines, as Balci (1994) says.

Along the same lines, *static VV&T techniques* concentrate on the source code of the model and need not the execution of the code (Hoffer et al., 2005), more importantly, Balci has stated that automated tools and the language compilers relay on this type of VV&T (Balci, 1994), since the *static VV&T techniques* category comprises of consistency checking, data flow analysis (Pressman, 2005), graph-based analysis (DMSO, 2005), semantic analysis, structural analysis, and syntax analysis (Sebesta, 2003).

Whereas, *dynamic VV&T techniques* distinguishing characteristic is for the model execution in order to evaluate the model as Balci (1994) states, as this category comprises of the following VV&T techniques: black-box testing (DMSO, 2005), bottom-up testing, debugging, execution monitoring, execution profiling, execution tracing, field testing, graphical comparisons, predictive validation, regression testing (Orso, Shi, & Harrold, 2004, p. 241),.and Mansour, (Mansour & Brardhi, 2001), sensitivity analysis, statistical techniques, stress testing, submodel testing, symbolic debugging, top-down testing, visualization, and white-box testing.

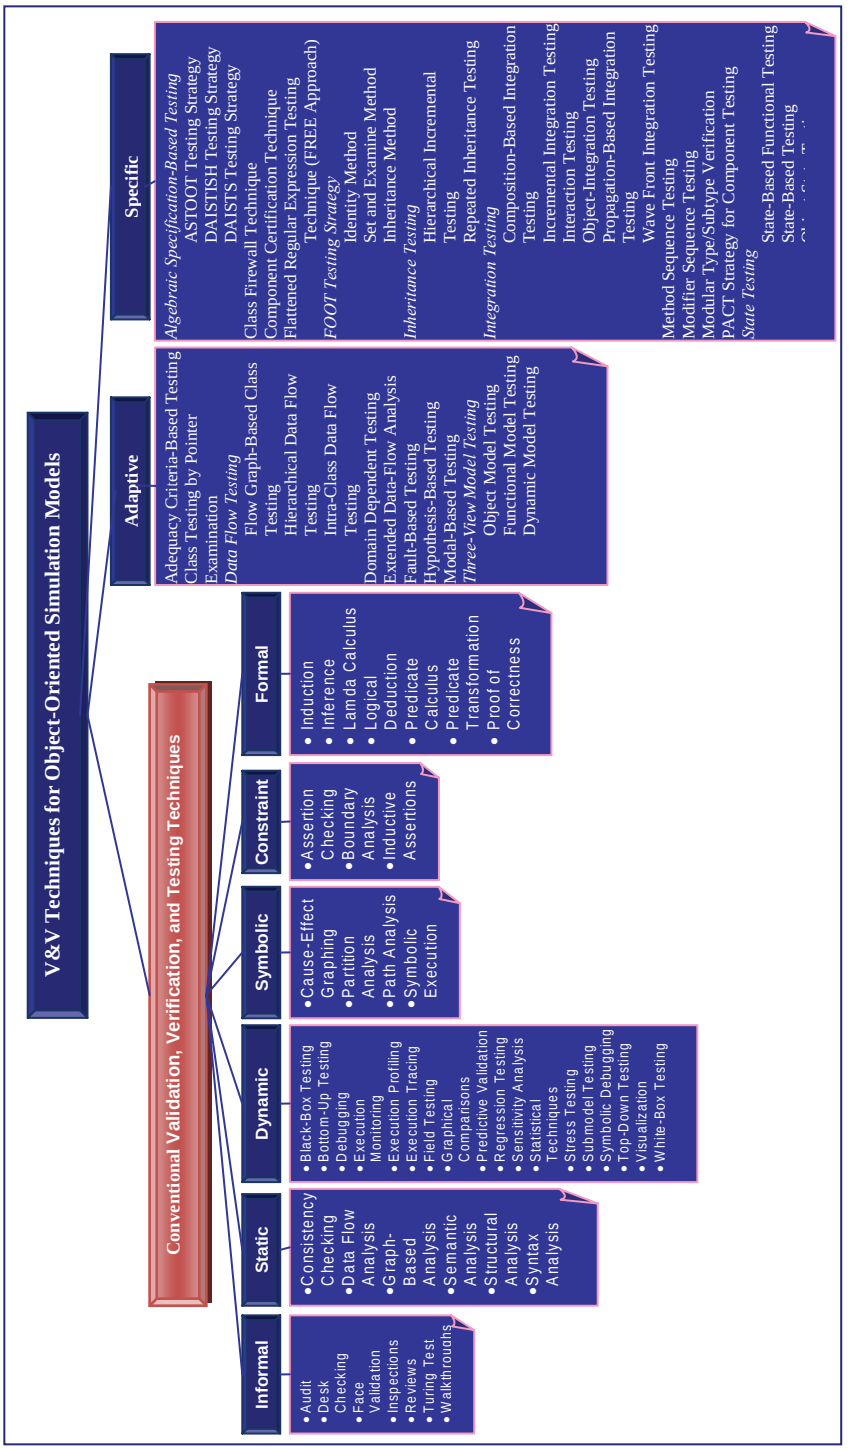
Nonetheless, the *symbolic VV&T techniques* category has been used to asses the model using VV&T techniques like cause–effect graphing, partition analysis, path analysis, and symbolic execution, noting that later in Balci's (1997), this category was incorporated with static category and dynamic category, while cause–effect graphing, and symbolic execution were incorporated in the static category, partition analysis, and path analysis were incorporated in the dynamic category. On another note, Balci has stated that *"Constraint VV&T techniques* are employed to assess model correctness using assertion checking, boundary analysis, and inductive assertions." (Balci, 1994, p. 218), later, however, such category also disappeared and was incorporated with others.

Balci, among others, admits that *formal VV&T techniques* are based on mathematical proof, stating that "Current state-of-the-art formal-proof of correctness techniques are simply not capable of being applied to even a reasonably complex simulation model" (Balci, 1994, p. 218).

Balci (1997) has developed taxonomy of VV&T techniques, Figure 3, that classified the VV&T techniques into three categories: conventional, specific, and adaptive. Moreover, the taxonomy defined 77 V&V techniques and 38 V&V techniques for object-oriented simulation, noting that most of the techniques are derived from the software engineering world, and modified to the needs of object-oriented simulation systems.

Within this context, *conventional techniques* refer mainly to VV&T techniques used in the object-oriented simulation without any adaptation to OOP, which is further classified as informal, static, dynamic, and formal categories, highlighting the fact that such categories were previously discussed. Likewise, *adaptive techniques*, the second category in the taxonomy, which refers to techniques that were adapted to object-oriented theory including adequacy criteria-based testing, class testing by pointer examination, data flow testing, (which includes flow graph-based class testing, hierarchical data flow testing, intra-class data flow testing), domain dependent testing, extended data-flow analysis, fault-based testing, hypothesis-based testing, modal-based

Figure 3. Taxonomy of validation, verification, and testing techniques (Balci, 1995, p. 152) and (Balci, 1997, p.140)



testing, three-view model testing (Pezz & Young, 2004) (which include object model testing, functional model testing, dynamic model testing).

Finally, *specific techniques*, the third category in the taxonomy, which are newly created based on object-oriented formalism and used for object –oriented software. Taking into consideration that those techniques are algebraic specification-based testing, ASTOOT testing strategy (Doong & Frankl, 1994), DAISTISH testing strategy (Hughes & Stotts, 1996), DAISTS testing strategy (Hughes & Stotts, 1996, p.1), class firewall technique, component certification technique, flattened regular expression testing, technique (FREE approach), FOOT testing strategy, identity method, set and examine method, inheritance method, inheritance testing, hierarchical incremental testing, repeated inheritance testing, integration testing, composition-based integration testing, incremental integration testing, interaction testing, object-integration testing, propagation-based integration testing, wave front integration testing, method sequence testing, modifier sequence testing, modular type/subtype verification, PACT strategy for component testing, state testing, state-based functional testing, state-based testing, object state testing, graph-based class testing.

FUTURE TRENDS

There are two major trends in the VV&T world: automation and correctness. The importance of correctness, which emphasizes the 100% correct software, is obvious in the use of Z specification language. Where the major idea is to prove mathematically that software is 100% error free.

The second trend is the automation of the VV&T. Indeed, testing is tedious, mind-numbing, lackluster, repetitive, and long process. Just as compilers started years ago to locate syntax errors, VV&T tools are becoming. In fact, there are many testing software tools that test software.

Whether the VV&T technique is static or dynamic, formal or informal, many tools have been developed to do the grubby work for the developer. Some tools, like *ProofPower,* go as far as supporting proof in higher order logic (HOL) and in the Z notation. As such, those mentioned hereinafter will be part of our life in validation, verification, accreditation, and surly independence.

CONCLUSION

In conclusion, this chapter showed the importance of VV&T that pertains to simulation through the eyes of research and researchers in the most famous front to simulation, Winter Simulation Conference. Then the chapter discussed why simulation fails and how VV&T of simulation is different than VV&T of the rest of software. Furthermore, this chapter has given a comprehensive synopsis of the simulation VV&T techniques, whether that may be procedural or object-oriented simulation, putting forth various taxonomies for both types of VV&T techniques.

KEY TERMS

Adaptive Techniques: Refers to *VV&T* techniques that were adapted to object-oriented theory.

Constraint VV&T Techniques: Employed to assess model correctness using assertion checking, boundary analysis, and inductive assertions." (Balci, 1994, p. 218).

Conventional Techniques: Refer mainly to VV&T techniques used in the object-oriented simulation without any adaptation to OOP.

Dynamic VV&T Techniques: Distinguishing characteristic is for the model execution in order to evaluate the model as Balci (1994) states.

Formal VV&T Techniques: Based on mathematical proof, stating that "Current state-of-the-art formal proof

of correctness techniques are simply not capable of being applied to even a reasonably complex simulation model" (Balci, 1994, p. 218).

Informal VV&T Technique: Includes tools and approaches that "relay heavily on human reasoning" (Balci, 1994, p.217) rather than "mathematical formalism" (Balci, 1994, p.217).

Simulation: "Is the imitation of the operation of a real-world process or system over time" (Banks, 1999).

Specific Techniques: Which are newly created based on object-oriented formalism and used for object –oriented software.

Static VV&T Techniques: Concentrate on the source code of the model and need not the execution of the code (Hoffer et al., 2005), more importantly, Balci has stated that automated tools and the language compilers relay on this type of VV&T (Balci, 1994).

Symbolic VV&T Techniques: Techniques that uses graphical or symbols to represent the VV&T process and to simplify it.

Validation: Raising the question "are we building the right product?".

Verification: Answering the question, "Are we building the product right?".

Robustness in Neural Networks

INTRODUCTION

The robustness analysis for neural networks aims at evaluating the influence on accuracy induced by perturbations affecting the computational flow; as such it allows the designer for estimating the resilience of the neural model w.r.t perturbations. In the literature, the robustness analysis of neural networks generally focuses on the effects of perturbations affecting biases and weights. The study of the network's parameters is relevant both from the theoretical and the application point of view, since free parameters characterize the "knowledge space" of the neural model and, hence, its intrinsic functionality.

A robustness analysis must also be taken into account when implementing a neural network (or the intelligent computational system into which a neural network is inserted) in a physical device or in intelligent wireless sensor networks. In these contexts, perturbations affecting the weights of a neural network abstract uncertainties such as finite precision representations, fluctuations of the parameters representing the weights in analog solutions (e.g., associated with the production process of a physical component), ageing effects or more complex, and subtle uncertainties in mixed implementations.

BACKGROUND

The sensitivity/robustness issue has been widely addressed in the neural network community with a particular focus on specific neural topologies. In particular, when the neural network is composed of linear units, the relationship between perturbations and the induced performance loss can be obtained in a closed form (Alippi & Briozzo, 1998). Conversely, when the neural topology is non-linear, we have either to assume the small perturbation hypothesis or particular assumptions about the stochastic nature of the neural computation (e.g., see Alippi (2002a), Alippi et al. (1998), and Pichè, 1995); unfortunately, such hypotheses are not always satisfied in real applications. Another classic approach requires expanding the neural computation with Taylor around the nominal value of the trained weights. A subsequent linearized analysis follows, which allows the researcher to solve the sensitivity issue problem (Pichè, 1995). This last approach has been widely used in the implementation design of neural networks where the small perturbation hypothesis abstracts small errors introduced by finite precision representations of the weights (Dundar & Rose, 1995; Holt & Hwang, 1993). Again, the validity of the analysis depends on the validity of the small perturbation hypothesis.

Differently, other authors avoid the small perturbation assumption by focusing the attention on very specific neural network topologies and/or by introducing particular assumptions regarding the distribution of perturbations, internal neural variables, and inputs as done for Madalines neural networks (Alippi, Piuri, & Sami, 1995; Stevenson, Winter, Widrow, 1990).

Some other authors tackle the robustness issue differently by suggesting techniques leading to neural networks with improved robustness ability by acting on the learning phase (e.g., see Alippi, 1999) or by introducing modular redundancy (Edwards & Murray, 1998); though, no robustness indexes are suggested there. The robustness of neural networks with respect to hardware implementations were also studied in Hereford and Kuyucu (2005) and Nugent, Kenyon, and Porter (2004) where authors proposed evolutionary and adaptive approaches.

Again, the study of robustness over training time has been evaluated for neural networks in the large, without assuming the small perturbation hypothesis (Alippi, Sana, & Scotti, 2004). In this direction, other authors have addressed the issue of the robustness analysis during the training phase (Manic & Wilamowski, 2002; Qin Juanyin, Wei Wei, & Wang Pan, 2004) by suggesting a genetic approach or by considering the use of the regression theory.

An overview of the sensitivity issues in neural networks can be found in Ng, Yeung, Xi-Zhao, and Cloete, (2004).

In this article, we suggest a robustness/sensitivity analysis in the large (i.e., without assuming constraints on the size or nature of the perturbation); as such, the small perturbation hypothesis becomes only a subcase of the theory. The suggested

sensitivity/robustness analysis can be applied to ALL neural network models (including recurrent neural models) involved in system identification, control signal/image processing and automation-based applications without any restriction to study the relationship between perturbations affecting the knowledge space and the induced accuracy loss.

A ROBUSTNESS ANALYSIS IN THE LARGE

In the following we consider a generic neural network implementing the $\hat{y} = f(\theta, x)$ function where $\hat{\theta}$ is the weight vector of the trained neural network.

In several neural models, and in particular in those related to system identification and control, the relationship between the inputs and the output of the system are captured by considering a regression vector φ, which contains a limited time-window of actual and past inputs, outputs, and -possibly- predicted outputs.

Of particular interest are those models, which can be represented by means of the model structures $\hat{y}(t) = f(\varphi)$ where function $f(\cdot)$ is a regression-type neural network, characterized by N_φ inputs, N_η non-linear hidden units, and a single effective linear/non-linear output (Hassoun, 1995; Hertz, Krog, & Palmer, 1991; Ljung, 1987; Ljung, Sjoberg, & Hjalmarsson, 1996).

We denote by $y_\Delta(x) = f_\Delta(\theta, \Delta, x)$ the mathematical description of the perturbed computation and by $\Delta \in D \subseteq \Re^p$ a generic p-dimensional perturbation vector, a component for each independent perturbation affecting the network weights of model $\hat{y}(t)$. The perturbation space D, is characterized in stochastic terms by providing the probability density function pdf_D.

To measure the discrepancy between $y_\Delta(x)$ and $y(t)$ or $\hat{y}(t)$ we consider a generic loss function $U(\Delta)$. A common example for U is the Mean Square Error –MSE- loss function:

$$U(\Delta) = \frac{1}{N_x} \sum_{i=1}^{Nx} (y(x_i) - \hat{y}(x_i, \Delta))^2 \qquad (1)$$

but a generic Lebesgue measurable loss function with respect to D can be taken into account (Jech, 1978). The formalization of the impact of perturbation on the performance function can be simply derived as:

Definition: Robustness Index

We say that a neural network is robust at level $\bar{\gamma}$ in D, when the robustness index $\bar{\gamma}$ is the minimum positive value for which:

$$U(\Delta) \le \bar{\gamma},\ \forall\ \Delta \in D,\ \forall \gamma \ge \bar{\gamma}. \qquad (2)$$

Immediately, from the definition of robustness index, we have that a generic neural network NN1 is more robust than another NN2 iff $\bar{\gamma}_1 < \bar{\gamma}_2$; the property holds independently from the topology of the two neural networks.

The main problem related to the determination of the robustness index $\bar{\gamma}$ is that we have to compute $U(\Delta)$, $\forall\ \Delta \in D$ if we wish a tight bound. The $\bar{\gamma}$-identification problem is therefore intractable from a computational point of view if we relax all assumptions made in the literature as we do.

To deal with the computational aspect we associate a dual probabilistic problem to (2):

Robustness Index: Dual Problem

We say that a neural network is robust at level $\bar{\gamma}$ in D with confidence η, when $\bar{\gamma}$ is the minimum positive value for which:

$$\Pr(U(\Delta) \le \bar{\gamma}) \ge \eta \ \text{ holds } \forall\ \Delta \in D,\ \forall \gamma \ge \bar{\gamma}. \qquad (3)$$

The probabilistic problem is weaker than the deterministic one since it tolerates the existence of a set of perturbations (whose measure according to Lebesgue is 1-η) for which $u(\Delta) > \bar{\gamma}$. In other words, not more than 100η% of perturbations $\Delta \in D$ will generate a loss in performance larger than $\bar{\gamma}$.

Probabilistic and deterministic problems are "close" to each other when we choose, as we do, η=1.

The non-linearity with respect to Δ and the lack of a priori assumptions regarding the neural network do not allow computing (2) in a closed form for the general perturbation case. The analysis, which would imply testing $U(\Delta)$ in correspondence with a continuous perturbation space, can be solved by resorting to probability according to the dual problem and by applying randomised algorithms (Alippi, 2002b; Bai, Tempo, & Fu, 1997; Tempo & Dabbene, 1999; Vidyasagar, 1996, 1998) to solve the robustness/sensitivity problem.

RANDOMIZED ALGORITHMS AND PERTURBATION ANALYSIS

In the following we denote by $p_\gamma = \Pr\{U(\Delta) \le \bar{\gamma}\}$ the probability that the loss in performance associated with perturbations in D is below a given—but arbitrary—value γ.

Probability p_γ is unknown, it cannot be computed in a form for a generic U function and neural network topology, and its evaluation requires exploration of the whole perturbation space D.

Anyway, the unknown probability p_γ can be estimated by sampling D with N independent and identically distributed samples Δ_i (intuitively a sufficiently large random sample explores the space); extraction must be carried out according

to the pdf of the perturbation. For each sample Δ_i we then generate the triplet:

$$\{\Delta_i, U(\Delta_i)\, I(\Delta_i)\},\ i = 1, N \text{ where } I(\Delta_i) \begin{cases} 1 \text{ if } U(\Delta_i) \le \gamma \\ 0 \text{ if } U(\Delta_i) > \gamma \end{cases}. \tag{4}$$

The true probability p_γ can now be simply estimated by means of the frequency as:

$$\hat{p}_N = \frac{1}{N}\sum_{i=1}^{N} I(\Delta_i). \tag{5}$$

Of course, when N tends to infinity, $\hat{p}_N$ somehow converges to p_γ. By introducing an accuracy degree ε on the difference $|p_\gamma - \hat{p}_N|$ and a confidence level 1– δ (which requests that the $|p_\gamma - \hat{p}_N| \le \varepsilon$ inequality is satisfied at least with probability 1– δ), our problem can be formalized by requiring that the inequality:

$$\Pr\{|p_\gamma - \hat{p}_N| \le \varepsilon\} \ge 1 - \delta \tag{6}$$

is satisfied for $\forall\gamma \ge 0$. In other words (6) states that the true probability and its estimates must be very close (they may differ not more than ε) and that the statement must be true with high probability. Of course, we wish to control the accuracy and the confidence degrees of (6) by allowing the user to choose the most appropriate values for the particular need. Finally, by extracting a number of samples from D according to the Chernoff bound (Chernoff, 1952):

$$N \ge \frac{\ln\frac{2}{\delta}}{2\varepsilon^2} \tag{7}$$

we have that $\Pr\{|p_\gamma - \hat{p}_N| \le \varepsilon\} \ge 1 - \delta$ holds for $\forall\gamma \ge 0$, $\forall\delta, \varepsilon \in [0,1]$.

As an example, by considering a 5% in accuracy and 99% in confidence we have to extract 1060 samples from D; with such choice we can approximate p_γ with $\hat{p}_N$ introducing the maximum error 0.05 ($\hat{p}_N - 0.05 \le p_\gamma \le \hat{p}_N + 0.05$) and the inequality holds at least with probability 0.99.

The Chernoff bound grants that the dual probabilistic problem related to the identification of the robustness index $\bar{\gamma}$ can be solved with a polynomial complexity algorithm in the accuracy and the confidence degrees independently from the number of weights of the neural model network. In fact, from (6) if accuracy ε and confidence δ are small enough we can confuse p_γ and $\hat{p}_N$ by committing a small error. As a consequence, the dual probabilistic problem requiring $p_\gamma \ge \eta$ becomes $\hat{p}_N \ge \eta$. We surely assume ε and δ to be small enough in subsequent derivations.

The final algorithm, which allows for testing the robustness degree $\bar{\gamma}$ of a generic neural network, can be summed up as:

1. Select ε and δ sufficiently small to have enough accuracy and confidence
2. Extract from D, according to its pdf, a number of perturbations N as suggested by (7)
3. Generate the indicator function $I(\Delta)$ and generate the estimate $\hat{p}_N = \hat{p}_N(\gamma)$ according to (5)
4. Select the minimum value γ_η from the $\hat{p}_N = \hat{p}_N(\gamma)$ function so that $\hat{p}_N(\gamma_\eta) = 1$ is satisfied $\forall\gamma \ge \gamma_\eta$. γ_η is the estimate of the robustness index $\bar{\gamma}$.

Note that with a simple algorithm we are able to estimate in polynomial time the robustness degree $\bar{\gamma}$ of a generic neural network. The accuracy in estimating $\bar{\gamma}$ can be made arbitrarily good by considering a larger number of samples as suggested by the Chernoff's bound.

SOME EXPERIMENTAL RESULTS

To shed light on how the methodology can be used to test the robustness of a neural network we focus the attention on a regression-type experiment. In particular, we consider the simple error-free function:

$$y = -x \cdot \sin(x^2) + \frac{e^{-0.23 \cdot x}}{1 + x^4}, \quad x \in [-3, 3]$$

and we approximate it with a regression-type neural network having 10 hidden units. Learning is then perfected with a Levenberg-Marquardt training algorithm (Hassoun, 1995).

We then wish to test the robustness of the trained neural network in the large (i.e., by not assuming the small perturbation hypothesis).

Perturbations affecting weights and biases of the neural network are defined in a perturbation space subject to a uniform distribution. In particular, a perturbation Δ_i affecting a generic weight w_i must be intended as a relative perturbation with respect to the weight magnitude according to the multiplicative perturbation model $w_{i,p} = (1 + \Delta_i)$, $\forall i = 1, n$ (e.g., see Edwards et al., 1998). As such, a t% perturbation implies that Δ_i is drawn from a symmetrical uniform distribution of extremes

$$\left[-\frac{t}{100}, \frac{t}{100}\right];$$

a 5% perturbation affecting weights and biases composing vector $\hat{\theta}$ hence requires that each weight/bias is affected by an independent perturbation extracted from the [– 0.05, 0.05] interval and applied to the nominal value according to the multiplicative perturbation model. By applying the algorithm suggested in the previous section we determine the $\hat{p}_\gamma = \hat{p}_\gamma(\gamma)$ functions corresponding to the 1%, 3%, 5%,

10%, 30% perturbations. Results are given in figure 1 where we considered $\varepsilon = 0.02$, $\delta = 0.01$ leading to N=6624.

From its definition, $\bar{\gamma}$ is the smallest value for which $\hat{p}_\gamma = 1$, $\gamma \geq \bar{\gamma}$; in the figure, if we consider the 5% perturbation case, $\bar{\gamma}$ assumes a value around 7. We observe that by increasing the strength of perturbation (i.e., by enlarging the extremes of the uniform distribution characterizing the pdf of D) $\bar{\gamma}$ increases. In fact, stronger perturbations have a worse impact on the performance loss function since the error-affected neural network diverges from the error-free one. Conversely, we see that small perturbations (e.g., the 1% one) induce a very small loss in performance since the robustness index γ_η is very small.

Another interesting use of the suggested methodology allows the neural network designer to test different neural models and identify, for instance, the most robust one.

To this end, we consider a set of performance-equivalent neural networks, each of which able to solve the application with a performance tolerable by the user. All neural networks are characterized by a different topological complexity (number of hidden units).

The $\hat{p}_\gamma = \hat{p}_\gamma(\gamma)$ curves parameterized in the number of hidden units are given in Figure 2 in the case of 1% perturbation. We see that by increasing the number of hidden units $\bar{\gamma}$ decreases. We immediately realize that neural networks with a reduced number of hidden units are, for this application, less robust than the ones possessing more degrees of freedom. For this application, large networks provide, in a way, a sort of spatial redundancy: information characterizing the knowledge space of the neural networks is distributed over more degrees of freedom.

It should be clear, anyway, that robustness is a property of the identified neural model and strongly depends on the neural network complexity, the envisaged training algorithm, the training starting point and the training data samples. Hence, for a generic application, it is not possible to assert that by increasing the network complexity (i.e., by increasing the number of hidden units) we improve the robustness of the obtained model.

We then tested the robustness of two trained neural networks in the large (i.e., by not assuming the small perturbation hypothesis) in case of a classification problem. We considered two equiprobable classes C0 and C1 with bidimensional Gaussian distributions:

$$(X,Y) \sim N\left(\begin{bmatrix} \mu_X & \mu_Y \end{bmatrix}, \begin{bmatrix} \sigma_X^2 & 0 \\ 0 & \sigma_Y^2 \end{bmatrix} \right)$$

$$\text{C0: } (X,Y) \sim N\left(\begin{bmatrix} 0 & 0 \end{bmatrix}, \begin{bmatrix} 9 & 0 \\ 0 & 9 \end{bmatrix} \right)$$

$$\text{C1: } (X,Y) \sim N\left(\begin{bmatrix} 10 & 10 \end{bmatrix}, \begin{bmatrix} 9 & 0 \\ 0 & 9 \end{bmatrix} \right).$$

We considered two neural networks: a feed-forward and a probabilistic neural network.

Similarly to what done for the regression-type experiment, we assumed perturbations affecting weights and biases to be defined in a perturbation space subject to the symmetrical uniform distribution of extremes

$$\left[-\frac{t}{100}, \frac{t}{100} \right],$$

Figure 1. $\hat{p}_\gamma$ as a function of γ for the 10 hidden units neural network

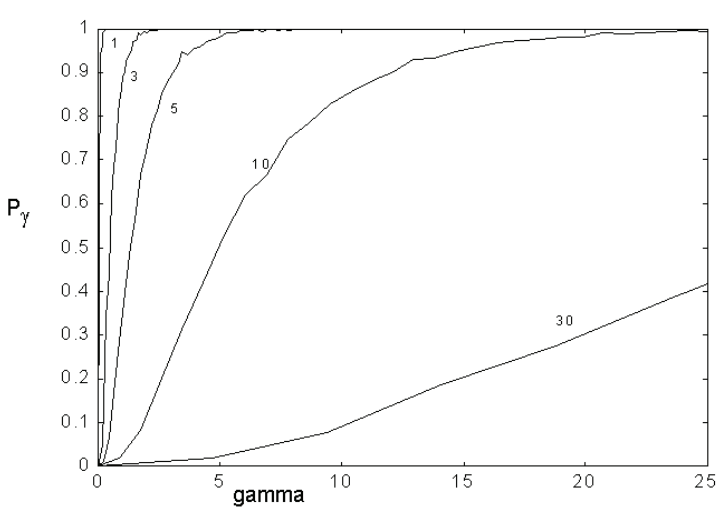

Figure 2. $\hat{p}_\gamma$ over γ and parameterized in the number of hidden units

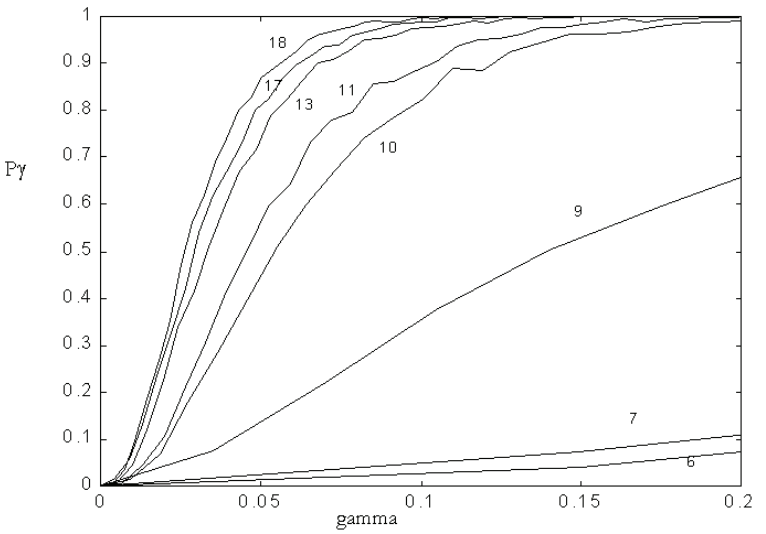

with t equals to 1,3,5,10 or 30. Even in this case, the perturbation Δ_i affecting a generic weight w_i must be intended as a relative perturbation with respect to the weight magnitude according to the multiplicative perturbation model $w_{i,p} = (1 + \Delta_i)$, $\forall i = 1, n$.

By applying the algorithm suggested in the previous section we determined the $\hat{p}_\gamma = \hat{p}_\gamma(\gamma)$ functions corresponding to the 1%, 3%, 5%, 10%, 30% perturbations for the feed-forward neural network (10 hidden units neural network). Results are given in Figure 3 where we considered $\varepsilon = 0.02$, $\delta = 0.01$ (N=6624).

Even in this case it is possible to identify $\bar{\gamma}$ by definition; for instance, in the figure $\bar{\gamma}$ assumes a value around 0.4 for the 5% perturbation case. As expected by increasing the strength of perturbation (i.e., by enlarging the extremes of the uniform distribution characterizing the pdf of D) $\bar{\gamma}$ increases. It is worth noting that even small perturbations (e.g., the 1% one, induce a not neglectible loss in performance).

We then applied the suggested algorithm to the probabilistic neural network, whose spread value was set at 0.1. We evaluated the $\hat{p}_\gamma = \hat{p}_\gamma(\gamma)$ functions corresponding to the 1%, 3%, 5%, 10%, 30% perturbation cases: results are given in figure 4. Even in this case we considered $\varepsilon = 0.02$, $\delta = 0.01$.

As expected by increasing the strength of the perturbation, $\bar{\gamma}$ increases. Differently from the feed-forward neural network, small perturbations induce a very small loss in performance since the robustness index γ_η is very small.

By analyzing the last two figures, we realize that, in the considered classification problem, the probabilistic neural network is more robust than the feed-forward neural network with 10 hidden units. This is evident by considering the different values of $\bar{\gamma}$ provided by the probabilistic and the feed forward neural network in case of the considered perturbations. The values of $\bar{\gamma}$ of the probabilistic neural network are significantly lower than the ones provided by the feed-forward network.

However, it is important to recall that, as previously defined, robustness is a property of the identified neural model and strongly depends on the neural network complexity, the envisaged training algorithm, the training starting point and the training data samples. It is thus impossible to state that the probabilistic neural networks are generally more robust than the feed-forward ones in case of classification problems.

FUTURE TRENDS

As explained in the article, the robustness analysis in the large issues allows the designer to solve all limits posed by the small perturbation hypothesis. Anyway, further research needs to be done in this direction by enlarging the application domain (e.g., by considering recurrent neural networks and assessing with the suggested methodology stability issues) and studying the training modality. The latter aspect is of primary relevance to understand the intrinsic nature of the learning algorithms, how it works for an ensemble of neural models, and their efficacy in proximity of the minimum of the figure of merit associated with training and validation.

CONCLUSION

A robustness analysis in the large (i.e., by not assuming any hypothesis about the perturbation strength) can be ad-

Figure 3. $\hat{p}_\gamma$ *as a function of* γ *for the feed-forward neural network*

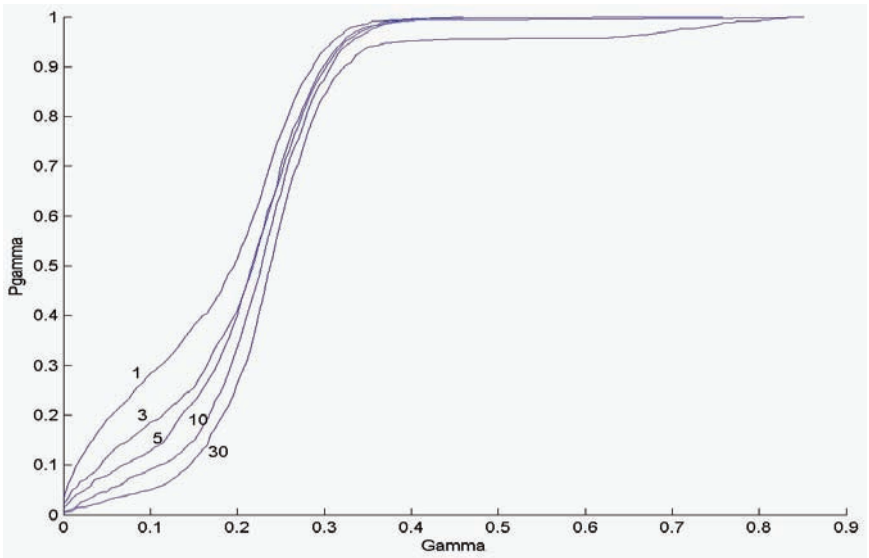

Figure 4. $\hat{p}_\gamma$ *as a function of* γ *for the probabilistic neural network*

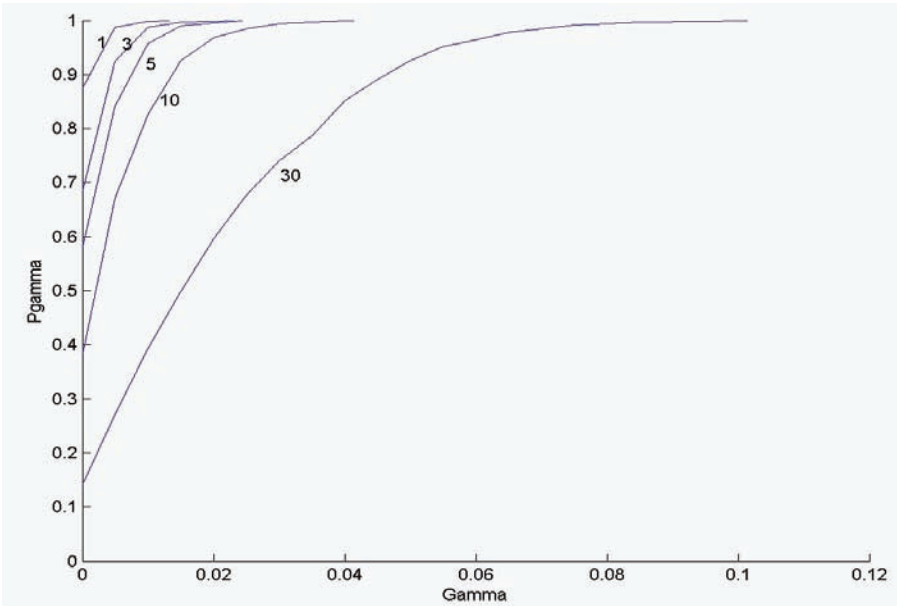

dressed for a generic neural network model and accuracy loss figure of merit by resorting to randomization. In reality, the robustness analysis is even more general and can be considered for any Lebesgue-measurable computation (basically, all functions involved in signal/image processing are Lebesgue-measurable).

Hence, by considering trained neural networks, we can easily estimate the effects induced by perturbations affecting a generic neural network by considering a probabilistic approach. The robustness index, which can be used to investigate the relationships between knowledge space and neural network accuracy, can be computed with an effective poly-time algorithm, which spouses Monte Carlo and learning theories sampling methods.

KEY TERMS

Knowledge Space: The space defined by the neural network weights.

Neural Network Weights: The free parameters of the neural model.

Perturbation: A behavioral entity affecting the weights of a neural network.

Poly-Time Algorithm: An algorithm whose complexity evolves polynomially with respect to the envisaged complexity parameter.

Regression-Type Neural Network: A neural network with one hidden layer and a unique linear output neuron used to approximate a mathematical function.

Randomized Algorithms: A probabilistic sampling technique for exploring a space combining learning theories and Monte Carlo approaches.

Robustness: A property possessed by a system. A system is robust with respect to a perturbation when the perturbation effect on the system performance is tolerable according to a predefined threshold.

Small Perturbation Hypothesis: The strength of the envisaged perturbations is small enough to guarantee effectiveness for a linearized sensitivity analysis.

Wireless Sensor Network: A network of distributed sensors linked by wireless connections.

The Role of Business Case Development in the Diffusion of Innovations Theory for Enterprise Information Systems

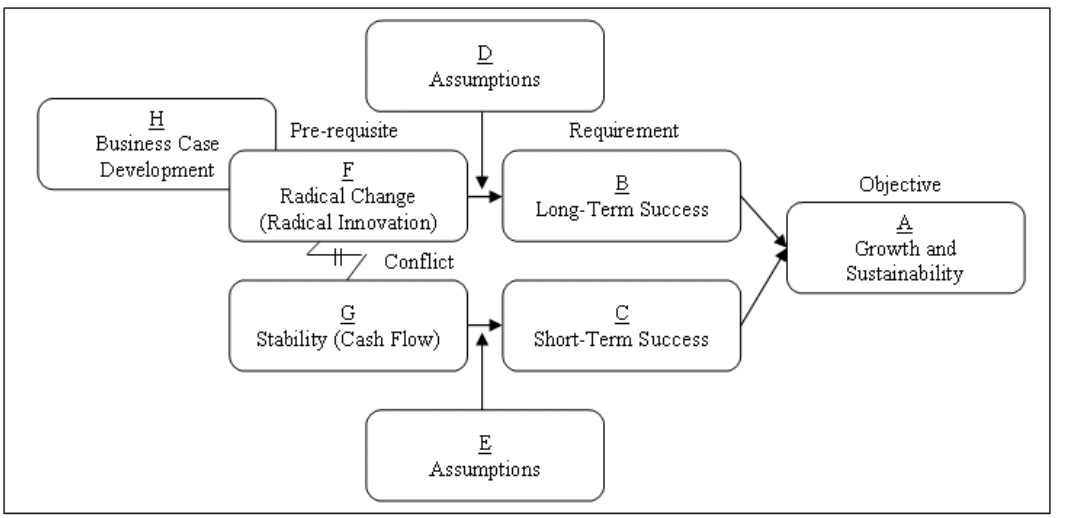
INTRODUCTION

A successful organisation continually initiates and implements radical innovations. The innovation must not only be new. A radical innovation has a significant impact on how the organisation undertakes its business process. Impacting is different from affecting. The former has a more substantial effect on the organisation. This is precisely why new enterprise information systems represent a radical innovation. To be successful, the organisation undertakes an innovation-decision process to align itself, as much as possible, with the ever-changing external realities. The **innovation-decision process** dictates selling an idea (the business case) that the new enterprise information systems possess economic value to upper management.

This paper depicts a bird's-eye view of how innovation, in this case, the new enterprise information systems, diffuses (episteme) via business case development (techne) in the innovation-decision process. As shown in Figure 1, the adoption and implementation of new enterprise information systems constitute a radical change (prerequisite F). New enterprise information systems represent radical innovation. An **innovation-decision process** starts with an **initiation phase** through which the individuals or decision-making units move from identifying and knowing the new enterprise information systems, to the forming of an attitude toward the different competing software packages, and subsequently to deciding whether to adopt or reject the implementation and use of the new idea. A **business case** is a formally written document that argues about the adoption to a certain course

Figure 1. Conflict between radical change and stability



Interpreted from Burrell & Morgan (2005), Dettmer (2003), Trompenaars & Prud'homme (2004)

of action. It contains a point-by-point analysis to making a decision for a set of alternative courses of action to accomplish a specific goal. A **business case process** walks through the **initiation phase** of the innovation-decision process and talks about the project plans that concern the **implementation phase**, which follows the initiation phase. The **business case document** justifies, in detail, the innovation-decision process: what has transpired in the initiation phase and what will transpire in the implementation phase. It takes into account the innovation-decision process. In short, a business case process develops a detailed business case document of the innovation-decision process. Thus, a business case is both a means and an end.

An innovation-decision process is required to foster long-term success (Figure 1; Burrell & Morgan, 2005; Dettmer, 2003; Trompenaars & Prud'homme, 2004). Stability is another factor, that enhances short-term success. The crucial component of stability is the cash flow, the lifeblood of the organisation. Profitability is vital in generating the cash flow. Profitability is a crucial issue to stability, while uncertainty, risk management, and governance are crucial issues to radical innovation. The organisation cannot exploit the radical innovation effectively unless it manages uncertainty, mitigates the risk related to the uncertainty, and governs the innovation-decision process appropriately. Because the innovation-decision process disrupts stability, radical innovation and stability are in **conflict** with each other.

Inasmuch as a business case document must justify the radical innovation and its innovation-decision process, the business case must resolve the many issues and assumptions that affect the radical innovation, stability, and the conflict between them. There are two questions about radical innovation at the broadest level (Borge, 2001; Nadler & Tushman, 2004, pp 554-555; Trompenaars & Prud'homme, 2004). What innovation should the organisation prioritise? How should the organisation carry out the innovation-decision process? The first overriding question concerns the radical innovation (the object of innovation) and the change vision (the expected consequence). The second question assumes that the short-listed options in the business case provide the solution to achieve the change vision. The change vision represents an expected consequence, preceding the innovation-decision process. Another antecedent is the expected bad outcomes to avoid. The proximate trigger and the perceived attributes of the innovation likewise influence the executive sponsor to be in favour or against a certain package (brand) of the enterprise information systems.

The **diffusion of innovations (DOI)** (Rogers, 2003) is the theory of focus. DOI has three constructs: the antecedents, the innovation-decision process, and the consequences, especially the unexpected consequences.

- DOI underscores the antecedents of the innovation-decision process. The change vision, the proximate trigger, the expected "bad outcome" to avoid, and the perceived attributes of the innovation are important antecedents. There are other antecedents, such as organisational innovativeness, and the external and internal environments.
- DOI draws attention to the innovation-decision process (Baskerville & Pries-Heje, 2001; Bradford & Florin, 2003; Dechow & Mouritsen, 2004, 2005; Dillard, 2000; Dillard, Ruchala, & Yuthas, 2005; Van de Ven & Poole, 1990; Zaltman, Duncan, & Holbek, 1973). DOI consists of the initiation phase and the implementation phase (Rogers, 2003). There are stages in each phase. The initiation phase incorporates the agenda-setting stage, matching stage, and adoption decision stage. The implementation phase of new enterprise information systems includes the preproduction, production, postproduction, and confirmation stages.
- DOI highlights undesirable consequences. The executive sponsor, who is the champion of the initiative to implement the new enterprise systems, acknowledges their success when the information systems go live. Yet research suggests that organisations fail to achieve outstanding bottom-line improvements even after 3 to 5 years of going live (Baskerville & Pries-Heje, 2001). This is **successful failure**, the undesirable consequence of implementing new enterprise information systems. Three illustrations of undesirable consequences are given in Section 2.

This section has stated the prerequisites and requirements to achieve growth and sustainability (Figure 1). It introduces DOI theory, and highlights its three main constructs: the antecedents, the innovation-decision process, and the consequences. Section 2 makes clear and illustrates the undesirable consequences of innovation. The terminologies of DOI differ, but not their essence. The business case is a part of the matching stage in the initiation phase. Understanding the framework of the innovation-decision process simplifies the complexity of business case development. It is particularly useful toward developing a structured approach to writing a business case. Section 2, section 3, and section 4 clarify the concepts and framework of DOI and the innovation-decision process. Section 5 ends with the implications of the business case development (that is, the *episteme* and *techne* of DOI and the business case development).

UNDESIRIBLE CONSEQUENCES

The studies of the villagers of Los Molinas in Peru illustrate an unexpected consequence. The villagers in Los Molinas stubbornly drank water from a canal floating with dead monkeys instead of a nearby tap with clean drinking water. To combat the infections caused by the contaminated water,

the Peruvian government and health authorities instructed the villagers to boil the water. Even after 2 years of diffusing the new idea to the villagers (e.g., getting the clean water from the tap, boiling the water, and drinking the boiled water), a majority continued to drink from the filthy river. The diffusion process ignored the culture of Peruvian villagers (Rogers, 2003, pp 1-5): Healthy people do not drink boiled water; only sick people do.

An undesirable consequence is also seen in what happened to FoxMeyer. In December 1995, FoxMeyer installed SAP and subsequently, went into Chapter 11 bankruptcy proceedings. It claimed that its innovation-decision process of the enterprise information systems was one of the factors that eventually led to its bankruptcy (O'Leary, 2000; "SAP and Deloitte Sued by FoxMeyer," 27 Aug 1998). The undesirable consequence in the context of the new enterprise information systems is the successful failure explained in the previous section.

Uncertainty and risk are unavoidable with the innovation-decision process of new enterprise information systems. Wrong turns and missteps occur frequently (Van de Ven & Poole, 1999). One thing is certain. Of the many factors affecting the success or failure of implementing new enterprise information systems, people are a significant variable and therefore, organisational risk is the greatest risk (O'Leary, 2000; Van de Ven & Poole, 1999).

The "*episteme*" (knowledge) of the business case development in context of the new enterprise information systems (Allen Sr, 2005; Benco, 2004; Carson III, 2005; Mabert, Soni, & Venkataraman, 2000) makes the "*techne*" (practice) of business case development less complicated in the end. The "*episteme*" requires understanding the exact evidences at every stage of the innovation-decision process. Only the evidence at the agenda-setting stage is clear in diffusion studies (Rogers, 2003). The evidence is not clear in the matching stage and decision stage of the initiation phase. There is very limited evidence in the implementation phase. These research gaps reiterate the rigour necessary in developing the business case.

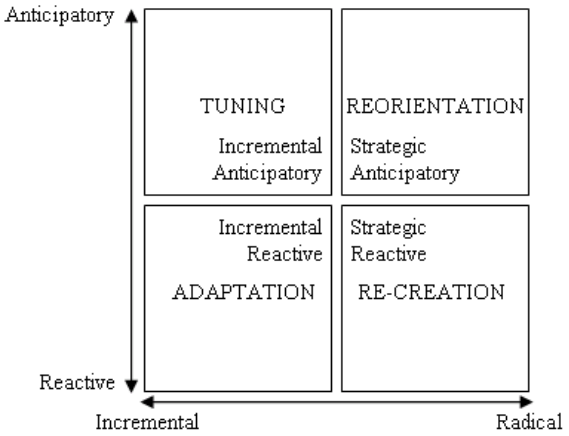
A cause of undesirable consequences relates to the quantity [and quality] of information, of knowledge, in the decision points (Ormerod, 2005, pp 23-25). The uncertainty or the probability of the consequences, of the new enterprise information systems, is in itself unknown. The concept of risk involves quantifying the probabilities. The business case document not only details the innovation-decision process, it quantifies the perceived risks inherent to the options in the decision stage of the initiation phase.

INNOVATION IN ORGANISATIONS

Organisational innovation generally involves a range of ideas that include reinvention (Van de Ven & Poole, 1999). The executive sponsor and the change agent learn and implement some ideas and discard others. The timeframe in radical innovation is generally long; so is the gestation during the innovation-decision process (Van de Ven & Poole, 1999). The innovation-decision process in organisations is like a mind map (Cua & Theivananthampillai, 2006). It diverges and converges, involving many people, multiple actions, and series of evaluations during implementation (Van de Ven & Poole, 1999). Not only is the innovation-decision process far more complex and unpredictable, with long gestation periods and multiple stops and starts, it is sensitive to [and constrained by] external influences (Van de Ven & Poole, 1999). With the new enterprise information systems, the radical innovation fosters new ways to undertaking the business process, and creates the environment that enhances the learning. Consequently, the new enterprise information systems create the environment, but are simultaneously constrained by the environment.

Innovation comes in a variety of dimensions (Christensen & Raynor, 2003; Cooper, 1998; Cua & Theivananthampillai, 2006; Nadler & Tushman, 1986; Tidd, Bessant, & Pavitt, 2001, p 7). Innovation may be sustaining or disruptive, anticipatory or reactive, and incremental or radical, process, service, or product, and technological or administrative. Organisations seek to build new-growth business in two ways. One is to build on the existing market from entrenched competitors with sustaining innovation by offering more functions and better features. The other way is to disrupt the competitors with innovation that creates new markets by targeting nonconsumers, or take root among the incumbent's worst customers (that is, the low end of an established market). The low-end product is cheaper with lesser or simpler functions. Christensen (1997) calls this type of innovation the disruptive innovation. Anticipatory innovation initiates innovation in anticipation of competitive advantage. Reactive innovation is an urgent, normally unplanned, response to an external event or change. Radical innovation redefines what the organisation is, and modifies the basic organisational framework composing of strategy, structure, people, processes, and core values. Incremental innovation does not modify the value, mode of organising, and general strategic framework. Furthermore, the innovation may be a business process, service, or product. The multiple dimensions allow upper and middle managers to investigate the innovation with their corresponding mechanisms and strategic advantages (Cooper, 1998). Regardless of the forms of innovation, exploiting the innovation must be understood beyond these dimensions. This is a necessary process that must happen. However, there must be diffusion before making this happens. The diffusion is the timely communication of the new idea through the business case. The business case document is a mechanism to facilitate the diffusion, which is the adoption decision.

Figure 2. Organisational innovation of Nadler and Tushman



Nadler and Tushman (1986) categorise innovation within an organisation as incremental rather than radical, and reactive as opposed to anticipatory. This results in two types of radical innovation (reorientation and recreation; Figure 2). As mentioned above, the change vision is a crucial antecedent to undertaking radical innovation. As an ongoing process, the strategic visioning must take place with enterprise redesign, value-stream reinvention, procedure redesign, and total quality management (TQM; Martin, 1995, pp 61, 384-385). Reorientation however requires greater strategic visioning than recreation. Recreation, however, demands greater care. Recreation is riskier than reorientation. It has a 90% mortality rate. The radical innovation, whether reactive or anticipatory, must balance with the stability (Figure 1) to mitigate the conflict between the radical change and stability. The business case development embodies the conflict.

PREREQUISITES FOR THE INNOVATION-DECISION PROCESS

The diffusion paradigm cuts across all social science disciplines (Rogers, 2003). The innovation-decision process, however, is articulated differently, depending on the discipline. One articulation is the business case development (project management, information technology, and information science). Other articulations are radical change process (change and innovation), strategic sourcing (logistics and supply chain), strategic investment decision (finance, accounting, and management), and capital investment process (finance and accounting).

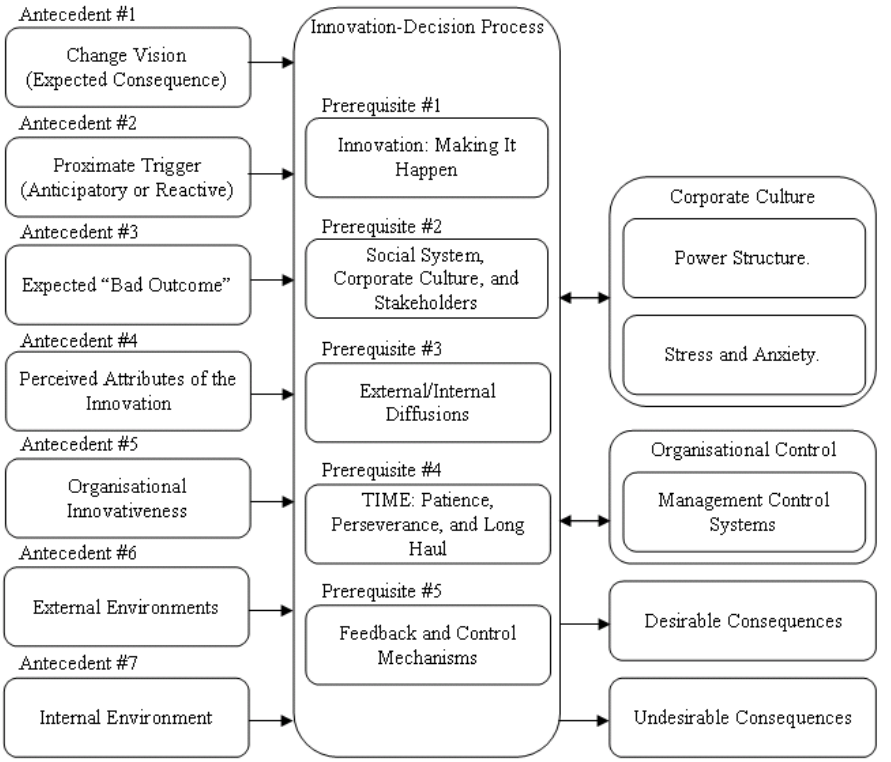
In finance and accounting parlance, organisations undertaking the innovation-decision process regards it as a "capital investment process" to maximise value and to enhance growth and sustainability (Figure 1) How the upper managers, the executive sponsor, and the project team members maximise shareholder value is an agency problem (Brealey & Myers, 2000). The shareholders are the ultimate principals. The upper management is their agent. The middle managers and the project team members are, in turn, the agents of the upper management. Thus, the middle managers are agents in relation to shareholders, and principals with regard to the rest of the organisation. The business case embodies the agency issue. Reflecting the agency issue, the exact evidence at each decision point in the initiation phase, the assumptions, the expected risk, and the performance measurement matter in the business case development.

However, shareholders are not the only concern. How the organisation is able to meet the needs of the other stakeholders defines the success of the innovation-decision process. The stakeholders analysis to maximise shareholder value in the longer-term (Morin & Jarrell, 2001; Rüegg-Stürm, 2005) is thus, an important prerequisite (#2 in Figure 3) in the business case development.

The five prerequisites of the innovation-decision process (Cua & Theivananthampillai, 2006; Nadler & Tushman, 1986, 2004; Rogers, 2003; Trompenaars & Prud'homme, 2004) are:

1. Innovation. An innovation is necessary for radical change (Trompenaars & Prud'homme, 2004). Foremost is its change vision (Slagmulder, 1997). The perceived newness, trialability, and observability (Rogers, 2003) ultimately affect the adoption (or rejection) decision. It involves analysing cost-benefit, mitigating uncertainty, and minimising risk necessary through information seeking and processing from RFI and RFP. Questions include (Rogers, 2003, p 14): What is the newness? How does the innovation work? Why does it work? What are the expected consequences? How cost-beneficial is it? What are the bad outcomes to avoid? With enterprise information systems, reinvention poses a difficult challenge.
2. Social system. Diffusion must occur in a social system (Rogers, 2003, p 24), which may comprise stakeholders (individuals, groups, organisations, or their subgroups). The success of diffusion lies in understanding the social system, the early adopters, their culture, norms, challenges, and value. How members in a social system interact or relate formally or informally matters. Because of their technical competence and accessibility, opinion leaders exert influence in their homogenous networks. Change agents, as will be explained in

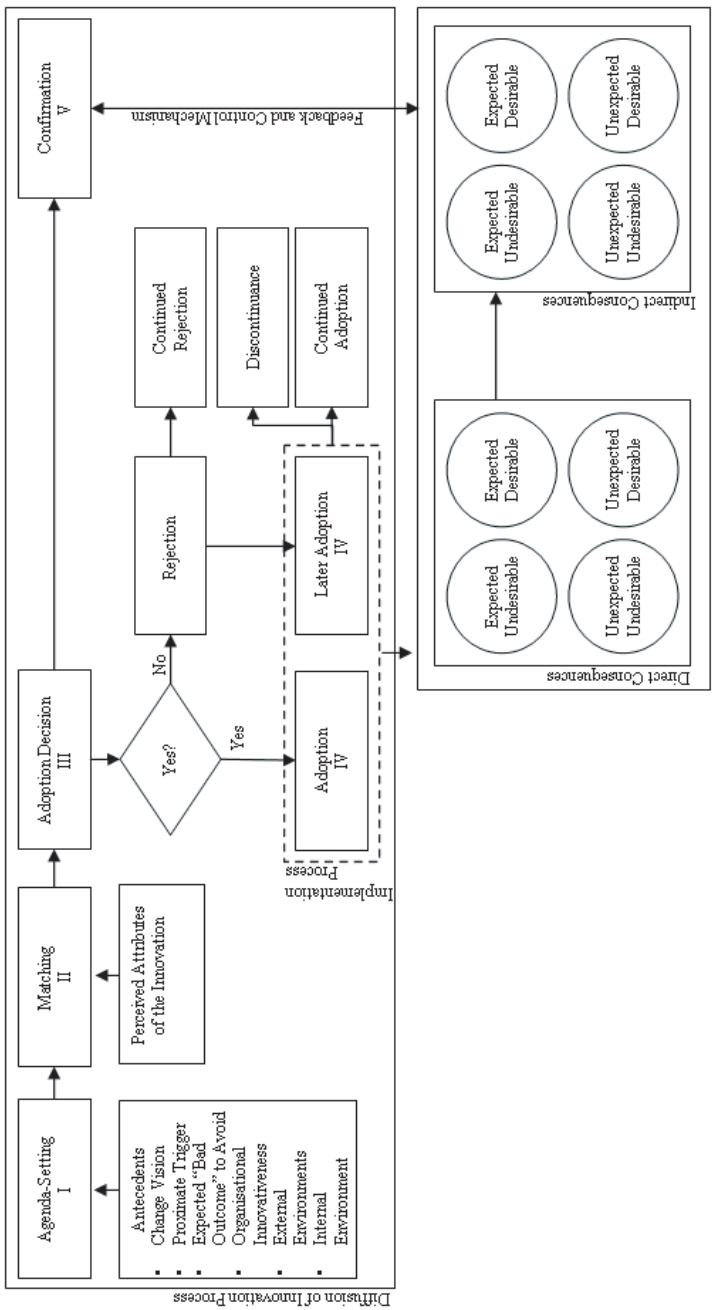
Figure 3. Conceptual framework of business case development Adopted from Burrell & Morgan (2005), Cua & Theivananthampillai (2006), Dettmer (2003), Nadler & Tushman (2004), Rogers (2003) , Trompenaars & Prud'homme (2004)



paragraph 5, are more effective with heterogeneous network, provided they employ the opinion leaders as their lieutenants. The middle managers also play important roles in the diffusion.

3. Communication channels. Studies show that most people do not analyse cost-benefit objectively (Cua & Theivananthampillai, 2006). Rather, they decide or respond to the innovation based on subjective evaluation from opinion leaders. In diffusion, interpersonal network is generally effective to foster a critical mass (Mahler & Rogers, 1999). Diffusion is more effective when people have similar culture or profile. Mass media channels are generally much faster and more efficient during the first stage of innovation-decision process. Interpersonal communication, however, is more effective in the next stage. In short, communication channels influence the speed of diffusion and the rate of adoption.
4. Time. The progress from one stage to another stage in the innovation-decision process discloses how crucial time functions in innovation. Patience is a virtue for adoption to advance toward reaching the critical mass. In context of time are the five broad categories of people who will adopt innovations, namely: the innovators, early adopters, early majority, late majority, and laggards.
5. Change agents. In a corporate setting undergoing radical change, there are individuals who influence an innovation-decision process and the people involved with the process (Rogers, 2003, p 366). They are the change agents. Their influences are usually in favour of the adoption of the new idea. Their priorities are different from those of the middle managers (Van de Ven & Poole, 1999). Change agents give emphasis to input criteria (antecedents) at the start of innovation process and later, to outcome criteria, whereas the middle managers are more concerned with the outcome criteria at the start and at the end, they look into the input criteria. The whole innovation-decision process embodies a range of information-seeking and informa-

Figure 4. The innovation-decision process



tion-processing activities pursued by decision makers to reduce uncertainty (Rogers, 2003). Inasmuch as radical change disrupts the status quo of organisation (Figure 1), organisational control (aka, management control systems) is vital. The conflicting priorities between the change agents and the middle managers compel timely and regular communications among the upper managers, middle managers, project team members, and other stakeholders.

Table 1. Important constructs of the business case development

Pre-requisites	1. Object of innovation (the new enterprise information systems)
	2. The social systems (the organisation, corporate culture, stakeholders, and extended social systems)
	3. External diffusion (external marketing) / internal diffusion (internal marketing)
	4. Time (patience, perseverance, long haul)
	5. Feedback and control mechanisms (management control systems)
Antecedents	1. Change vision (expected consequence)
	2. Proximate (anticipatory or reactive) trigger
	3. The expected "bad outcome" to avoid
	4. The perceived attributes of the innovation
	5. Organisational innovativeness
	6. External environments
	7. Internal environment
Process	1. Initiation phase: Agenda-setting stage, matching stage (RFI, RFP, and Business Case), adoption (or rejection) stage
	2. Implementation phase: Pre-production stage, production stage, post-production stage, confirmation stage
Consequences	1. Desirable consequences
	2. Undesirable consequences

In summary, Figure 3 maps out the five prerequisites in a change process. Diffusion of innovation shows innovation (#1 the new idea) as a process diffuses. Communication about innovation happens through mass media and personal interaction (#3 communication channels), and progresses through a structure of a social system (#2 social system) over a relatively long time frame (#4 time).The vital missing link in the process, where people are aware, make decisions, and manage uncertainty, is information. Timely information highlights the crucial management control systems (#5 organisational control) in a corporate setting undergoing change. Table 1 summarises the important constructs of the business case development.

THE COMPLEX INNOVATION DECISION PROCESS

The innovation-decision process of new enterprise information systems generally pass through the finance division (Rogers, 2003). It consists of five complex stages (Figure 4). The agenda-setting stage begins with learning about the innovation and understanding what it does and how it works. The matching stage happens when the executive sponsors and their team members incline toward or away from the innovation. The decision stage includes all activities leading to acceptance or rejection of the innovation. The implementation stage represents actual use of innovation, while the confirmation stage involves a search of evidence to support that the decision was right. Sometimes, it may lead to abandoning the innovation when the experiences or messages show conflict.

The innovation-decision process moves from something known to something unknown and disrupts status quo. The uncertainty exerts pressures on organisational power, anxiety, and control (Figure 3) and subsequently affects the innovation-decision process itself. The uncertainty and the complex interactions of the critical elements of the innovation-decision process threaten the desirable expected consequences. The risk of being unable to achieve the expected consequences and the risk of encountering unexpected consequences are inevitable.

CONCLUSIONS

Growth and sustainability! Organisations consider these big words the ultimate goal, and utilise radical innovation as the engine to achieve them. While exploiting the radical innovation, life has to go on. The stability of the current state makes it possible to maintain stability and generate cash flow amidst chaos and radical innovation. Both radical change and stability are necessary to ensure longer-term growth and sustainability. However, the essence of change opposes stability.

The business case development embodies the radical change and its conflict with the stability (Figure 1). The adoption and implementation of new enterprise information systems represent a radical business process innovation, which is complex and risky. A reactive radical innovation has greater risk, and demands greater care than an anticipatory radical change (Figure 2). In undertaking the innovation-decision process, the first question concerns thoroughly understanding the change vision, justifying why the organisation should prioritise the new enterprise information systems, and determining whether the radical innovation is anticipatory or reactive. The upper managers will be interested in getting detailed answers to the second set of questions. Why should the organisation prioritise the new enterprise information systems? How did the organisation carry out the initiation phase? How does the organisation undertake the adoption decision stage? How will the organisation implement the enterprise information systems? What assumptions underlie the innovation-decision process?

The diffusion of innovation theory, with its constructs listed in Table 1 and the model depicted in Figure 3, provides the insights of diffusing the innovation (*episteme*) via the business case development (*techne*). Table 2 suggests the area for future research. The DOI provides the big picture and a mind map necessary to succeed in undertaking the complex innovation-decision process and developing a good business case. The stakeholders of the radical innovation will have better opportunities to solve the many challenges if they possess the adequate *episteme* of the diffusion paradigm. Introducing a reinvention, adopting, and implementing new enterprise information systems, or extending the current management control systems to encompass linkages with suppliers and customers, are challenges that pose the diffusion problems. The knowledge of DOI certainly offers opportunities in these pursuits toward the development of the business case.

KEY TERMS

Business Case: Completed business case document. Business case process.

Business Case Process: Walks through the initiation phase of the innovation-decision process and talks about the project plans that concerned the implementation phase.

Completed Business Case Document: A formal written document that argues a course of action. It contains a point-by-point analysis to making a decision for a set of alternative courses of action to accomplish a specific goal.

Diffusion: Communicating the new idea within a social system, such as an organisation. It culminates in the adoption of the idea, which is the intention of diffusion.

Diffusion of Innovations: Theory concerns the how, why, and at what rate the new idea (commonly referred to as innovation) diffuses.

Implementation Phase: Proceeding after the initiation phase, the implementation phase of enterprise information systems consists of pre-production, production, and post-production (also known as upgrade and maintenance). Refer to innovation-decision process.

Initiation Phase: Consists of awareness stage, matching stage, and lastly, the decision stage. It is the first phase of the innovation-decision process. The second phase is the implementation phase. Refer to innovation-decision process.

Innovation-Decision Process: Starts with an **initiation phase** through which the individuals or decision-making units move from knowing (understanding/identifying) the new idea (the innovation), to forming of an attitude toward the innovation, and subsequently, to deciding whether to adopt or reject the implementation and use of the new idea. The awareness stage is the agenda setting stage. The attitude formation stage is the matching stage. In addition, the decision stage to adopt or reject the innovation terminates the initiation phase. An adoption decision continues the process toward the **implementation phase**, which consists of the pre-production, production, post-production, and confirmation stages.

The Role of E-Services in the Library Virtualization Process

Ada Scupola
Roskilde University, Denmark

INTRODUCTION

The networked ICT technologies (such as the Internet) are having a dramatic effect on how services and especially knowledge services are innovated, designed, produced and distributed. In addition ICT-networks such as the Internet have created the basis for the development of new types of services. E-services are defined here as services that are produced, provided and/or consumed through the use of ICT-networks such as for example Internet-based systems and mobile solutions. E-services can be used by both consumers and businesses, and can be accessed via a wide range of information appliances (Hoffman, 2003, p.53). E-services include also selling of physical goods on the Internet as for example an airline ticket that is purchased online, but delivered by surface mail to the buyers or government services offered on the Internet or e-government. There are three main characteristics of e-services:

- The service is accessible across the Internet or other electronic networks
- The service is consumed by a person across the Internet or other electronic networks
- There might be a fee that the consumer pays the provider for using the e-service, but that might not always be the case as for example in some e-services offered by the government.

Normally the production, provision or consumption of a service requires the interaction between the service provider and the user of the service. Traditionally this has been based on personal interactions, most often face-to-face interactions. In e-services, the production, consumption and/or provision of services takes place through the intermediation of an ICT-network such as Internet-based systems or mobile solutions. Examples of e-services are e-banking, e-library services, e-publishing, airline tickets, e-government, information and location services. The advent of e-commerce and e-services has raised a number of challenges for knowledge intensive service organizations such as consulting companies, libraries and publishers, as well as for companies selling physical goods.

The purpose of this study is to investigate the challenges that e-services are posing and will pose for research or academic libraries. The study has focused on the issues that Roskilde University Library (RUB) has had to deal with as a result of e-services adoption as well as the future challenges that e-services provide for RUB. The study is based on a number of interviews with RUB management, other secondary material provided by Roskilde University library and information provided on the Web page.

BACKGROUND

In order to understand how digitalization and e-services are changing the library and its activities it is important to understand what a library is, and what its major roles in learning are. Libraries can be defined as "an organized set of resources, which includes human services as well as the entire spectrum of media" (e.g. text, video, and hypermedia). Libraries have physical components, such as space, equipment, and storage media; intellectual components such as collection policies that determine what materials will be included and organizational schemes that determine how the collection is accessed; and people, who manage the physical and intellectual components and interact with users to solve information problems" (Marchionini & Maurer, 1995, p. 68). Marchionini and Maurer (1995) distinguish three major roles that academic and research libraries serve in learning. The first role is sharing expensive resources. These resources are physical resources such as books, periodicals, media, and human resources such as the librarians that provide a number of responsive and proactive services. The second role that libraries serve is a cultural role in preserving and organizing artefacts and ideas. Libraries have historically had the role of preserving material to make it accessible to future learners in addition to ensuring access to materials trough indexes, catalogues and other aids that allow users to find what they need. The third role of the library is that of serving as a physical knowledge space, where people meet to study and read and often to exchange ideas.

Roskilde Universtiy Library

Roskilde University Library (RUB) is a research library serving the students and staff at Roskilde University. Roskilde University is a smaller university located in Roskilde, a city about 35 km from Copenhagen, the capital City of Denmark.

The university counts circa 10,000 students. According to Roskilde University Statute (www.ruc.dk/library), Roskilde University Library has the following purposes:

1. To give teachers and students at Roskilde University access to information and materials containing information, that are necessary for research and teaching, as well as ensure information on and access to the university's teachers and students' research.
2. As a public research library to make available its collection to external users, among which regional research and teaching institutions, business, and citizens.
3. Participate to the national and international library collaboration.
4. To conduct research and development within the library subjects and functions, but also the surrounding community and businesses as well as anybody who would like to use the library because it is a public library.

Today the library counts circa 45 employees, and the number of employees has decreased due to the digitalization process and e-services adoption. The library acquires still 8,000-9,000 books in paper format per year. However they expect this number to go down, while the number of e-books to go up especially as the quality of e-books improves. In addition RUB counts today circa 18,000 e-journals, while the number of paper journals has gone down from circa 5,000 to 2,000. Today, in Denmark, libraries are the heaviest users of ICTs among the public sector institutions. The advent of the World Wide Web circa 10 years ago has completely revolutionized the way RUB operates and has made possible a number of e-services and self-services. The adoption and implementation of e-services and self-services has resulted into a number of organizational changes, changes in the organizational structure, the competencies of the librarians and relationships between the library and the publishers and the library and the users. In addition also the business model is changing as RUB is trying to sell the services to private businesses. RUB is moving towards a combination of physical and virtual library, as many services are getting transformed into e-services and self-services. Therefore Internet and e-services might change many aspects of the library and its relationships with users and publishers. However, RUB might preserve its historical role of knowledge space, even though after the implementation of library's online communities, such knowledge space can become also a virtual knowledge space.

E-Services Adoption at RUB

Over the last few years RUB has adopted a number of e-services and self-services that are changing many aspects of the way the library operates. Many of the services provided by RUB have been transformed into e-services after the advent of the World Wide Web. Nowadays RUB offers a number of e-services and Web based self-services. The main e-services offered at RUB are as follows:

1. Access to electronic journals
2. Access to electronic books
3. Digital repository of all the students projects
4. Chat with a librarian

Examples of self-services include:

1. Rucforsk: a self-service system for the online registration of research and other activities of the teachers.
2. Online reference search, online reservation of material not available in the library, etc.

The library is also working on developing a digital repository of the compendia used in the courses. These e-services and self-services are developed on the base of open source software, although the IT department at RUB modifies it to make the software fit to their needs. However they try to use the original open source software as much as possible since it is very expensive to modify it.

MAIN FOCUS OF THE CHAPTER

This session presents the main issues that RUB has encountered in e-services' adoption, the organizational transformations RUB had to go through as a consequence and the challenges that RUB is presently facing and expecting to face in the future.

Back Office

Back office processes have been completely automated as a result of e-service adoption and they have changed from manual to electronic. All library work is today done with the use of ICTs. Even when they get the physical magazine, they insert it into an integrated library system. Everyone working in the library is using ICTs to do their job.

Innovation

Innovation is very important at RUB. The entire e-services and self-services business model is based on one key word: innovation and especially IT-driven innovation. E-services related innovations at RUB are both user-driven and employees-driven. The sources of innovation are very different. A lot of projects are based on ideas coming from people employed at RUB such as librarians, management, the director, and the IT department. Also they provide courses to new enrolled students and faculty about how to use the e-services, and a

lot of ideas come from these teaching sessions. In addition they have a customer-complaint box and library users may send e-mails to the library. These e-mails get screened and RUB may use such suggestions for incremental innovations. DEFF, a major initiative of the Danish government (www.deff.dk), is also an important source of innovation especially regarding the technology aspect of e-services implementation. Through DEFF RUB can get ideas from and share experiences with other libraries. For example each library might be in charge of testing an IT solution, then they share experiences and finally they decide to choose and adopt a system. DEFF is also important in financing new ideas or innovation projects, as RUB might lack the financial resources to start all the projects they believe are worth pursuing.

The main driving forces of e-services adoption have been the government visions and policies for an "IT society for all", the technological development of Internet, World Wide Web and related IT solutions mainly in a technology push fashion, the pressure from cutting costs in the public sector coming either from the government or local university authorities, an IT innovation culture that has always existed in the Danish libraries, (as the director of reader services says "you want to be a little bit better then your neighbour library"), competition among the different libraries' top management and, even though to a less extent, the customer's wishes.

Organizational Change

The digitalization process has changed the structure of RUB's organization in several ways. First of all, a new organizational level, a management level has been introduced that can make the organization look more hierarchical then before, but it cannot really be compared with a classical hierarchical structure. In addition such a management level is mainly dealing with library development and with political issues. Most importantly the division of labor has changed. Especially the number of IT-related jobs has grown; for example 13 years ago RUB had 1 employee dealing with IT, while today they employ 6-7 people in the IT department. The IT department is expected to grow in the future in special fields. In addition almost everybody in the library has to be IT literate and librarians have to grow together with IT, as the trend goes fast. Each employee is participating into several projects, mostly dealing with e-services and e-services development. When Roskilde University started, RUB employed circa 70 people and was servicing circa 1/3 of the number of students and faculties that has today. Today, RUB employees 45 people and serve a number of students and faculties which is 3 times as large as the one that was servicing when the university was founded. The number of RUB's employees might decrease with in the next decade or so. This is because the adoption of e-services and self-services has decreased the need for competences such as the classical librarian, as more and more services that earlier were done by RUB employees are now done by the users of the library. There is a shift from the librarians to the users in the production-consumption of (e-) services. The use of e-services and self-services is increasing; circa 80-85% of the users of the library are using e-services and self-services. Earlier they needed 2-3 librarians at the reference desk, now one is enough. Due to all the organizational changes, this is causing resistance among the employees and users of e-services. As a matter of fact, even though most of RUB users (about 80-85%) are very satisfied with the digitalization trend and the introduction of e-services, there is still a small group that is missing the "old" library and is unsatisfied with e-services.

RUB Business Model

RUB's business model is changing as a result of e-services and self-service adoption and is going into different directions. Within Roskilde University RUB is getting more involved with Campus IT, which is presently developed by the IT department at Roskilde University. However, collaboration is sometimes difficult due to different priorities. RUB believes that they will play a central role in future e-learning projects at Roskilde University. In addition they are trying to collaborate with the teachers and instructors on how to best use the library for teaching and research, including a number of courses on how to use the e-services and self-services that the library offers. Outside Roskilde University, RUB is looking at offering consulting in the field of e-services for other libraries, including business libraries. They are also trying to open their market not only to the campus' students and faculties, but also to companies, especially small and medium enterprises. Participation to the DEFF project can influence the future RUB's business model as well. For example they presently provide an e-service called chat with a librarian, which they are running not only for RUB, but for all the other research libraries in Denmark as well.

Relationships with Customers/Users

Since the introduction of e-services and self-services the relationships with the users of the libraries have changed immensely. The number of users coming to the physical reference desk is decreasing quickly, while the number of inquiries at the virtual desk is increasing; yet the total number of inquiries is decreasing, and in addition the user behavior is changing as well. For example while paper books are still important for the readers, the total number of library loans is decreasing and the number of downloads of e-books is increasing. This trend is also observed for the journals. While RUB still has a substantial number of paper journals, more and more downloads of e-journals articles are taking place. They expect that the loans of physical books and journals will not be important in 5 years and that most of the material

will be provided in electronic form. The users that have a login to the library can access the e-services 24/hours per day, 7 days a week no matter where they are. So they will have everything they need on the computer. Some things are printed, but others are not. The relationships with the users are expecting to change even more in the future as a result of implementation of library blogs. In fact RUB is looking at blogs and how to use them or integrate them with e-services such as electronic journals or e-books. Blogs would have the objective of creating online communities around specific topics, specific books or journal articles. In addition RUB is negotiating with Google to have all its collection retrievable through Google search engines. Therefore e-services are leading to a digitalization of knowledge that was already codified in printed form. E-services are making it easier and quicker for users to find, store and analyze such knowledge. In addition e-services are making it easier for more users to get access to the same piece of knowledge or information. In fact if only one user at a time could get access to a specific journal in print form, in electronic form many users can get access to the same journal, article, or book chapter simultaneously. In addition e-services are pushing customer relationships towards a virtual form. This is the case both regarding the relationship user-librarian and the relationship among the library's users which, after the implementation of blogs, is expected both to become more virtualized and to increase in number due to the formation of online communities.

Relationships with Publishers (or Providers)

This relationship has also changed as a result of e-services. Many of the traditional transactions such as ordering, cataloguing, and so forth of journals has almost disappeared. The total number of transactions with the publishers has decreased. The e-journals are kept at the publishers' repository and RUB only buys the access or license to them. Initially the publishers offered a huge amount of e-journals at a smaller extra cost. As a result RUB cut the number of paper journals from circa 5,000 to circa 2,000 and instead has acquired access to circa 18,000 e-journals. However the publishers are now increasing prices on e-journals, therefore the total costs might increase as a result in the future. This kind of license agreement has contributed to the formation of a Danish library consortium, whose purpose is to get better prices to electronic journals and e-books from the publishers.

Relationships with Other Research Libraries

The trend towards adoption of e-services by the Danish libraries has changed the relationship between RUB and other research libraries in Denmark by increasing collaboration and partnerships among them. While earlier they were competing on services, number and type of journals and books offered, after adoption of e-services there is much more collaboration among Danish research libraries. Two key examples of this collaboration and partnerships which RUB is part of are Denmark Licensing Consortium and the DEFF initiative. Denmark Licensing Consortium is a consortium of libraries getting common licenses to publishers' e-journals and e-books. The major purpose is to put pressure on the publishers and decrease costs for the single library. Therefore the adoption of e-services is causing a convergence and standardization of the (e-) services offered by the different Danish libraries. Libraries were differentiating from each other much more before the adoption of e-services. Now all the research libraries members of the license consortium offer the same types of e-journals and e-books, and more or less the same type of e-services. Those few that are ahead get caught up within a six month period.

DEFF is a major initiative undertaken by the Danish government with the purpose of developing a network of electronic research libraries that make available their electronic and other information resources in a coherent and simple way. This is obtained partly through government funding and partly by joint license purchase (www.deff.dk). By participating to DEFF the libraries can achieve economies of scope and scale in the development of e-services.

FUTURE TRENDS

There are many challenges laying ahead for RUB. RUB will continue to exist and keep the role of library as an information centre, but the way the information and knowledge is provided will change. RUB will still face several organizational and technological challenges in the future.

From a technology point of view, the ICTs platforms used in delivering e-services become obsolete quite periodically and new e-services solutions have to be found. For example with the development of WEB 2.0 they will have to make new types of systems. Integration of RUB e-services into one simple system is also an important technical future challenge. Presently the e-services located on the Web page are connected to 6-7 different systems and a future challenge is to integrate all these different systems. Standardization is another technological challenge. Customers want fast response and RUB is working on this by looking at standardization issues and they have to keep doing so also in the future. Standards are very important for library's e-services. Finally, ensuring to get the best and same results for the same search is also a future technical challenge.

Copyrights and licenses are another important obstacle and challenge for the development of RUB's e-services. For

example they are running a project to convert the library's videos into files to be kept on the local servers. The problem is though that whenever a student wants to see a video, instead of seeing the file on the computer screen, they have to save the file on the tape, since the material that they loan out has to be in analog form due to copyrights restrictions. So copyrights of what can be digitized are a big barrier to further e-services development and especially use by the customers. Licenses on the other hand limit the use of the e-services for remote users that are not connected to the university and therefore do not have a log in to the library system. This implies that these users still have to walk into the library to be able to use the e-services, thus limiting to some extent their functionality.

Another future challenge comes from the library users. The users are becoming much more advanced and sophisticated in their online searches, young people have a lot of ideas about how to do things better. Here the challenge is to understand their needs and implement user-driven innovations in e-services. Budget problems are another challenge for RUB. In the last few years the budgets allocated to research libraries have been decreasing. This trend has been worsened by decentralizing the budgets concerning the research libraries from the government to the university the libraries are connected to. This creates the possibility for management at Roskilde University to cut the library's budget in favour of other activities.

Organizational challenges are also lying ahead. As the number of physical loans will decrease and the number of electronic downloads keeps on increasing, there is going to be less need for the reference desk and the number of positions in the library might decrease. The way of working in the library is changing, therefore the type of competences needed might change moving more towards IT specialists and going away from the classical librarians skills. Disagreement on e-services future development between the different groups in the library is also a major organizational and human resource challenge, even though most RUB's employees like e-services. This requires RUB to explore new functions and new directions to change their business model.

CONCLUSION

This chapter has contributed to the project "E-service—Knowledge services, entrepreneurship, and the consequences for business, customers and citizens" sponsored by the Danish Research Council by investigating a particular type of e-services: research library e-services. Specifically the study has investigated the implication of the advent of Internet and e-services for Roskilde University library (RUB) as well as the future challenges that e-services provide for RUB. The study has also investigated the consequences of e-services for Roskilde University library organization, its business model and relationships with customers, publishers (providers of information) and other research libraries. The picture that emerges is one of fast innovation, big transformations and change at organizational and business model level, as well as in the relationships with customers, publishers and other research libraries. In addition there are a number of challenges that RUB has to face in the future in response to e-services. Some are IT-related; others have to deal with copyrights, licenses, standardization, and user-driven innovation. The general trend is that RUB is becoming a combination of a virtual and physical library, moving more and more towards a virtual library by providing resources and knowledge mainly in digital form and by offering blogs and possibilities of online communities to discuss books and articles. On the other hand RUB is still keeping the traditional library function of a physical knowledge space. How will RUB look like 10 years down the road? The only certain answer according to RUB management is that it will still exist.

KEY TERMS

Library: Can be defined as an organized set of resources, which includes human services as well as the entire spectrum of media (e.g., text, video, and hypermedia). Libraries have physical components, such as space, equipment, and storage media; intellectual components such as collection policies that determine what materials will be included and organizational schemes that determine how the collection

is accessed; and people, who manage the physical and intellectual components and interact with users to solve information problems.

E-Services: Are defined as services that are produced, provided, and/or consumed through the use of ICT-networks such as for example Internet-based systems and mobile solutions.

Knowledge Intensive Service Organizations: Are service organizations whose core product is knowledge such as consulting companies.

Danish Research Library: Has the purpose to give teachers and students access to information and materials that are necessary for research and teaching, as well as ensure information on and access to the university's teachers and students' research.

Innovation: Is defined as a new idea, a new product, a new process or an organizational form. It is characterized by three stages: invention, innovation, and diffusion. An invention is a new idea or product, which becomes which becomes an innovation when it starts diffusing in the society or move into a usable form.

IT-Driven Innovation: It is defined as any innovation the creation of which is based on information technology.

Adoption: E-services adoption is here defined as the decision to make use of e-services in the daily operations of the library.

The Role of Human Factors in Web Personalization Environments

INTRODUCTION

The explosive growth in the size and use of the World Wide Web as a communication medium as well as the new developments in ICT allowed service providers to meet these challenges, developing new ways of interactions through a variety of channels enabling users to become accustomed to new means of service consumption in an "anytime, anywhere and anyhow" manner. However, the nature of most information structures is static and complicated, and users often lose sight of the goal of their inquiry, look for stimulating rather than informative material, or even use the navigational features unwisely. Hence, researchers and practitioners studied adaptivity and personalization to address the comprehension and orientation difficulties presented in such systems, to alleviate such navigational difficulties and satisfy the heterogeneous needs of the users, allowing at the same time Web applications of this nature to survive.

There are many approaches to address these issues of personalization but usually, each one is focused upon a specific area, that is, whether this is profile creation, machine learning and pattern matching, data and Web mining or personalized navigation.

Some noteworthy, mostly commercial, applications in the area of Web personalization that collect information with various techniques and further adapts the services provided, are among others the Broadvision's One-To-One, Microsoft's Firefly Passport, the Macromedia's LikeMinds Preference Server, the Apple's WebObjects, and so forth. Other, more research-oriented systems, include ARCHIMIDES (Bogonikolos et al., 1999), Proteus (Anderson et al., 2001), WBI (Magglio & Barret, 2001), BASAR (Thomas & Fischer, 1997), and mPERSONA (Panayiotou & Samaras, 2004). Significant implementations have also been developed in the area of adaptive hypermedia, with regards to the provision of adapted educational content to students using various adaptive hypermedia techniques. Such systems are, among others, INSPIRE (Papanikolaou, Grigoriadou, Kornilakis, & Magoulas, 2003), ELM-ART (Weber & Specht, 1997), AHA! (De Bra & Calvi, 1998), Interbook (Brusilovsky, Eklund, & Schwartz, 1998), and so forth.

BACKGROUND

Once considering adaptation and personalization categories and technologies we refer to Adaptive Hypermedia and Web Personalization, respectively, due to the fact that they both make use of a user profile to achieve their goal, and consequently they can together offer the most optimized adapted content result to the user.

A Constructive Comparison of Adaptive Hypermedia and Web Personalization

In view of the aforementioned statement, it would be essential to highlight their similarities and differences and furthermore, to identify their convergence point which is their objective to develop techniques to adapt what is presented to the user, based on the specific user needs identified in the extracted user profiles.

Generally, Adaptive Hypermedia refers to the manipulation of the link or content structure of an application to

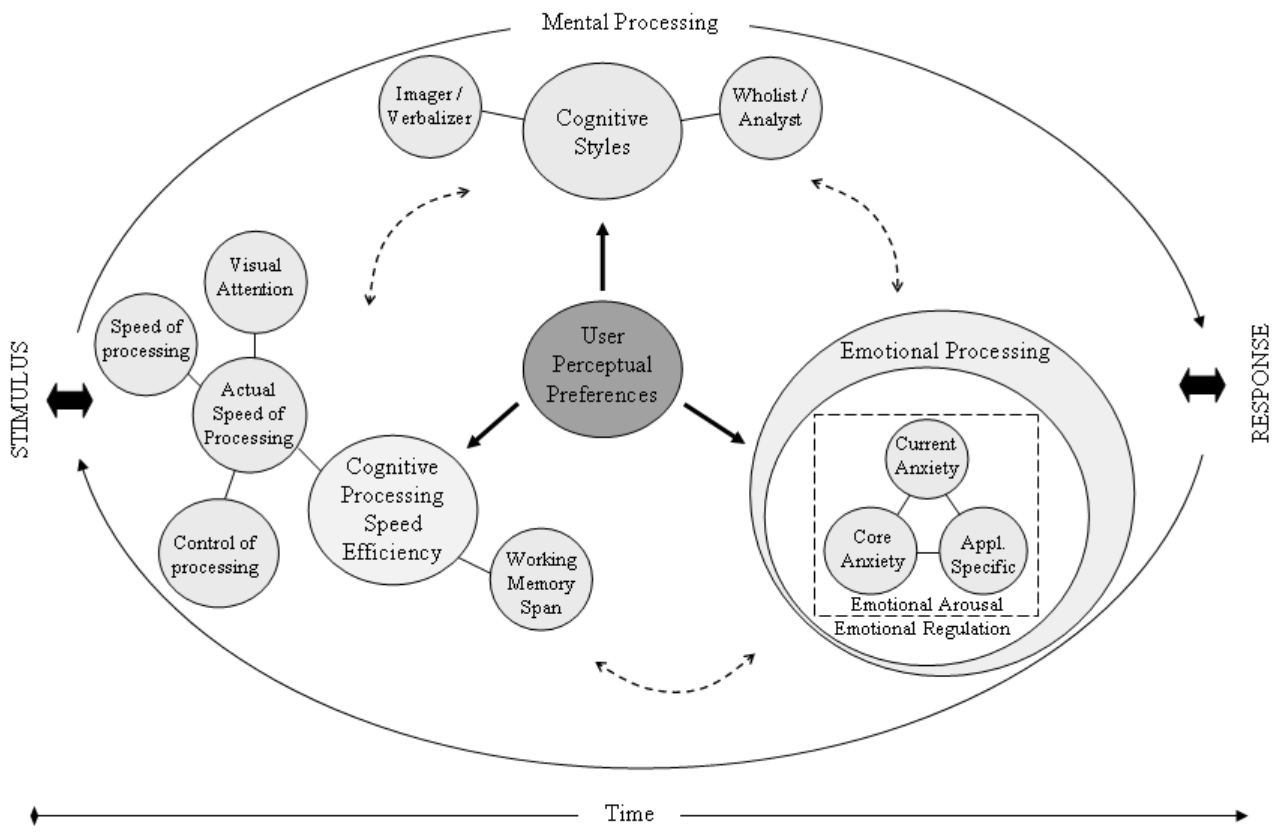
achieve adaptation and makes use of an explicit user model (Brusilovsky, 2001; Eklund & Sinclair, 2000). Adaptive Hypermedia is a relatively old and well established area of research counting three generations (Brusilovsky & Peylo, 2003). Educational hypermedia and online information systems are the most popular, accounting for about two thirds of the research efforts in adaptive hypermedia. Adaptation effects vary from one system to another. These effects are grouped into three major adaptation technologies: adaptive content selection (Brusilovsky & Nejdl, 2004), adaptive presentation (or content-level adaptation) and adaptive navigation support (or link-level adaptation) (Brusilovsky, 2001; Eklund & Sinclair, 2000).

On the other hand, Web personalization refers to the whole process of collecting, classifying and analyzing Web data, and determining based on these the actions that should be performed so that the user is presented with personalized information. Personalization levels have been classified into: Link Personalization, Content Personalization, Context Personalization, and Authorized Personalization (Lankhorst, Kranenburg, & Peddemors, 2002; Rossi, Schwade, & Guimaraes, 2001). The technologies that are employed in order to implement the processing phases mentioned above as well as the Web personalization categories are distinguished into Content-based Filtering, Rule-based Filtering, Collaborative Filtering, Web Usage Mining, Demographic-based Filtering, Agent Technologies, and Cluster Models (Pazzani, 2005; Mobasher, Dai, Luo, Nakagawa, & Wiltshire, 2002).

As inferred from its name, Web personalization refers to Web applications solely, and is a relatively new area of research. One could also argue that the areas of application of these two research areas are different, as Adaptive Hypermedia has found popular use in educational hypermedia and online information systems (Brusilovsky, 2001), whereas Web personalization has found popular use in e-business services delivery. From this, it could be implied that Web personalization has a more extended scope than Adaptive Hypermedia.

The most evident technical similarities of them are that they both make use of a user model to achieve their goal and they have in common two of the adaptation / personalization techniques: the adaptive-navigation support and the adaptive presentation. Last but not least, it is noteworthy to mention that they both make use of techniques from

Figure 1. User Perceptual Preference Characteristics – Three-Dimensional Approach



machine learning, information retrieval and filtering, databases, knowledge representation, data mining, text mining, statistics, and human-computer interaction (Mobasher, Anand, & Kobsa, 2007).

The User Profile Fundamentals

One of the key technical issues in developing personalization applications is the problem of how to construct accurate and comprehensive profiles of individual users and how these can be used to identify a user and describe the user behaviour, especially if they are moving (Panayiotou & Samaras, 2004). User profiling can either be *static*, when it contains information that rarely or never changes (e.g., demographic information), or *dynamic*, when the data change frequently. Such information is obtained either *explicitly*, using online registration forms and questionnaires resulting in static user profiles, or *implicitly*, by recording the navigational behavior or the preferences of each user (Germanakos, Tsianos, Lekkas, Mourlas, & Samaras, 2007a).

THE SIGNIFICANCE OF HUMAN FACTORS IN THE WEB PERSONALIZATION PROCESS

But, do the designers and developers attempt to build user-centric Web-based applications, taking into consideration the real users' preferences in order to provide them a really personalized Web-based content? Many times this is not the case. How can a user profile be considered complete, and the preferences derived optimized, if it does not contain parameters related to the user perceptual preference characteristics (see Figure 1)? *User Perceptual Preference Characteristics* could be defined, as all the critical factors that influence the visual, mental and emotional processes liable of manipulating the newly information received and building upon prior knowledge, that is, different for each user or user group.

These characteristics, which have been primarily discussed in Germanakos, Tsianos, Lekkas, Mourlas, Belk, and Samaras (2007a), and formulate a three-dimensional approach to the problem of building a user model that determines the visual attention, cognitive and emotional processing taking place throughout the whole process of accepting an object of perception (stimulus) until the comprehensive response to it (Germanakos, Tsianos, Mourlas, & Samaras, 2005).

The first dimension investigates users' *cognitive style*, the second their *visual and cognitive processing efficiency*, while the third captures their *emotional processing* during the interaction process with the information space.

Cognitive Style

Cognitive styles represent an individual's typical or habitual mode of problem solving, thinking, perceiving or remembering, and "are considered to be trait-like, relatively stable characteristics of individuals, whereas learning strategies are more state-driven…" (McKay, Fischler, & Dunn, 2003). Among the numerous proposed cognitive style typologies (Cassidy, 2004) has been selected Riding's Cognitive Style Analysis (Riding, 2001), because it is considered that its implications can be mapped on the information space more precisely, because it consists of two distinct scales that respond to different aspects of the Web. The imager/verbalizer axis affects the way information is presented, while the wholist/analyst dimension is relevant to the structure of the information and the navigational path of the user. Moreover, it is a very inclusive theory that is derived from a number of pre-existing theories that were recapitulated into these two axises.

Cognitive Processing Efficiency

The cognitive processing parameters (Demetriou & Kazi, 2001) that have been included in the model are:

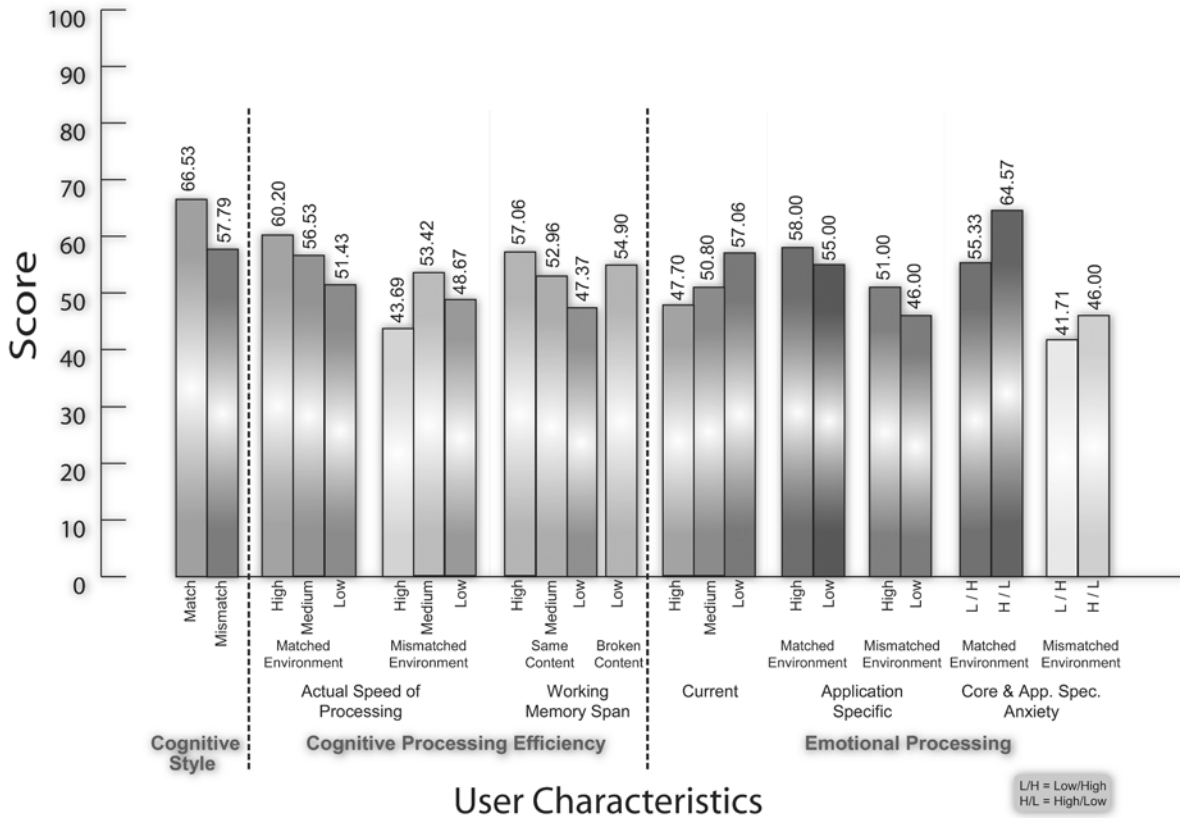
i. *control of processing* (refers to the processes that identify and register goal-relevant information and block out dominant or appealing but actually irrelevant information),
ii. *speed of processing* (refers to the maximum speed at which a given mental act may be efficiently executed),
iii. *working memory span* (refers to the processes that enable a person to hold information in an active state while integrating it with other information until the current problem is solved (Baddeley, 1992)), and
iv. *visual attention* (based on the empirically validated assumption that when a person is performing a cognitive task, while watching a display, the location of his/her gaze corresponds to the symbol currently being processed in working memory and, moreover, that the eye naturally focuses on areas that are most likely to be informative).

Emotional Processing

Emotional processing is a pluralistic construct which is comprised of two mechanisms:

- Emotional Arousal, which is the capacity of a human being to sense and experience specific emotional situations, and

Figure 2. Aggregated differences in matched/mismatch condition



- Emotion Regulation, which is the way that an individual perceives and controls his emotions.

The main focus has been placed on anxiety, as the main indicator of emotional arousal, because it is correlated with academic performance (Cassady & Johnson, 2004), as well as with performance in computer-mediated learning procedures (Smith & Caputi, 2007).

The construct of emotional regulation that has been used includes the concepts of emotional control (self-awareness, emotional management, self-motivation) (Goleman, 1995), self-efficacy (Bandura, 1994), emotional experience and emotional expression (Halberstadt, 2005). By combining the levels of anxiety with the moderating role of emotion regulation, it is possible to examine how affectional responses hamper or promote learning procedures (Lekkas, Tsianos, Germanakos, & Mourlas, 2007).

Evaluation: The Case of AdaptiveWeb System

Subsequently, an adaptive Web-based system has been built, the AdaptiveWeb[1] (Germanakos et al., 2007b), that takes into account users' cognitive and emotional parameters and provides them with information matched to their preferences. All the tests implemented so far to prove components efficiency have been based on a predetermined online content in the field of e-learning multimedia environment, due to the fact mainly that there is an increased interest on distant education via the Web. In this case, it has been feasible to control factors as previous knowledge and experience over distributed information. More specifically, the main research hypotheses drawn has been investigated:

- Are the cognitive and emotional parameters of the model significantly important in the context of an educational hypermedia application, and
- Does matching the presentation and structure of the information to users' perceptual preferences increase academic performance?

Sampling and Procedure

All participants were students from the Universities of Cyprus and Athens; phase I was conducted with a sample of 138 students, while phase II with 82 individuals. Thirty-

five percent of the participants were male and 65% were female, and their age varied from 17 to 22 with a mean age of 19. The environment in which the procedure took place was an e-learning course on algorithms. By controlling the factor of experience, the sample has been divided in two groups: almost half of the participants were provided with information *matched* to their Perceptual Preferences, while the other half were taught in a *mismatched* way. In order to evaluate the effect of matched and mismatched conditions, participants took an online assessment test on the subject they were taught as soon as the e-learning procedure ended, in order to control for long-term memory decay effects. The dependent variable that was used to assess the effect of adaptation to users' preferences was participants' score at the online exam.

Results

As expected, in both experiments the matched condition group outperformed those of the mismatched group (Tsianos, Germanakos, Lekkas, Lourlas, Mourlas, & Samaras, 2007). Figure 2 displays the aggregated differences in performance (the dependent variable of exam score), in matched and mismatched conditions.

Table 1 shows the differences of means (one way ANOVA) and their statistical significance for the parameters of Cognitive Style, Cognitive Efficiency Speed, and Emotional Processing.

Moreover, in many cases there is a high correlation between the dimensions of the various factors of the model, validating the psychometric tools that have been used. This fact also demonstrates the effectiveness of incorporating a variety of human factors in Web-based personalized environments.

Finally, emotional processing, and more specifically anxiety, turned out to be an equally important factor; medium levels of anxiety are supportive of increased performance, while aesthetics and extra navigation support helped significantly students that were highly (not extremely though) anxious, always in terms of performance.

FUTURE TRENDS

Future and emerging trends include the further investigation of constraints and challenges arising from the implementation of such issues on mobile devices and channels; study on the structure of the metadata coming from the providers' side, aiming to construct a Web-based personalization architecture that will serve as an automatic filter adapting the received content based on a comprehensive user profile; the incorporation of physiological measurements of emotions and anxiety in such a model, with the use of biometrical sensors; as well as the use of an eye-tracker device to clarify the role of visual attention in Web-based communication environments.

CONCLUSION

Adaptive hypermedia and Web personalization are two distinct, well-established areas of research, both investigating methods and techniques to move conventional static systems beyond traditional borders to more intelligent, adaptive and personalized implementations. They share a common goal: to alleviate navigational difficulties and satisfy the heterogeneous needs of the user population by adapting according to user specific characteristics. In order to do that, the user profile construction is considered necessary.

The basic objective of this article was to make an extensive reference of a combination of concepts and techniques coming from different research areas, adaptive hypermedia and Web personalization, all of which focus on the user. It has been attempted to approach the theoretical considerations and technological parameters that can provide the most comprehensive user profile, under a common filtering element

Table 1. Differences of means in the matched/mismatched condition for Cognitive Style and Cognitive Efficiency Speed

	Match Score	Match n	Mismatch Score	Mismatch n	F	Sig.
Cognitive Style	66.53% 5	3	57.79% 6	1	6.330	0.013
Cognitive Efficiency Speed	57.00% 4	1	48.93% 4	1	5.345	0.023
Emotional Processing	57.91% 2	3	48.45% 2	9	4.357	0.042

(User Perceptual Preference Characteristics), supporting the provision of the most apt and optimized user-centred Web-based result.

KEY TERMS

Cognition: A human-like processing of information, applying knowledge and changing preferences. Cognition or cognitive processes can be natural and artificial, conscious and not conscious; therefore, they are analyzed from different perspectives and in different contexts, in anesthesia, neurology, psychology, philosophy, systemics and computer science.

Cognitive Styles: They are consistent individual differences in preferred ways of organizing and processing information and experience

Emotional Intelligence: It describes an ability, capacity, or skill to perceive, assess, and manage the emotions of one's self, of others, and of groups.

User Modeling: User modeling is a subarea of human-computer interaction, in which the researcher/designer develops cognitive models of human users, including modeling of their skills and declarative knowledge. User models can predict human error and learning time.

User Perceptual Preference Characteristics: User Perceptual Preference Characteristics are all the critical factors that influence the visual, mental and emotional processes liable of manipulating the newly information received and building upon prior knowledge, that is, different for each user or user group. These characteristics determine the visual attention, cognitive and emotional processing taking place throughout the whole process of accepting an object of perception (stimulus) until the comprehensive response to it.

Visual Processing: It is the sequence of steps that information takes as it flows from visual sensors to cognitive processing.

Web Personalization: It is the process of tailoring pages to individual users' characteristics or preferences. It is a means of meeting the user's needs more effectively and efficiently, making interactions faster and easier and, consequently, increasing user satisfaction and the likelihood of repeat visits.

The Role of Information in the Choice of IT as a Career

Elizabeth G. Creamer
Virginia Tech, USA

INTRODUCTION

Practitioners, researchers, and policy makers alike are puzzled by the continued intransigence to the integration of women to undergraduate and graduate majors, as well as occupation, in fields like engineering and information technology (IT). While strong advances in the direction of gender equity have been made in the last two decades in fields like biology and mathematics and in the professional fields of medicine and law, women only still represent about 20% of the undergraduate enrollments in engineering and computer science (NSF, 2000). This gender gap persists persist despite the near evaporation of evidence of gender differences in performance in these fields, such as in the dramatic narrowing of gender differences in the high school course taking patterns, including in advance placement courses (Clewell & Campbell, 2002). Gender differences in the enrollment in computer-related courses and out-of-class, informal programs in science and engineering persist, however (Volman & van Eck, 2001).

Academics have used several major groups of theories to try to understand the reasons for women's under-representation in IT and engineering. Social psychological theories are one of four major groupings of theoretical frameworks identified by Clewell and Campbell (2002). As compared to perspectives that seek biological or cognitive explanations for women's disinclination to pursue careers in some fields, social-psychological theorists consider environmental, social, and attitudinal influences. Factors such as teachers' and advisors' attitudes and beliefs, pedagogical practices in the way math and sciences courses are taught, and the influence of parents and the media are some of the factors considered by social-psychological theorists (Clewell & Campbell, 2002).

The research described in this entry belongs to the group of social-psychological theories that look to environmental, rather than individual, explanation for women's under-representation in certain fields in science and engineering, including information technology. It considers the role of parents and the role of interactions with teachers, counselors, and important others in interest in a career in information technology.

BACKGROUND

Career choice is often approached as if it were entirely a rational process whose outcome can be predicted by simply understanding an individual's abilities, attitudes, and interests. Researchers with a less individualistic perspective, however, point out that individual qualities are far less predictive of women's career choices than they are of men's (O'Brien & Fassinger, 1993) and that a number of social and cultural factors are required to understand the types of environments that promote women's interest in sex atypical careers, including IT (Blum, Frieze, Hazzon, & Dias, 2007). This fits with other research that documents that women continue to enter the IT field through nontraditional venues. Rather than taking a more direct route through an IT-related major in college, women often enter positions in IT as a result of propitious exposure or opportunity (Turner, Brent, & Percora, 2002). This is why some authors prefer to refer to "pathways" rather than to continue to utilize the "pipeline metaphor" as a way to capture the various career paths women follow prior to entering IT in a professional capacity (Leventmen, 2007).

A socio-cultural perspective considers career interest and choice to be the product of a complex interplay of factors that is primarily understood empirically through relatively sophisticated statistical procedures. This theoretical perspective frames research about gender and interest and success in fields in science, engineering, and technology (SET) to be the result of the interplay of personal and environmental factors. Key individual qualities related to interest in IT include positive attitudes about computers and computing fields (Dryburgh, 2000; Shashaani, 1997), and characteristics of parents, including their familiarity with IT and their views about the appropriateness of IT as a career choice (Meszaros, Laughlin, Creamer, Burger, & Lee, 2006). Attachment to parents is positively associated with career exploration among college women (Ketterson & Blustein, 1997).

Social qualities related to an interest in IT refer to dimensions of the environment, such as encouragement from educators, family and friends, role models, and peers. It also includes elements of the family, community, and educational environment that introduce opportunities to experience

creative and interactive applications of computing (Volman & Van Eck, 2001).

The stereotyping of many SET fields as inherently unfeminine is a key cultural dimensions that impacts women's' perceptions of the opportunity for success and advancement in the field (Blum et al., 2007).

CAREER INFORMATION AND INTEREST IN IT AS A CAREER

This entry summarizes key research findings about the relationship between sources of career information and information seeking behavior and interest in IT among high school and college men and women. Findings reported here are based on responses to multiple administrations of questionnaire *Career-Decision Making Survey* (Creamer, Lee, Meszaros, Laughlin, & Burger, 2006) and the response of 1,147 high school and college men and women in rural and urban locations in the US. The focus in this entry is on the "information processing" section of a larger, complex causal model that was confirmed through statistical analysis using path analysis. The term "information processing" refers to the impact of others on interest in IT. Details about the complete model are reported elsewhere (Creamer, Meszaros, & Lee, 2007; Creamer, Lee, Meszaros, Burger, & Laughlin, 2006).

Our findings indicate that for both young women and men, there is a startling gap between knowledge about job options in IT, the extent of career exploration, and interest in IT. The nature of the relationship is quite different, however, for men and women. Figure 1 summarizes key findings about career information processing related to interest in IT as a career field and how this varies by gender.

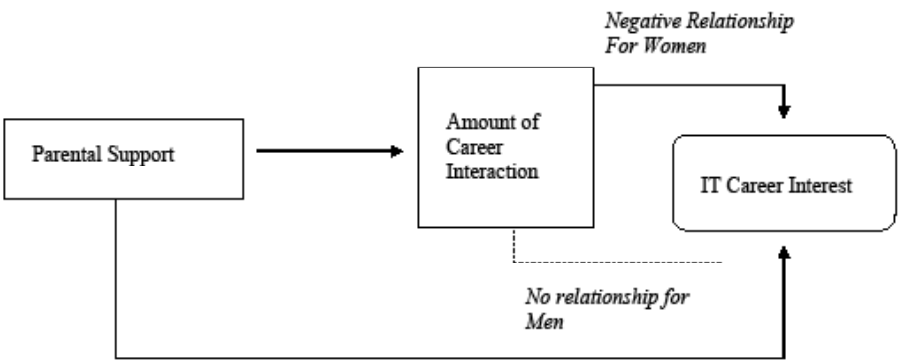
As shown in Figure 1, there is no significant or direct relationship for men between amount of career exploration, sources of career information, and interest in IT as a career option. Interactions with others about career options had no significant positive or negative effect on interest in IT. For men, computer use and positive attitudes about the attributes of IT workers were the only factors directly related to IT career interests.

The relationship between information and interest in IT as a career choice was even more surprising for women. Women were more significantly more likely than men to report talking to others about career options. For women, however, there is a significant, *negative* relationship between career information about IT and interest in IT as a career. The more interactions women had with others about IT as a career field, the less interest they reported in IT as a viable career choice. This is consistent with other research that suggests women are more influenced than men by the opinions of others when making career choices (Seymour & Hewitt, 1997). This is probably even more so when the choice involves a sex-atypical career, like IT. While it is not possible to determine from our data exactly what is occurring during these interactions, what is clear from our analysis is that many women are walking away from interactions with teachers, peers, counselors and others with less than positive views about IT as a personally viable career option.

The amount of interaction with others about career options increased for women with uncertainty about career choice and/or the ability to make a good career choice. Another possible explanation for why women may walk away from exchanges about career options with negative views about IT is that the more people they talk to, the more likely they are to encounter different viewpoints about appropriate career alternatives. Making a reasoned decision in the face of differing viewpoints is not something most high school or college students are developmentally equipped to handle.

For both men and women, parents play a significant role in the development of IT as a career interest. Perceptions of parents support for IT as an appropriate career choice directly impacted the amount of career exploration students

Figure 1. The impact of career information on IT career interests among high school and first- and second-year college students, by gender



reported, as well as whether they had positive views about the attributes of IT workers and the amount of computer use. The role of parents' expectations and attitudes, particularly mothers, had a stronger direct effect on women's than men's interest in IT.

During one-on-one interviews, female participants repeatedly highlighted the role of trusted and immediate others in the development of their career interests. These findings underscore the importance of involving parents activities designed to promote students' interest in IT as a career options.

FUTURE TRENDS

Some key findings from our research, such as about the role of trust in women's willingness to consider unfamiliar career options, only arose through the concurrent analysis of qualitative and quantitative data from the same participants. This points to one of the principal advantages of mixed methods research design and the value of intentionally engaging differences that appear from the analysis of qualitative and quantitative research (Creswell, Clark, Gutmann, & Hanson, 2003; Greene & Caracelli, 2003). Future researchers considering issues related to women and IT would gain immeasurably by pursuing research questions through both qualitative and quantitative data, particularly when opportunities are created to engage participants in discussions of differences in data they supply.

CONCLUSION

Findings from this research indicate that it is far too simplistic to assume that the key reason for the under-enrollment of women in IT majors is the lack of access to up-date information about the field. Although middle-class young women in urban and suburban settings have a clear advantage over their lower-income counterparts and those in rural settings because of the visibility of role models in the IT occupations, the Internet offers ready access to career information for those with the tools and willingness to invest the time to explore them. What is needed in the K-12 setting is a commitment of resources to provide up-to-date training to counselors about the day-to-day activities of people holding different types of professional IT jobs.

Engagement in out-of-class activities, often called informal education, has been found to be key to developing and sustaining women's interest in science, engineering, and technology fields (Campbell, Acerbo, & Hoey, 1999). Industry can contribute to the recruiting of women to the IT field by providing resources and expertise to the creation of informal activities outside of the classroom, such as intensive summer programs, that create the opportunity for students to engage in creative, interactive, and socially meaningful computer applications. These are the types of activities that can build on student's fascination with computers, create a sense of playfulness and experimentation, and help them to begin to see the link between enjoyment in using computers and IT as a viable career option. The development of a sense of community that is possible in intensive residential programs may promote the trust instrumental to widening the range of career options women consider beyond those modeled and/or supported by important people in their immediate environment.

While there is a good deal of overlap in what men and women find attractive about a career in IT, there are some important differences that should be considered in developing effective recruiting materials. Some of these are addressed in a professionally produced DVD developed by the WIT team, *The Power of Partners* (Meszaros, Laughlin, Burger, Creamer, & Lee, 2007). Highlighting IT as a demanding field with the potential for a competitive income appears, for example, to be persuasive to recruiting men, but not women to IT. The potential for flexibility in work schedules, and thus the potential to achieve some work-life balance, is an issue of growing importance in the career choices of women (Rosser, 2004) and one that human resource personnel in the IT field could leverage effectively in recruiting material.

KEY TERMS

Direct Effect: In a statistical model, a variable that impacts the dependent variable, or the variable being predicted in a direct and statistically significant way.

Information Processing: Relates to student's self-reports about (1) how much they know about job options within IT, (2) what information sources about IT they consider credible, and (3) how often they have interacted with others about career options.

Information Technology: Refers to a variety of jobs that involve the development, installation, and implementation of computer systems and applications. Careers in IT encompass occupations that require designing and developing software and hardware systems, providing technical support for computer and peripheral systems, and creating and managing network systems and databases.

IT Career Interest and Choice: The dependent variable in our statistical model that identifies the characteristics of respondents who express either an interest in a career in IT or who have already made a choice to pursue a career in IT.

Mixed Methods Research: Involves the analysis of both quantitative and qualitative data in a single study and the integration of findings at one or more stages in the process of research (Creswell et al., 2003).

Parental Support: In the statistical model presented in this entry, parental support was calculated from nine questionnaire items relating to the respondent's perceptions that her parents support the importance of a career and encourage career exploration, as well as agreement with the statement that parents have an idea about what would be an appropriate career choice.

Social-Psychological Theorists: Theories that consider environmental and social influences on career interests, including such factors as parents' attitudes, teachers' and advisors' attitudes and beliefs, and experiences and interactions in- and out-of-the-classroom.

Sources of Career Information: A set of questionnaire items in the *Career Decision Making Survey* where respondents indicated how often they had discussed career options and plans with ten groups of people: mother, father, teacher or professor, counselor or advisor, other family members, male friends, female friends, spouse or significant other, employer or boss, and family friends.

Satellite Network Security

Marlyn Kemper Littman
Nova Southeastern University, USA

INTRODUCTION

Satellite networks play a vital role in enabling essential critical infrastructure services that include public safety; environmental monitoring; maritime disaster recovery and reconnaissance; electronic surveillance; and intelligence operations for law enforcement, the military, and government agencies (Jamalipour & Tung, 2001). As demonstrated by the events following the terrorist attacks in the U.S. on the Pentagon in Washington, D.C. and the World Trade Center in New York City on September 11, 2001, satellite networks also provide redundant communications services when terrestrial networks are disrupted and/or unavailable. Despite their merits, satellite networks are nonetheless vulnerable to cyber attacks that pose threats to national security and the economy.

Satellite networks transport voice, video, images, and data through the air as electromagnetic signals, thereby making these transmissions susceptible to interception. Technical advances enable the interconnectivity of satellite systems to public and private wireless and terrestrial networks including the Internet. These advances, however, amplify the risk of cyber attacks that can compromise critical infrastructure functions dependent on satellite networks in sectors that include information technology (IT) and telecommunications; defense; government; banking and finance; utilities; agriculture; emergency services; public health; and transportation (U.S. Department of Homeland Security (DHS), 2003; U.S. Government Accounting Office (GAO), 2004). As a consequence, satellite networks employ an array of security tools and mechanisms for countering costly and widespread cyber incursions and, thereby, ensuring the continuity of critical infrastructure operations. Those cyber attacks that are politically motivated and specifically designed to disrupt essential services are generally attributed to *cyber terrorism*.

This chapter describes the technical fundamentals of satellite networks; examines security vulnerabilities; and explores initiatives for protecting the integrity of satellite network transmissions and operations from cyber incursions and physical attacks. Standards and protocols that safeguard satellite networks from unauthorized use and intentional disruptions and policies, and legislation that facilitate cyberspace asset protection are described. Capabilities of *encryption* in supporting secure satellite services and the distinctive attributes of the InterPlanetary Internet (IPN), also called the InterPlanetary Network**,** are explored.

BACKGROUND

Satellite Network Technical Fundamentals

Satellite networks consist of ground and space segments. The ground segment includes a ground or earth station that delivers communications services and monitors satellite operations by providing tracking, telemetry, and control (TT&C) functions. The space segment consists of the artificial satellite and its payload.

In contrast to a natural satellite or a celestial body that revolves around a larger sized planet, an artificial satellite is a wireless receiver/transmitter that orbits the earth and employs microwave technology in the super high and extremely high radio frequency (RF) bands of the electromagnetic spectrum to enable wide area interactive communications (Littman, 2002). The payload includes transceivers and antennas for RF signal reception, amplification, and retransmission.

The quality of the satellite signal reflects the quality of the uplink and downlink. An uplink describes signal transmissions from an earth station such as a gateway, teleport, hub, or very small aperture terminal (VSAT) to the satellite. A downlink refers to signal transmissions from the satellite to the designated reception site. Typically, satellite transmissions are asymmetrical with more information transported on the downlink than on the uplink (Littman, 2002). Generally classified in terms of the orbits in which they operate, satellite constellations are categorized as geosynchronous or geostationary earth orbit (GEO), medium earth orbit (MEO), and low earth orbit (LEO).

Satellite Network Vulnerabilities

Satellites' transmissions are subject to lengthy delays, low bandwidth, and high bit-error rates that adversely impact real-time, interactive applications such as videoconferences and lead to data corruption, performance degradation, and cyber incursions. Atmospheric and interstellar noise; cosmic radiation; interference from electronic devices; and precipitation and rain absorption in the spectral frequencies employed

by satellites impede network performance and information throughput and negatively affect provision of quality of service (QoS) guarantees (Littman, 2002).

Satellite network applications and services are also adversely impacted by geophysical events. In 1998, for example, tremendous explosions on the sun disrupted operations onboard PanAmSat's Galaxy IV Satellite. As a consequence of these solar flares, digital paging services, bank transactions, and cable television programs across the U.S. were disabled (U.S. GAO, 2002).

According to the U.S. GAO (2002), satellite network functions can be compromised by ground-based antisatellite weapons, high-altitude nuclear explosions, stealth micro satellites, space mines, space-to-space missiles, and directed energy space weapons. For instance, as a consequence of intentional jamming resulting from cyber attacks on a Telestar-12 commercial satellite in 2003, U.S. government-supported broadcasts promoting regime changes in Iran were blocked by the Iranian Ministry of Post, Telegraph, and Telephone (Waldrop, 2005). Satellite-based telephony services in Tehran were also disabled.

Satellite network operations are subject to denial of service (DoS) and distributed DoS (DDoS) attacks generated by automated tools that prevent authenticated users from accessing network services; the spread of viruses to mobile satellite-enabled appliances such as cellular phones; worms that self-propagate malicious data; and spy ware that enables intruders to gain unrestricted access to classified documents (U.S. GAO, 2005) as well. denial of information (DoI) attacks on satellite networks such as spam or unsolicited commercial e-mail and phishing or transmission of fraudulent e-messages are typically designed to deceive legitimate users into revealing confidential information to unauthorized sources (Conti & Ahamad, 2005; Wilson, 2005).

Satellite networks are also vulnerable to cyber terrorism or coordinated space-based and ground-based threats and attacks committed by unlawful and/or politically motivated terrorist groups who target critical communications systems such as satellite networks to cause data corruption, disruption of critical infrastructure services, economic damage, harm, and loss of life (Wilson, 2005). Satellite network attacks attributed to cyber terrorism can result in disruptions in financial markets and disclosure of government, law enforcement, medical, and/or military classified data (U.S. GAO, 2004). Intentional satellite system incursions motivated by cyber terrorism raise questions about the dependability, reliability, availability, and security of satellite network services and erode public confidence in the integrity of satellite-dependent, critical infrastructure applications (Bosch, 2002).

SATELLITE NETWORK SECURITY INITIATIVES

A multifaceted approach with multiple levels of security is required to protect satellite networks against cyber attacks that can culminate in malicious data corruption; system and service disruptions; unauthorized information disclosure; and physical destruction of satellite assets. Implementation of procedures for safeguarding satellite space and ground segments, TT&C functions, and satellite uplink and downlink transmissions; strategies to optimize satellite network performance; and satellite security protocols to provide authentication and authorization services must be based on a systematic assessment of satellite network risks and a comprehensive determination of satellite network security requirements (Roy-Chowdhury, Baras, Hadjitheodosiou, & Rentz, 2005). Tools, procedures, and measures that aid in safeguarding satellite operations include the enactment of public policies and legislation; the implementation of satellite security protocols and standards; and the utilization of security mechanisms and tools such as encryption.

Public Policies and Legislation

Presidential Decision Directives Nos. 49 (1996) and 63 (1998) define U.S. satellites' space activities as critical to national defense, economic security, and public health and safety and are essential in supporting critical infrastructure protection. U.S. National Security Telecommunications and Information Systems Security Policy (NSTISSP) No.12 establishes a foundation for a nationwide information assurance policy to guide the planning, design, implementation, and operations of secure U.S. space systems (NSTISSC, n.d.). NSTISSP No. 12 measures also mandate that U.S. space systems support information confidentiality, data integrity, user authentication, the availability of information services to authorized users, and service nonrepudiation. Empowered by the U.S. Homeland Security Act of 2002, the U.S. DHS supports comprehensive vulnerability assessments and coordinates nationwide response to threats and attacks classified as cyber terrorism in conjunction with entities that include the U.S. National Infrastructure Protection Center (U.S. DHS, 2003).

International cyber security agreements and public policies such as the Council of Europe's Convention on Cybercrime endorsed in 2001 by 38 countries including the U.S. promote development of international legislation to deter cyber terrorism activities (Wilson, 2005). In 2003, a joint declaration of Cooperation to Combat Terrorism supported by the European Union and the Association of South East Asian Nations (ASEAN, 2003) called for international cooperation in detecting and responding to threats of attacks on satellite assets.

SATELLITE STANDARDS AND PROTOCOLS

Space Communication Protocol Standards

Developed by the Consultative Committee for Space Data Systems (CCSDS), an international consortium that includes space agencies in countries such as Japan, Canada, and the U.S. among its membership, CCSDS establishes the Space Communication Protocol Standards (SCPS) to promote space system interoperability and security. The SCPS suite is based on the Transmission Control Protocol/Internet Protocol (TCP/IP) specifications that also serve as the foundation for the public or commodity Internet. Endorsed by the International Organization for Standardization (ISO) in 1999, the SCPS suite defines approaches for space data transmissions; secure communications to and from space and ground segments; and satellite information management (Hooke, 2001).

The CCSDS SCPS-File Protocol (SCPS-FP) describes processes for error recovery, access control, and privacy. Developed for the U.S. National Aeronautics Space Agency (NASA) Mercury, Surface, Space Environment, Geochemistry, and Ranging (MESSENGER) mission in 2004, the CCSDS-File Delivery Protocol (CCSDS-FDP) , also known as CFDP, supports dependable and secure file transfers across interplanetary distances and standardized file downlink operations between satellites and ground stations (Krupiarz et al., 2002). CFDP uses forward error correction coding to detect data loss and request retransmission.

The SCPS-Transmission Protocol (SCPS-TP) employs algorithms to control data loss resulting from congestion and signal corruption (CCSDS, 1999). Performance enhancing proxies (PEPs) such as TCP spoofing algorithms optimize SCPS-TP operations by enabling header compression, dynamic buffering, and reliable and fast transmissions.

Based on the Integrated-Network Layer Security Protocol (I-NLSP) and the Internet Protocol Security (IPsec) Encapsulation Security Header (ESH) and Authentication Header (AH) protocols, the SCPS-Security Protocol (SCPS-SP) supports data confidentiality; access controls for space operations with minimal overhead; and data protection, authentication, and authorization services (CCSDS, 1999). SCPS-SP encapsulates transport protocol data units (TPDUS) into secure protocol data units (SPDUS) to maintain integrity of space transmissions. It is important to note that SCPS-SP does not recommend the use of specific cryptographic algorithms or key management systems since these functions are handled by the Data-Link Layer or Layer 2 and the Physical Layer or Layer 1 of the seven-layer Open Systems Interconnection (OSI) Reference Model.

Satellite Internet Protocol Security (SatIPSec)

Endorsed by the Internet Engineering Task Force (IETF) and based on IPSec**,** SatIPSec facilitates secure IP unicast transmissions between a single sender and a single receiver and multicast transmissions between a single sender and a multiple group of receivers. In addition to working with IPv4 (IP version 4) and IPv6 (IP version 6), SatIPSec safeguards satellite network operations that are vulnerable to threats and incursions ranging from satellite terminal cloning to eavesdropping (Duquerroy, Josset, Alphand, Berthou, & Gayraud, 2004). SatIPSec maintains data integrity through the use of symmetric encryption that enables authorized multicast group members to verify the origin, identity, and source of multicast transmissions.

Satellite-Reliable Multicast Transport Protocol

Satellite-Reliable Multicast Transport Protocol (SAT-RMTP) was developed by the University of Aberdeen (n.d.) and endorsed by the IETF, SAT-RMTP enables reliable transport and delivery of multimedia files and video clips via GEO satellite constellations to terrestrial networks. Capabilities of SAT-RMTP were verified in tests supported by GEOCAST (Multicast over Geostationary Extremely High Frequency [EHF] Satellites), a European Commission Information Society Technologies (IST) initiative.

Security Tools and Mechanisms

Satellite network security operations are supported by an array of satellite tools and mechanisms ranging from antivirus software and stateful firewalls to attack-resistant or hardened satellite components and physical and logical access controls requiring the use of devices such as smart cards and biometric systems that employ retinal scans and fingerprints for authentication. Redundant security systems for surveillance and fire, flood, and windstorm protection safeguard satellite ground station operations from deliberate cyber attacks, unauthorized use, and natural and artificial disasters.

In the U.S., the Department of Defense Advanced Research Projects Agency (DARPA) is evaluating the security capabilities of pseudolites or pseudo satellites that support redundant communications services if ground station equipment is deliberately disabled. The U.S. Air Force employs antijamming units to safeguard ground station operations; outbound filters to prevent forged source addresses from infiltrating satellite systems; and space telescopes to monitor space activities classified as cyber terrorism. The U.S. Air Force also supports development of sophisticated high-power

space weapons equipped with laser beams to temporarily disable adversary satellites attempting to deny the U.S. utilization of its own space network (U.S. DHS, 2003).

A popular satellite network security tool—encryption—enables safe transmissions via insecure satellite uplinks and downlinks. Conventional encryption systems employ algorithms to scramble plaintext into ciphertext or a meaningless format prior to transmission (Littman, 2002). A key or a secret piece of information typically consisting of a string of random bits enables decryption and the restoration of the message to plaintext or its original format. Digital signatures and time stamps are used in conjunction with encryption to authenticate message integrity. In asymmetric cryptosystems, a public key that is shared by two or more individuals supports encryption, and a private key known only to the message recipient facilitates decryption. In symmetric cryptosystems, the same public key is used for encryption and decryption.

In the absence of strong encryption, cyber intruders can compromise satellite operations by eavesdropping and conducting brute force attacks of weakly encrypted data. In 2002, for instance, unauthenticated subscribers to satellite television programming in the European Union viewed unencrypted surveillance video of U.S. military bases in Bosnia when the cryptosystem was compromised. Satellite television providers generally use conventional encryption systems that employ mathematical algorithms for decryption to ensure that only subscribers with authorized receivers can decrypt television signals and receive delivery of television and pay-per-view entertainment programs. In accordance with NSTISSP No. 12 (NSTISSC, n.d.), U.S. space systems must employ robust encryption to safeguard command and control data and national security information transported between satellite space and ground segments.

The U.S. Army provides access to classified and unclassified information and support services to field units in Iraq via the Combat Service Support Satellite Communications VSAT network. This network employs Triple Digital Encryption Standard (3DES) and complies with the Federal Information Processing Standard (FIPS) 140-2 that specifies security requirements for cryptographic modules. Since 3DES and its forerunner DES are susceptible to hacker attacks, the U.S. National Institute of Standards and Technology (NIST) recommends their replacement by Advanced Encryption Standard (AES), a block cipher encryption algorithm that is unclassified, available without royalty charges worldwide, and complies with FIPS 197 (Burr, 2003). Also called the Rijndael block cipher after its developers Vincent Rijmen and Joan Daemen, AES uses 128-bit, 192-bit, and 256-bit encryption keys.

FUTURE TRENDS

Established by DARPA as a state-of-the-art, next-generation, Internet initiative, the IPN is a deep space backbone network that features a delay-tolerant network (DTN) architecture capable of operating in terrestrial and interplanetary environments with minimal bandwidth, limited power, high error rates, and latencies or delays in the length of time required for information transport from source to destination (Akyildiz, Akan, Chen, Fang, & Su, 2004). The IPN is designed to interlink terrestrial networks including the Internet with remotely located Internets on other planets or spacecraft in transit. Based on CFDP, the IPN bundle layer consists of a delay-tolerant protocol stack that complements DTN architecture. By supporting store-and-forward operations, the bundle layer relays voice, video, image, and data message fragments as bundles from heterogeneous networks via IPN nodes for secure transmission when forward links are established (Burleigh et al., 2003). The store-and-forward operations accommodate uncertain and intermittent interconnectivity between IPN nodes and lengthy propagation delays associated with space-based transmissions. Importantly, the bundling layer also supports the use of multiple data-protection mechanisms to ensure the security of IPN backbone operations and the integrity of information transmitted and exchanged across interplanetary distances in harsh space environments (Hooke, 2001).

Since deep space missions may not have direct line of sight between the earth and the final destination address, IPN bundles may also be transported to recipient locations via satellites that function as intermediate IPN nodes (Akyildiz et al., 2004). Approaches for ensuring secure and reliable IPN transmissions, protecting IPN infrastructure operations from cyber attacks, and utilizing access controls and authentication mechanisms to ensure bundle integrity and data privacy are in development.

CONCLUSION

Satellite network security is dependent on carefully designed and effectively implemented security tools, mechanisms, standards, and protocols; policies and legislation; and procedures that prevent unauthorized entities from gaining access to ground stations; eavesdropping on confidential satellite transmissions; altering satellite information in transit; falsifying command and control data; and destroying satellite assets (Roy-Chowdhury et al., 2005). Even when multiple security devices and countermeasures are in place, however, satellite networks remain vulnerable to ground-based and space-based attacks. The mounting incidents of satellite network cyber incursions attributed to cyber terrorism and the potentially

adverse impacts of these attacks on critical infrastructure operations underscore the importance of building secure satellite networks to protect the integrity, reliability, sustainability, and availability of critical infrastructure resources, services, and initiatives.

KEY TERMS

Cyber Attack: A computer network attack that involves the use of wireline and/or wireless network connections to gain unauthorized access to computing resources in order to control network operations (Wilson, 2005).

Geostationary or Geosynchronous Earth Orbit (GEO): A satellite constellation with three to five satellites that orbit the earth at altitudes of 35,800 kilometers (km) such as military strategic and tactical relay satellite (MILSTAR) that provides jam-resistant communications services for the U.S. military.

Ground Segment: Terrestrial component in a satellite network that manages and controls satellite operations and processes data for storage and transmission.

IPv6: Developed by the IETF. IPv6 extends IP addresses from 32-bits to 128-bits, thereby overcoming IPv4 address shortages and ensuring continued Internet growth and expansion.

Low Earth Orbit (LEO): Satellite constellations that orbit the earth at altitudes ranging from 500 km to 900 km and support applications such as Internet connectivity.

Medium Earth Orbit (MEO): Mid-sized satellite constellations such as the U.S. Global Positioning System (GPS). GPS satellites maintain orbits at approximately 20,200 km above the earth and provide precise positioning services.

Open Systems Interconnection (OSI) Reference Model: Seven-layer architectural model developed by the International Organization for Standardization (ISO) to describe standardized network operations.

Space Segment: Refers to the artificial satellite and its payload in a satellite network. It enables diverse applications in sectors that include e-government, e-learning, and e-medicine.

Satellite-Based Mobile Multiservices Platform

Alexander Markhasin
Siberian State University of Telecommunications and Information Sciences, Russia

INTRODUCTION

The future fourth generation (4G) of the satellite-based wireless and mobile communications is particularly important for global providing of the mobile broadband global information technologies (IT) multi-services and mobile e-applications (m-applications) for geographically dispersed mass users in support of anytime, anywhere, and any required quality of service (QoS) capabilities in a low-cost way. The recent broadband satellite systems described in Ivancic et al. (1999), Evans et al. (2005), Skinnemoen, Vermesan, Iuoras, Adams, and Lobao (2005) are based mainly on *centralized low-meshed architecture* with very high traffic concentration. Such structure is not adequate in context of the traffic topology for *rural, remote, and difficult for access* (RRD) regions. Markhasin (2001) noted that the cost of centralized systems is unacceptably large for deployment of future mass broadband communications in RRD regions (North Siberia, Scandinavia, Greenland, Canada, Alaska, Central and South East Asia, South America, Australia, etc.).

As it was shown in Markhasin (2001, 2004), the future low-cost IT multi-service platforms for RRD regions can be built optimal on a mix of the terrestrial and satellite-based mobile and wireless communications with *radically distributed* (*neural-like) all-IP/ATM architecture* that requires breakthrough steps for search advanced satellite, mobile, and wireless 4G technologies. Markhasin (1996) and Frigon, Chan, and Leung (2001) noted that the improvement of medium access control (MAC) protocols has a dominant effect on ensuring the breakthrough features of future QoS-aware mobile and wireless technologies. The survey and analytical comparison of the fundamental principles of QoS-oriented MAC protocols were described in Markhasin, Olariu, and Todorova (2004, 2005). The radically novel *multi-functional MAC technology* (MFMAC) for long-delay space mediums with fully distributed dynamic control of QoS, traffic parameters, and bandwidth resources was proposed in Markhasin (2001, 2004). This article will be focused on future QoS-aware, satellite-based, fully distributed, mesh, and scalable mobile IT multi-service and m-Applications platform's networking technology 4G for RRD regions.

BACKGROUND

Fundamental Challenges

The fundamental challenges of the future 4G technologies provide answers to the following questions:

1. Can it be true everywhere the 4G declaration "Mobile broadband for all anytime, anywhere, any QoS, any bandwidth?"
- In fact: Now it can be ensured only for urban regions with big population density.
2. Evolutionary or revolutionary way?
- The technological restrictions and "rudiments" of outdated generations will be a burdensome "pay" for evolution way.
3. Multimodal (heterogeneity, the "Babel" of MAC protocols) or multi-functional (homogeneity, universal, scalable, adaptable, the "Esperanto" of MAC protocols)?
- The big-cost's of the multimodal solution prevails up to this time.
4. IP or ATM?
- It will effectively integrate the merits of both these perspective technologies on the base of the developing next generations of asynchronous transfer mode (ATM) and multi-protocol label switching (MPLS) technologies based on breakthrough QoS and space-aware MAC protocols.
5. Centralized, hierarchic or decentralized, distributed, peer-to-peer?
- The cost of centralized systems is unacceptably large for deployment of future mass broadband communications for RRD regions, which include many geographical distributed customers.
6. Ultrahigh bit rates and local areas (wireless technology, WiMAX) or middle bit rates and global areas (mobile technology, 4G)?
- The characteristics of the traditional known broadband MAC protocols depend strongly on wireless area distances, and degrade quickly, if this area is increasing (Markhasin, 2001; Markhasin et al., 2004).

This article will be focused on these 4G fundamental challenges.

Integration of IP and ATM Technologies

What is the most promising telecommunication technology of the future global wireless multimedia communication environment 4G: Internet Protocol (IP) technology or ATM? We suppose that an integration of next generations of these two leading technologies will provide the most promising basis for the near future. The *IP over ATM* integration technologies (IP/ATM, for short) have emerged as advanced concepts that are expected to provide broadband multi-service to the end users by making the best utilization of the advantages of IP (packet switching, adaptive routing, heterogeneous flexibility, scalability, etc.) and of QoS-oriented MAC-based ATM (soft QoS provisioning; fully distributed; dynamical traffic engineering and resource allocation; multimedia; high speed; guarantying; etc.) in a cost-efficient way.

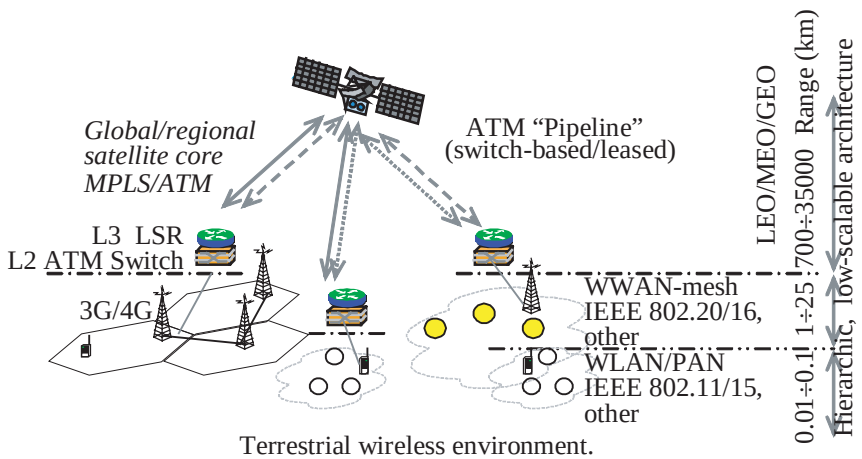
As it was described in Ivancic et al. (1999), Peyravy (1999), and many other authors, the widespread global wireless IP/ATM multimedia systems are based mainly on switch-based centralized architecture (Lawrence, 2001) with very high traffic concentration (see Figure 1). This global/regional satellite core networks domain will be built upon the big ATM switching/*label switch routing* (LSR) nodes, which are conned via satellite switch-based or leased "pipelines." Such structure is adequate to high urban areas especially. The wireless and mobile access networks domain may include the personal (WPAN), the local (WLAN), wide (WWAN), vehicular (VAN) area networks levels, and also cellular systems (B3G/4G, UMTS, S-UMTS). Salkintzis (2004) and many authors of the Special Issue "Migration Toward 4G Wireless Communications" (2004) define a key role of integration of the previously listed wireless and cellular technologies in the 4G of mobile data networks.

The another concept *IP-VAN over Digital Video Broadcast Satellite* of satellite-based broadband access VAN system (DVB-S) was proposed in Oh, Kim, Song, Jeon, and Lee (2005). Its satellite access channel consists of forward and return links having asymmetric star topology. The time division multiplexing (TDM) based forward link is transmitted over DVB-S channels where vehicle's IP packets are encapsulated into MPEG2-TS packets. The return links are composed of multi-frequency multiple access channels with time division (MF-TDMA) or code-division (MF-CDMA) based on Digital Video Broadcast-Return Channel Satellite (DVB-RCS) standard. Unfortunately, the DVB-S/RCS channels' opportunities limited the dynamical control of the QoS, symmetry, and other required characteristics of the VAN system.

MPLS over ATM

The MPLS over (MPLS/ATM, for short) were proposed as very promising extensions to the existing IP/ATM technique (Lawrence, 2001). Lawrence noted that the recent MPLS/ATM is based mainly on routing, switching, and also on further developing the IP capabilities. Switch-based MPLS/ATM's *label distribution protocol* (LDP) supports *hop-by-hop label routing* through the network. Switch-based (L3 LSR) up to date have been based on ATM switches. The ATM cell forwarding mechanism supports also *hop-by-hop ATM label switching*. In Markhasin (2001, 2004) it was

Figure 1. Switch-based MPLS on ATM centralized global satellite/mobile/wireless hierarchic architecture



Terrestrial wireless environment.
Mobile/wireless broadband access networks B3G/4G

shown that switch-based mechanisms support effectively the multimedia satellite networks with highly centralized architecture only (see Figure 1), because the number of such "hops" is strictly limited, and their main components—big ATM switches and high rate "pipeline"—need very high traffic concentration. Unfortunately, its cost is unacceptably high for the satellite multimedia personal networks in context of remote users with geographical distributed traffics and supporting mass market.

The strategic starting point for improvement of next generation of MPLS/ATM technology represents the thesis about dominant effect of MAC layer modernization to the ensuring of novel required abilities. The overview and analytical comparison of the QoS-oriented MAC protocols were considered in Markhasin et al. (2004, 2005). In fact, many MAC protocols proposed for multimedia wireless and satellite (Peyravy, 1999) are based on published per 1970-1980s' years (Rubin, 1979; Tobagi, 1980) classical free, controlled (reservation), and hybrid multi-access methods. As it was described in Markhasin (1996), Peyravy (1999), Rubin (1979), Tobagi (1980), and Wong, Zhy, and Leung (2001), the hybrid or reservation MAC protocols with the defined or fixed *superframe formats* (SFR) are often used in wireless and satellite long-delay mediums.

Requirements to Novel MAC Technology

In Markhasin (1996, 2004) it was shown that the specific conditions of the satellite-based wireless and mobile networks 4G (the long-delay space medium, the geographical distributed multimedia traffics, the soft QoS-oriented MAC, the completely distributed all-MPLS/ATM architecture, the mass market, and others) require the MAC protocol abilities to overcome three principal problems: so-called (1) *time barrier*, (2) *dynamical barrier*, and (3) *economic barrier*.

The time barrier appears due to the effect of *degradation* of long-delay MAC efficiency when the round trip time increases. The dynamical barrier occurs from such essential reason as dynamical instability of the well-known parallel processing reservation MAC schemes with the defined or fixed SFR (Markhasin, 1996). The economic barrier is due to unacceptable costs incurred by any well-known satellite centralized architecture, making a low-cost wireless broadband, ATM mass-market implementation difficult.

In summary, the following abilities must be achieved during creation of soft QoS-oriented long-delay-mediums multi-functional MAC, so-named MFMAC technology:

- high efficiency and throughput of access control to long-delay wireless and space mediums: the time barrier overcoming aspects;
- high controllability, differentiation, stability, and guarantee of dynamical control of QoS, traffic parameters (TP), and bandwidth resource (BR): soft QoS and the dynamical barrier overcoming aspects;
- multi-functional and universal abilities on the basis of the common dynamically controlled and adaptive ATM MAC protocol through the entire network hierarchy—core, backbone, and access networks: all-MPLS/ATM-MFMAC aspects; and
- low-cost, neural-like, fully distributed hyperbus architecture supporting of the MAC sublayers through all networks hierarchy: economic barrier overcoming aspects.

FULLY DISTRIBUTED MOBILE TECHNOLOY 4G

MFMAC Technology

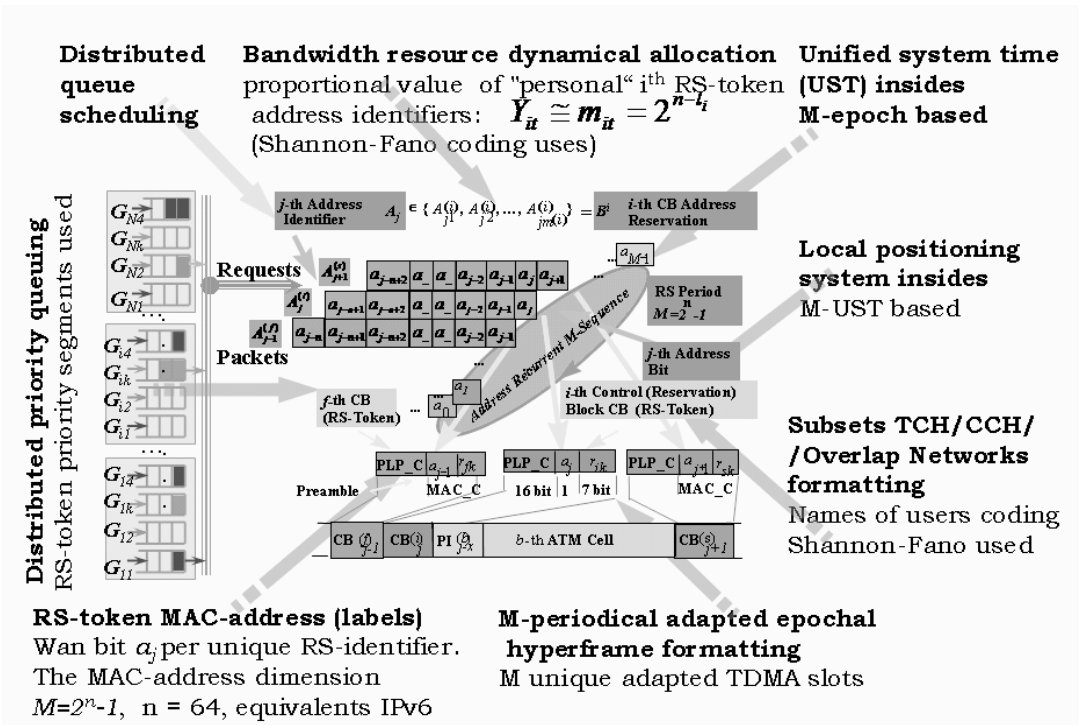
As it was shown in Markhasin et al. (2004), the best required QoS-oriented MFMAC technology capabilities ensure the MAC protocols with adaptive time frame access processes, controlled (reservation) access mechanisms, and parallel conveyer processing of MAC instruction. In one of them, such capabilities can be successfully realized on the basis of developing the *RS-token broadcast reservation* (RS-TBR) *MAC protocol* (Markhasin, 1996, 2001). This protocol uses the recurrent M-sequences (RS) MAC addressing opportunities in order to organize RS-token tools *all-by-one* for highly effective multiple access to long-delay space medium; soft QoS provision and distributed dynamical control of traffic parameters; and bandwidth resources (Figure 2).

Two types of ATM blocks are introduced: control mini-blocks (CB) and information blocks (IB). The control mini-blocks contain a 16 bit preamble PLP_C and an 8 bit access control field MAC_C, including an address bit and the request of the i^{th} station for a block transmission from some number of ATM cells of the k^{th} service class. The information blocks include a packet layer preamble (PLP_I), a field *logical linking control* (LLC), and a variable number of ATM cells. The RS-TBR described in Markhasin (1996, 2001) is used for completely distributed long-delay MAC. Each station adaptively divides the time axis into equidistant synchronous RS-labeled time slots using the common deterministic algorithm of parallel-conveyer requests processing, based on RS-token requests listened to in the broadcast channel. The M-subsequences $A_j = a_{j-(m-1)}, a_{j-(m-2)},...,a_j$ serve as RS-identifiers of the MAC addresses and other protocol subjects, including the labels. Some number m_{it} of "personal" identifiers

$$\{A_{jit}\} = \{A_{ji1},...A_{ji2},...,A_{jim_{it}}\} = B_{it} \quad (1)$$

for passing of requests r_{ik} in proportion to the required bandwidth resource value $[Y_{it}]$ is dynamically assigned to

Figure 2. RS-token "all-by-one" MAC control's mechanism



each i^{th} station on a decentralized basis by Shannon-Fano method. Each j^{th} RS-MAC address can be identified by a unique RS-token using one RS-bit a_j per one MAC address. The dynamical bandwidth assignments and requests scheduling mechanisms are based on this RS-token intensity (the number of RS-token per second) soft regulation in proportion to required resource. The bandwidth dynamical assignments policy can be defined on the basis of the game theory task (Markhasin, 2005). These tasks can create an analytical base for bandwidth brokers (BB). One can show that protocol's realized efficiency can be near to potential capacity (Markhasin, 2004). To support the required k^{th} service classes and queuing discipline, a mechanism of *priority segments* $[(j\text{-}l_{kt}),j)$, $M \geq l_{Kt} \geq ... \geq l_{Kt} \geq ... \geq l_{2t} \geq l_{1t} = 0$ is used (Markhasin, 1996).

At the same time, this protocol allows us to realize a universal RS-token MAC tools *all-by-one* for dynamical (up to real time) soft control of QoS, traffic parameters, and bandwidth resources. This tool implements effective RS-token MAC mechanisms for the optimal planning of control policies, the bandwidth resource scheduler, traffic shaping, dropping discipline, united system time, local positioning date, and, possibly, other added functions simultaneously.

MFMAC-Based Novel ATM Technology

The novel opportunities of the proposed MFMAC technology create a perspective base for developing the next generation of satellite, mobile, and wireless ATM technologies (ATM-MFMAC), which will be highly effective for RRD regions. The fundamental definition of the next generation satellite ATM-MFMAC technology presents the *Virtual Space Medium ATM Hyperbus*, which operates by MFMAC protocols (Brandt et al., 2001; Markhasin, 2001). In fact, it is a QoS-aware, fully distributed, dynamically controlled, and broadband ATM wireless hyperbus, which "was lifted up to the sky," that is, "Sky-Bus." The Space Medium ATM Hyperbus builds a virtual bus between all the users (which are in sight of a given satellite). The satellite in this case is merely a retranslator so those users in different geographical locations can share the same virtual bus.

The MFMAC's *all-by-one* mechanism implements an adaptive highly effective multiple access to long-delay space medium; soft QoS provision and distributed dynamical control of traffic and bandwidth resources; and other important MAC mechanisms. The dimension of this MAC-address space can be equivalent to IP-address capacity of

Table 1. Comparison of the recent ATM and the satellite next generation ATM-MFMAC

Features	The recent generation ATM	The proposed satellite next generation ATM-MFMAC
Physical channel topology	"Multipoint-to-multipoint," *not distributed ("pipe")*	"Multipoint-to-multipoint," *radically distributed ("hyperbus")*
Multiple access (MA) technology	*Single* station MA with statistical multiplexing, *fully centralized*	*Multi* station MA with statistical multiplexing, *radically distributed*
MAC technology	*Not QoS-aware*, *not adapted*, long-delay-aware only for *"pipe"* topology	*QoS-oriented*, multifunctional, *adapted "on-the-fly,"* long-delay-aware for fully distributed *"hyperbus"* topology
MAC address dimension	The dimension M = 256, used time resource—*eight* address bit per one address	$M=2^n-1$, n = 64÷128, equivalents IPv6, used time resource—*one* address bit per one address
QoS control	*Static* planning a set of fixed class of quality (CBR, ABR, etc.), *Hard QoS (not proportional)*	*Dynamical* ("on-the-fly") control of QoS, traffic parameters, and bandwidth resources, *Soft QoS (proportional)*
Cells format	53 octets	It is possible and expedient to increase
Used networks	Transport and corporative networks	Access and transport networks, integrated satellite/mobile/ wireless, and so forth.
Supports region conditions	*High urban*	*Rural, remote, difficult of access* (mountains, oceans, islands, tundra, etc.)
Supports services and applications	*Stationary* multimedia services and e-Applications	*Mobile* multimedia services and m-Applications
Cost	*Large-cost* per customer	*Low cost* per customer

IPv6. The ATM Hyperbus builds a virtual bus connection between all L2 nodes.

The proposed ATM Hyperbus architecture provides a wide range of services with different traffic streams and different QoS characteristics. QoS guarantees are essential for the support of real time services such as telephone and video. ATM technology allows temporal QoS requirements to be taken into account, flexibility for bursts traffic, and bandwidth allocation to isochronous applications with various adaptation layer (AAL) protocols.

The comparison of the recent ATM technology and the proposed next generation satellite ATM MFMAC-based technology is shown in Table 1.

MFMAC-Based Novel Generation Satellite MPLS/ATM

In Markhasin (2001) a novel MFMAC-based next generation MPLS over ATM-MFMAC integration technology (MPLS/ATM-MFMAC, for short) was proposed.

The proposed generation MPLS/ATM-MFMAC technology is suitable for completely distributed all-MPLS/ATM satellite networks architecture and soft QoS provisioning. This generation was based on the principle of using an ATM *selecting technique,* rather than ATM *switching technique*. In fact, the novel alternative solution combines a multi-functional, long-delay, broadband next generation L2 ATM-MFMAC technology (Markhasin, 2001) with fully distributed multi-functional L2 ATM Hyperbus architecture (Brandt et al., 2001; Markhasin, 2001), and the L3 MPLS over ATM routing technique (Lawrence, 2001).

The topology of virtual bus can be represented by a passive optic tree, wireless or satellite bus, cross-hexagonal (see Figure 3), ring-radial ("metro") topology, and so forth. The suggested MPLS/ATM structure can include a few of L3 LSR/MFMAC *routing nodes* (RN) for buses or edge interworking, and possibly many hundreds of L2 ATM/MFMAC scalable *transit nodes* (TN) for ATM data cells *label selecting*. The novel MFMAC-based MPLS/ATM does not require hop-by-hop switching mechanisms. The label distribution protocol uses a label selecting mechanism for TN and *label routing mechanism* for RN for setup in the selected path through the network. The ATM cell-forwarding protocol uses also a non-hop-by-hop label selecting mechanism for transit and routing.

CONCEPTUAL MODEL OF A SATELLITE-BASED FULLY DISTRIBUTED MOBILE PLATFORM'S TECHNOLOGY 4G

The conceptual look of the fully distributed (neural-like) all-MPLS/ATM-MFMAC architecture of future global

Figure 3. The next generation alternative MPLS over ATM-MFMAC (fiber optic analogy)

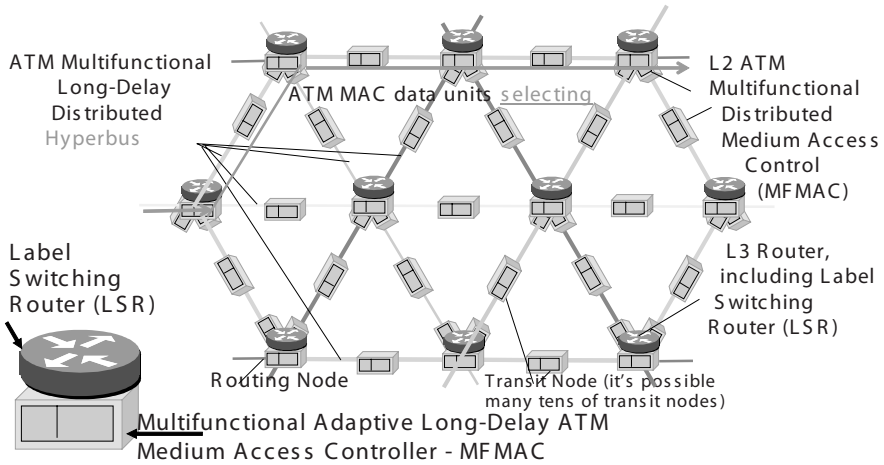


Figure 4. The conceptual model of global fully distributed scalable all-IP/ATM wireless mesh environment 4G: L2-MF-MAC—Universal MAC controller; L3 LSR—Label switch router; S-TN—Transit/selecting node; S-RN—Routing node; HBMN—Hyperbus managing node; MBWAN—Mobile broadband wireless access network; MBT—Mobile broadband terminal 4G; S-MBT—Satellite MBT terminal 4G; MPT—Mobile broadband PCS terminal 4G; S-MPT–Satellite PSC terminal 4G; BAP—Broadband access point; S-PCS—Satellite personal communication system 4G; T-PCS—Terrestrial PSC 4G.

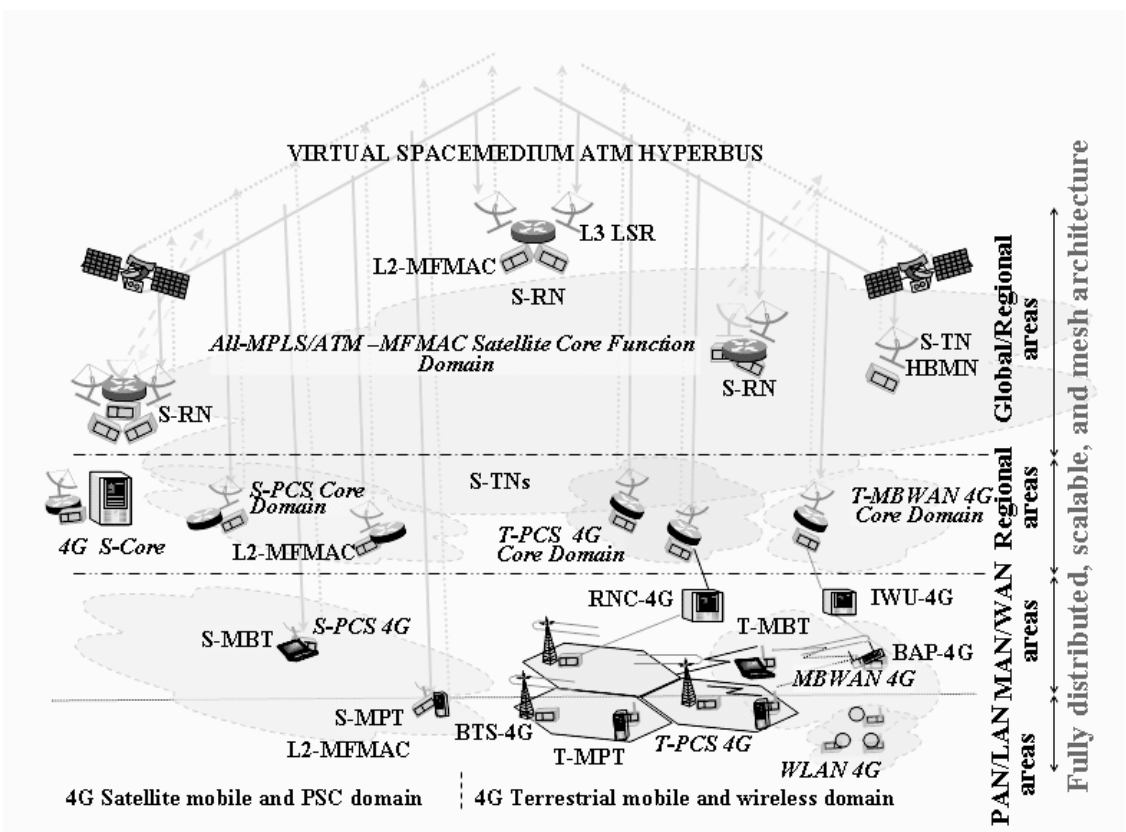

satellite/mobile/wireless multimedia networks is explained in Figure 4.

The proposed architecture of the global wireless and mobile environment is based on previously described novel alternative MPLS over ATM-MFMAC integration, and advanced soft-QoS-oriented multi-functional MFMAC technology. Their structure is created on so-called distributed Virtual Spacemedium ATM Hyperbuses and uses the common universal dynamically adapted MFMAC protocol through the entire networks hierarchy—core, backbone, and access networks. The orbital groups geostationary (GEO), medium Earth (MEO), or low-Earth/high elliptical (LEO/HEO) orbits of satellite broadband digital retranslator ensure the global coverage.

The retranslator forms a multi-access up channel and broadcast down channels. The virtual hyperbusses L2 for various wireless and satellite MPLS/ATM systems, which differ according to the classes of the topology scales (W-MAN, W-WAN, S-UMTS, S-PSC), function hierarchy, technical characteristics, and kinds of medium, can be configured using up to three logically homogeneous basis components: (1) universal adaptive medium interface with medium type cartridge—L1-UAMI, (2) universal adaptive multifunctional distributed ATM-MFMAC medium access controller—L2-MFMAC, and (3) the hyperbus's bandwidth broker server (HBBS) of the distributed dynamical control of QoS, traffic parameters (TP), and bandwidth resource assignment (BR). Moreover, the same hyperbus can implement simultaneously (in parallel) a function of access network, and function of core network or/and backbone, that is, it is mult-ifunctional.

FUTURE TRENDS

The satellite-based domain will be having a common core of high layer standard protocols of the eMobility Technology Platform, and different (MFMAC-based) physical and channel layers protocols. In fact, it is necessary to develop the added MFMAC-based Universal Adaptive Interface with Mediums Type Cartridge (L1-UAMI) and Universal Adaptive Multifunctional Distributed ATM-MFMAC Medium Access Controller (L2-MFMAC) standards, and possibly some overhead extending of the high layers protocol, which realizes the soft QoS and other MFMAC novel opportunities (L2/L3 QoS Manager/Bandwidth Broker, etc.). For example, it is necessary to develop the novel 4G Air Interface (mobile MFMAC), IEEE 802.16x/20y (wireless mesh, soft QoS, long-delay, multi-functional, reconfigurable) IEEE 802.2Xz (satellite MFMAC), and so forth, standards.

CONCLUSION

What is our vision of the place in the future mobile and wireless world of the described MFMAC-based fully distributed neural-like All-IP/ATM integrated satellite, wireless and mobile networking technology 4G? It is very expedient and well grounded to consider this fully distributed networking technology 4G as satellite-based RRD-domain of the future mobile IT/ITC-Multiservices, m-Applications, and eMobility (Tafazolly, Correia, & Saarnio, 2005) Platform's Technology 4G, which will guarantee a low cost and friendly access to global/regional IT-Resources/Multiservices for mass subscriber by covering the RRD areas.

KEY TERMS

All-IPArchitecture: A networks interworking's architecture based on the set of Internet protocols (IP) end-to-end.

Asynchronous Transfer Mode (ATM): A QoS-aware, broadband communications technology that supports multistreams transfer of traffic of any kind (multimedia, video, voice, date, etc.) into so named cells with fixed length of 53 bytes.

Medium Access Control (MAC): According to the Open System Interconnection (OSI) terminology, an interface between the Physical Layer (PhL) and Logical Link Control (LLC) layers.

Mobile Multi-Service: An integrate provisioning of the several kinds of mobile services (voice, video, data, mobile Internet, etc.).

Multi-Functional MAC (MFMAC): Universal multifunctional MAC technology which guarantees QoS-oriented, fully distributed, and dynamical control of the MA to long-delay mediums by any networks function—access, core, transport backbone, and so forth.

Multiple Access (MA): Procedures regulating the simultaneous use of a common transmission medium by multiple users.

Quality of Service (QoS): Collection of performance parameters for network service including bandwidth, average delay, jitter, packet loss probability, among many others.

Sectoral Analysis of ICT Use in Nigeria

Isola Ajiferuke
University of Western Ontario, Canada

Wole Olatokun
University of Ibadan, Nigeria

INTRODUCTION

Information and communications technologies (ICTs) have become key tools and had a revolutionary impact of how we see the world and how we live (Dabesaki, 2005). They have the potential to be a major driving force behind the economic growth of any nation because of their potentially strong restructuring impact on existing economic activities and the ability to affect economic activities in a variety of ways. These include improving the quality of existing services, creating new services, raising labor and productivity, increasing capital intensity, enhancing economics of scale, and creating new economic structures. ICTs are also paving the way for greater ease of movement of technical and financial services, and are instrumental to development during the rapid globalization process. From the information technology revolution, a new kind of economy emerges. This is the information-based economy in which information along with capital and labor is a critical resource for creation of income and wealth for the enhancement of competitiveness. ICTs have also left their mark on the political and social dimensions of development, specifically by enhancing participation in decision-making processes at the corporate, local, and national levels.

It is an established fact that a few developing countries like China, India, and Brazil are successfully taking advantage of the opportunities information and communications technologies offer and have made significant improvement in their economic, and many more developing countries (including Nigeria) are beginning to derive some of the potential benefits. For most of the developing world, however, information and communications technologies remain just a promise, and it seems a distant one at that. There is little evidence from past experience of national and international development policies, strategies, and programs to suggest that much will change for large segments of the world's poorest people.

Nigeria, like most developing countries, is an "information-poor" country where the deployment and application of ICTs is still in its infancy. This article, which is an updated version of an earlier one (Ajiferuke & Olatokun, 2005), presents the current status of ICT in Nigeria, particularly its applications in some sectors of the nation's economy. It also identifies some inhibitions to the effective deployment and exploitation of ICT in Nigeria and concludes with a discussion of the policy issues, challenges, and prospects of ICT use in Nigeria.

BACKGROUND

ICT Initiatives, Policy Formulation, and Implementation

The Federal Government of Nigeria has accorded ICT a national priority. This is evident in the approval of the National Information Technology Policy (NITP) and the subsequent establishment of the National Information Technology Development Agency (NITDA) in 2001 to serve as a bureau for the implementation of the NITP. The policy recognized the private sector as the driving engine of the ICT sector. NITDA is to enter into strategic alliance, collaboration, and joint venture with the private sector for the actualization of the ICT vision, which is to make Nigeria an ICT-capable country using ICT as an engine for sustainable development and global competitiveness. It is also to be used for education, job creation, wealth creation, poverty eradication, and global competitiveness.

A sectoral application of ICT has been recognized in the formulation of the ICT policy, which involves the development of the following areas of the economy: Human Resource Development, Infrastructure, Governance, Research and Development, Health, Agriculture, Urban and Rural Development, Trade and Commerce, Arts, Culture and Tourism, National Security and Law Enforcement, Fiscal Measures, and so forth. According to Ajayi (2002), NITDA has embarked on a number of projects aimed at stimulating the growth of ICT in the country. The Public Service Network (PSNet) is one such project, aimed at addressing the major problem of ICT infrastructure, which will serve as a pipeline for ICT services. It consists of a Very Small Aperture Terminal (VSAT) sited in each state capital. This VSAT provides Internet access for that central location and all other locations connected to this center using broadband wireless access (BWA) technology. The various sites around the country are then connected to each other through a vir-

tual private network (VPN). Nine states have already been connected in the first phase of the project.

Human capacity building has been another focus of NITDA. Towards realizing this goal, NITDA has forged a thriving partnership with public and private organizations in what has become a public-private partnership (PPP). The Enterprise Technology Center (ETC) is one such PPP that is worthy of note. The ETC is a partnership between NITDA and two private companies to provide ICT training for civil servants. NITDA has also collaborated with several multinationals and international organizations to deliver specialized training in some train-the-trainer workshops. These institutions include UNESCO, the International Center for Theoretical Physics (ICTP), and Cisco Systems.

The Telephone System in Nigeria and the GSM Revolution

The telephone system in Nigeria has been challenged for years. A breakthrough in telephone infrastructure emerged in January 2001 when the sector was totally liberalized, leading to the Nigerian Communications Commission (NCC) issuing four wireless licenses to MTN Nigeria Communication, Econet Wireless Nigeria Limited (now Celtel), Communications Investment Limited (CIL), and state-owned NITEL. CIL, however, had its license withdrawn because of its inability to meet the deadline for payment of the license fee. The fourth GSM provider, Glomobile (Globalcom), though it won its multiple licenses in September 2002 for the provision of telecommunications services, did not commence provision of mobile phone services until August 2003. Since the GSM launch, mobile telephony has rapidly become the most popular method of voice communication in Nigeria. Indeed these developments have been truly explosive: today Nigeria has about five million mobile lines and about one million fixed lines, compared with just about 450,000 working lines from NITEL four years ago.

Internet Usage in Nigeria

The Internet has experienced relatively slow growth in Nigeria and other countries in the poorer regions of the world such as sub-Saharan Africa. Nigeria is among the nine countries in Africa that achieved full Internet access in their capital cities and some secondary towns by 1998 (Jensen, 1998). Available statistics show that Internet usage in Nigeria between 2000-2003 stood at 200,000, representing 0.1% of the total population. For Nigeria with a population of over 120 million, growth rate has been stagnant. This may have contributed to the slow pace in socio-economic development in the country. According to Internet Usage statistics for Africa, Internet usage in Nigeria remained stable until 2003, but increased to 5 million in 2006, about a 3.1% penetration rate (see Table 1). Many factors, including high cost of bandwidth and telephone lines, might have made the majority of the operators to charge within the range of N100 per hour, which many surfers might not be able to afford as a result of the prevailing economic realities.

MAIN THRUST OF THE ARTICLE

ICT Application in Various Sectors

ICT Usage in Manufacturing

ICT usage in manufacturing companies in Nigeria has improved production and made it easier to perform difficult tasks. ICT is used in product design, such as in computer-aided design and computer-aided manufacturing. ICT is also used in the control of processes, as well as the control of machinery. A survey of 22 manufacturing companies conducted in Lagos and Ibadan in March 2005 showed that ICT facilities exist at various levels and departments in the companies (Lasaki, 2005). ICT is also being used to capture information at all stages of design, manufacturing, and marketing. According to Lasaki (2005), "There is considerable evidence that the Nigerian manufacturing sub-sector is moving towards proper integration into the information society."

Use of ICT in Education

Education helps in the development of skills and the acquisition of knowledge. There is a need for continuous improvements in education. ICT is playing a tremendous role in educational developments in Nigeria. Online admission into Nigerian schools is becoming more and more popular. Many schools have institutional Web sites where information about

Table 1. Nigeria's Internet usage and population growth (ITU, 2003; Internet World Stats, n.d.)

Year	Users	Population	% Penetration	Usage Source
2000	200,000	142,895,600	0.1 %	ITU
2006	5,000,000	159,404,137	3.1 %	ITU

them is available to the public. There are students in Nigeria who will eventually obtain degrees via the Internet from institutions of higher learning that are outside the country. Within the country, admission registration processes have improved in schools and agencies that make good use of ICT facilities. ICT use has also improved distance learning, especially with the resuscitation of the national Open University of Nigeria (NOUN), which delivers its courses through a combination of Web-based modules, textual materials, audio and videotapes, as well as CD-ROMs.

Use of ICT in Banking

Use of ICT in banking has resulted in electronic banking (e-banking). E-banking in Nigeria has been in an upbeat mode. Some of its features include the use of automated teller machines (ATMs), pay-by-phone systems, personal computer banking, point-of-sale transfers, and the electronic check conversion. The financial marketplace has been actively promoting its online publications and functionalities. Nigerian banks are becoming very innovative, launching new services with the use of ICT facilities. For example, an automated check clearing system (NAACCS) was launched last year through the Central Bank of Nigeria.

Use of ICT in the Print Media

Print media are involved in publishing written materials such as newspapers and magazines for the public. However, the advent of the information age has brought about major changes in the Nigerian print media with the adoption of ICT in the industry. Some of the benefits of the use of ICT in the print media are enhanced performance (speed, skills, and quality), improvement in communication, improvement in picture resolution and general graphics, reduced cost of production (which results in increased profits), better page layout, good image, high rating, and realization of corporate goals (Ehikhamenor, 2003). Use of ICT therefore helps to gain competitive advantage, which is necessary for survival in the print media industry.

A survey of 19 print media houses to evaluate the level of utilization of ICTs in Nigerian print media industries found that all the print media houses surveyed have ICT facilities like computers, printers, scanners, telephone facilities, lithographic machines, FAX machines, and photocopiers (Erigha, 2006). Many of them now have online versions of their newspapers on the Internet.

Use of ICT in Medicine

Technological advancements have greatly improved healthcare delivery worldwide. Nigeria is not excluded in this development. Use of ICT in medicine has helped both in routine work and complicated medical procedures. ICT has especially helped in the area of public awareness and enlightenment about health issues, as there are over 10,000 health-related Web sites (Ashville Citizens Times, 1997, as cited in Ibeguam, 2004). In Nigeria for example, many people are aware of HIV/AIDS (means of infection, prevention, proper attitude towards those infected, and management of the infection) as a result of good use of ICT facilities. Medical research also depends a lot on the effective use of ICT. Data collection, analysis, interpretation, and report of findings are usually done by means of ICT facilities. For example, the University College Hospital (UCH), a center for medical research in Nigeria, has embarked on a study on effective diagnosis of cancer by electronic means.

ICT in Governance

Electronic government (e-government) involves the use of ICT facilities to deliver public services to citizens and businesses. It entails the transformation of public services to citizens using new organizational processes and new technologies (Gunter, 2006). E-government aims at making government services more accessible, more customer focused, and more relevant to citizens. It encourages citizens' involvement in governance, enhanced communication links, harmonized organizational practices, and partnerships between different layers of government. It focuses on improving public services and internal workings of government organizations.

E-governance has been partially adopted by the Federal Government of Nigeria and a few states. For example, the voters' registration for the April 2007 general elections was done electronically, while a few state governments are providing their citizens with online access to important forms. However, some states are still lagging behind in the adoption of ICT in governance. For example, a recent survey that sought to measure the preparedness of Oyo state government for e-governance shows that the level of computerization of government agencies in Oyo state is low, perception of e-governance is low, and information dissemination records and information management practices are poor (Ogunsola, 2006).

Issues and Challenges of ICT Usage In Nigeria

No doubt, there has been substantial improvement in access to telecommunications facilities and unprecedented growth in the telecommunications network in Nigeria. However, in view of Nigeria's size and requirements, the telecommunications infrastructure is still grossly inadequate. Among others, the following are the major challenges and barriers inhibiting ICT usage in Nigeria:

a. *Cost:* In Nigeria, high access cost is still a major barrier. While prices have definitely come down, the cost of access is still too high to have a transformatory impact. There are presently price competition battles going on involving private telecommunication operators (PTOs) and GSM providers which are steps in this direction. The provision of the Internet by PTOs is also bringing down the cost. But more needs to be done about bringing down call tariffs and rates, not just communications acquisition cost.
b. *Poor Energy Infrastructure:* Epileptic public power supply in Nigeria increases the cost of access. Supply of electricity needs to be optimal to enable businesses and banks to provide seamless online services through local areas networks, wide area networks, and the Internet. Inefficiency is the word to describe a situation where power generators are the only reliable suppliers of power. This constitutes a barrier to growth and sustainable development. The growth of real e-business cannot take place or be of any significance in an environment with unreliable public power supply.
c. *Quality of Service:* While availability has grown, this has not been matched by quality of service. It is not enough to have cheap lines and low-cost bandwidth. Efficiency and accessibility of telecommunications service should be paramount. Most operators have a lot of work to do in the area of quality of service, especially congestion control and support services. The National Communications Commission (NCC) may need to wield the big stick to ensure quality service by sanctioning poor performers.
d. *Appropriate Licensing Fees:* NCC has done a lot as a pacesetter. But NCC needs to review the appropriateness of its license fees. How realistic are such fees for healthy competition? Will such fees as they are stimulate telecommunications growth or increase the number of competent market players?

CONCLUSION AND FUTURE TRENDS

Nigeria's present status and indicators point to a possible growth in ICTs. For example, Africa's growth in the number of telephone subscribers from 14 million fixed lines and 1 million mobile lines in 1996 to 22 million fixed lines and 28 million mobile lines in 2001 and over 32 million fixed lines and 82 million mobile lines in 2005 (BBC News, 2005) is a strong indication that the growth of ICT in Africa and indeed Nigeria is real. It is noteworthy that Nigerian banks are beginning to embrace electronic banking (e-banking), and in spite of all the bottlenecks and assumed odds, e-banking will help produce a better banking industry, one that is accessible *anytime, anywhere.* Also, the adoption and deployment of ICTs in distance education is beginning to gain ground as presented in the preceding sections. So also is the usage of ICTs in governance becoming a reality in transacting business in some federal government ministries and agencies, as well as in some states.

Potential investors are attracted because of the country's size and population. But is the environment conducive for growth in the ICT sector? Is there ICT growth for the benefit of Nigerians? Considering Nigeria's size and potential, growth in ICT is definitely poor. The future of Nigeria depends not on oil, but on the quality of human capital. In the digital age, Nigeria needs quality manpower. We must get our priorities right by investing seriously in human capital. This means focusing on increased computer literacy and ICT professionalism.

In sum, for Nigeria to reap from the numerous opportunities offered by ICT and for ICT to be effectively deployed and applied in the various sectors, it is an imperative to adopt policies aimed along the following areas and directions:

- finding a holistic solution to the perennial energy problem;
- developing ICT infrastructure;
- increasing the telephone and mobile phone penetration rates;
- increasing general literacy of Nigerians;
- increasing ICT literacy through the introduction of computer education from the early stages of education, and organizing ICT training for civil servants in government ministries and agencies;
- further deregulating and liberalizing the mobile telephony sector;
- reducing tariffs on ICT equipment for it to become more affordable and widespread with a view to increasing accessibility;
- making the National Information Technology Development Agency (NITDA) more autonomous; and
- adopting strategies to bridge the digital divide (gender, income, literacy, etc.).

KEY TERMS

Global System for Mobile Communication (GSM): A digital mobile telephone system that is widely used in Europe and other parts of the world. GSM uses a variation of TDMA and is the most widely used of the three digital wireless telephone technologies (TDMA, GSM, and CDMA). GSM digitizes and compresses data, then sends it down a channel with two other streams of user data, each in its own time slot.

Information and Communications Technology (ICT): An umbrella term that includes any communication device or application, encompassing radio, television, cellular phones, computer and network hardware and software, satellite systems, and so on, as well as the various services and applications associated with them.

Information Technology: Encompasses all forms of technology used in processing and disseminating information.

Internet: An interconnected system of networks that connects computers around the world via the TCP/IP protocol.

Policy: A plan of action to guide decisions and actions. The term may apply to government, private sector organizations and groups, and individuals.

Security and Privacy in Social Networks

INTRODUCTION

Web-based social networks (WBSNs) are online communities that allow users to publish resources (e.g., personal data, annotations, blogs) and to establish relationships, possibly of a different type ("friend," "colleague," etc.) for purposes that may concern business, entertainment, religion, dating, and so forth. In the last few years, the usage and diffusion of WBSNs has been increasing, with about 300 Web sites collecting the information of more than 400 million registered users. As a result, the "net model" is today used more and more to communicate, share information, make decisions, and 'do business' by companies and organizations (Staab et al., 2005).

Regardless of the purpose of a WBSN, one of the main reasons for participating in social networking is to share and exchange information with other users. Recently, thanks to the adoption of Semantic Web technologies such as FOAF and other RDF-based vocabularies (Brickley & Miller, 2005; Davis & Vitiello, 2005; Golbeck, 2004), accessing and disseminating information over multiple WBSNs has been made simpler (Ding, Zhou, Finin, & Joshi, 2005). If this has been quite a relevant improvement towards an easier sharing of information, it makes more urgent that content owners have control over information access. In fact, making available possibly sensitive and private data and resources implies that they can be used by third parties for purposes different from the intended ones. As a matter of fact, users' personal data and resources are regularly exploited not only by companies for marketing purposes, but also by governments and institutions for tracking persons' behaviors and opinions, and in the worst case, by online predators (Barnes, 2006).

It is then a challenging issue to devise security mechanisms for social networks, able to protect private information and regulate access to shared resources. In this article, besides providing an overview of the characteristics of the WBSN environment and its protection requirements, we illustrate the current approaches and future trends to social network security, with particular attention paid to the emerging technologies related to the so-called Web 2.0.

BACKGROUND

Usually, a social network is defined as a *small-world network* (Watts, 2003), consisting of a set of individuals (persons, groups, organizations) connected by personal, work, or trust relationships. Social networking is then a quite broad and generic notion, which in the Web context might be applied to any kind of virtual community. For instance, users registered to a Web service, such as Web mail, online journals, or newspapers requiring a subscription, can be considered as a social network. In the following, we adopt the definition provided by Golbeck (2005), according to which an online community's Web site can be considered a Web-based social network only if it satisfies the following conditions:

- Relationships are explicitly specified by its members, and not inferred from existing interactions (e.g., a mailing list can be used to infer implicit relationships).
- Relationships are stored and managed by using technologies, such as database management systems, allowing relationship analysis and regulating access and retrieval of relationship data.
- Members are able to access relationship information, at least partially.

Born in the late 1990s, in the last few years WBSNs gained increasing interest and diffusion. Although the first and most successful ones, such as MySpace, Friendster, and Facebook, were formerly designed for entertainment and socialization purposes, they are currently establishing themselves as a business model, through which institutions and organizations can set up a collaborative environment for specific purposes, and where it is possible to share resources at an intra- and inter-organizational level. Due to the great amount of collected data, WBSNs are currently the subject of great interest for statistical analysis (Wasserman & Faust, 1994; Freeman, 2004), since they may provide useful information not only to social researchers, but also for marketing purposes.

WBSNs may provide different kinds of services, ranging from information and contact sharing, to collaborative

rating, collaborative work environments, and so on. However, independently from the specific purposes of a WBSN, members' relationships are the core information on which all the provided services are based. In fact, they can be used not only to create connections among people sharing similar interests, but also to customize WBSN services themselves. This is particularly true in WBSNs supporting collaborative rating: in such a context, ratings may be given different weights, depending on the relationships existing between WBSN members. For instance, it may be the case that a given WBSN member m_1 considers more relevant (or trustworthy) the opinions of member m_2 than, say, those of member m_3. For this purpose, some WBSNs allow their members not only to specify personal relationships (e.g., "friend of," "colleague of") but also to establish *trust* relationships, which express how much they trust the other members either with respect to a specific topic (*topical trust*) or in general (*absolute trust*). For a thorough discussion on trust relationships and how they can be used, we refer the reader to the work by Golbeck and Hendler (2006).

As far as security is concerned, current WBSNs enforce simple protection mechanisms, which only allow their members to label given information as public or private, or to make it available to WBSN members with whom there exists a direct relationship of a given type (friend, colleague, etc.). However, these solutions on one hand may dramatically reduce the possibility of sharing information, which is the basic function of a WBSN, and on the other hand, they do not necessarily grant the required protection to personal information. In fact, giving to WBSN members just the choice of stating whether a given resource is public or private may result in hiding a huge amount of information. Moreover, it may frequently happen that WBSN members make publicly available resources that are accessed by people different from the ones they intended—the most typical case is a student publishing photos or blogs in recreational WBSNs, without considering that they can be accessed by his or her teachers.

Additionally, personal information and relationships among WBSN members must be protected when WBSN data are analyzed by data mining tools, that is, tools capable of analyzing massive datasets of personal information with the purpose of extracting models of social and commercial interest.

SECURITY AND PRIVACY REQUIREMENTS IN SOCIAL NETWORKS

In this section we consider the security and privacy issues related to WBSNs from two different points of view. First, we discuss the privacy-preserving techniques adopted to allow statistical analysis on social network data without compromising WBSN members' privacy, and then we illustrate the current approaches aimed at enforcing privacy protection when performing access control.

Privacy-Preserving Social Network Analysis

Data collected by WBSNs are an important source for social and marketing analysis, which may provide useful information on the evolution of a social community, collaborative problem solving, information distribution, and so on. Additionally, they can also be used to optimize social network services and customize them with respect to users' preferences and interests. However, when analyzing WBSN data for statistical purposes, it is necessary to avoid as much as possible disclosing private information about WBSN members.

So far, this issue has been addressed by anonymizing the network graph according to two main strategies, namely, *node anonymization* and *edge perturbation.* The former strategy aims at hiding members' identities by labeling the corresponding network nodes with random identifiers (naïve anonymization). In case nodes are associated with attributes which can be used to identify the corresponding user, the possibility of using techniques based on k-anonymity (Sweeney, 2002) has been discussed−see, e.g., Zheleva and Getoor (2007). By contrast, edge perturbation performs a set of random edge deletions and insertions, which prevent an attacker from inferring the identity of network nodes based on the existing relationships but, at the same time, preserve the utility of the graph for network analysis.

It has been noticed that the proposed solutions to node anonymization do not grant total privacy protection. In particular, Backstrom, Dwork, and Kleinberg (2007) carried out an extensive analysis of the possible attacks, and argued that the most effective strategies for privacy protection are those based on *interactive* techniques. According to this approach, the anonymized network graph is not disclosed; rather it is analyzed by the social network management system itself upon submission of a query, and then the result is perturbed by adding noise to the real answer.

By contrast, edge perturbation, when combined with node anonymization, grants a greater degree of protection. Examples of how such techniques are applied are provided by Frikken and Golle (2006), Hay, Miklau, Jensen, Weis, and Srivastava (2007), and Zheleva and Getoor (2007). In particular, Hay et al. (2007) report experimental results which show that random edge deletions and insertions grant graph anonymity when the perturbation affects a percentage of graph edges ranging from 5% to 10%. By contrast, a perturbation rate greater than 10% dramatically increases information loss, thus making useless the results obtained by

analyzing the perturbed graph. Although Zheleva and Getoor (2007) do not provide experimental results, they enhance the edge perturbation strategy by considering the different possible methods according to which it can be performed, and by evaluating the obtained perturbed graph with respect to information loss and link re-identification attacks.

Note, however, that graph anonymization is based on the assumption that the only information that can be obtained by an attacker is the one publicly released by the social network service. By contrast, this strategy is useless when applied to social networks, as most WBSNs are, to which any Web user can register, and where each member has a total or partial view of the network graph. In such a case, attackers can infer the network structure and members' identity with more or less accuracy by using techniques like *node bribing*, that is, by obtaining access to the partial view of the WBSN graph of one or more of its members, as illustrated by Korolova, Motwani, Nabar, and Xu (2008). The authors argue that it is possible to reduce the effectiveness of such attacks by limiting the neighborhood visibility of a member (his or her *lookahead* ℓ) to his or her neighbors ($\ell = 0$), and to the neighbors of his or her neighbors ($\ell = 1$). By contrast, in case $\ell > 1$, the possibility of obtaining correct information on the WBSN graph exponentially increases.

In conclusion, available privacy-preserving techniques, both those based on graph anonymization and those limiting WBSN members' lookahead, have the goal of preserving users' privacy when network data are analyzed through data mining tools. An additional issue is to enable a WBSN user to state which information should be public or private, and which members are authorized to access it. In this respect, current WBSNs enforce very naïve default protection mechanisms which cannot be personalized by WBSN members. We elaborate more on this issue in the next section.

Privacy-Aware Access Control

WBSN resources have protection requirements that cannot be enforced by simple mechanisms, as those currently adopted by WBSNs. An access control model for WBSNs should therefore take into account the specific characteristics of the application domain, in order to devise the most suitable access control strategies. In the following, we first discuss the main requirements for an access control mechanism tailored to WBSNs. Then, we survey the solutions proposed so far.

According to the traditional approach, access control requirements are expressed by *authorizations*, which in their basic representation are tuples of the form $\langle s, p, o \rangle$, where s is the subject authorized to access object o under privilege p (Bertino & Sandhu, 2005). However, such an approach is not suitable for dynamic and distributed environments, as WBSNs are, since a member may be required to update the authorizations applying to his or her resources whenever he or she knows new members, or if relationships he or she participates in are revoked. In such a scenario, it is preferable to *intensionally* denote authorized members by specifying the *requirements* they must satisfy to access a given resource. According to this strategy, whenever any modification to the state of the WBSN structure occurs, the set of authorized members will dynamically change, without the need to modify the existing authorizations.

So far, a variety of access control models have been proposed, which denote authorized users in terms of their characteristics, and not only by their identities. The role-based model (Ferraiolo, Kuhn, & Chandramouli, 2003) is the most popular one; others are those based on credentials (e.g., Winslett, Ching, Jones, & Slepchin, 1997; Agarwal, Sprick, & Wortmann, 2004) or certificates (e.g., Thompson et al., 1999; Palomar, Estevez-Tapiador, Hernandez-Castro, & Ribagorda, 2006). An analogous approach can be applied to WBSNs. In fact, WBSN members usually publish resources having in mind a specific audience consisting of, for example, their friends or colleagues. Therefore, in a WBSN context, *relationships* can be used to intensionally denote authorized members.

The enforcement of relationship-based access control requires addressing two main issues. First, it must be possible to verify the authenticity and reliability of information about relationships, in order to avoid security attacks based on forging faked relationships. Second, relationship information may have privacy protection requirements, and thus mechanisms should be enforced to regulate their disclosure.

A further requirement is related to the support of content-based access control (Adam, Atluri, Bertino, & Ferrari, 2002). Actually, the practice of 'tagging' resources is currently diffused among WBSN members, and content analysis is another possible solution to enforce content-based access control. However, since resource rating is performed by each single member and content analysis gives only probabilistic results about the actual content of a resource, strategies should be devised in order to obtain accurate and unambiguous descriptions, usable for access control purposes.

Finally, access permissions should take into account the possible operations to be performed on WBSN resources. Besides the traditional 'read' privilege, in collaborative environments WBSN members may be authorized to modify/delete a resource or add content to it. In such a case, it may be useful to support different types of 'write' privileges, such as 'modify' (authorized members can modify existing content or add new content), 'delete', and 'append' (authorized members can only add content, but not modify existing content). Additionally, when supporting 'write' privileges, it is important that any modification performed on a resource can be associated with the member who performed it. This means that supporting different privilege types requires enforcing accountability in the WBSN framework.

A last issue to be addressed concerns the access control architecture to be adopted. According to the traditional ap-

proach, access control is enforced on the side of the content provider. However, this solution may not be suitable to WBSNs, which may have millions of registered members and, as a consequence, the WBSN management service would be a bottleneck to the whole system.

As far as we are aware, the only two proposals of an access control mechanism based on WBSN relationships are the ones by Carminati, Ferrari, and Perego (2006) and Hart, Johnson, and Stent (2007).

In the proposal by Carminati et al. (2006), access control requirements are expressed by *access conditions,* which denote authorized members not only in terms of relationship types (e.g., friend, colleague), but also with respect to the relationship *depth* and *trust level*. The depth of a relationship corresponds to the distance between two members, considering only the edges labeled with a given relationship type. Thanks to this, it is possible to specify authorizations stating that a given resource can be accessed only by the friends of Alice, or by the friends of Alice's friends. By contrast, the trust level denotes how much confidence a member has on the fact that another given member does not reveal protected information to unauthorized members.

As far as access control enforcement is concerned, Carminati et al. (2006) adopt the rule-based approach proposed by Weitzner, Hendler, Berners-Lee, and Connolly (2006). More precisely, access authorizations are expressed by Horn-like clauses (rules), and it is the requestor who is in charge of demonstrating to the content provider of being authorized to access a given resource, by providing a proof of the corresponding access rules. WBSN resources and the corresponding access rules are managed by the resource owner, whereas relationship certificates are stored in a central directory, stored and managed by the WBSN management system. Whenever an access control request is submitted, the resource owner sends back to the requestor the set of associated access rules. The requestor then contacts the WBSN management system, in order to retrieve the relationship certificates concerning the relationships denoted by the received access rules. Then, he or she computes a proof, if any, demonstrating that he or she satisfies the rules. The resource owner sends the resource to the requestor only in case the provided proof is valid.

Also the access control model proposed by Hart et al. (2007) in their position paper uses existing WBSN relationships to denote authorized members, but only the direct relationships they participate in are considered, and the notion of trust level is not used in access authorizations. In addition, differently from Carminati et al. (2006), resources are not denoted by their identity, but based on their content. Information about resources' content is derived based on users' tags and content analysis techniques. Hart et al. (2007) do not provide any information about access control enforcement.

Both the approaches by Carminati et al. (2006) and Hart et al. (2007) assume that relationships are public. Later, Carminati et al. (2007) have extended their earlier research (Carminati et al., 2006) by proposing a privacy-aware access control mechanism, where the existing relationships are protected by a set of rules, called *distribution rules.* Such rules are used to regulate the distribution of relationship certificates to authorized members. Carminati et al. (2007) also address the issue of protecting relationship information that may be inferred by access rules, when enforcing access control. In fact, if an access rule states that, in order to be able to access a given resource, the requestor must be a friend of Alice, it is possible to infer that Alice participates in at least one relationship of type *friendOf,* otherwise no member will be able to access that resource. In order to deal with this issue, WBSN members are equipped with a set of group keys (Rafaeli & Hutchinson, 2003), called *relationship keys,* used to encrypt access conditions. More precisely, each WBSN member *m* holds a key for each type of relationship he or she participates in. These keys are shared by all the WBSN members in his or her social network group, that is, all the WBSN members connected to *m* by paths labeled with those relationship types. Whenever *m* receives an access request to a resource he or she owns, he or she does not send the corresponding access rules in plaintext. Rather, each access condition in the access rule is encrypted with the corresponding relationship key. For instance, if an access condition puts a constraint on relationships of type *friendOf, m* will encrypt it with the key corresponding to that relationship type. As a consequence, the requestor will be able to read that access condition only when he or she belongs to the same group of type *friendOf m* participates in.

It is important to note that all the approaches we have described so far support 'read' privileges only. Of course, they can be extended with other types of access modes, but enforcing accountability would require a relevant extension to the access control mechanisms described above.

FUTURE TRENDS

WBSN security and privacy is quite a new and challenging research area, and as such, the proposals discussed in this article are just a starting point. It is then difficult, given the state of the art, to provide an exhaustive summary of all the possible future trends and research directions. However, some general considerations can be done on the main open issues with respect to the topics discussed in the previous sections.

First of all, it is clear that privacy-preserving social network analysis and privacy-aware access control address WBSN privacy from two different points of view: the former, from an *external* perspective—that is, the one of an

analyst carrying on social network analysis; the latter, from an *internal* perspective—that is, the point of view of WBSN members themselves. In privacy-preserving data mining, the goal is to provide, on average, an acceptable degree of privacy (e.g., by using anonymization techniques) to all the WBSN members to whom the data refer. By contrast, in privacy-aware access control, each WBSN member can explicitly state his or her privacy and/or access control requirements—for instance, some members may have stricter privacy requirements than others. This means that potential conflicts between social network analysis tools and WBSN privacy requirements may arise. Therefore, in the future it is desirable that these two research directions find some common points, in order to proceed towards the definition of a comprehensive framework, able to address all the privacy and security requirements of WBSNs. It must also be taken into account that social network analysis is carried out based on the assumption that the social network management system is able to release periodically, or upon demand, the network graph (or a perturbed version of it). This implies that the existing relationships must be stored in a central repository, accessible by the social network management system itself. However, this is not always the case. For instance, privacy protection mechanisms enforced in a WBSN might adopt approaches according to which relationship information is stored by WBSN members themselves, to avoid that the social network management system infers private information from the existing relationships. Therefore, privacy-preserving data mining tools must also take into account the different architectures according to which access control is enforced.

As far as privacy-aware access control is concerned, we argued in the previous sections that, when adopting a relationship-based approach to specify access control requirements, it is necessary at the same time that access to relationship information is regulated by proper protection mechanisms. The strategy proposed by Carminati et al. (2007) addresses this issue, but other solutions are also possible. For instance, instead of assuming that relationship information is directly distributed by the WBSN members involved in them, as in Carminati et al. (2007), an alternative is to support negotiations and privacy policies, similar to those provided by P3P (Cranor et al., 2006) and trust negotiation mechanisms. According to this approach, relationship information is held by WBSN members and released upon request after having verified whether the requestor satisfies given privacy protection policies, and/or whether he or she can be considered trustworthy about the use he or she will make of such information and the protection he or she can assure to it.

Content-based access authorizations are one of the other open issues. By using content-based access control, it is possible to simplify the task of policy specification as well as to express access control requirements related to the semantics of the protected objects. However, applying it to distributed environments such as WBSNs, where any member can use any vocabulary and any language (either standard or user defined) for describing resources, might make such strategy ineffective for access control purposes. Using content analysis tools has similar drawbacks, since, independently of the efficiency and effectiveness of the adopted tools, it may happen that a given resource is incorrectly described, thus granting unauthorized access to it or denying access to authorized members. Finally, the trade-off between accuracy and complexity in describing resources must be taken into account. Inaccurate and ambiguous descriptions are useless for access control purposes, but evaluating too complex descriptions may have computational costs that make unfeasible, in practice, the enforcement of content-based authorizations.

We think that a solution to this issue must satisfy two main requirements. First, resource descriptions should be encoded by using standard schemes, and the vocabularies used for describing resources must enforce semantic interoperability. Second, mechanisms should be devised that are able to confirm the actual validity of a description.

As far as the former issue is concerned, a possible solution might be provided by the outcome of the work currently carried on by the W3C working group named, "Protocol for Web Description Resources" (POWDER, 2007), which aims at defining a standard metadata format for describing the content/characteristics of a group of resources. In addition, POWDER aims at granting the accountability of such descriptions, referred to as *description resources* (DRs, for short), thus making any Web user able to verify their trustworthiness. Finally, DRs provide a simple mechanism for enforcing semantic interoperability. In fact, any Web user describing a resource can state that such description, independently of how it is specified, is equivalent to one or more given DRs released by other users.

However, POWDER DRs by themselves do not ensure the trustworthiness of resource descriptions. A possible solution is to use a content analyzer to validate the description provided by a given user. However, the results of a content analyzer are reliable when applied to resources all belonging to a given content domain, which is not the case of WBSNs. An alternative is to use social networking itself in order to validate resource descriptions, by exploiting *collaborative rating*. According to this strategy, WBSN members, on one side, can express their opinions on the trustworthiness of a description, and on the other side, can specify their personal descriptions of the same resource. The result is that, for the same resource, more descriptions are available, whereas a description is associated with ratings stating whether it is trustworthy. Given the huge population of WBSNs, it is possible to collect a data set having a size suitable to perform statistical analysis, which can provide a more accurate measure of how much the claims made by a given

description can be trusted. Such an approach is currently under development in the framework of the QUATRO Plus EU project (*http://www.quatro-project.org*).

Support for different types of access privileges is another of the issues not addressed by Carminati et al. (2006, 2007) and Hart et al. (2007). As we mentioned, a key issue is the support for accountability, in order to be able to identify who performed which access operation on which resource. This is extremely important for 'write' operations, especially in collaborative environments where the members of the working group should be able to identify, for instance, who inserted/modified/deleted given portions of a shared document. Finally, it is worth noting that future WBSNs may rely on architectures different from the current one, where the WBSN management service is in charge of running almost all the supported services. In fact, from the privacy protection and access control approaches proposed by Carminati et al. (2006, 2007), it comes out that a decentralized architecture grants a more accurate protection to WBSN data. In such a scenario, WBSN members themselves store and manage their personal data, relationships, and resources, and are in charge of carrying on most of the tasks concerning relationship establishment/revocation and the enforcement of privacy and access control policies. By contrast, the WBSN management system provides just basic services, such as user registration, and may be used as a common space from which it is possible to access all the information WBSN members wish to share publicly. Such decentralized architectures pose challenging research issues with respect to security and privacy protection as well as efficiency.

CONCLUSION

With the increasing diffusion and usage of online social networks, protecting personal data and resources of their members is becoming a fundamental issue. Contributions to this research area are currently very limited, and can be grouped into two main classes: on one side, anonymization techniques able to protect the privacy of social network members when performing social network statistical analysis, and on the other side, privacy-aware access control mechanisms, making social network members able to regulate access to their data, relationships, and resources by, at the same time, protecting the privacy of their relationships. The proposed solutions are far from addressing all the privacy and security requirements of social networks, and not all the potential approaches have been investigated. Although it is difficult to predict with enough precision the possible evolution of this new research area, it is very likely that the enforcement of security and privacy mechanisms for social networks, more sophisticated than the ones currently available, may have two main relevant results. First, it might lead to the development of new security paradigms able to address the distributed nature of social networks. Moreover, it might determine a dramatic modification of current online social networks into a decentralized architecture, where the management of social network information, and of the social network itself, will be carried out collectively by its members inside a collaborative framework.

KEY TERMS

Edge Perturbation: Graph anonymization technique aimed at hiding the actual social network relationships by performing a set of random edge deletions/insertions in the network graph.

Graph Anonymization: Technique aimed at hiding private information about social network members when performing social network analysis. Node anonymization and edge perturbation are the two main graph anonymization techniques currently used.

Node Anonymization: Graph anonymization technique aimed at hiding social network members' identities by labeling the corresponding nodes with random identifiers (naïve anonymization), or, in case nodes are associated with attributes which can be used to identify the corresponding user, by using techniques based on k-anonymity (Sweeney, 2002).

Privacy-Aware Access Control: In the context of social networks, denotes an access control paradigm where access control requirements of social network members are enforced without disclosing private information about the relationships they participate in.

Relationship Trust Level: In a social network, denotes the value associated with a trust relationship, providing a measure of how much a given member considers another member trustworthy. Depending on the purpose for which it is used, this notion may have different meanings. For instance, in a collaborative rating environment, it denotes how much a given member trusts the opinions of another member with respect to a specific topic (*topical trust*) or in general (*absolute trust*) (Golbeck & Hendler, 2006). By contrast, in an access control context, it has some similarities to the notion of *security level* used in mandatory access control models (Carminati et al., 2006, 2007).

Relationship-Based Access Control: An access control paradigm specifically tailored to social networks, according to which social network members authorized to access a given resource are denoted in terms of the relationships they must participate in to get the access.

Social Network: A *small-world network* (Watts, 2003) consisting of a set of individuals (persons, groups, organization) connected by personal, work, or trust relationships. Usually modeled as a graph, where nodes correspond to social network members, whereas edges denote the relationships existing between them.

Social Network Analysis: A discipline aimed at collecting statistical data from the analysis of social network topology (Wasserman & Faust, 1994; Freeman, 2004).

Social Network Relationship: A relationship concerning two members of a social network. In WBSNs, besides personal/work relationships (e.g., friend/colleague), also trust relationships may be supported which denote how much a one member trusts another. In the graph representation of a social network, relationships are usually denoted by edges, labeled with a relationship type and/or a relationship trust level.

Web-Based Social Network: A Web-based system that allows its registered members to establish relationships with other members and to share different types of information (e.g., personal data, contacts, multimedia resources). A precise, but not normative definition of Web-based social network has been provided by Golbeck (2005).

Security and Reliability of RFID Technology in Supply Chain Management

Vladimír Modrák

Peter Knuth
Technical University of Košice, Slovakia

INTRODUCTION

RFID (radio frequency identification) technology can be expressed in the most universal manner as wireless identification technology, which does not need the line-of-sight to be read or written. It offers enhancement of identification technologies like barcode technology. Optical barcode technology was developed in 1948 by Silver and Woodland at Drexel Institute of Technology and first commercially used in 1966 (Adams, 2002). Barcode technology stores data in the widths and spacings of printed parallel lines, or in patterns of dots, concentric circles, and hidden within images. The most extended is UPC code which was invented in 1973 and since then became everyday part of our life. Other commonly used types of barcodes are Code 128, Code 93 (Groover, 1980) and DataMatrix 2D barcode. At this time, mostly the barcodes are keeping inventory and shipments moving. RFID and barcode technology complement each other because both of them are beneficial in different situations and can be used together in many applications.

RFID technology has several advantages for managing and collecting object's data or tracking it as it moves through the supply chain (SC). Two of them are related to the increased abilities of security and reliability of the identification systems. These two properties of identification technologies are equally important for their use in supply chain management (SCM).

The purpose of this chapter is to highlight selected areas of this technology that may be critical specific aspects of further RFID development and applications. We have also discussed about differences between RFID and barcode technologies especially in terms of their use in SCM and concluded this article with expectations of further development of this still progressive technology.

BACKGROUND

Security and reliability issues have their roots in history of RFID technology (RFID Journal, 2005). Principles of RFID technology are based on the fundamentals of electromagnetic energy, radio broadcast technology and radar technology. The first active identification friend or foe (IFF) system was developed by the British during World War II. It was radio frequency identification technology for identification of friendly aircrafts. Each plane was equipped with a transmitter, which began to broadcast signal back after receiving signals from radar stations on the ground (Landt, 2001). System was very simple and was not very secure. This is the point where not only reliability, but also security becomes significant issue. The reasons why security and reliability of RFID technology became important are at most actual and are implicitly involved in numerous polemics about security and reliability of RFID technology (Karygiannis, Eydt, Barber, et al., 2007; Rieback, Crispo, & Tannenbaum, 2006a; Thorton et al., 2006; Wyld, 2005; Rieback, Crispo, Tanenbaum, 2006b; Macaulay, Abeysinghe, 2004; Bono, 2005). Explicitly we can see the reasons in existing precedence about potential serious impacts that are mentioned later in this chapter. Another important milestone can be considered the patent on RFID that was granted to Mario Cardullo in 1973. In the same year Charles Walton invented access control system based on RFID (Rieback et al., 2006a). The first widespread RFID tag was 1-bit tag (the bit is either on or off) as a part of electronic article surveillance (EAS). EAS could only detect the presence or absence of the tag. In other words if someone does not pay, the tag remains on and the readers at the door detects the tag and the alarm sounds to alert un authorized removal. The U.S. government was also supporting research and development of RFID systems. Los Alamos National Laboratory in New Mexico soon became a leading center for R&D of this technology (Shepard, 2005). This laboratory developed automated toll payment systems and passive RFID tag to track cows. Both are still used all around the world. Further development lead to use higher frequencies

that allowed greater and faster data transfer rates. In 1999 Uniform Code Councile, EAN International, Procter and Gamble, and Gillette founded an Auto-ID Center project at Massachusetts Institute of Technology for development of RFID standards. The main result of this project was electronic product code (EPC). Other results are air interface protocols (Class 1 and Class 0) and network architecture scheme, which links objects to the Internet through the tag. After that Uniform Code Council and EAN International created joint venture EPCglobal Inc. to commercialize EPC technology due to high importance of EPC technology, since it could dramatically improve efficiencies within supply chain. Previous research responsibilities of Auto-ID center were delegate to EPC global. Recently, more attention is given to security of RFID technology. To corroborate it by facts the following events can be mentioned. In January, 2005, students at Johns Hopkins University broke encryption of SpeedPass electronic payment and RFID point of sale (POS) system. In February, 2006, Adi Shamir reported that he could monitor power levels in an RFID tag which can be used to compromise the secure hashing algorithm 1 (SHA-1) used in some RFID tags (Thorton et al., 2006). However, it is not the reason for a resignation, as a level of risks depends in generally, but also in the specific area, on preventive actions. The example supporting this statement offers the situation in privacy protection. In contrast to barcode technology, RFID technology has greater implications on individuals' privacy, because RFID tags used in personal identification cards can be read from an abundant distance without that person's knowledge or consent. This led to creation of groups like FoeBud or CASPIAN that are against this technology, because they fear, that they could be tracked by tags. In the meantime, blockers for passport RFID tags in a form of passport jackets containing physical barrier and other countermeasures as unique identifier numbers, encryption, and mutual authentification were developed to ensure greater security. On the other hand, the more sophisticated protections bring more opportunities for potential failures.

COMPARISON OF SECURITY AND RELIABILITY BETWEEN THE RFID AND BARCODE TECHNOLOGY

The main difference between barcode technology and RFID technology is that barcode technology is optical technology and RFID technology is radio technology. All other advantages, disadvantages and differences result from this fact. In the supply chain, the biggest advantage that RFID has over barcode is the ability to automatically read large groups of tags eliminating the labor needed to manually scan the large volumes involved in the supply chain. Improving visibility in the supply chain systems gives "management programs better visibility into the supply chain, which enables identification of bottlenecks, targeted recalls, and new forms of market research" (Karygiannis et al., 2007). "Both active and passive RFID tags have significant potential to provide low-cost, short-range, identification for many consumer goods and can help to identify objects" (Finkenzeller, 2003). Potential benefits of RFID implementation in the supply chain management are counterfeit and fraud reduction, improved efficiency, labor cost reduction, stock shrinkage reduction, stocking management improvements and return goods facilitation (improved customer satisfaction). RFID technology can be used in several levels in supply chain management (see Table 1).

When talking about reliability of automatic identification technology, an attention might be focused on the ability of readers to identify codes from tags at the first time. The potential interferences of barcodes make optical barriers such as objects placed between barcode and reader or dirt. Also, they are unreadable under extreme atmospheric conditions such as steam or when vertical damage occurs. Barcode readers are sensitive to dirt, dust, or other foreign object obstructing the lens. But 2D barcodes can be read even if part of the tag is destroyed. Passive RFID tags can interference with environments or fields and various materials such as liquids and metals that affect transmission of radio frequency. Active tags are less susceptible to interference. Despite this, they can be read under extremer weather conditions than barcodes. It is not clear whether tags, that could not be read, can be entered manually as barcodes. Reliability seems to be solved these days by knowing RFID physics (Schlosser, 2004). But there is no universal solution for implementation of RFID at all. It is always necessary to fit RFID system to meet company needs (if company really needs RFID) as far as 100 percent reliability. And because there are numerous types of RFID tags the selection of proper RFID tag system is essential. It is better to start with smaller project and obviously in detail defined problem rather than to fail (Sweeney, 2005).

Security of RFID technology in supply chain management can be seen from many aspects: health (radiation of devices), personnel or vehicle access control and tracking, inventory location, privacy issues, third-person attacks, software and hardware protection, encryption and tracking origin of goods

Table 1. Levels of RFID in supply chain application (Source: D'Hont, 2003, p. 13)

Level	Use	Application
Item	Consumer units	Products and individual items
Case or Carton	Traded units	Boxes (packaging) product carriers
Pallet	Distribution units	Pallets / Trucks

Table 2. RFID applications (Source: Wyld, 2005, p. 13)

Traditional RFID Applications						
Security/access control	Electronic article surveillance	Asset/fleet management	Mass transit	Library access	Toll collection	Animal identification
Emerging RFID Applications						
Warehouse management	Supply chain management	Reverse logistics	Shipment tracking	Asset tracking	Retail management	Document tracking	Anti-counterfeit
Advance access control	Mass transit —monthly and single trip	Airline baggage handling	Aircraft parts and tools	Healthcare applications	Regulatory compliance	Payments	

(very important for food safety). Data security of RFID technology depends on the class and generation of RFID tag. From the health aspect, there are no concerns about the risks. One can never be sure, but this is scientifically proved. For example frequencies 13.56 MHz, 915 MHz and 2.45 GHz have been used for many years without any known problems if levels are below 1 watt or 4 watt at frequency 13.56 MHz (Wyld, 2005).

The biggest security risks are related with privacy concerns, with ability of RFID system to identify, track and monitor each good uniquely and link it with the owner. It is possible to automatically track individuals or even to be a victim of robber just because you are carrying expensive product and the theft have read the tag of that product. U.S. based group CASPIAN worries about people-tracking with the help of tagged goods after they leave the store.

RFID security threads can be classified as sniffing, tracking, spoofing, denial of service or relay attacks. In the field of cryptography new low-power algorithms like stream ciphers (Finkenzeller, 2003), block ciphers (Feldhofer, Dominikus, & Wolkerstorfer, 2004), lightweight protocols for authentication (Vajda & Buttyán, 2003) and public key cryptographic primitives have been created. Other techniques like trusted RFID readers or access control mechanism that are located either on a tag like hash locks (Weis, Sarma, Rivest, & Engels, 2004) pseudonyms (Juels, 2004) or off the tag can prevent unauthorized threats and attacks too. Off the tag RFID access control mechanisms are RFID Guardian (Rieback, Gaydadjiev, Crispo, et al., 2006), RFID Enhancer Proxy (Juels, Syverson, & Bailey, 2005), The Blocker Tag (Juels, Rivest, & Szydlo, 2003) and FoeBud Data Privatizer. The easiest way still remains deactivating RFID tag permanently through "frying," "clipping"(Karjoth & Moskowitz, 2005) or "killing," or temporarily using sleep/wake modes (Spiekerman & Berthold, 2004) or Faraday cage.

FUTURE TRENDS

It is expected that modern technologies like proxies and firewalls will be adopted through central monitoring and managing of the communication environment. Also, development of privacy enhancing technologies is very important for future RFID implementation and acceptance of public. For example in the future mobile RFID technology will allow consumers to scan particular tag attached to an item using mobile phone and then connect to the manufacturer's EPCIS (electronic product code information service) accessing application in order to verify if product is genuine or fake (Konidala & Kim, 2006). RFID can also be used to trace the location of soldiers in a battle or to sense certain parameters as glucose level when implanted in human body. RFID tags with identification information implanted under the skin can soon replace credit cards and enable non-contact reading of bank account. The European Union is thinking to implement RFID tags in the Euro currency.

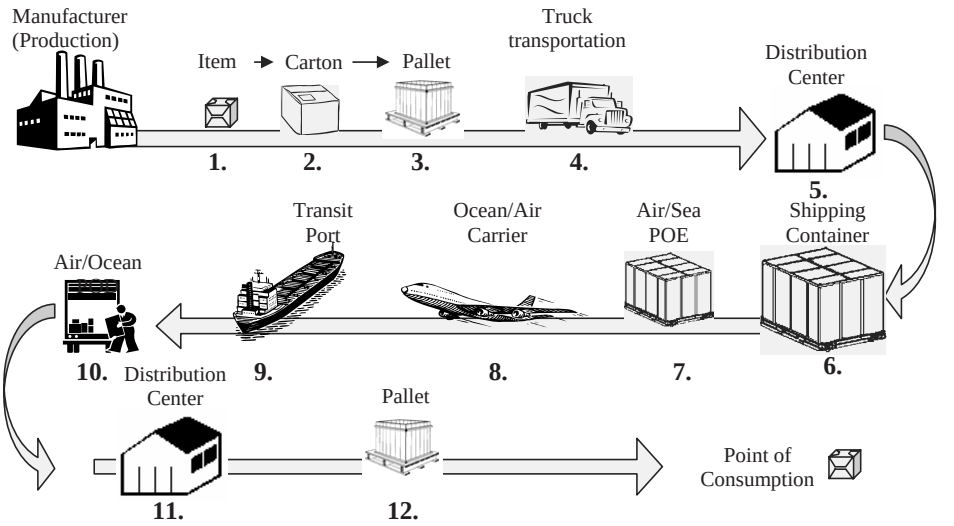
The RFID technology is here for a very long time, but with new research and inventions are coming into existence also new ideas and fields of use (see Table 2).

Likely we can expect that the barcode will be considerably replaced by the RFID. Due to unpredictable changes in corporate environment, the horizon of the milestone is question of the guesswork. In opposite case of predictable corporate environment, the business would not be so complicated, complex and fascinating.

As reliable indicator of the future trends advanced ideas and solutions that present challenge for new development programmes of companies can be considered. An example of such advanced idea is the supply chain model based only on the RFID technology connected to a global positioning system depicted on Figure 1.

Because entire supply chains present multimodal transport systems, number of transloadings in the whole supply chain is much greater than in unimodal transport. Then, the RFID plays important role in entire SC by eliminating human

Figure 1. Future supply chain model (Adopted from Wagner, 2006)



1.	*Passive tag labeling*	7.	*Tag reads at the gate; manifest for shipment*
2.	*Passive tag labeling*	8.	*Carrier track ship/airplane, provides visibility*

6.	*Active tag with manifest data labeling*	12.	*Breaking pallets into individual items*

labor, which is needed when using barcodes. Furthermore, RFID systems reduce operator costs during discharge and multiply accelerates acquisition of item data into information system.

CONCLUSION

Questions about reliability and security issues of RFID technology are very important not only for the future development of RFID technology, but for all of us. It is obvious that RFID technology is not taken just with a great interest, but it is also facing rejection and concerns. Despite this, development of this technology will continue with the aim to reveal all potentials of RFID and not only in supply chain management. Over the next few years, it is theorized that decreasing price of tags, return on investment and better knowledge of this technology will allow wider spread of RFID technology in other business and civic areas.

KEY TERMS

Automatic identification (auto-ID): A broad term encompassing technologies used to help machines identify objects. A host of technologies fall under the automatic identification umbrella, including barcodes, biometrics, smart cards, voice recognition and RFID.

EAS (electronic article surveillance): Loss-prevention technology using passive RFID surveillance. This surveillance uses simple electronic tags that can be turned on or off. When an item is purchased at a store or checked out

EPC (electronic product code): A unique number, stored in the chip on an RFID tag, that identifies an item in the supply chain allowing for tracking of that item (EPC number). Also it is a protocol for data communication and data storage (EPC protocol).

Interrogation Zone: The area where RFID tag can be powered up and read, often between an array of antennas.

Middleware: Software for processing the streams of tag or sensor data from one or more readers and filters, aggregate and counts tag data. This process reduces amount of data before sending them to enterprise application.

Reader (also called an interrogator): A device that communicates with RFID tags. The reader has one or more antennas, which emit radio waves and receive signals back from the tag. Readers may have a digital display to relay information to the operator and may transmit data on to an organization's computer network infrastructure. Readers can be either fixed or portable, and today they are beginning to be integrated into other electronic devices, such as PDA (personal digital assistant) and cell phones, and even into objects such as pens.

Transponder: It receives and transmits radio signals at a prescribed frequency range. After receiving the signal a transponder will at the same time broadcast the signal at a different frequency.

UPC (universal product code): The barcode standard used in North America and administered by the Uniform Code Council (UCC).

INTRODUCTION

E-commerce permits a dematerialized financial transaction between a customer and a merchant (Schafer, Konstan, & Riedl, 2001). It uses a complex architecture involving many aspects in computer science (security, database management) and in electronics (smartcards, tokens) (Tang, Waichee, & Veijalai, 2004). E-commerce is in a constant growth (Herrmann & Herrmann, 2004). To be used by the majority of individuals, electronic transactions must be secured to increase the confidence in the e-commerce. Security is necessary in commercial relationships for many reasons. First, the customer must be sure that the goods he/she is buying will be the expected ones, and will be well delivered at his/her address. Second, the merchant must be sure to be paid. If the customer uses banknotes or electronic payment, two or more partners are involved in that transaction: the customer's bank and the merchant's one. The two banks must be sure of the customer's identity and of the merchant's one in order to avoid banking frauds.

In the transaction process, many security systems are used to ensure the confidentiality, authentication, and integrity of exchanges. The security is guaranteed by using specific procedures and hardware. The objective of this chapter is to present how the classical security concepts are applied for an electronic payment and especially to limit the fraud.

The background section first gives a general idea of the problem generated by the electronic commerce. Second, we present briefly the public key infrastructure approach that is generally used for authentication within this context. The main thrust introduces two protocols that have been developed: SSL (secure sockets layer) and TLS (transport layer security), to create a secure channel where all transactions are encrypted by using specific architectures and algorithms. For the payment part of the transaction process, banks have been considered that SSL and TLS are not sufficiently secure. The main reason is that the cardholder is not authenticated by the issuer bank and the responsibility stays on the merchant side. Banks have so tried to implement different architectures to meet these requirements. These different methods, use of token with SET (secure electronic transaction) or a smartcard such as C-SET developed in the last fifteen years, began to converge to the 3D-secure (three domains security) protocol. These methods to secure the distant payment was adopted together by the card scheme Visa© and MasterCard©. The last, but not the least problem, concerns the distant authentication of the client by its bank, which is described in the future trends.

BACKGROUND

We first make a brief description of the e-commerce issues.

E-Commerce Description

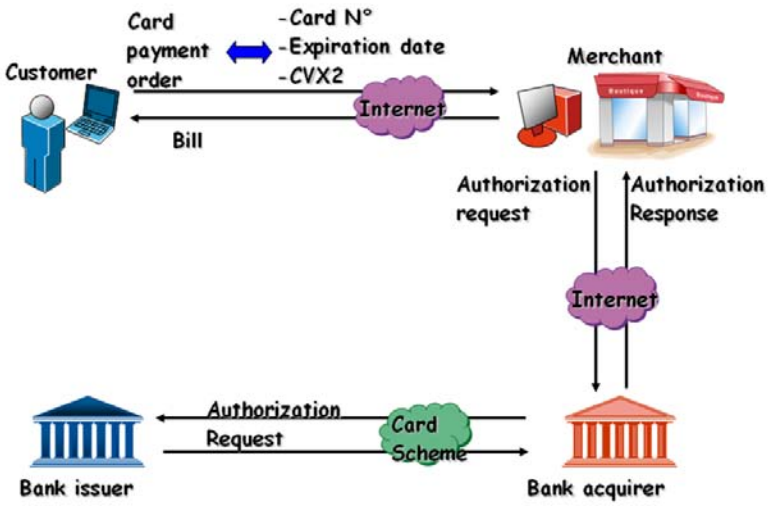
In order to better understand how the e-commerce works, Figure 1 shows the different partners and the different exchanges between them. A financial transaction between a customer and a merchant is, in fact, a transaction between the issuer and the acquirer banks. The payment is achieved through many authorization requests (customer authentication, bank transfer authorization) involving many security and cryptographic concepts.

In order to help the e-commerce development, some good practices are necessary to be applied:

- *The risk control*. The risk is partly taken by:
  - The merchant to not finally be paid;
  - The consumer to not receive the goods or the services;
  - The consumer bank in case of a systemic attack.

This risk, assumed by these different partners, must be as low as possible. The risk is as much loss of confidence in the system, as waste of money.

Figure 1. The different partners and flux in e-commerce payment



- *The facility of use for the consumer.* The reference model is the face-to-face commerce, and an ideal solution for the e-commerce must not create more constraints;
- *The use of international standards*. In one hand, Internet protocol is the base for e-commerce and in the other hand, the banking payment systems with chip or/and stripe cards, should also be used for e-payments;
- *The deployment of the different measures with a communication between banks and merchants.* The constraints and the added value must be studied with a great attention. If one of the four partners of the transaction (the customer and his/her bank and the merchant and his/her bank) is not interested in one architecture implementation, the system will have much more difficulties to be developed.

As conclusion, it is necessary to:

- Well balance the responsibilities between the four partners;
- Adapt the security level to the risk level;
- Integrate the legal constraints.

The Security Problematic

Additionally, in order to help the electronic commerce development, banks have to implement different solutions (Furnell & Karweni, 2000):

- *Visual cryptogram:* To improve the identification process, the EMV (Eurocard MasterCard Visa) cards include, on the back, a three figure code called CVX2, that the consumer must give to complete a payment transaction;
- *Authorization:* More than 7% of authorizations come from the e-commerce, and that part increases every year;
- *Individual supervision of frauds*: Coming from consumers or merchants;
- *PKI (public key infrastructure) for data protection*: To create the better possible protection for the different exchanges between all the transaction partners;
- *Authentication services*: To avoid the risk at the consumer level (CAP (chip authentication program ©MasterCard), SET, 3D-secure).

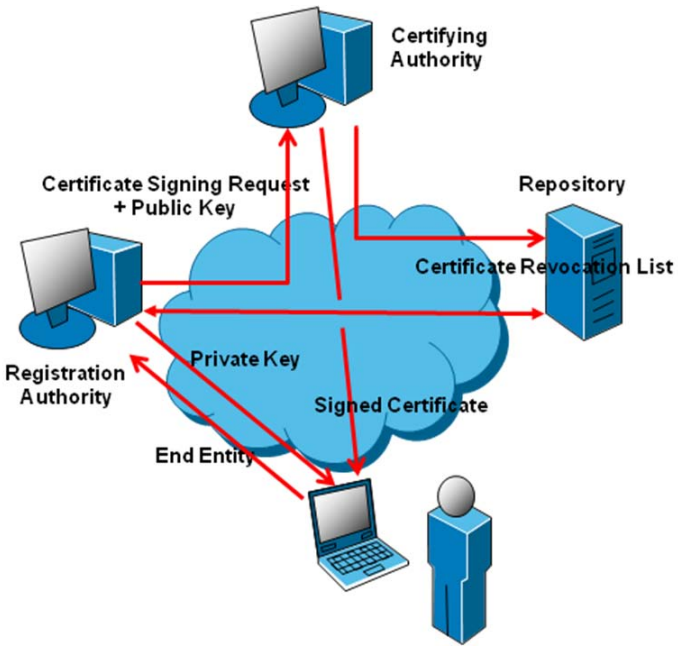
The Public Key Infrastructure

A public key infrastructure (PKI) includes a set of physical components (computers, cryptographic algorithms and equipments, smartcards), human procedures (verifications, validations), and software (systems and applications) to manage the life cycle of electronic keys or certificate. A certificate can be considered as proof of the existing relation between the identity of a customer or merchant and a public key. The major element is the certifying authority (CA) that signs the certificate, the registration authority (RA) that creates the pairs of keys, and the repository that stores the certificates.

Figure 2 shows the different transactions in a PKI infrastructure (Chanson & Cheung, 2002). There exist many certifying authorities (EuroPKI, E-certify Corporation, ID.Safe, Identrus, E-Commerce PKI CA, SwisSsign…).

A public key infrastructure delivers a set of services for its users (Critchlow & Zhang, 2004). The main services are:

Figure 2. The different parts of the PKI



- Users recording (or computers);
- Users identification and authentication;
- Pairs of keys generation (an encrypted message with a public key can be decrypted only with the corresponding private key);
- Public key certification;
- Certificate management (generation, renewal, revocation, publication, storage).

A PKI generates electronic certificates used for cryptographic operations, such as encryption and electronic signatures that offer some security guaranties for e-transactions such as:

- Confidentiality: Only the legitimate addressee of a message can read this message;
- Authentication: When a message is sent, the sender identity is perfectly known;
- Integrity: It is possible to know if a message has been deteriorated or falsified;
- Nonrepudiation: The message sender cannot deny he/she sent it.

MAIN TRUST

We focus in this part on existing solutions to secure e-payment.

SSL and TLS

The SSL security transaction process in HTTPS (hyper text transfer protocol secured) communication is detailed in Figure 3 (Guitart, Carrera, Beltran, Torres, & Ayguade, 2007; Nabi, 2005).

The pair of keys (public and private) has been received from one of the PKI registration authority. The security process continues by using the secret key AB (see Figure 4) all along the transaction. When the customer is ready to pay, he/she clicks on the corresponding option and one form asks him/her to give his/her card number, the expiration date, and the CVX2 writes on the back of the card. The merchant sends an authorization request to his/her bank and waits for an authorization response to conclude the transaction.

The SSL is limited for a payment use:

- Vulnerability to attack when keys less than 128 bits are used;
- The customer identification is not always done;
- SSL is not well protected in case of man in the middle attack. The attacker is able to receive the totality of presumably protected flow.

Very similar to the protocol SSL version 2, the TLS (transport layer security) protocol is promoted by Microsoft on its Windows browsers for the HTTPS communication. Only few differences can be pointed (Kwon, Cho, & Chae, 2001):

Figure 3. Security process. A= merchant site, B= customer PC

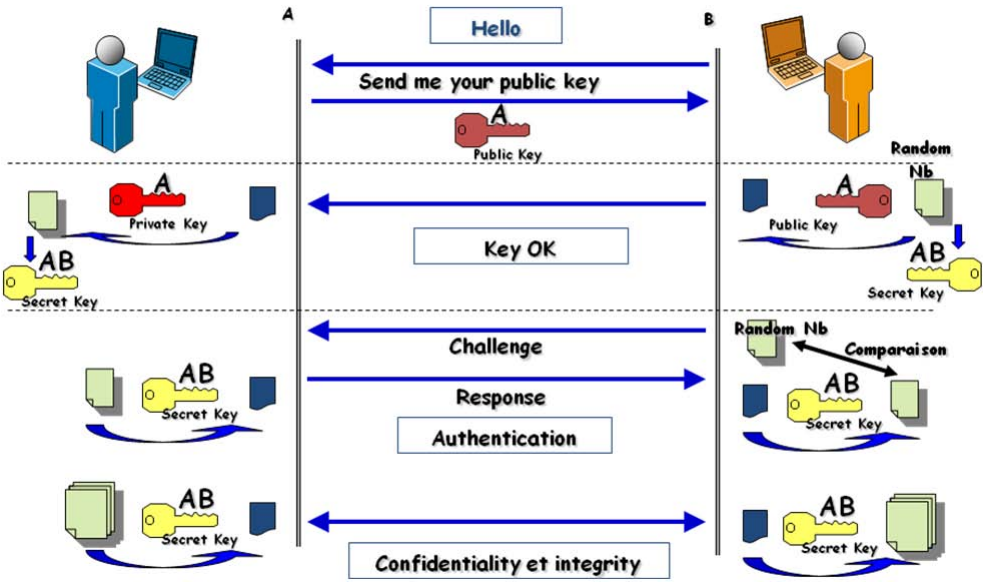


Figure 4. The different flux in SSL payment

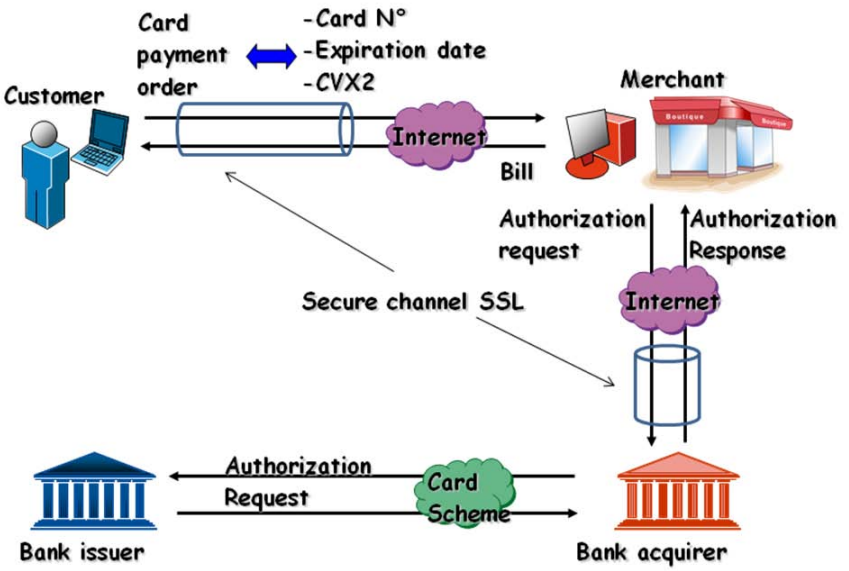

- Encryption with the AES (advanced encryption standard) algorithm (256 bits key) instead of the DES (data encryption system) algorithm;
- More rigorous in the certificates use and less vulnerable to the man in the middle attack.

Trusted Partner and Electronic Purse

To protect the customer during the transaction, another solution is possible: use of a trusted partner that stores your banking information, debit your account, and pays for you without giving any information about your smartcard or your account to the merchant (Hawk, 2004). There are many methods, like Digicash or PayPal, that provide a digital cash implementation (see Figure 5). However, the limits of that type of payment are very quickly reached: You must be registered to the right trusted partner accepted by the merchant or having several trusted partners to pay freely on the Web.

The electronic purse is a similar solution:

Figure 5. The different flux in PayPal payment

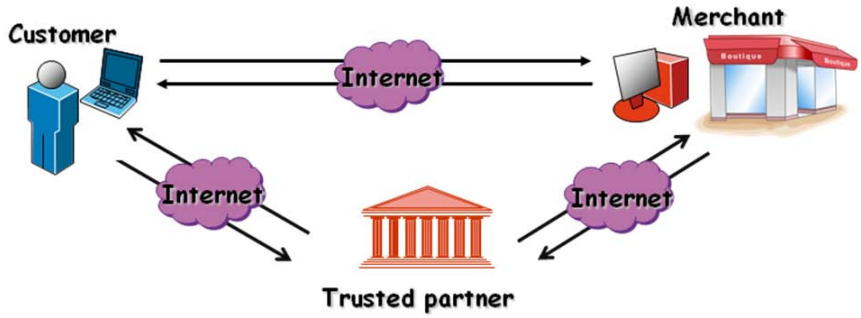

Figure 6. The different flux in SET payment

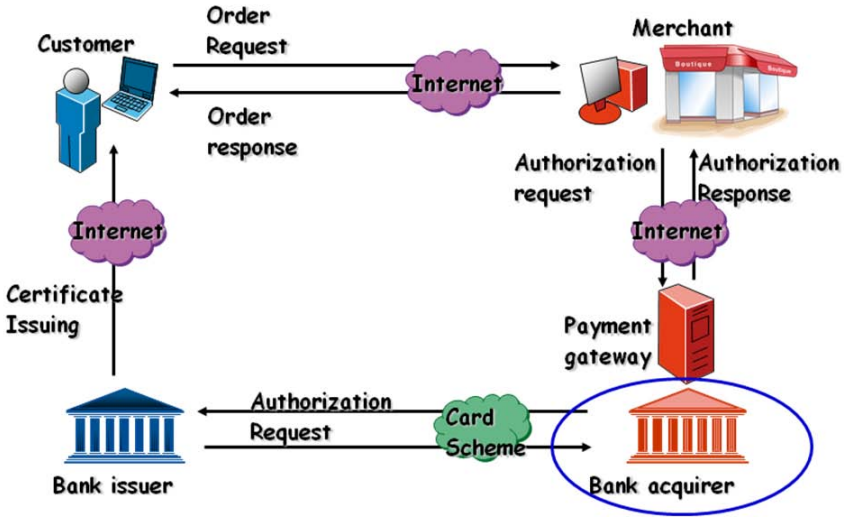


- It is a preloaded account evaluated in monetary units stored in the system of cashing of a nonbanking operator;
- The access to this electronic purse is done using software installed on the customer's PC to pay online.

SET

To limit the risk that the customer can repudiate his/her payment transaction, a set of companies (Visa, MasterCard, GTE, IBM, Microsoft, Netscape, SAIC, Terisa system, Verisign) have developed, in the eighties, one solution called SET (secure electronic transaction). The customer's bank sends him/her a certificate issued from one CA of a PKI that is stored on his/her computer. When he/she wants to make a payment on the Web, the customer must sign with the PKI keys as shown in Figure 6 (Rennhard, Rafaeli, Mathy, Plattner, & Hutchison, 2004).

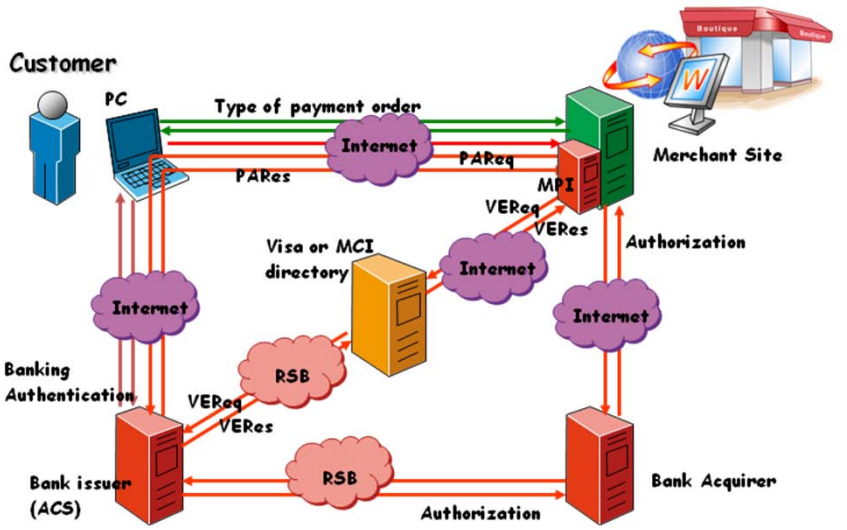
SET has not been deployed so much, but was at the origin of C-SET then to 3D secure (Visa) and SPA UCAF (MasterCard), and finally, to the 3D Secure generalization (Brlek, Hamadou, & Mullins, 2006). The idea developed by C-SET was to use banking smartcards and their certificates, through small card readers connected to the customer's computer, to secure the payment transactions. The price of that card reader working as a POS (point of sale) was a limit to the deployment of that solution.

3D-Secure

The current solution to solve the problem of electronic payments is 3D secure (3D–Secure Functional Specification, 2001), developed by VISA and used by MASTERCARD, which has gave up from SPA UCAF.

3D Secure is not only an authentication method; it is a payment architecture on Internet, launched by Visa in 2001. The commercial trademarks are « Secure Code » for MasterCard and « Verified by Visa » for Visa. The term 3D is the contraction of "Three Domains":

Figure 7. The different communications in 3D-secure payment



- Acquiring domain (bank acquirer and merchant);
- Issuer domain including the customer authentication;
- Interbank field, which makes it possible the two other fields to communicate on Internet.

3D Secure describes the different processing between the three domains to carry out a payment by bank smartcards and distributes the responsibilities in a balanced way between these domains:

- The customer's bank authenticates its client;
- The merchant's bank authenticates its merchant;
- The interbank domain makes it possible the merchant to start the customer's authentication using services of directories (MasterCard or Visa).

In the 3D-Secure authentication diagram, the first stage is the recording of the cardholder by his/her bank. Figure 7 presents the different communications for a transaction in the 3D-secure architecture. The recording procedure contains a series of questions, after which, the cardholder chooses a password, for example, that will ensure his/her authentication by its bank for each transaction.

In 3D-secure, the security of transactions lay on the banks and not on the merchant. The merchant benefits from the same level of payment guaranty as in the face-to-face trade in card payment. More than that, there is a responsibility transfer from the customer towards the issuer (or "Liability Shift"). During the payment phase, the bank issuer becomes responsible for the authentication of its cardholder as a preliminary step in the authorization request.

However, the programs "Secure Codes" and "Verified by Visa" leave the bank issuer free to choose the authentication method of their cardholder. Those complex exchanges are transparent for the merchant and the customer, and secure, very well, the e-commerce. The last problem is the customer authentication by his/her bank issuer. This will concern the future trends described in the next section of this chapter.

FUTURE TRENDS

We present, in this part, several issues concerning the perspectives of security in e-commerce.

Authentication

In fact, with 3D-secure, the authentication problem from the customer/merchant domain is replaced by the customer/issuing bank domain. The problem seems easier to solve because there is a constant relationship between the cardholder and his/her bank (Torres, Izquierdo, Ribagorda1, & Alcaide, 2005). Many solutions have been proposed to meet this need for safety, some based on biometrics (Jain & Pankanti, 2006), others on the use of the couple reader-smartcard, allowing a dynamic authentication of the cyber-consumer.

Whatever the chosen solution, the cost of the system of security is a key element, at the same time for the bank and the customer. For the bank, they are, concretely, the

technical and organizational costs of integration, deployment, management, and maintenance. On his/her side, the customer is interested by a simple tool of use at a moderate cost. It must represent a compromise between the security constraints and a convivial use of the tool of security of the bank-customer exchanges. Actually, bank payment chains use, mainly, two types of proof together to create a strong authentication:

- A smartcard to identify the cardholder and so, to authenticate the smartcard with the use of cryptographic keys and certificates ;
- A password to authenticate the cardholder.

The MasterCard initiative CAP integrates this type of strong authentication. We present, in the next two sections, two possible solutions that are explored in research works within this context.

Sopas Project

Connecting a simple terminal to the computer is realized in a project called SOPAS, in which we are involved. This project consists in developing a card reader with just a keyboard with 12 keys and a screen with two lines of 10 characters. The card reader is connected to the cardholder's computer by the USB port. A set of development software is installed on the computer. When the smartcard is introduced in the card reader, the screen indicates to type a PIN code. Then, the smartcard generates a token sent to the ACS, as shown in Figure 8.

To create a reader as simple as possible, it is necessary to use the new ISO 7816 specifications for cards that have an I^2C bus and a USB bus at one's disposal. All the certificates are calculated by the smartcard. The different protocols are indicated in Figure 9.

Dynamic Tokens

Another solution consists in using a smartcard reader unconnected, which generates a dynamic token that the customer has to enter on the computer keyboard. It is enough for the smartcard holder to insert its card, which can be a debit/credit card, in a pocket EMV reader in conformity with the CAP standards, such as ActivReader Solo (TM) of ActivCard, and to compose its code PIN there.

A dynamic onetime-password is generated with the card and can be used to check or sign a transaction. This password or signature is then subjected to the bank, through its Web site (or by telephone where it is confirmed by an operator),

Figure 8. Sopas secured solution for authentication

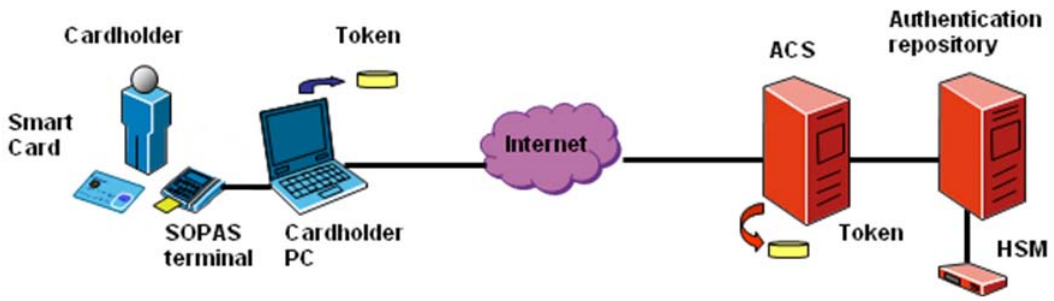


Figure 9. Protocols in SOPAS solution

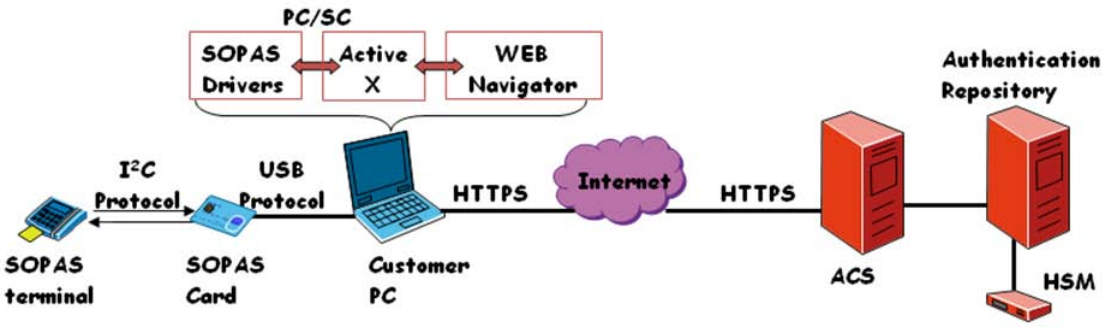

for authentication, with an aim of checking the identity of the cardholder and the specific parameters of the transaction.

CONCLUSION

There are, currently, a great increase of the use of payment in e-commerce because many of their needs tend to be satisfied. Under no one circumstance, is it possible to create an absolute secured system, but new developments seem to be strong enough to protect, correctly, the e-commerce. The 3D-secure solution is now well implemented and will become a leader in the next few years for three main reasons:

- It is a method recommended by the card scheme Visa and MasterCard;
- There is a responsibility transfer from the customer towards the issuer ("Liability Shift");
- Banks are free to choose the authentication method, which is the visible part of the iceberg that is seen by the client of the bank, and can allow the banks to create a differentiation from their concurrent.

The authentication part is in progress (Walton, 2005), but there is, today, no one solution that can be considered as an emerging leader. The new authentication methods will be developed with three main principles: the solution must be secure, cheap, and easy to manipulate by a user. Today, many solutions are very secure but expensive, certain are complex for the cardholder, and certain are not secure enough. Many research and development laboratories are working today on that problem, and we can expect some good solutions in the near future.

KEY TERMS

CA: The certifying authority (CA) signs the certificates.

CAP: Chip authentication program (©MasterCard), CAP provides one line chip-based cardholder authentication within the SecureCode™ (3D-secure) program.

EMV: Eurocard, MasterCard and Visa specifications define the electronic payment transaction and its security.

PKI: Public-key infrastructure. The use of cryptography with public key on large scale, creates the need to manage large lists of public keys, for entity often repartee on the network. The public-key infrastructure manages that problem.

RA: The registration authority (RA) creates the pairs of keys

SET: Secure electronic transaction was a solution developed by a set of companies (Visa, MasterCard, GTE, IBM, Verisign...) to limit the risk that the customer can repudiate an e-commerce electronic payment transaction.

3D-SECURE: The current solution to solve the problem of e-commerce electronic payments, 3D-secure is used by VISA and by MASTERCARD.

Security Issues in Distributed Transaction Processing Systems

R. A. Haraty
Lebanese American University, Lebanon

INTRODUCTION

Transaction-processing systems (TPS) are becoming increasingly more available as commercial products. However, the approaches to the issues associated with using TPS in multilevel secure environments are still in the research stage. In this article, we address the issues of multilevel security in distributed transaction-processing systems. A distributed transaction-processing system (DTPS) is a collection of a finite number of centralized transaction-processing systems connected by a computer network. Each of these transaction-processing systems is controlled by a software layer and can be accessed both remotely and locally. Properties of a DTPS, such as data replication, may have a substantial effect on the security of the system. The security policies and integrity constraints adopted at each site may result in global security having inconsistent states. We address the issues of achieving a multilevel secure DTPS, and discuss the security constraints and data replication.

In this work, we address the issues of achieving a multilevel secure DTPSs system and discuss the security constraints and the replication of data items. The next section provides some background. Then, next, an overview of a distributed transaction-processing system is presented. In the fourth section, security-related issues are discussed. In the fifth section, a multilevel secure distributed transaction-processing system is presented. Then, in the next section, future trends are presented. The final section concludes the article.

BACKGROUND

Several commercial and military applications require a multilevel secure transaction-processing system (MLS/TPS). In an MLS/TPS, users are assigned classification levels that we denote by "clearances," and data items are assigned sensitivity levels. There are three interesting architectures that have been used to build MLS/TPSs from untrusted ones. These architectures are known as the integrity lock architecture, the kernelized architecture, and the data distribution architecture (Air Force Studies Board, 1983). While most of the techniques for TPS security are developed for traditional centralized TPSs, more TPS researchers are making substantial contributions to the development of a distributed TPS (Getta, 2003; Haraty, 1999; Haraty & Rahal, 2002; O'Connor & Gray, 1988).

A DTPS is a collection of a finite number of TPSs connected by a computer network (Ozsu & Valduriez, 1999). Each of these TPSs is controlled by a transaction management software layer and can be accessed both remotely and locally. A DTPS integrates information from the local TPS and presents remote users with transparent methods to use the total information in the system. An effective TPS system serves to maintain the ACIDity properties (i.e., atomicity, consistency, isolation, and durability) of transactions and must be superimposed on the preexisting local TPSs (Gray & Reuter, 1993).

One proposed architecture for MLS/TPS is the replicated architecture. This approach is being explored in several ongoing research efforts, including the Naval Research Laboratory Secure Information through replicated architecture (SINTRA) project (Thuraisingham, 1987). Data replication in DTPS has several implications for the security of the system. Replication allows data items in different local TPSs to be identified as logically belonging to the same entity. The security policies adopted by each site may result in global security having inconsistent states, because of the difference of local representation and management.

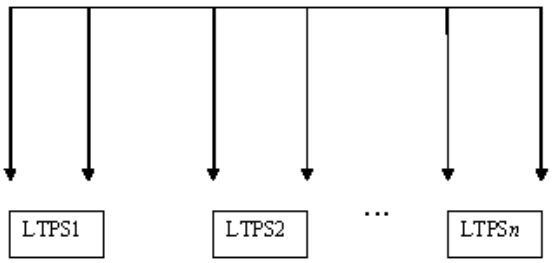
OVERVIEW OF DISTRIBUTED TRANSACTION-PROCESSING SYSTEMS

A DTPS consists of a set of preexisting local TPSs {LTPS*i* | 1 d•*i* d" *m*}, distributed among several interconnected sites. Each LTPS*i* is a software layer on a set of data items D*i*. Figure 1 depicts the architecture of a DTPS.

SECURITY ISSUES

Processes that execute on behalf of users are referred to as subjects. Objects, on the other hand, correspond to a data item. Objects can be files, records, or even fields. In this section, we present the notion of object classification with emphasis on the problem of conflicting security constraints due to replication.

Figure 1. Distributed transaction-processing system



A security classification is a function that associates each subject and each object with a given level of security. Many classifications, such as the security lattice, exist (Denning, 1976). However, a well-known classification is four-value function (DOD paradigm) that classifies objects into unclassified (U), confidential (C), secret (S), and adopt top secret (TS). A simple policy that can be established using a classification function SL is as follows:

Subject X can access (read) Object Y iff SL (Y) ≤ SL(X)

A security constraint consists of a data specification and a security value. The data specification defines any subset of the TPS. The security values can be given by a classification function. Specific values are unclassified, confidential, secret, and top-secret. Thuraisingham (1987) defined two types of security constraints—internal constraints and external constraints:

1. Internal constraints classify the entire TPS as well as relations, attributes, and tuples within a relation. These constraints can be applied to data, as they are actually stored in the TPS.
2. External constraints classify relationships between data and the results obtained by applying operations on the stored data, such as sum, average, and count. Among these constraints are the functional constraints and the dynamic constraints.

These security constraints are subject to inconsistency and conflicting local security constraints. A good global security approach should reject inconsistent security constraints and inconsistent clearance of users. Examples of the inconsistencies encountered include:

- **Conflicting security constraints:** Such constraints classify the same facts into different categories.
- **Overlapped security constraints:** These constraints cover overlapped data domains.
- **Inconsistent security level of replicated data:** Cases where different copies of replicated data may belong to different security cases.
- **Access privileges of users to replicated data:** Instances where a user may have different access rights on replicated data at different sites.

Several solutions have been proposed to solve these inconsistencies and define a global security policy that respects the local ones (Pfleeger, 1989; Thuraisingham, 1987).

There are several ways to combine local policies. The optimal combination should give a policy that defines all component policies and is still secure.

MULTILEVEL SECURE DISTRIBUTED TRANSACTION-PROCESSING SYSTEMS

There are two strategies for building MLS/DTPS from DTPS. These strategies include data replication and per-level-based distribution. The scope of this article does not include the issues associated with network security; but, it is particularly important to have the various local TPSs. Instead, we will assume that interconnection between the various local TPSs is secure and focus attention on security that has to be provided due to replication and other properties specific to the TPS.

The data distribution approach physically replicates low-level data at all higher-level TPSs. The advantage of the replicated architecture is that is fairly secure (McDermott & Sandhu, 1991). No performance overhead is associated with multilevel queries, because they are locally executed. On the other hand, because data is replicated, there is overhead associated with broadcasting updates of lower-level data to higher-level TPSs in a correct and secure manner. This broadcasting mechanism is known as "data synchronization" (Air Force Studies Board, 1983).

In the per-level-based approach, data are physically stored in separate local TPSs according to sensitivity level. Early examples of this approach were presented by Hinke and Schaefer (1975). The advantage of this approach is that updating transactions does not produce inconsistencies. Performance overhead associated with multilevel queries is a major disadvantage.

Global Commitment in Secure Environment

An important aspect of a correct TPS is atomic commitment (Bernstein et al., 1987). Unfortunately, the local TPS in a MLS/DTPS system cannot support atomic commitment, so the two-phase commit (2PC) protocol (Bernstein et al., 1987) cannot be implemented. 2PC is known to introduce covert channels. In order to establish a covert channel, there must be two cooperating agents/subjects in the system and an encod-

ing scheme. There are two main types of covert channels: covert storage channels and covert timing channels.

Covert storage channels disclose information from high to low subjects by manipulating a physical object that can or cannot be seen by the low subjects. For example, suppose there are two subjects of different security levels. Suppose also that these processes share a common resource—the available disk space. The secret subject creates a secret file that takes all of the available disk space to store the file. When the low subject attempts to create a file and store it onto the common disk, its request is denied. Through this denial, the high subject can signal information to the low subject. These signals are in terms of 0 and 1 bits that the low subject has to decode and turn into useful messages.

Covert timing channels can covertly send information by modulating observable delays of a common resource. This delay must be measured by low subjects cleanly; otherwise, the channel becomes noisy. For example, suppose we have two subjects again operating the low and high levels. The high subject can modulate the disk access time of the low subject by issuing numerous disk requests (thus transmitting a bit of 1) or zero disk requests (thus transmitting a zero). A system that is free from any type of covert channel is called covert channel secure.

Several distributed commitment protocols have been defined. A scheduler in MLS/DTPS that produces committable execution guarantees that a distributed transaction (a unit of work with execution sites: TPS1, TPS2, …, TPS*n*) becomes committed after it has been locally committed. The commitment of a distributed transaction means all of its subtransactions are committed. In this article, we follow the definition proposed by Bernstein et al. (1987):

If one subtransaction commits, then all other subtransactions will eventually commit.

We assume, in this article, that each subtransaction of a distributed transaction is designed to be executed in only one container. One can then say that a subtransaction has a security level.

FUTURE TRENDS

Future work will involve taking a closer look at MLS/DTPS and defining new and better ways of handling transaction management as well as query processing. Future work will also involve extending security issues to temporal and multimedia databases.

CONCLUSION

The security issues presented in this article highlight the intricacies required to architect a MLS/DTPS. We hope to address these issues further and to identify potential prototypes and engineering solutions that meet the requirements of MLS for DTPS.

KEY TERMS

Covert Channel: This is a channel that is not meant to route information, but nevertheless does.

Multilevel Secure Transaction-Processing System: This is a system whereby database users are assigned classification levels, and data items are assigned sensitivity levels.

Security Lattice: This is a partial (or total) order of security classes, where there is a least upper bound that dominates all the other security classes and a greatest lower bound that is dominated by all security classes.

Subject: This corresponds to a user or, more correctly, to a process that is running on behalf of a user.

Two-Phase Commit (2PC): This is an atomic commitment protocol that behaves as follows: The coordinator asks the participants to vote on commitment; if any votes No, the coordinator informs all participants to Abort; if all participants voted Yes, then the coordinator informs all participants to Commit.

This work was previously published in Encyclopedia of Information Science and Technology, edited by M. Khosrow-Pour, pp. 2455-2458, copyright 2005 by Information Science Reference, formerly known as Idea Group Reference (an imprint of IGI Global).

Security Issues in Mobile Code Paradigms

Simão Melo de Sousa
University of Beira Interior, Portugal

Mário M. Freire
University of Beira Interior, Portugal

Rui C. Cardoso
University of Beira Interior, Portugal

INTRODUCTION

Unlike mobile computing, in which hardware moves, *mobile code* moves from nodes to other nodes and can change the machines where it is executed. A paradigmatic example of such *mobile code* are Java applets that can be downloaded from a distant machine and executed by a virtual machine embedded in a browser. Multi-application smart cards (like Javacards) are an example of an execution environment that allows the loading and the execution of (mobile) programs into a card after its issuance. Code mobility allows the software reconfiguration without delivering a physical support, as done by Sun initially with Java to reprogram cable TV boxes, or nowadays, by Microsoft to promptly distribute software patches. PostScript files are another type of mobile programs which execute in printers to produce graphic images. Mobile code may also be used in distributed systems to adapt autonomously in order to balance loads or compensate for hardware failures (Brooks, 2004). Mobile code has received a great deal of interest as a promising solution to increase system flexibility, scalability, and reliability. However, to reach such objectives, some issues need to be matured, namely security issues. This article addresses security issues in *mobile code* paradigms.

BACKGROUND

Several *mobile code* paradigms have been reported (Brooks, 2004; Brooks & Orr, 2002; Fuggetta, Picco, & Vigna, 1998; Milojicic, Douglis, & Wheeler, 1999; Tennenhouse, Smith, Sincoskie, Wetherall, & Minden, 1997; Wu, Agrawal, & Abbadi, 1999). These paradigms differ on where code is executed and who determines when mobility occurs (Brooks & Orr, 2002; Brooks, 2004) and can be classified as follows:

- **Client-Server:** The user node invokes code resident on a distant node: the server or program node. This node fetches the required data from data nodes, executes the invoked program, and returns the result to the user node. Examples include the common object request broker architecture. CORBA integrates remote procedure calls (RPCs) with the object-oriented paradigm.
- **Remote Evaluation:** The user node requests the execution of code resident on a distant node. This node uploads the code to the node containing the data needed for its execution. The execution takes place in this node, and the result is then sent to the user node. Examples include CORBA, Simple Object Access Protocol (SOAP) and Web Services.
- **Code-On-Demand:** The user node requests the execution of code resident on a distant node. This code is downloaded on user node and locally executed. Examples include Java applets and Active X programs.
- **Process Migration:** The operating system dispatches processes from one node to others nodes in order to balance the load. Examples include Mosix and Sprite.
- **Mobile Agents:** The user node executes a program, called agent, which moves, along with its execution context, from node to node. The decision to move from one node to another node or to execute a specific set of operations on a particular node is made by the agent itself. The result of the execution is, at the end, transmitted within the program to the user node. There are several agent and multi-agent platforms.
- **Active Networks:** In this paradigm, the network configuration and infrastructure can be modified by the transmitted packets. Here, the packets act as mobile code. An example would be Capsules.

A mobile agent is a program that encapsulates code, data, and execution context. The mobile agent is sent by the client to another node. Unlike a procedure call, the agent does not have to return data to the client. The agent can migrate to other node, send information to the client, or come back to the client. However, the efficiency of each approach depends on network configuration and the size of programs and data files.

SECURITY ISSUES IN MOBILE CODE

One of the major challenges in the context of mobile code is the safety of the execution of untrusted code. This concern occurs naturally when we verify that mobile code to be executed comes from an eventually unknown source, or it was designed or compiled by unknown methods. In fact, the code may have been produced or changed by malicious sources. Thus, an execution environment for mobile code must be able to execute mobile code without allowing it to produce damages in the case of being a malicious code.

From a theoretical point of view, the problem of stating if a given program is inoffensive or malicious is not decidable in general. Thus, the quest of finding a universal filter that rejects every malicious code and accepts innocuous programs is an utopia. It is indeed very hard to universally and formally define what is a malicious program is. However, there exist several partial solutions which increase the safety of execution environments. They can be classified in these four approaches (Rubin & Geer, 1998; Zachary, 2003):

- Sandboxes, which limit or control the context in which code is executed;
- Code signing, which ensures that code comes from a trusted source and its integrity;
- Firewalls, which limits the accessibility; and
- Proof-carrying code (PCC), in which code carries explicit proof of its safety.

The first approach consists in the isolation of the code execution zone. Each mobile program is executed within a controlled context and isolated from the other processes (including memory). Control is assured by runtime monitoring of the performed operations. For instance, sensitive operations (whether operation on resources such as disks, memory, etc., or operations such as communications or data/files handling) may be forbidden or, at least, supervised. Enforcing security policies by confinement and runtime access control is relatively easy to implement (when compared with other approaches), easy to use, and provides a reasonable level of confidence. A successful example of such approach is the Java virtual machine and its security manager mechanism. However, runtime checking induces a penalty in terms of execution performance. In the same vein, access control policies limit the computational ability of mobile code (for instance, an innocuous applet could have access to the whole instruction set).

The next approach, the *code signing* approach, allows the execution of code which presents enough credentials. This mechanism is based on the extraction and the verification of a digital signature which is included in the code to be executed. This signature allows the identification of the code producer and the code integrity. If code comes from a source identified as secure and if the code has not been changed since it had to leave the source, then the execution environment may allow its execution. Such a mechanism takes place before the execution stage. Unfortunately, it does not provide information about the actions performed by the program and must be associated with other security mechanisms. Therefore, most popular mobile code execution/support systems such as Java and .NET integrate a combination of the two approaches, since this increases the flexibility of policy securities.

Another way to guarantee the security in a mobile context is based on the restriction and control of the mobility or the communication capability. These mechanisms rely on *firewalls* and other similar mechanisms. This approach allows precise control of the generated interactions by the executed program. However, since this mechanism acts in runtime, it leads to performance degradation of program execution and of the infrastructure that supports the execution. Another drawback is that the safety cannot be fulfilled exclusively in terms of safe interaction, but this approach can be used in conjunction to other security mechanisms.

Recent and emerging approaches try to minimize the need of runtime verification. Such approaches are known as proof-carrying code (Appel, 2001; Appel & Felty, 2001;Barthe, Grégoire, Kunz, & Rezk, 2006; Colby, Lee, Necula, Blau, Plesko, & Cline, 2000; Hamid, Shao, Trifonov, Monnier, & Ni, 2002) or static program analysis. These mechanisms operate on the code as soon as it is received and can get conclusions about the safety of the program without requiring its execution. From the code consumer point of view, the penalty is located in the loading time. The underlying principle is the following: the code to be executed is enriched in such a way that it contains enough information for the execution environment to verify the conformance of the program with respect to the security policies of the code consumer. If the program is approved, then it can be executed in a safe way and these policies do not need to be verified at runtime. The several approaches in these families of mechanisms differ in the quantity of the information required in the code to be executed. This information can vary from complete demonstrations (as the name "proof-carrying code" suggests) to simple type annotations. For instance, Java bytecode, the code executed by the Java virtual machine, is a typed low level language. This allows the Bytecode Verifier (BCV) of the Java platform to perform the static analysis of several safety policies. Because *proof-carrying code* is an emerging approach and a very promising technology (as witness recent initiatives like the European project MOBIUS IST 15905, the literature, or the emergence of certifying compilers (see the next section) for languages like JAVA), we will postpone its detailed description to the next section.

FUTURE TRENDS

The concept of *proof-carrying code* (PCC) was first defined by G. Necula and P. Lee in 1996 (Necula & Lee, 1996; Necula, 1997) and is based on two actors: the code consumer (the node which executes the code), the code producer (the node where the executable code is produced) and on the following two statements:

1. A proof is lot easier to check than to build (Aristotelian Principle); and
2. The code producer must be responsible for the behavior of the produced executable code.

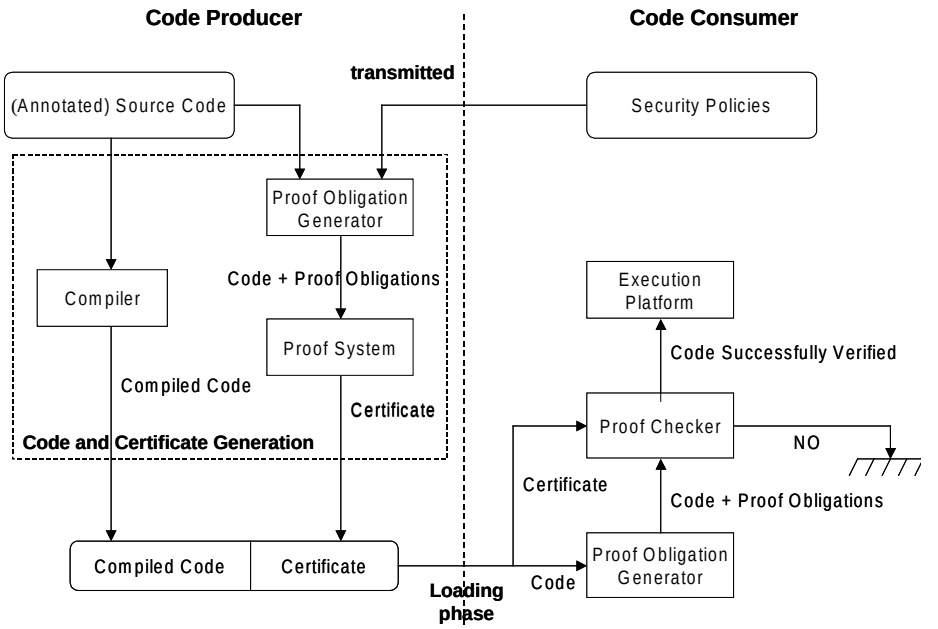
This gives rise to the following scenario:

- The code consumer defines a set of security policies and makes them available to the code producer.
- The code producer designs the program.
- The code producer annotates the program with pre-post-conditions, and invariants in order to provide enough information for the verification of the security policies.
- The code producer uses the compiler to produce executable code and verification tools to produce the formal proof that the executable code is compliant with the required policies. This formal proof is called certificate.
- The code consumer receives the executable code with its certificate. The code consumer verifies that the certificate is proof that the code is secure.
- In the positive case, the code can be safely executed without runtime checking.

Figure 1 summarizes the typical PCC architecture. The code and certificates generation stage (the emphasized rectangle in Figure 1) varies following the different implementations of PCC depending on whether the proof generation is done before, during, or after the compilation (or alternatively with the source code or with the compiled code). The overall infrastructure responsible for the generation of executable code and formal proofs (emphasized in Figure 1) receives source code and security policies and produces executable code and certificates. This is the reason why such a module is often referred in the literature by *certifying compiler*. Code annotations are used by both the producer and the consumer to produce proof obligations. These are the properties that the code must verify in order to be compliant with the security policies. The code producer must prove them and the code consumer must reproduce them to verify that the certificate contains exactly their proofs.

One definitive advantage of PCC is that the certificate only needs to be verified once during the loading time, and this process is automatic, efficient, and trustworthy. Moreover, the consumer does not have to trust the code producer, and a validated formal proof of a property is

Figure 1. General proof-carrying code architecture



a strong argument for its safety with respect to what the consumer assumes to be safe. Finally, PCC can be easily combined with other security mechanisms.

But, despite these interesting features, a lot of work around PCC remains to be done.

This is why PCC is an active and prolific research area essentially because the following challenges or open problems must be solved before engaging a real deployment of PCC architectures:

- Coupling certificates with executable code induces a network loading overhead. Certificates must be concise. This point is particularly difficult because this is not just a question of defining an adequate format for the certificate: For a property, there exist several proofs. Some are longer than others.
- On the other hand, the certificate must be checked as efficiently as possible.
- It is not reasonable to ask the code producer to carefully look at the compiled code. The producer side of the PCC architecture must provide tools that allow the programmer to focus its attention at the source level. The compiler is then a key element. Unfortunately, it is difficult to implement certifying features and mix them with code optimizers.
- Another point is the proof construction automation. It is possible to provide automatic tools for simple proofs. But proofs of security properties tend to be tricky and, so, hard to automate. PCC relieves the consumer from heavy verifications but must not weigh down the code producer effort.
- Designing a good security policy is an art, and the good performance of a PCC architecture strongly depends on it.

CONCLUSION

An overview of mobile code paradigms and its security has been presented. Safe execution of untrusted code, which is one of the major challenges in mobile code security, has been analyzed. The sandboxes, code signing and firewalls approaches have been described, and special attention has been taken in the description of the proof-carrying code approach. As an emerging trends, it has been shown that the Proof-carrying code technology is a powerful and very promising technique, but despite recent and outstanding advances these past few years, its challenges can still be resumed by: Is the PCC approach able to fill the gap between its alluring, underlying principles and a practical and industrial use?

KEY TERMS

Active Networks Paradigm: In this mobile code paradigm, packets moving through the network reprogram the network infrastructure.

Client-Server Paradigm: In this mobile code paradigm, client invokes code resident on another node.

Code-On-Demand Paradigm: In this mobile code paradigm, local clients download and execute code as needed.

Mobile Agents Paradigm: In this mobile code paradigm, a program moves from site to site. It represents the current more advanced stage of mobile computing paradigms.

Process Migration Paradigm: In this mobile code paradigm, processes move from one node to another to balance the load.

Proof-Carrying Code: This approach for security in mobile code is based on two actors: the code consumer and the code producer, and on the following two statements: 1) a proof is lot easier to check than to build and 2) the code producer must be responsible for the behavior of the produced executable code.

Remote Evaluation Paradigm: In this mobile code paradigm, a remote node downloads code before executing it.

SOAP (Simple Object Access Protocol): Protocol developed by Microsoft, DevelopMentor, and Userland Software. It allows the communication between a program executed in a given operating system with a program in the same or in another operating system using HTTP and XML as a mechanism for message exchange.

Security-Based Knowledge Management

Shuyuan Mary Ho
Syracuse University, USA

Chingning Wang
Syracuse University, USA

INTRODUCTION

As knowledge is recognized as intellectual (or intangible) assets that can enhance an organization's competitive capability, how to effectively manage knowledge assets has become an important issue in the information age (Alavi, 2000). Literature in knowledge management (KM) emphasizes issues on knowledge creation, knowledge codification, knowledge sharing, and knowledge utilization; however, security perspectives on assuring knowledge confidentiality and knowledge integrity are left unaddressed.

This article takes an initial step to address different perspectives of security centric knowledge management. This article first presents the background of security-based knowledge management. It then discusses sources of security threats in knowledge-based organizations and identifies challenges in four aspects of knowledge management practices, which are culture-based, strategy-based, content-based (or standard-based), and technology-based, along with a discussion of 10 corresponding security domains. Real-world cases are intertwined with the challenges faced by knowledge-based organizations. This article ends with further envisioning the future trends of the security-based knowledge management.

BACKGROUND

While knowledge management enables collaboration within an organization to retain and share knowledge and experience, threats to knowledge confidentiality and integrity have raised corporate concern.

Threats against organizations are multi-faceted. Hackers and crackers have greatly threatened information[1] transmission over the virtual world such as the Internet, intranet and extranet. Many corporations have applied multi-layered security solutions to prevent threats of this kind. System-layered security solutions include system logs, host-based intrusion detection, file encryption, identity-based, or role-based access control. Network and infrastructure-layered security solutions include firewall, virtual private network, public key infrastructure, cryptography, network-based intrusion detection, and intrusion prevention. Physical separation of the networks is seen as the fundamental practice to protecting information assets. One of the best examples would be the practice of the de-militarized zone[2] (called DMZ). In the social context, personnel with a knowledge base of the corporate assets could pose potential threats to the organizations. Corporate regulations, best practice, and ethical codes could be security solutions to threats of this nature.

With the advance of information technology, threats to information security have come to corporations with increasing frequency and subtlety, and so information security should be an emphasis in the field of knowledge management for the new information era.

SOURCES OF INFORMATION THREATS

Threats against information security can be intentional or unintentional. These threats can be further differentiated into internal threats and externals threats. Sources of security threats are tabulated in Table 1.

External Threats

In a networked environment, intentional threats from outsiders include attacks from hacker/crackers (Harris, 2003).

Table 1. Sources of threats to information security

	Intentional	**Unintentional**
External	Malicious Hacker/Cracker; outsider ID theft	Natural disasters
Internal	Personnel fraudulence; unauthorized modification/leakage of knowledge/information[1];	System failure

These attacks include man-in-the-middle, Trojan Horse, denial-of-service (DOS), logic bombs, viruses, and so forth. These attacks could cause malfunctions of the systems and result in loss in terms of time and money. For instance, *The New York Times* suffered attacks in 1998, which resulted in its web servers being compromised and its Web front page replaced.

Identification (ID) theft is another type of external threat. The purpose of those malicious hackers in this scenario is to steal personal information such as social security numbers, credit card numbers, or to conduct banking transactions without authorized permission. Additionally, they could commit identification (ID) fraud by falsely presenting stolen identification in exchange of goods and services in this virtual e-commerce world. These misconducts could cause huge losses and creditability damage to innocent victims.

On the other hand, external threats from natural forces such as earthquakes, tornadoes, or tsunamis are generally unintentional and thus become difficult to prevent in advance. Damages caused by natural forces could be devastating and hard to restore. The tsunami that devastated Southern Asia in December 2004 was an example of this kind.

Internal Threats

Threats from insiders are subtle and complex (Hayden, 1999; Park & Ho, 2004). Like a double-edged sword, the knowledge from internal personnel could bring beneficial advantages, but also ironically, could bring potential security threats as well to an organization (Benkoil, 1998; Powell & Rosenberg, 1987). For example, in 1985, Jonathan Pollard, a U.S. Navy intelligence analyst, was arrested for passing classified U.S. intelligence information to Israel. The Israeli government was then able to analyze U.S. intelligence infrastructure such as the locations of facilities and identities of intelligence agents. As such the General Accounting Office (GAO) reported in 1993 that insiders' abusive use of the National Crime Information Center (NCIC) for personal reasons had threatened the safety of U.S. citizens (Benkoil, 1998; Powell & Rosenberg, 1987). Insider threats have been statistically increased since late 1980, and, more so, the cost of loss from the insider threats has exceeded the threats from outsiders (Hayden, 1999; Park & Ho, 2004). Normally insiders are not interested in sabotaging hardware systems or applications but in obtaining critical information and accessing the internal level of resources. Due to the insider threats, the paradigm has shifted toward a more sophisticated and security centric collaborative environment

On the other hand, infrastructure failures such as power outage and destruction of infrastructural devices such as routers and switches are seen as unintentional internal threats. These threats bring up issues on operational site redundancy, system maintenance, and information preservation.

ASPECTS OF KNOWLEDGE MANAGEMENT AND INFORMATION SECURITY

Knowledge management can be classified into four aspects: culture-based, strategy-based, content-based, and technology-based (Alavi & Leidner, 1999; Oostveen & van den Besselaar, 2004). These four aspects represent four major themes in managing knowledge. Each theme of knowledge management has related security concerns. International Information System Security Certification Consortium, Inc. (known as (ISC)2) has identified 10 domains of information security that would assure knowledge management practices in organizations. These 10 information security domains include law, investigation and ethics, risk assessment, operations security, business continuity planning, physical security, security architecture technology standards, access controls, telecommunications and network security, applications security, and cryptography. These aspects are not mutually exclusive but overlap one another. We map the 10 domains of information security (Hansche, Berti, & Hare, 2004; Harris, 2003) with four aspects of knowledge management identified in literature (Table 2).

Table 2. Conceptual map of knowledge management aspects and domains of information security

Aspects of Knowledge Management	Corresponding Domains of Information Security
Culture-based	Law, Investigation and Ethics
Strategy-based	Risk Assessment Physical Security Operations Security Business Continuity Planning
Standard-based	Security Architecture
Technology-based	Access Controls Telecommunications & Network Infrastructure Security Applications Security Cryptography

Culture-Based Aspect

This aspect of knowledge management focuses on cultivating both learning and sharing cultures in organizations (Alavi & Leidner, 1999; Oostveen & van den Besselaar, 2004). While creating a willing-to-share organization culture could enhance collaboration and productivity, this process is vulnerable to unethical information misuse (Alavi & Leidner, 1999; Oostveen & van den Besselaar, 2004). This brings up the legal aspect of information security in terms of laws, investigation, and ethics. As such, it is important to establish information policies, regulations and "boundary control" to govern information sharing and usage (Liddy, 2001). It is also important to establish an internal audit and monitoring system to supervise information activities. Proper background check and security clearance toward authorized insiders should be conducted to ensure organizational security.

Strategy-Based Aspect

Objective goals of an organization can be achieved with various corporate strategies which are applicable to knowledge management practice. An organization may face challenges from different levels of practices such as information collecting, processing, and storage (Green, Hurley, & Shaw, 2004; Nyaboga & Mwaura, 2004); it could enact different coping strategies to manage the challenges they experienced.

Strategy-based aspect of knowledge management relates to a wider scope of security issues that could be further differentiated into pre-stage security, in-stage security, and post-stage security. Risk assessment is a pre-stage security wherein it analyzes potential risk (or threats) and rates vulnerabilities so that effective controls can be implemented (Hall, 2004; Siponen, 2001). Pre-staged risk assessment informs operations security and physical security that are in-stage security. Operation security concerns the organization's ability to audit, monitor, and identify events when there are security breaches, and report to the right entities for incident response (Hall, 2004; Siponen, 2001). Physical security is a mandatory guard to protect knowledge-based organization from unethical or even brutal physical intrusion. Preventative, detective, and corrective systems are commonly used for security checks around the organization's buildings (Hall, 2004; Siponen, 2001). Although disaster management, disaster recovery, incidents response, and business continuity planning ought to be considered beforehand and planned for, they are indeed countermeasures that would strategize the post-stage security (Hall, 2004; Siponen, 2001).

Content-Based Aspect

This aspect of knowledge management defines how the content of information is collected or stored, which relates to security architecture (Alavi & Leidner, 1999). When applying security to ensuring corporate information and knowledge, it is important to adopt the standards that have been widely used. Standards in information security upon systems and applications always prevent the uncertain applets, codes, or backdoors programmed in the organizations critical knowledge-based systems. The standards that evaluate the security property and assurance level of the IT systems and products include Common Criteria and ITSEC[4]. They are transactional standards being recognized and practiced internationally. TCSEC[5], IETF[6] and IPSec[7], on the other hand, are Internet security standards. The challenges that most organizations would face remain in how to comply the security architecture of hardware, firmware, and software during system development cycle with the standards of the information technology security evaluation (Hall, 2004).

Technology-Based Aspect

Technology-based aspect of knowledge management relates to transforming the actionable and readily accessible information into knowledge with enabling technologies such as data mining, data warehouse, information retrieval, expert system, smart system, intranet/extranet, multimedia, and so forth security issues that are applied to ensuring technological aspect of knowledge management include access control, telecommunications and network infrastructure security, applications security, and cryptography.

Access Controls generally include mandatory access control, discretionary access control, and role-based access control (RBAC). All access control mechanisms guard the information assets from unauthorized access which specifies who has the permission to access what resource. For example, RBAC indicates the granted permission assigned to specific sets of roles in that organization. In other words, an authenticated personnel or insider with a specific set of role functions is only allowed to conduct authorized activities. The activity is defined as the work that an insider conducts over a permitted resource. RBAC's protection mechanism controls the gates that determine whether the authorized personnel are able to enter into an authorized area for authorized activities. In sum, non-legitimate activities are excluded and legitimate activities are guarded.

Telecommunications and Network Infrastructure Security emphasizes on securing the communication links. The technologies used are virtual private network with cryptography implementation, firewall to block out unspecified ports and services, and router to ensure the routed packets sent to the right destination address, and so forth. The challenge here is not only to adopt preventive, detective, and corrective measures at the infrastructural level, but also correlate security incidents from various infrastructural devices into meaningful threat analysis and knowledge. How to determine threat indicators, eliminate false positives and false negatives, and

generate early warnings of the intrusion would be the keys to secure intranet and extranet communications before the information is stolen or modified.

Applications Security Control should be adopted and implemented within systems and applications software in their early development stage. Information assurance at this domain refers to securing agents, applets, software, databases, data-warehouses, and knowledge-based systems from implanted backdoor programs or system development holes. Boundary control over software releases becomes essential in preventing software exploitation attack (Liddy, 2001). Understanding the system life-cycle and how to incorporate security features into a knowledge-based system would be key challenges.

Cryptography ensures the confidentiality and is used to encrypt texts, e-mails, messages, and documents that are transmitted over the link. It can further work with identification and authorization systems to specify designated recipients for the encrypted messages or documents. The challenges here remain in how to maintain confidentiality while the speed of transmission and encryption/decryption is not sacrificed. How to effectively integrate the security technologies such as public key infrastructure, digital signature, and key management into different user-centric applications becomes critical to a successful transformation of a knowledge-based organization.

FUTURE TRENDS

The challenges faced by today's knowledge-based organizations have been subtly shifted from sharing knowledge to protecting knowledge against all sorts of threats. The ethical and technical aspects of monitoring and detecting personnel's anomalous behavior based on their roles and functions within the organization have increasingly attracted public attentions. The ability to audit, monitor, encounter security threats and breaches would lead to successful implementations of the mechanism of security preventive control and incident response. The technological solutions for digital forensics and electronic crime investigation will change the way how a knowledge-based organization would plan and develop efficacious corporate security policy and procedure.

Although knowledge management is deemed a critical role to organization's competitive capabilities, the enabling aspect of information security toward a knowledge-based organization should be emphasized. Information security procedures and techniques not only protect intellectual assets from unexpected or unethical intrusions but also remedy the potential losses from the threats. In summation, information security ensures knowledge confidentiality from unauthorized disclosure, knowledge integrity from unauthorized modification, and knowledge availability and sharing in today's dynamic, but still vulnerable, digital world.

KEY TERMS

Asymmetric Cryptography: A technique using different keys to encrypt and decrypt messages. Usually, a public key is used to encrypt a message, and a private key is used to decrypt it.

Buffer Overflow Attacks: A technique an attacker use to overwrite the data. Buffer overflow occurs when the program writes more information into the space than the buffer has in its memory. This allows the attackers to control the program and execute the code they wrote.

Cryptography: A technique that encrypts and decrypts a message for ensuring security and privacy during the exchange and communication process.

Denial-of-Service (DOS) Attack: A type of attack that intends to deprive legitimate users of access to services of a resource they would normally have.

Identification (ID) Fraud: Unauthorized use of other's personal information to commit crimes, usually in exchange of economic gains.

Identification (ID) Theft: Illegally obtaining other's personal information such as social security number, credit card number, and password without authorized access and permission. ID theft is related to ID fraud.

Information Security: Policy, procedure and techniques used to protect information from unauthorized use or other misconducts.

Knowledge Management: Refers to the managerial process of acquiring, storing and transferring knowledge intra- or inter-organizationally with the purposes of fulfilling tasks and enhancing competitiveness.

Symmetric Cryptography: A technique using the same secret key to encrypt and decrypt a message. Also called secret-key cryptography or conventional cryptography.

Trojan Horse Attacks: A maliciously security-breaking backdoor program that is disguised as benign so that dangerous program can be unleashed. It could result in damage to the disk, ID theft, a denial-of-service attack, and so on.

ENDNOTES

1 The difference between information and knowledge has been under debate for a long time. Due to the fact that its differentiation is outside the scope of this article, the terms of "information" and "knowledge" are used interchangeably.

2 Demilitarized zone (abbreviated as DMZ) is in a subnetwork that is located in between the intranet and Internet.

3 The difference between information and knowledge has been under debate for a long time. Due to the fact that its differentiation is outside the scope of this article, the terms of "information" and "knowledge" are used interchangeably.

4 ITSEC stands for Information Technology Security Evaluation Criteria.

5 TCSEC stands for Trusted Computer System Evaluation Criteria (commonly called the Orange Book). It sets the standards for trusted computer products.

6 IETF stands for Internet Engineering Task Force. It regards the development of the Internet architecture and the operations.

7 IPSEC stands for Internet Protocol Security, which defines a set of protocols developed by the IETF to support secure IP packet exchange over the network.

Self Organization Algorithms for Mobile Devices

INTRODUCTION

Self-organization is a phenomenon in nature which has been studied in several areas, namely biology, thermodynamics, cybernetics, computing modeling, and economics. Systems exhibiting self-organization have well defined characteristics such as robustness, adaptability, and scalability, which make self-organization an attractive field of study for two kinds of applications: a) maintaining the communication among mobile devices in wireless networks, and b) coordination of swarms of mobile robots.

In ad hoc networks, there is not necessarily an underlying infrastructure in which the nodes can maintain communicated with other nodes; so due to this feature, it is necessary to provide efficient self-organization algorithms for routing, managing, and reconfiguring the network.

Furthermore, self-organization in nature provide clear examples about how complex behaviors can arise from only local interaction between entities, namely the ants colony, feather formation, and flock of birds. Based on the above mentioned examples, several algorithms have been proposed to accomplish robot formations using only local interactions.

Due to resource constraints in mobile devices, self-organization requires simple algorithms for maintaining and adapting wireless networks. The use of resources for establishing robot formations can be reduced by improving simple rules to accomplish the formation. This article first presents a brief overview of several works developed in ad hoc networks; then, delves deeper into the key algorithms; and finally, challenges arising in this area are discussed.

Figure 1. Wireless mesh network

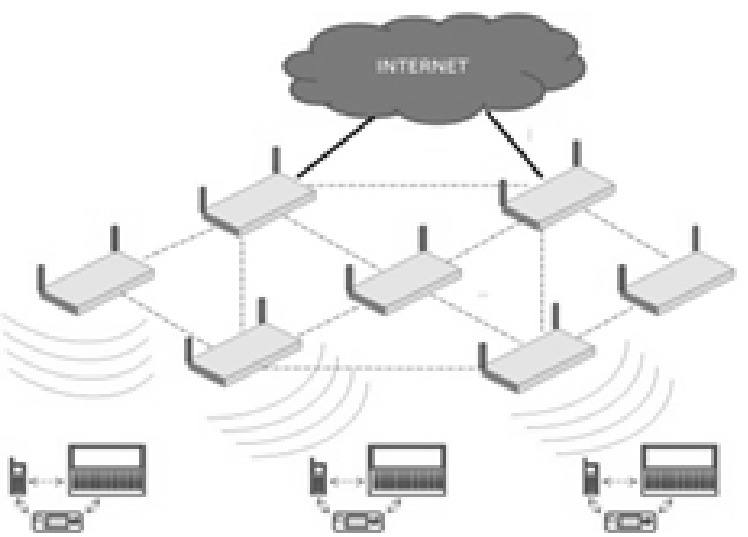

Figure 2. Wireless sensor network

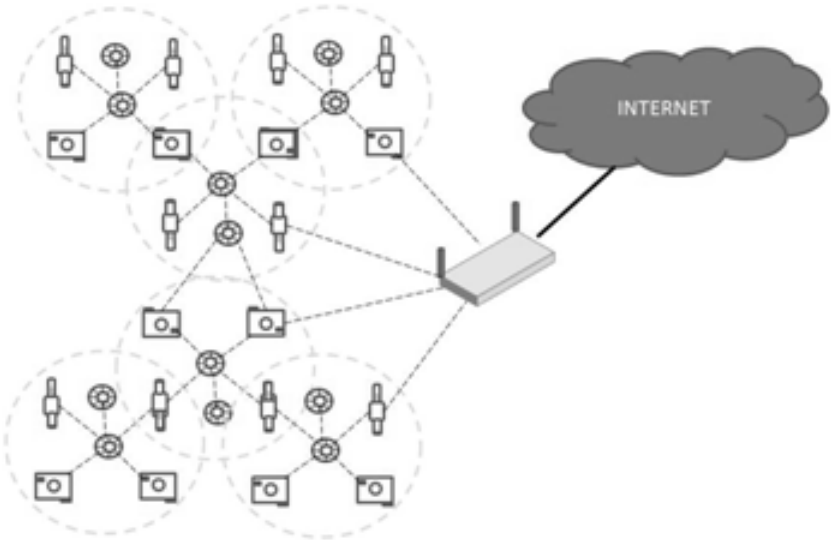

Figure 3. Vehicular ad hoc network

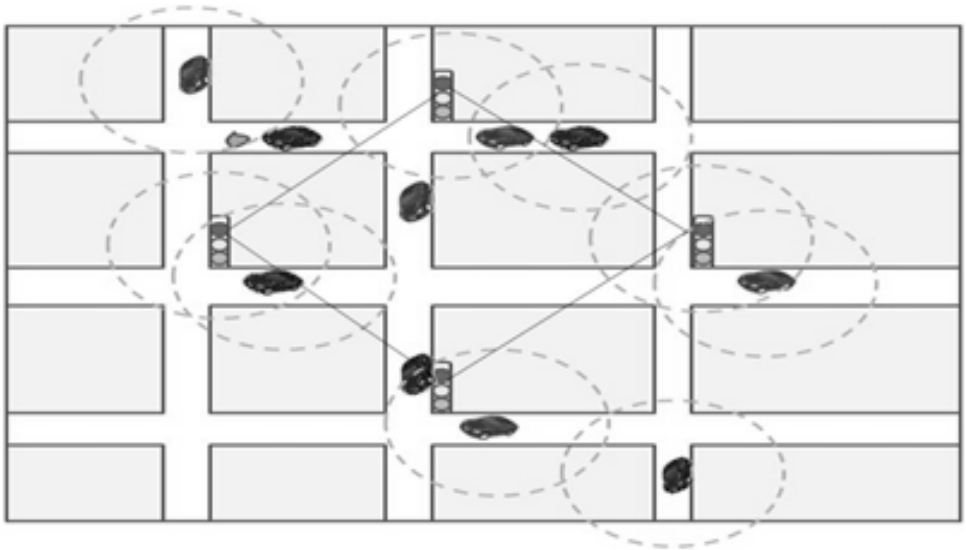


BACKGROUND

Self-organizing networks can be classified as follows:

- Mobile Ad hoc Networks (MANET). In this kind of network the nodes are mobile devices operating under energy consumption constraints.
- Wireless Mesh Networks (WMNs). The backbone of the network consists of mesh routers (which have reduced mobility) allowing the communications between mobile mesh clients. (Figure 1).
- Wireless Sensor Networks (WSNs). They are composed of a large number of sensor nodes widespread on a field; they are used for collecting information on the environment and transmitting such information to themselves or to a base station (Figure 2).
- Vehicular Ad Hoc Networks (VANETs). These networks use ad hoc communications for detecting obstacles on the road and emergency events by exchanging information obtained from the roadside or from other vehicles (Figure 3).

A common feature of these networks is the mobility of nodes; furthermore, there exists not always a relaying structure. These facts evidence the need for including within

the network management systems, strategies for maintaining communication between nodes despite the mobility.

In next section, several approaches for solving this problem are presented. Although there are some issues not addressed yet, this overview may be aware to the reader about the state of art in this area.

SELF-ORGANIZATION IN AD-HOC NETWORKS

An ad-hoc network may be structured in three ways: flat topology, hierarchical topology, and hybrid topology (Dressler, 2006; Tang & Tienfield, 2006). Hierarchical topology is the most widely used because it is scalable, allowing for efficient routing protocols for large networks; furthermore, it has well stated battery consumption schemas. The hybrid topology is suitable for combining ad hoc networks with existing network infrastructures.

Self-organization algorithms applied to networks can be classified as cluster-based, role-based, location information-aided, biological inspired, and economically inspired (Dressler, 2006; Tang & Tienfield, 2006). Cluster-based self-organization algorithms have received more attention, because they intend to provide efficient ways for creating and maintaining organization of nodes according to a hierarchical topology.

Cluster-based self-organizing algorithms

Several approaches have been proposed to self-organize nodes of an ad-hoc network in a cluster-based fashion. The work presented in Basagni (1999a) models the network as a graph G = (V, E) where V is the set of nodes and E is the set of links that exists between two communicating nodes. Every node is classed as either ordinary or clusterhead; it has an identifier and a weight w which depends on the characteristics of the node.

The key properties of the clusters formed by the algorithm are the following:

- Every ordinary node has at least a neighboring clusterhead (dominance property).
- Every ordinary node affiliates with the neighboring clusterhead which has the bigger weight.
- Two clusterheads cannot be neighbors (independence property).

The main idea of the algorithm is based on the ability of a given node for deciding its role that it has to play only when all its neighbors have decided their own roles. The algorithm is executed in every node with the sole knowledge of its ID, weight, and neighbors' ID. In order to accomplish the task, two procedures are considered: On Receiving_Clusterhead, which is executed when a node receives a Clusterhead message from other node, and the On Receive JOIN procedure, which is executed by the node that has received a JOIN message from a neighbor.

The disadvantage of the proposed approach is that the stability of the network is affected by a high mobility in the network, mainly in clusterheads. In order to avoid this problem a new approach is proposed (Basagni, 1999b) where the properties of the clusters are modified as follows:

- Every ordinary node affiliates with one and only one clusterhead.
- For every ordinary node, there is no clusterhead in the neighborhood of the node such that its weight is bigger than the clusterhead of the node, plus a threshold h.
- A clusterhead cannot have more than k neighboring clusterheads.

The modifications implemented in this work preserve the network topology, even though new clusterheads move into a cluster with a clusterhead assigned. When the new clusterhead weight is lower than the current clusterhead weight, plus a given threshold, it changes its role to ordinary node.

In Blazevic, Buttyan, Capkun, Giordano, Hubaux, and Le Boudec (2001), routing algorithms, positioning methods, mobility management, and algorithms including incentives for cooperation are proposed for designing a self-organized mobile ad-hoc network.

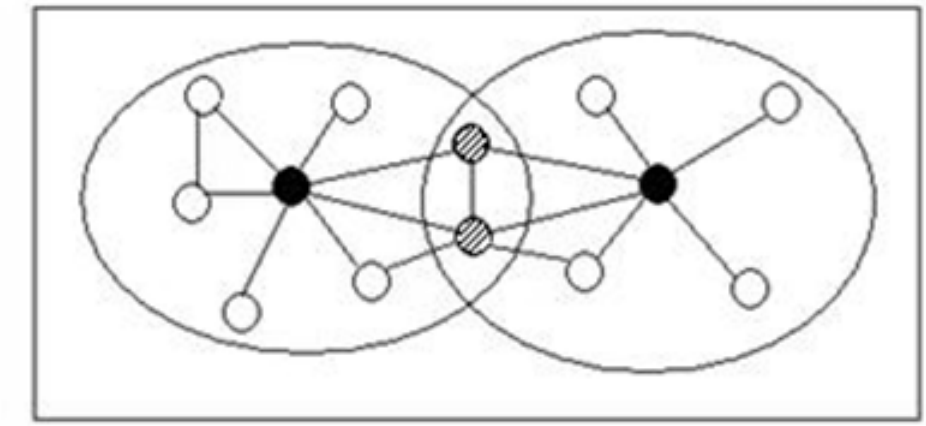
In order to accomplish the packet forwarding, two routing algorithms are proposed. Terminode Local Routing (TLR) allows reaching nodes located a limited number of hops away. Terminode Remote Routing (TRR) allows sending data to nonreachable nodes using the TLR algorithm. A Terminode attempts to maintain several paths for every destination. Several paths can be used by a terminode at the same time.

When the nodes are located in different geographical areas the packets are sent first to anchors, which are points specified by cartesian coordinates. The source nodes compute the anchors by using path discovery methods.

In this approach the mobility management is achieved by defining virtual home regions (VHR), where every node advertises its current position. The VHR has a fixed center and a variable radius, which adapts according to the density of the area, for maintaining a constant number of nodes.

However, in a network with resources constraints, every node will try to reduce the resource consumption; this behavior reduces the performance of the overall network. In order to avoid this situation an algorithm including incentive for cooperation has been proposed, where a nuglet is used as currency, then every time a node is used to forward a packet, it receives nuglets in return. When a node needs to send a packet it pays some nuglets for the service.

Figure 4. Black nodes represent the clusterheads, and dashed nodes represent the nodes acting as connection between clusters



Other works have proposed to organize the network nodes according to the preferences of the users, as in Herrmann and Geihs (2003), where a socio-aware approach is proposed. The goal of a socio-aware system is clustering users according to their common interest. The clusters are formed by nodes with the same preferences; different clusters are joined by nodes with shared preferences. An organized cluster is showed in Figure 4.

An important problem to solve in these networks is service allocation; it is necessary to find the nodes that have the highest number of interactions with other nodes, which could be good candidates for running services. Services should be placed in these nodes to facilitate the access to as many members as possible.

In the works mentioned above, the way to decide which node is a clusterhead depends on the weight of the node, which is obtained according to their characteristics; however, sometimes this is not enough for maintaining the topology in long time periods. In Mitton and Fleury (2003), a new metric called density is proposed. The k-density of a node is defined as the ratio of the number of edges between the node and its k-neighbors (the degree of the node), the number of edges between the k-neighbors of the node, and the number of nodes inside the k-neighborhood of the node.

To form the cluster and select the clusterhead, each node computes its k-density and broadcast it to all its k-neighbors. The node with the bigger value is the winner, and it is elected as a clusterhead; once the clusterhead is elected, its ID and its density is broadcasted by all nodes which have joined this cluster. The clusterheads will be distant at least three hops between them.

The cluster organization has to adapt to topology changes caused by the node's mobility. In order to accomplish the adaptation, the nodes have to check periodically their environment and their mobility. When a node becomes too mobile it will not join any cluster; but if the node is able to communicate, it joins to its neighbor that has the highest density.

The approach proposed above allows constructing a robust topology, which is not affected by nodes that become too mobile; however, the nodes defined as clusterheads will consume their energy faster than the ordinary nodes, because they have to forward packets coming from many nodes. For this reason it is necessary to establish a balance between energy consumption, and the number of nodes that belong to a cluster.

In Sivavakeesar, Pavlou, and Liotta (2004), the concept of virtual clusters is introduced, which facilitates the formation of stable clusters. A virtual cluster is a circular region that represents a geographical area in such a way that every node can determine the virtual region it is in. Every virtual cluster has a unique identifier based on the geographic location.

In order to maintain the topology of the network, it is necessary to construct models that allow adapting the topology based on the node mobility. In this approach an intelligent mobility prediction is proposed. It is accomplished by deriving probabilistic prediction of particular user mobility, by using its accumulated movement-history.

The movement-history is represented by a mobility tree constructed using the LZ78 algorithm (Bhattacharya & Das Sajal, 1999). The probability of a node arriving to a given virtual cluster is obtained by applying a second order Markov model. The algorithm proposed in this work predicts the availability of the nodes giving the possibility to provide QoS applications; however, it is necessary to consider energy constraints to avoid the waste of network resources in a disproportionate way.

The mobility management has been studied also in Bluetooth ad-hoc networks; in Song, Chaegwon, and Choi (2004), the scatternet topology management is dealt along with packet routing. In order to obtain a robust scatternet topology, is necessary to configure the structure for having

sufficient bridges to forward the packets. But if a bridge participates in many piconets, it could cause the decreasing of the network performance; so it is necessary to limit the degree of a bridge.

The steps followed for every node to form a scatternet are given below:

- Start the inquiry procedure.
- Establish a temporary connection.
- Examine the collected information.
- If there is a master, join the master's piconet as a slave through a master/slave role change.
- When there are several masters, become a slave/slave bridge that links the masters.
- If all nodes are slaves, make its own piconet by acting as a master.
- If it cannot find nearby nodes, repeat process.

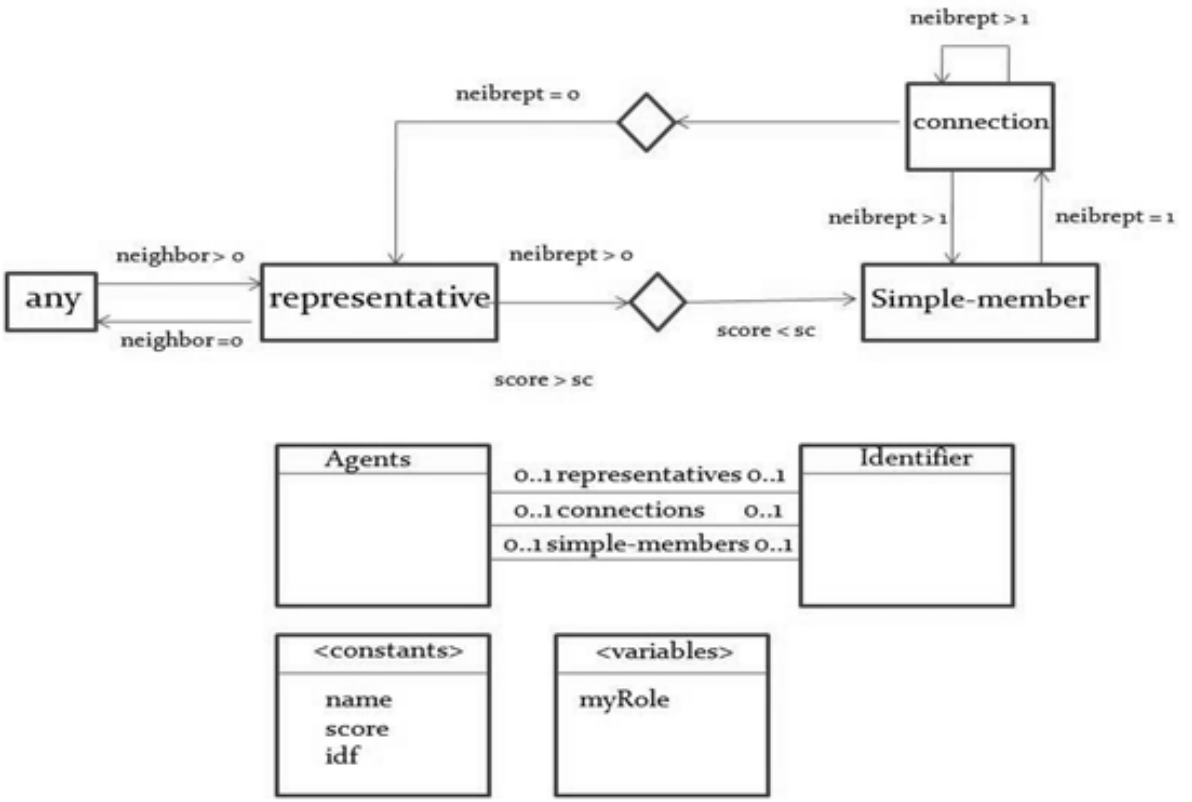
Every master in the network maintains three tables for routing the packets; when a bridge is created, this bridge node sends to each master an APT (Adjacent Piconet Table) update message. A master renews its PMT (Piconet Member Table) when it gets a PMT update message. When the PMT update message contains information about an unknown piconet, the master creates a new entry for this piconet in its PMT. The master also rebuilds its PRT (Piconet Routing Table), using the information contained in the updated PMT.

This approach forms a robust scatternet; however, in scenarios with high mobility, the network partition is increased.

According to the increase in mobile devices and wireless technology advances, new applications try to be implemented in wireless networks. As an example, in Wellnitz and Wolf (2006), an algorithm to support multiplayer games in wireless ad-hoc networks is proposed. The approach implements a server selection algorithm using three phases, discovery, determination, and marking.

In the discovery phase, every node determines its weight and degree, and broadcast them periodically. During the determination phase, the games servers are determined based on the highest weight among all neighboring nodes. Finally, in the marking phase, every node which has been determined as a game server tags itself as a server; the nodes who are neighbors of a server tag themselves as neighbors, and the nodes which are not servers or neighbors keep an empty tag.

Figure 5.Modeling self-organization algorithm with AUML



Nodes mobility and environment changes are dealt by a four phase process, where each node monitors changes during the game. When a node gets three or more hops away from a server, it initiates a new discovery phase. If there are no servers near, it starts a new server determination process.

The problem in game applications resides on the fact that the game state has to be stored by every server, so when a server is going to leave the network, it is necessary to move the information into the new server; if the network has high mobility or there is not a stable structure, the network performance is affected considerably.

Several works have tried to formalize and validate the self-organizing ad-hoc networks for proving properties' desirables in a network. In the next section we are going to present the main approaches.

Formalizing Self-organization in Ad-hoc Networks

In Fadil, Koning, Ramos, Jamont, and Occelo (2006), a graphical design technique for achieving cluster-based self-organization is proposed. In this approach, three roles are considered in the network structure. The representative node acts as a clusterhead, the node which can communicate with more than one representative play the role of connection, and the rest of nodes are simple members.

The assignment of a representative role is based on the weight of the node; the node with the bigger weight becomes a representative; if there is another node with the same weight, the identifier id is used to solve the conflict. This algorithm is modeled using first AUML, shown in Figure 5, and then translated into B language to prove safety and liveness properties. Two algorithms are proposed for detecting and resolve conflicts in role assignments for every node.

In Oleshchuk (2003), the network is modeled as a directed graph that may change dynamically; in the graph the set of vertices represent the nodes, and the set of edges represent the arcs between nodes which can communicate directly.

In this work two assumptions are made:

- The nodes are mobiles, not trusted, and have a unique id.
- The communication links are bidirectional and not trusted.

Every node is described as a process in Promela, and the properties that will be proven are described in Linear Temporal Logic (LTL). Such properties can be seen as part of requirement specification.

With this descriptions, the model checker SPIN (Holzmann,1997) can be used for proving the network properties described in LTL, and the network is modeled by processes in Promela. The LTL formulas and the processes are translated into a Büchi automaton by the model checker; then, an intersection of the two automata is obtained, and an acceptance cycle is searched.

The disadvantage of creating automatons is the state explosion; however, new techniques for reducing the space needed to store information have been implemented, increasing the possibility of solving more problems.

Another approach proposed in Johnen and Nguven (2006), give a self-stabilized version of the algorithms proposed in Basagni (1999a, 1999b), where the properties of the algorithms constitute attractors for the system, and it is proven that the self-stabilization is obtained in a finite time.

FUTURE TRENDS

There exist many issues which have to be addressed before the self-organized networks can be engineered, for example, how to ensure that the self-organized networks are secure, how to implement QoS policies in the network to be able of build multimedia networks, how to validate that the communication protocols are efficient, and how to prove that the self-organizing algorithms always converge to a stable state in an acceptable time. Bio-inspired self-organization algorithms are being used also in robot formation applications.

CONCLUSION

In this article, we reviewed the approaches proposed for accomplishing self-organization in wireless networks; we could see this is probably the main feature of future networks. The importance of self-organization due to computation cost, and for obtaining complex behaviors which are robust, scalable and adaptable, is clear. The approaches presented here give the line to continue addressing these issues.

Finally, we pointed out several issues to be addressed before self-organization can be engineered in wireless networks. In the next few years, the wireless networks in all the fashions presented in this article are going to be part of our daily life.

KEY TERMS

Mobile Devices: Computer-based communication devices that give us the possibility to be connected wherever we are at any time.

Self-Organization: Phenomenon in nature which allows the spontaneous appearing and maintaining of a functional structure (Tang & Tienfield, 2006).

Wireless Networks: Networks that do not need wires to allow the communication; instead they use wireless technologies as 802.11, WiFi, WiMax, Zigbi, and so forth.

Bio-Inspired Algorithms: Algorithms based on living beings' behaviors to accomplish a task efficiently.

Ad-Hoc Networks: Networks that do not need an infrastructure to allow the communication. The communication is established between devices using a wireless technology.

Cluster-Based Algorithms: These kinds of algorithms organize the nodes in clusters where a clusterhead is elected. The members of the cluster can communicate with nodes in other clusters through clusterhead.

QoS (Quality of Service): Set of technologies that provide a reliable data transmission ensuring data quality.

Self-Organization in Social Software for Learning

Jon Dron
Athabasca University, Canada

INTRODUCTION

The Internet has long been touted as an answer to the needs of adult learners, providing a wealth of resources and the means to communicate in many ways with many people. This promise has been rarely fulfilled and, when it is, often by mimicking traditional instructor-led processes of education.

As a large network, the Internet has characteristics that differentiate it from other learning environments, most notably due to its size: the sum of the value of a network increases as the square of the number of members (Kelly, 1998), even before aggregate effects are considered. Churchill (1943) said, "We shape our dwellings and afterwards our dwellings shape us." If this is true of buildings then it is even more so of the fluid and ever-changing virtual environments made possible by the Internet. Our dwellings are no longer fixed but may be molded by the people that inhabit them. This article discusses a range of approaches that make use of this affordance to provide environments that support groups of adult learners in their learning needs.

BACKGROUND

Darby (2003) identifies three generations of networked learning environments used in adult education. First-generation systems are direct analogues of traditional courses, simply translating existing structures and course materials. Like their traditionally delivered forebears, they are dependent on individual authors. Second-generation systems tend to be team-built and designed for the medium from pedagogical first principles, but still within a traditional course-based format. Third-generation systems break away from such course-led conventions and provide such things as just-in-time learning, guided paths through knowledge management systems, and personalized curricula. This article is concerned primarily with such third-generation environments.

Saba's interpretation of Moore's theory of transactional distance predicts that in an educational transaction, as structure increases, dialogue decreases and vice versa (Moore & Kearsley, 1996; Saba & Shearer, 1994). What is significant in differentiating learning experiences is not the *physical* distance between learners and teachers, but the *transactional* distance, measured by the degree of interaction between them. Highly structured educational activities have a high transactional distance, while those involving much discussion have a lower transactional distance.

In a traditional learning environment, the structure of the experience is provided by the teacher or the instructional designer. However, learners will not benefit equally from any given structure, as different learners learn differently. It would be better if learners could select appropriate approaches for their needs—to choose whether or not to choose, to control or to be controlled (Dron, 2007a). Without a teacher, help with this might be provided by the opinions of other learners. However, eliciting those opinions, assessing their reliability/relevance, actually finding the resources in the first place, and once found, fitting them into a structured learning experience is difficult. Several approaches to these problems are available, but first it is necessary to introduce a few concepts of self-organization.

SELF-ORGANIZING PROCESSES

Self-organization processes are emergent: the interactions of many autonomous agents lead to structure, not due to central control, but to the nature of the system itself. Such processes are very common in nature and in human social systems. Two in particular are of interest here, *evolution* and *stigmergy.*

Based primarily on work following that of Darwin (1872), evolution is one of the most powerful self-organizing principles, whereby a process of replication with variation combined with natural selection (survival of the fittest) leads to a finely balanced self-adjusting system. It is important to note that "fittest" does not mean "best" by any other measure than the ability to survive in a given environment.

Stigmergy, a form of indirect communication through signs left in the environment (Grassé, 1959), leads to self-organized behavior—examples range from ant trails and termite mounds to forest footpaths, money markets, and bank-runs. For example, ants wander randomly until they find food, after which they return to the nest, leaving a trail of pheromones. Other ants are more likely to wander where such pheromone trails mark the route. When they too find food,

they too leave a trail. The stronger the trail, the more other ants are drawn to it. This positive feedback loop continues until the food runs out, after which the trail evaporates.

A full discussion of the many factors that result in a successful self-organizing system is beyond the scope of this article. However, the following brief discussion should give a flavor of what is involved.

Self-organizing processes occur through local interactions. For systems to develop any sort of complexity, it is necessary for these interactions to occur at a number of scales. For instance, the interactions of bacteria in an ant's gut affect the ant, groups of ants can affect tree growth, tree growth can affect climate. Local interactions should form small clusters, which in turn interact with each other, leading to ever-increasing scales of self-organization. However, in general, the large and slow-moving affect the small and fast far more than vice versa, which is a common feature of self-organizing systems, from forests to cities (Brand, 1997). Parcellation is also an important feature of such systems (Calvin, 1997). As Darwin found in the Galapagos Islands, isolated populations tend to develop differently and more rapidly than their mainland counterparts. Any self-organizing system relies on interactions between more or less autonomous agents. The precise level of interactivity varies, but it is interesting to note that, for a system which teeters at the edge of chaos, neither too stable to change nor too changeable to develop, the average number of connections between interacting agents tends to stabilize around just over two (Kauffman, 1995). Systems must be capable of change, being in a more or less permanently unfinished state. Already perfect systems cannot evolve (Shirky, 1996). Equally, systems in perpetual flux can never achieve the stability to achieve self-organization.

SOCIAL SOFTWARE AND THE IMPORTANCE OF THE GROUP

Social software has been defined by Clay Shirky as that in which the group is a first-class object within the system (Allen, 2004). Early social systems such as discussion forums and mailing lists tended to provide a means of supporting individual interactions, with little consideration of the combinatorial effects of the behavior of the many. Typically, they scaled badly, suffering equally from too many as from too few users. In newer social software that underpins the hype-laden term 'Web 2.0', emergent patterns are capitalized upon and reified. For example, tag clouds provide a snapshot of aggregates of classifications by many individuals, social networking software provides structured webs that are generated from individual links between users, wikis gain their structure from individual decisions to link pages, and clusters of linked blogs give texture to the blogosphere. In all cases, the primary determinant of structure is the bottom-up, local behavior of the many. This means that (in general) social software gets better as more people use it.

Interactions within an e-learning environment have previously only considered agents such as the individual learner, the teacher, and the software with each other and with others of the same kind (Anderson, 2003). If the group is a distinct entity from the individuals of which it is composed, then there are more potential interactions to consider. In particular, the group may be seen as, in some ways, a potential teacher within the system (Dron, 2006a).

SOME EXAMPLES OF SELF-ORGANIZED LEARNING IN PRACTICE

For many knowledge-seekers, the starting point is often Google (*http://www.google.com*), perhaps the largest and most pre-eminent example of social software available today. Google's PageRank™ algorithm (Brin & Page, 2000) is based on the assumption that most Web pages provide links to other sites when those sites are considered in some way valuable. Implicitly, the more links that point to a given site, the higher its approval rating. Combined with a content-based search for keywords, documents returned therefore should have a high degree of relevance and reliability. This approach is self-organized, incorporating evolution as unlinked sites "die" and stigmergy as more-visited sites get more links pointing to them (Gregorio, 2003). It is social, not relying on a central controlling authority to provide decisions on resources' usefulness or give a structure to the content that is returned. However, limited parcellation, problems with term ambiguity, and the lack of a support for identifying relevant resources for specific learner needs beyond content-based searching make Google a relatively poor learning tool.

Social navigation, which explicitly capitalizes on stigmergy to enable the navigation or classification behavior of previous users to influence those who follow, is becoming almost ubiquitous on social sites. Tag clouds of the sort found on del.icio.us (*http://del.icio.us*), Flickr (*http://www.flickr.com*), or MySpace (*http://www.myspace.com*) emphasize popular tags by increasing the font size relative to those that are less popular and limiting the display to popular tags, providing a constantly changing map of a community's interests. Applied in an educational setting, such systems offer many benefits, but at the cost of many distractions, inappropriate content, and a breadth of focus that is as likely to discourage as to enthuse learners.

Wikis allow anyone, or sometimes a more closed community, to edit any page. The potential for chaos is enormous, and yet Wikipedia (*http://www.wikipedia.org*), an encyclopedia generated by thousands of volunteers with

little central authority, is hugely successful. At the time of writing, the English version of the site had well over a million articles. Soft-security (Cunningham, 2006) allows the wisdom of the crowd to override intentional or unintentional errors introduced by the individual: the fact that it is easier to undo changes than to make them, combined with a large community, leads to a highly reliable and comprehensive source of knowledge (Giles, 2005), which is widely used by learners as a means of tapping into collective expertise. Wikipedia's success is in part due to its strong structure and simple policies. Interestingly, it makes use of a meta-wikipedia where Wikipedians may discuss issues relating to articles to be posted. This scaled parcellation contributes greatly to the evolution of ideas.

Blogging communities form through links between blogs. These may occur inline, or through trackbacks (two-way hyperlinks between blog postings) or blogrolls (explicit lists of links to related sites), which together generate emergent webs of related blogs. As links between blogs grow, they start to form small, stigmergic clusters (Gregorio, 2003). As long as an appropriate cluster can be found, such networks provide a powerful means of finding structure in a subject. This may be facilitated through a recommender system or dedicated blog search tool such as Technorati (*http://www.technorati.com*), which itself uses social navigation in the form of tag clouds. Blogs usually offer interaction and can enable learners to discover and actively participate in relevant communities to help them to learn.

Collaborative filters are recommender systems that make use of implicit and/or explicit preferences to provide recommendations based on similarities between user models. Collaborative filters are very useful for matching users' preferences, but tend to be less successful when seeking learning resources, because to learn is to change. My previous preferences for particular resources will be a less reliable guide to my future needs than preferences for books, movies, or Web sites because the act of using a learning resource will (if successful) change me in ways that are likely to differ from how they have changed you. Nonetheless, systems such as Altered Vista (Recker, Walker, & Wiley, 2000) and RACOFI (Anderson et al., 2003) have achieved some success in this area.

Social networking sites, which are concerned with finding like-minded or otherwise related people, offer another means of structuring the environment from the bottom up. Sites such as MySpace, Orkut (*http://www.orkut.com*), Ecademy (*http://www.ecademy.com*), and FriendsReunited (*http://www.friendsreunited.co.uk*) are concerned with establishing webs of links between people. Again, no centralized controller determines the structure, which forms because of local links provided by individual users. When used to seek fellow learners or experts, such systems offer promising benefits for the learner.

EXPLICITLY EMERGENT LEARNING ENVIRONMENTS

Some social software explicitly exploits self-organizing principles for learning. The selection presented here is a relatively small subset that indicates how this area is developing.

An exception to the rule that collaborative filters cannot cope well with changing needs is CoFIND (Dron, Mitchell, & Boyne, 2003), which combines both evolutionary and stigmergic principles to provide both social navigation and collaborative filtering. Rather than simple good-bad ratings, it employs a multi-dimensional matrix of "qualities," which loosely translate into those things that learners find useful about a resource—for instance, if it is good for beginners, detailed, exciting, and so on. Because qualities are created by learners and used by other learners to provide explicit ratings, they provide a kind of footprint of the learning needs that led to a particular resource being recommended. This remains even after the learner has moved on. By basing its recommendations on an explicit metadata model, rather than a user model, it overcomes the problem of changing user needs that afflicts other collaborative filters. In keeping with evolutionary principles, not just the resources in the system but the metadata which describe them are in competition with each other. Combined with positive feedback loops generated by social navigation using stigmergy, this means that each CoFIND instance develops into a unique ecosystem composed of smaller, interacting ecosystems.

Elgg (*http://elgg.net*) is a powerful social networking system that enables learners to blog, podcast, share resources, and find other users with similar interests. Like many systems, it uses tags and stigmergic tag clouds to identify shared interests. With a focus on the educational sector, every resource, be it a file, a podcast, a blog entry, or a comment, offers fine-grained user control over the permissions to view or change it that are offered. It thus supports strong parcellation as communities can be as private or public as their members wish, while always providing weaker connections between clusters of interest. It has been used extensively around the world in educational settings (Anderson, 2006; Campbell, 2005; Dron, 2006b) as a means of breaking free of the strictures of more top-down learning management systems and of giving control to the end user.

Wiki-based systems for education are becoming increasingly sophisticated. For example, Sloep, van Rosmalen, Kester, Brouns, & Koper (2006) describe an application of latent semantic analysis to automatically generate wiki pages from a knowledge base in response to questions which may then be edited by humans to become more relevant, thus creating a hybrid combination of the strengths of automation with those of human experts. OurWeb (Miettinen, Kurhila, Nokelainen, & Tirri, 2005) overlays footprints and annotations on a wiki page, providing stigmergic social navigation

to structure a constantly evolving environment. Emergent patterns of use lend structure to temper the potential chaos of unconstrained wiki growth.

The Knowledge Sea II uses navigation behavior to identify resources of interest to a community of C programmers, using a combination of explicit and implicit ratings to generate a visualization resembling a sea, with greater depth of color representing greater levels of interest. Again, stigmergic self-organization develops through individual interactions with the system (Brusilovsky, Chavan, & Farzan, 2004).

EDUCO (Kurhila, Miettinen, Nokelainen, & Tirri, 2002) uses social navigation to provide not only visual indicators of the relative popularity of documents within the system, but also real-time indicators of who is currently viewing them. This is combined with a chat system that enables interactions between users, providing a powerful incentive to visit pages that are currently being viewed. A similar technique is employed in Dron's (2005, 2007b) Dwellings, which makes use of stigmergic self-organizing principles suggested by Jacobs (1961) in *The Death and Life of Great American Cities.*

The Comtella system uses peer-to-peer protocols to enable its users to share documents, and thence to find documents that others have found useful. Incorporating a ranking system partly inspired by self-organizing market mechanisms, Comtella is replete with emergent structure based on the aggregated behavior of individuals (Vassileva, 2004). Comtella is extensible and has spawned an interesting discussion forum that uses similar mechanisms to help find relevant people and postings (Webster & Vassileva, 2006).

FUTURE TRENDS

The tensions between bottom-up design and the top-down needs of educational institutions and organizations make it uncertain that, despite widespread use, self-organizing, social software will notably impact existing institutional education structures. The large and slow will always dominate the small and fast. Darby's third generation of learning environments already exists, but the majority of effort is still being expended on first- and (occasionally) second-generation systems. However, as the need for lifelong, just-in-time learning becomes ever more significant, it is certain that software combining the wisdom of crowds will have an important role to play in all walks of life.

With a trend towards meaningful metadata being appended to resources using tags or standards such as RDF (Resource Description Framework), the relevance of search results may be improved over the coming years. However, to turn such information into useful knowledge and learning, social software is needed that combines the knowledge of many people, effectively amplifying intelligence and operating in some senses as a kind of group mind. The massive growth in the use of social software and the technologies of Web 2.0 seems irrepressible, offering structure through dialogic processes, with many consequent benefits, enabling the learner to choose whether to be in control or to accept control by the emergent systems that arise (Dron, 2006a).

Interoperability is central: increasing use will be made of mashups, combinations of Web services, and RSS feeds that merge content from many sources (O'Reilly, 2005). Applications that are composed of constantly changing hosted services are quick to build and therefore easy to evolve as needs and communities change. This merging of parcellated populations offers many opportunities for cross-fertilization between systems and communities, as can be seen in sites such as Mappr (*http://www.mappr.com/*), The Daily Mashup (*http://dailymashup.com/*), or Doggdot (*http://doggdot.us/*). Evolutionary change in systems employing mashups occurs on a different scale from that of its individual components, potentially enabling richer and more complex structures to develop at more hierarchical layers. Exactly how this will be adopted in educational settings remains to be seen, but there are already some effective uses of the principle. Elgg, for example, integrates RSS feeds from other sites seamlessly into the local environment, allowing local, parcellated, evolutionary processes to transform the structure from another site into one that is more relevant to a given community's needs.

CONCLUSION

The World Wide Web is becoming ever-more dynamic. Because of social software, the generation of resources to learn from is moving away from rule-based machine- or human-governed information to a more symbiotic relationship, where the strengths of machines and the strengths of people are combined and, in the process, mutually enhanced. In the process, the high transactional distance of resource-based learning is reduced by glimpses of the footprints of others. In a world where roles are changing faster than the traditional course-based approaches to the delivery of learning can address, the resulting group mind can adapt itself more readily and effectively than any single person to the needs of individual learners.

KEY TERMS

Collaborative Filter: A form of recommender system that uses implicit or explicit recommendations of others to provide advice based on similarities between user models.

Emergent Behavior: Behavior that arises out of the interactions between parts of a system and which cannot easily be predicted or extrapolated from the behavior of those individual parts.

Latent Human Annotation (LHA): The unintentional communication of a recommendation or other information as a by-product of another process, for example the provision of hyperlinks in a Web page that are then used by search engines to provide rankings of the linked pages.

Recommender System: A computer program that recommends some sort of resource based on algorithms that rely on some sort of user model, some sort of content model, and some means of matching the two.

Social Navigation: The transformation of an interface (usually Web based) by using the actions of visitors.

Social Software: Software in which the group is a distinct entity within the system.

Stigmergy: A form of indirect communication whereby signs left in the environment influence the behavior of others who follow.

Transactional Distance: A measure of the relative amounts of dialogue and structure in an educational activity. Of necessity, as one increases, the other decreases and vice versa. More autonomous learners require less dialogue than more dependent learners.

INTRODUCTION

Access to video content, either amateur or professional, is nowadays a key element in business environments, as well as everyday practice for individuals all over the world. The widespread availability of inexpensive video capturing devices, the significant proliferation of broadband Internet connections and the development of innovative video sharing services over the World Wide Web have contributed the most to the establishment of digital video as a necessary part of our lives. However, these developments have also inevitably resulted in a tremendous increase in the amount of video material created every day. This presents new possibilities for businesses and individuals alike. Business opportunities in particular include the development of applications for semantics-based retrieval of video content from the Internet, video stock agencies or personal collections; semantics-aware delivery of video content in desktop and mobile devices; and semantics-based video coding and transmission. Evidently, the above opportunities also reflect to the video manipulation possibilities offered to individual users. Besides opportunities, though, the abundance of digital video content also presents new and important technological challenges, which are crucial for the further development of the aforementioned innovative services.

The cornerstone of the efficient manipulation of video material is the understanding of its underlying semantics, a goal that has long been identified as the "Holy grail of content-based media analysis research" (Chang, 2002). Efforts to understand the semantics of video content typically build on algorithms that operate at the signal level, such as temporal and spatiotemporal video segmentation algorithms that aim at partitioning a video stream into semantically meaningful parts. To support the goal of semantic analysis, these signal-level algorithms are augmented with a priori knowledge regarding the different semantic objects and events of interest that may appear in the video and their signal-level properties. The introduction of a priori knowledge serves the purpose of facilitating the detection and exploitation of the hidden associations between the signal and semantic levels, resulting in the generation of semantically meaningful metadata for the video content.

In this article, existing state-of-the-art semantic video analysis and understanding techniques are reviewed, including a hybrid approach to semantic video analysis that is outlined in some more detail, and the future trends in this research area are identified. The literature presentation starts in the following section with signal level algorithms for processing video content, a necessary prerequisite for the subsequent application of knowledge-based techniques.

BACKGROUND

Segmentation is in general the process of partitioning a piece of information into meaningful elementary parts termed segments. Considering video, the term segmentation is used to describe a range of different processes for partitioning the video into meaningful parts at different granularities (Salembier & Marques, 1999). Segmentation of video can thus be temporal, aiming to break down the video to scenes or shots, spatial, addressing the problem of independently

segmenting each video frame to arbitrarily shaped regions, or spatio-temporal, extending the previous case to the generation of temporal sequences of arbitrarily shaped spatial regions. The term segmentation is also frequently used to describe foreground/background separation in video, which can be seen as a special case of spatio-temporal segmentation. In any case, the application of any segmentation method is often preceded by a simplification step for discarding unnecessary information (e.g., low-pass filtering) and a feature extraction step for modifying or estimating features not readily available in the visual medium (e.g., texture, motion features , etc., but also color features in a different color space, etc.).

Temporal Video Segmentation

Temporal video segmentation aims to partition the video to elementary image sequences termed shots. A shot is defined as a set of consecutive frames taken without interruption by a single camera. A scene, on the other hand, is usually defined as the basic story-telling unit of the video, that is, as a temporal segment that is elementary in terms of semantic content and may consist of one or more shots.

Temporal segmentation to shots is performed by detecting the transition from one shot to the next. Transitions between shots, which are effects generated at the video editing stage, may be abrupt or gradual, the former being detectible by examining two consecutive frames, the latter spanning more than two frames and being usually more difficult to detect, depending among others on the actual transition type (e.g., fade, dissolve, wipe, etc.). Temporal segmentation to shots in uncompressed video is often performed by means of pair-wise pixel comparisons between successive or distant frames or by comparing the color histograms corresponding to different frames. Methods for histogram comparison include the comparison of absolute differences between corresponding bins and histogram intersection (Gargi, Kasturi, & Strayer, 2000). Other approaches to temporal segmentation include block-wise comparisons, where the statistics of corresponding blocks in different frames are compared and the number of "changed" blocks is evaluated by means of thresholding, edge-based and motion-based methods.

Other recent efforts on shot detection have focused on avoiding the prior decompression of the video stream, resulting to significant gains in terms of efficiency. Such methods consider mostly MPEG video, but also other compression schemes such as wavelet-based ones. These exploit compression-specific cues such as macroblock-type ratios to detect points in the 1D decision space where temporal redundancy, which is inherent in video and greatly exploited by compression schemes, is reduced. Regardless of whether the temporal segmentation is applied to raw or compressed video, it is often accompanied by a procedure for selecting one or more representative key-frames of the shot; this can be as simple as selecting by default the first or median frame of the shot or can be more elaborate, as for example in Liu and Fan (2005), where a combined key-frame extraction and object segmentation approach is proposed.

Spatial and Spatio-Temporal Segmentation

Several approaches have been proposed for spatial and spatio-temporal video segmentation (i.e., segmentation in a 2D and 3D decision space, respectively), both unsupervised and supervised. The latter require human interaction for defining the number of objects present in the sequence, for estimating an initial contour of the objects to be tracked or for grouping homogeneous regions to semantic objects, while the former require no such interaction. In both types of approaches, it is typically assumed that spatial or spatio-temporal segmentation is preceded by temporal segmentation to shots and possibly the extraction of one or more key-frames, as discussed in the previous section.

Segmentation methods for 2D images may be divided primarily into region-based and boundary-based methods. Region-based approaches rely on the homogeneity of spatially localized features such as intensity, texture, and position. They include among others the K-means algorithm and evolved variants of it, such as K-Means-with-Connectivity-Constraint (Mezaris, Kompatsiaris, & Strintzis, 2004a), the Expectation-Maximization (EM) algorithm (Carson, Belongie, Greenspan, & Malik, 2002), and Normalized Cut, which treats image segmentation as a graph partitioning problem (Shi & Malik, 2000). Boundary-based approaches, on the other hand, use primarily gradient information to locate object boundaries. They include methods such as anisotropic diffusion, which can be seen as a robust procedure for estimating a piecewise smooth image from a noisy input image (Perona & Malik, 1990). Additional techniques for spatial segmentation include mathematical morphology methods, in particular the watershed algorithm, and global energy minimization schemes, also known as snakes or active contour models.

Regarding spatio-temporal segmentation approaches, some of them rely on initially applying spatial segmentation to each frame independently. Spatio-temporal objects are subsequently formed by associating the spatial regions formed in successive frames using their low-level features (Deng & Manjunath, 2001). A different approach is to use motion information to perform motion projection, that is, to estimate the position of a region at a future frame, based on its current position and its estimated motion features. In this case, a spatial segmentation method need only be applied to the first frame of the sequence, whereas in subsequent frames only refinement of the motion projection result is required (Tsai, Lai, Hunga, & Shih, 2005). A similar approach is followed in Mezaris, Kompatsiaris, and Strintzis (2004b), where the need for motion projection is substituted by a Bayes-based approach to color-homogeneous region-tracking

using color information, and the resulting spatio-temporal regions are eventually clustered to different objects using their long-term motion trajectories.

Alternatively to the above techniques, one could restrict the problem of video segmentation to foreground/background separation. In Chien, Huang, Hsieh, Ma, and Chen (2004), a fast moving object segmentation algorithm is developed, based upon change detection and background registration techniques; this algorithm also incorporates a shadow cancellation technique for dealing with light changing and shadow effects.

Finally, as in temporal segmentation, the spatio-temporal segmentation of compressed video has recently attracted considerable attention. Algorithms of this category generally employ coarse motion and color information that can be extracted from the video stream without full decompression, such as macroblock motion vectors and DC coefficients of DCT-coded image blocks (Mezaris, Kompatsiaris, Boulgouris, & Strintzis, 2004).

SEMANTIC VIDEO ANALYSIS AND UNDERSTANDING TECHNIQUES

The result of pure segmentation techniques, though conveying some semantics, such as the complexity of the key-frame or video, measured by the number of generated regions, or the existence of moving objects in the shot, is still far from revealing the complete semantic content of the video. To alleviate this problem, the introduction of prior knowledge to the segmentation procedure, leading to the development of domain-specific knowledge-assisted analysis techniques, has been proposed.

Prior knowledge for a domain (e.g., F1 racing) typically includes the important objects that can be found in any given image or frame belonging to this domain (e.g., car, road, grass, sand, etc.), their characteristics (e.g., corresponding color models) and any relations between them. Given this knowledge, there exists the well-posed problem of deciding, for each pixel, whether it belongs to any of the defined objects (and if so, to which one) or to none of them.

Depending on the adopted knowledge acquisition and representation process, two types of approaches can be identified in the relevant literature: implicit, realized by machine learning methods, and explicit, realized by model-based approaches. The usage of machine learning techniques has proven to be a robust methodology for discovering complex relationships and interdependencies between numerical image data and the perceptually higher-level concepts. Moreover, these elegantly handle problems of high dimensionality. Among the most commonly adopted machine learning techniques are Neural Networks (NNs), Hidden Markov Models (HMMs), Bayesian Networks (BNs), Support Vector Machines (SVMs) and Genetic Algorithms (GAs) (Assfalg, Berlini, Del Bimbo, Nunziat, & Pala, 2005; Zhang, Lin, & Zhang, 2001). On the other hand, model-based video analysis approaches make use of prior knowledge in the form of explicitly defined facts, models and rules, that is, they provide a coherent semantic domain model to support "visual" inference in the specified context (Hollink, Little, & Hunter, 2005).

Knowledge Representation and Ontologies

Ontology, being a formal specification of a shared conceptualization (Gruber, 1993), provides by definition the formal framework required for exchanging interoperable knowledge components. By making semantics explicit to machines, ontologies enable automatic inference support, thus allowing users, agents, and applications to communicate and negotiate over the meaning of information. Typically, an ontology identifies classes of objects that are important for the examined subject area (domain) under a specific viewpoint and organizes these classes in a taxonomic (i.e., subclass/super-class) hierarchy. Each such class is characterized by properties that all elements (instances) in that class share. Important relations between classes or instances of the classes are also part of the ontology. Consequently, ontologies can be suitable for expressing multimedia content semantics so that automatic semantic analysis and further processing of the extracted semantic descriptions is allowed (Hollink et al., 2005). In (Dasiopoulou, Mezaris, Papastathis, Kompatsiaris, & Strintzis, 2005), an ontology was developed for representing the knowledge components that need to be explicitly defined for video analysis. More specifically, domain knowledge is combined with object low-level features and spatial descriptions realizing an ontology- aided video analysis framework. To accomplish this, F-logic rules (Angele & Lausen, 2004) are used to relate the extraction of the semantic concepts, the execution order of the necessary multimedia processing algorithms and the low-level features associated with each semantic concept, thus integrating knowledge and intelligence in the analysis process. The overall system thus consists of a knowledge base, an inference engine, the algorithm repository containing the necessary multimedia analysis tools and the system main processing module, which performs the analysis task, using the appropriate sets of tools and multimedia features, for the semantic multimedia description extraction.

Semantic Video Analysis Approaches

Few semantic video (or, visual content in general) analysis approaches have been presented so far in the literature. Starting with image analysis, a knowledge-guided segmentation and labeling approach for still images is presented in Zhang,

Hall and Goldgof (2002), where an unsupervised fuzzy C-means clustering algorithm along with basic image processing techniques are used under the guidance of a knowledge base. The latter is constructed by automatically processing a set of ground-truth images to extract cluster-labeling rules.

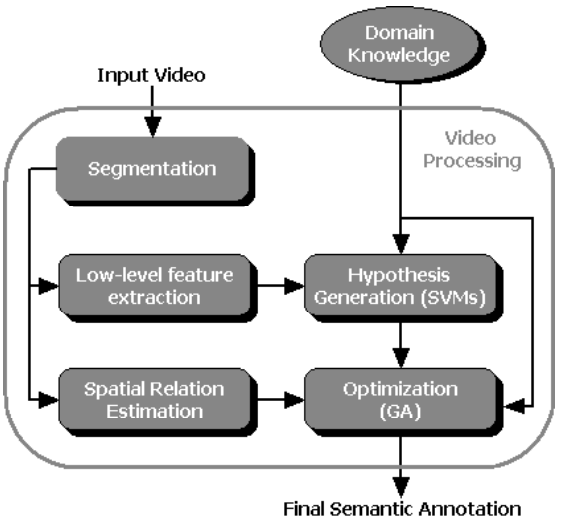
In Naphade, Kozintsev and Huang (2002), the understanding of the semantics of the video content for the purpose of indexing and in particular the association of low-level representations and high-level semantics is formulated as a probabilistic pattern recognition problem and is addressed with the introduction of a factor graph framework. Another approach to video semantic object detection is presented in Tsechpenakis, Akrivas, Andreou, Stamou and Kollias (2002), where semantic entities in the context of the MPEG-7 standard are defined; moving regions are extracted at the signal level by an active contour technique and then their low-level features are matched against those assigned to the previously defined semantic entities, resulting in the identification of associations between the latter and the video segments corresponding to moving objects. In Dasiopoulou et al. (2005), domain knowledge is combined with object low-level features and spatial descriptions realizing an ontology-aided video analysis framework, as described in the previous section. This approach is extended in Voisine et al. (2005), where a genetic algorithm is applied to the atom regions initially generated via simple segmentation in order to find the optimal scene interpretation according to the domain conceptualization. With respect to event detection, existing approaches include among others Sadlier and O'Connor (2005), where a framework for event detection in broadcast video of multiple different field sports is developed, based on robust detectors.

A Hybrid Approach to Semantic Video Analysis

In this section, an example of a semantic video analysis approach that combines two types of machine learning algorithms, namely SVMs and GAs, with explicitly defined domain-specific knowledge in the form of an ontology, is discussed Papadopoulos, Panagi, Dasiopoulou, Mezaris, and Kompatsiaris (2006). SVMs are used for acquiring the implicit knowledge that is required for the analysis process. Additionally, an ontology is developed for representing the knowledge components that need to be explicitly defined, that is, the semantic objects of interest for the selected domain, as well as their spatial relations. The latter appear in the form of fuzzy directional relations, which are used for denoting the relative positions of the depicted real-world objects. The GA is employed for exploiting the aforementioned spatial-related contextual information and deciding upon the final image semantic interpretation.

According to this approach, the video sequence is initially segmented into shots (temporal segmentation) and key-frames are extracted. Then, for every resulting key-frame, spatial segmentation is performed and, subsequently, low-level visual features and fuzzy directional relations are estimated at the region level. Region low-level visual features include the Scalable Color, Homogeneous Texture, Region Shape and Edge Histogram standardized MPEG-7 descriptors. Following the extraction of low-level visual features, SVMs employ them for performing an initial mapping between the image regions and the domain objects in the developed ontology (i.e., generating an initial hypothesis set for every image region). Finally, after the application of SVMs to each region independently, a GA is used to optimize the region-object mapping over the entire image, taking into account the region fuzzy directional relations and the corresponding spatial-related contextual knowledge that is stored in the ontology. This architecture is schematically presented in Figure 1. Application of the proposed approach to video frames of the specified domain results in the generation of fine granularity semantic annotations, that is, segmentation maps with semantic labels attached to each segment. A sample analysis outcome of this hybrid approach is illustrated in Figure 2.

Figure 1. Outline of hybrid semantic video analysis approach



FUTURE TRENDS

In the future, efforts will continue to concentrate on two different subfields of semantic video analysis and understanding: (a) the low-level analysis aiming at effectively decomposing the signal into semantically meaningful entities or parts thereof, without concentrating on understanding

Figure 2. Sample analysis outcome of a hybrid approach to semantic video analysis

Original Frame

Semantic Annotations

the actual semantics of them, and (b) the efficient use of knowledge, including the resolution of issues regarding the efficient acquisition, formulation and representation of it, for understanding the semantics of the signal parts formed after the application of a low-level analysis method. Of particular attention will most certainly be the closer interaction between the two aforementioned subfields: low level image analysis can benefit from the use of some form of knowledge about the content, though this may have to be represented in, for example, the form of a probability distribution (Freedman & Zhang, 2004), and thus may be different in nature from the knowledge used for understanding the semantics of already formed parts of the visual medium. Similarly, the latter task will most probably require the extension of existing knowledge representation formalisms, which were originally designed for tasks far different from the semantic analysis of video or multimedia content in general, so as to address the needs of analysis and provide support for improved reasoning based on the output of the latter.

CONCLUSION

In this article, semantic video analysis and understanding was discussed, starting with a literature review of the elementary task of video segmentation, which constitutes the first necessary step for the analysis and understanding of video content. Following that, the article focused on techniques that go beyond traditional segmentation to incorporate prior knowledge in the analysis procedure, so as to extract a high-level representation of the video content comprising semantic class memberships and recognized video objects. The dominant types of approaches presented in the literature for accommodating this task were identified and a hybrid approach combining machine learning algorithms with explicitly defined knowledge in the form of an ontology was presented in more detail. The future trends identified in the relevant section provide insights on how the algorithms outlined or presented in more detail in this article can be further evolved, so as to more efficiently address the problem of semantic video analysis and understanding and consequently pave the way for the development of innovative video applications.

KEY TERMS

Compressed Video Segmentation: Segmentation of video without its prior decompression.

Knowledge-Assisted Analysis: Analysis techniques making use of prior knowledge for the content being processed.

Machine Learning Techniques: Training-based techniques for discovering and representing implicit knowledge, such as complex relationships and interdependencies between numerical image data and perceptually higher-level concepts.

Ontology: Knowledge representation formalism, used for expressing explicit knowledge.

Semantic Video Analysis: Extraction of the semantics of the video, that is, detection and recognition of semantic objects and events.

Spatiotemporal Video Segmentation: Partition the video to elementary spatio-temporal objects, that is, sequences of temporally adjacent arbitrarily-shaped spatial regions.

Temporal Video Segmentation: Partition the video to elementary image sequences termed shots, defined as a set of consecutive frames taken without interruption by a single camera.

Semantic Web and E-Tourism

INTRODUCTION

Offering tourist services on the Internet has become a great business over the past few years. Heung (2003) revealed that approximately 30% of travelers use the Internet for reservation or purchase of travel products or services.

Classic sites of tourist agencies enable users to view and search for certain destinations and book and pay for vacation packages. At a higher level of sophistication are tourism Web portals, which integrate the offers of many tourist agencies and enable searching from one point on the Web. Still, when using this kind of systems one is forced to spend a lot of time analyzing Web content with destinations that match his/her wishes. This problem is identified by Hepp, Siorpaes and Bachlechner (2006) as the "needle in the haystack" problem.

Applying artificial intelligence (AI) techniques in E-tourism could help resolve this problem by providing:

1. Data that are semantically enriched, structured, and thus represented in a machine readable form;
2. Easy integration of tourist sources from different applications;
3. Personalization of sites: the content can be created according to the user profile;
4. Improved system interactivity.

As an example of using AI in e-tourism, we present *Travel Guides*—a prototype system that offers tourists complete information about numerous destinations. They can search destinations by using several criteria (e.g., accommodation type, food service, budget, activities during vacation, and user interests: sports, shopping, clubbing, art, museum, monuments, etc.). He/She can also read about the weather forecast and events in the destination.

In a way, Travel Guides complements traditional information systems of tourist agencies. These systems require a lot of maintenance effort in order to keep the huge amount of data about tourist destinations up-to-date.

Travel Guides is created to minimize the user's input and his/her need to filter information. It shows how usage of semantically enriched data in a machine readable form can

- Increase interoperability in the area of tourism,
- Decrease maintenance efforts of tourist agents, and
- Offer tourists a better service.

Nowadays, there are just a few e-tourism systems that use AI techniques. We briefly discuss them in the next section. In this article, we explain why it would be good to use such techniques and how Travel Guides does it. Specifically, using Semantic Web technologies in the area of tourism can improve already existing systems (which are mostly available online) that do not use Semantic Web techniques yet. Likewise, the Semantic Web approach can help decrease the maintenance efforts required for existing e-tourism systems and ease the process of searching for vacation packages.

Travel Guides was initially developed as a large-scale expert system. Over time, it has evolved into a modern Semantic Web application.

BACKGROUND

According to Aichholzer, Spitzenberger and Winkler (2003), e-tourism comprises electronic services which include:

- Information services (e.g., destination, hotel information);
- Communication services (e.g., discussion forum);
- Transaction services (e.g., booking).

Transaction services are offered at many places on the Web, such as Expedia, Travelocity, and so forth. These Websites include some of the information services, but for complete details about certain destination (e.g., activities, climate, monuments, and events) one must search for other sources. Some Websites even help in planning the whole itinerary (e.g., HomeAndAbroad). Apparently, there is an "information gap" between these online services, and no interoperability. Semantic Web technologies can be used to overcome this problem and thus increase the quality of e-tourism.

Cunningham (2002) presents GATE (General Architecture for Text Engineering) as an infrastructure for developing and deploying software components that process human

language. It can annotate documents and recognize concepts such as: locations, persons, organizations and dates. GATE can annotate documents with respect to a particular ontology. Some of the recently built Knowledge Management Platforms, like KIM (Popov, Kiryakov, Ognyanoff, Manov, & Kirilov, 2004**),** use GATE for information extraction and retrieval.

Similar to other AI technologies, Semantic Web is not frequently used in real-time tourism applications. Integrating AI tools into mainstream applications can result in benefits to both sides (Djuric, Devedzic & Gasevic, 2007). Standard organizations like the Internet Engineering Task Force and the World Wide Web Consortium (W3C) are making major efforts at developing languages for sharing meaning (Shadbolt, Berners-Lee & Hall, 2006). Speaking at the WWW2006 conference in Edinburgh in May 2006, W3C director Tim Berners-Lee pointed out that Semantic Web has all the standards and technologies it needs to succeed and that it was time for Web developers and content producers to start using semantic languages in addition to HTML (Bennett, 2006).

Cardoso (2006a) addresses the lack of standards in the tourism domain: the prices for tourism activities are expressed in different currencies; the time units also do not follow the standards. He argues that use of Semantic Web and ontologies could overcome this problem. In Cardoso (2006b) he describes the ontology developed to achieve integration and interoperability through the use of a shared vocabulary and meanings for terms with respect to other terms in the area of tourism. His system creates vacation packages dynamically using previously annotated data in respect to the ontology. This is performed with a service that builds itinerary by combining user preferences with flights, car rentals, hotel, and activities in a single price. Similar to this, Jakkilinki, Georgievski and Sharda (2007) presents a tool for tour planning that is intelligent in the meaning that it generates travel plans by matching user preferences and available tourist offers from different travel agents in respect to the ontology which enables reasoning.

To use Semantic Web in e-tourism, two approaches could be applied. One is to make applications from scratch, based on the existing standards. The other one is to enrich already existing content with annotations based on ontology. The first approach is not cost-effective for tourist agencies. Although the second approach sounds more reasonable, it seems that there are not enough data in the domain of tourism on the Web. Hepp et al. (2006) made a research in this field using a sample of 100 accommodations in Austria. Their results showed that neither some of the hotels had their Web pages, nor the biggest Austrian portal for e-tourism (Tiscover) had any information about them. An additional problem they noticed was the incompleteness of the details such as the availability of the accommodation and the prices.

Many e-tourism portals store their data internally, and not on the Web. This means that even a perfect annotation of the Web content would not be sufficient enough; hence, it is limited to persistently published information (Hepp, 2006). To exceed this problem Stojanovic, Stojanovic and Volz (2002) developed a mapping mechanism for migrating relational database schemas into ontologies in order to form the conceptual backbone for metadata annotations which are automatically created from the database. A better approach would be to use Semantic Web services, for example, Web Service Modeling Ontology-WSMO (Roman et al., 2005) or OWL-based Web service ontology - OWL-S (Smith & Alesso, 2005).

Dell'erba, Fodor, Hopken, and Werthner (2005) present the Harmonize project that integrates Semantic Web technologies and merge tourist electronic markets using ontology as a mediator. Their ontology was taken over by the E-tourism Working Group (2004) at Digital Enterprise Research Institute (DERI). This group plans to develop an advanced e-tourism Semantic Web portal, which will connect the customers and virtual travel agents. This portal could be of importance to the travel industry in Austria, whereas for the rest of the world it could be an example of using Semantic Web technologies in a real business system.

In 2001, the industry tried to address the interoperability issue by forming a consortium called the Open Travel Alliance. OTA is producing XML specifications (schemas) for messages to be exchanged between the trading partners, for example, availability checking, booking, rental, reservation, query services, insurance, etc. The precondition for this improvement method to succeed is that each travel agent's application can produce and consume OTA-compliant messages.

Dogac et al. (2004) present the SATINE project as a peer-to-peer network that enables peers to deploy their semantically-enriched travel Web services and allows others to discover these services semantically.

In addition to attempts to semantically enrich tourism sources on the Internet, it has been very popular to develop Location Based Tourism Systems (LBTS). LBTS are computerized systems that depend on an automated location of a target which either deliver or collect information. Currently, LBTS applications are being used by mobile phones, iPods, and PDAs (Hawking et al., 2005). LBTS provide search for hotels and ATM machines near by the user's current location and additional information when the user visits a city for the first time. An example of such a system is "Mobility Agent" (Edwards, Blythe, Scott & Weihong-Guo, 2006). This system delivers Internet-based travel and tourism-related services through fixed and mobile devices. Intelligent agent technology (Devedzic, 2003) was used to provide European visitors the dynamic, mobile, personalized, location-based information and services, especially related to travel in complex urban environments. Kanellopoulos

and Kotsiantis (2006, p. 86) predict that "in a collaborative travel environment, agents will be essential in addressing the issues of security, negotiation, personalisation and Web Service procurement."

TRAVEL GUIDES

Travel Guides is a Semantic Web portal in the area of tourism. Designed with the idea to gather all vacation packages from different tourist agencies, this system is built to help searching for a "perfect" vacation package. It is also personalized, so that its content is adapted to the user regarding his/her interests and activities. It is an example of using Semantic Web to increase the interoperability, provide better interaction, and intelligent reasoning in the domain of tourism.

Requirements for an E-Tourism Intelligent Portal

To make a tourism portal capable of intelligent reasoning, it is necessary to:

- Build some initial knowledge in the system,
- Introduce user profiles, and
- Maintain the knowledge automatically during the user's interaction with the system.

That way, the knowledge collected in a machine-readable form reduces the user's input and improves search.

In addition, the portal should be able to gather useful Web content and extract information of potential interest to the user.

In order to produce knowledge in a machine-readable form, it is necessary to develop and use a set of *ontologies* to represent all important concepts and their relations. Ontologies also enable knowledge sharing and reuse between applications, and development of intelligent Web services by using Semantic Web technologies and tools.

In case of search-intensive applications like tourism portals, ontologies bring up an important feature of *semantic search*. Unlike keyword-based syntactic search, ontology-supported semantic search returns better-quality information, because of the possibility to find the pages that contain semantically similar albeit possibly syntactically different text. A related concept is that of *semantic interoperability*. It is best understood by contrasting it to syntactic interoperability: syntactic interoperability is about parsing the data, while semantic interoperability means using ontologies to define mappings between data and known concepts. For example, a tourist agency may use the term "day trip" on its Web site, whereas another one may use "1-day excursion." Ontology from the domain of tourism may be used to make the equivalence mapping between the two terms, thus enabling the portal to treat the related pieces of information equally.

User Profiles

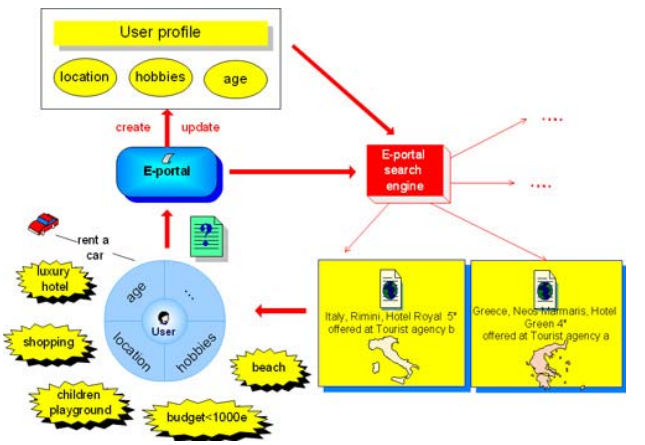
Personalization implies adapting content to a particular user and enhances the interactivity of the system. User profiles are based on the data that the system has about the user. These data are provided in two ways:

1. The user is willing to fill the forms where he/she inputs data about him/herself: gender, birth date, social data, address, profession, education, languages, interests and activities, budget, or visited destinations (cities, countries).
2. The system collects data about the user's interests and preferences while the user is visiting the portal and reading about or searching for vacation packages. Each time the user clicks on some of the vacation package details, the system stores his/her action in a database.

With the user profile, the system can adapt its look-and-feel and, more importantly, its content to the user. For example, the results of search for a destination (based on the requested criteria) can be additionally filtered according to the user profile, Figure 1. Each destination is identified by its latitude and longitude. When the system is aware of the user's location, the search results could be sorted by destinations that are physically closer to the user.

Whenever possible, the user profile extension and maintenance is performed dynamically by the system itself without the user's explicit intervention, using specific heuristics. There is a need to "observe" the user constantly and to use a built-in reasoner to infer the user's preferences and inten-

Figure 1. An adaptive portal using the user's profile



tions from the observations, that is, to create and maintain a valid user profile based on his/her behavior.

The Portal Architecture

Figure 2 depicts the architecture of the Travel Guides portal for tourism management. The *User interface* component collects data from the user and sends them to the *Controller*. *Controller* manages the requests from the interface and fires appropriate actions.

The *User Manager* takes care of the user data. It uses the *User DAO* (Data Access Object) to store or fetch the needed data from/to a database. These data are user details that are not subject to frequent change and are not important for determining the user profile: the username, password, first name, last name, address, birth date, phone and e-mail. The *User Profile Expert* is aware of the *User ontology* and also of the *User profile knowledge base* that contains instances of classes and relations from the *User ontology*.

The *Travel Manager* is responsible for fetching, storing and updating the data related to vacation packages. Storing and retrieving data from the database is performed by the *Vacation Package DAO*. The data stored in the database are those that are subject to frequent changes and are not important in the process of reasoning: start date, end date, prices (accommodation price, food service price, transport price), benefits, discounts, and documents that contain textual descriptions with details about the vacation packages. Some of these data are used in search queries as constraints. Actually, retrieving a "perfect" vacation package is performed in two steps:

1. Matching the user's wishes to certain destinations—the user profile is matched with certain types of destinations. This is performed by the *Travel Offer Expert* and the *World Expert*.
2. The list of destinations retrieved in the first step is filtered using the constraints the user may want to set (e.g., the start/end dates of the vacation). The filtering is done by the *Vacation Package DAO*.

The *Travel Manager* aggregates the *Tourist Offer Expert* and *World Expert* components, which include inference engines. These inference engines are aware of the *Travel* and *World ontology,* respectively. Their main role is to validate the content in the knowledge bases.

The *System Scheduler* is running daily at scheduled times. It takes data about the type of destinations that the user has visited and updates his/her user profile. Those data are fetched from the logged user's activities in the relational database, semantically processed and stored in a temporal knowledge base. After the temporal knowledge base is validated, it is merged with an already existing user-profile knowledge base. This validation is performed by an inference engine built inside the *User Profile Expert*.

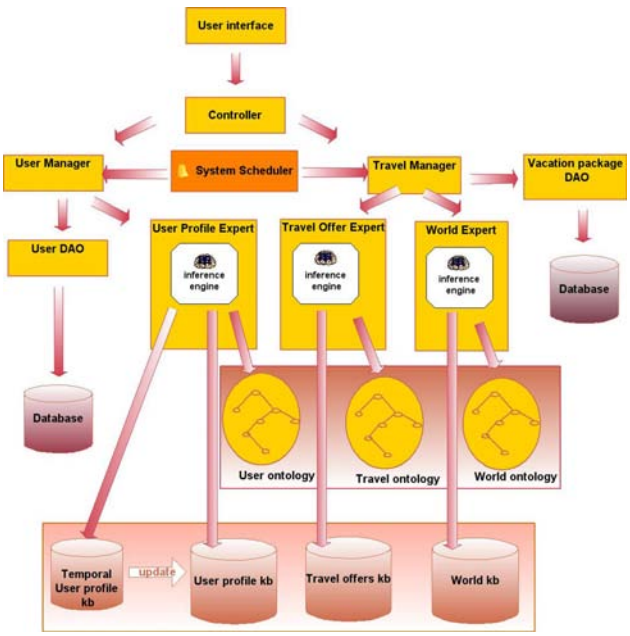
A similar process is performed to update tourist offers in the knowledge base. This happens when a travel agent updates data about new vacation packages, as well as when the portal administrator updates the *World knowledge base* (see Figure 2).

The relations and restrictions stored in Travel Guides ontologies represent the core of this system. Ontologies allow machine-supported travel-related data interpretation and integration (Kanellopoulos, Kotsiantis, & Pintelas, 2006).

The *World ontology* contains concepts and relations from the real world: geographical terms, locations with coordinates, land types, time and date, time zone, currency, languages, and all other terms that are expressing some concepts that are in a way related to tourism or tourists, but not to vacation packages that could be offered by tourist agencies. Because Travel Guides is intended to support semantic annotation, indexing, and retrieval of documents, this ontology is also meant to contain the general concepts necessary for expressing semantic annotation, indexing, and retrieval.

The *User ontology* is meant to contain data about the users–the travelers who visit the Travel Guides portal. This ontology describes user interests and activities, age groups, favorite travel companies, and other data related to user profiles. Each user can have one or more user profiles, depending on his/her behavior while visiting the portal, and also depending on the data he/she has provided to the system.

Figure 2. The architecture of the Travel Guides portal for tourism management



The *Travel (Tourism) ontology* includes all terms being specific to types of vacations, traveler types, and vacation packages offered in tourist agencies and being important to travelers, like the type of accommodation, food service type, transport service, type of room in a hotel, and the like. It is an ontology that makes an indirect connection between users and destinations.

The ontologies are implemented in OWL (Antoniou & Harmelen, 2004) and developed using the Protégé tool (Horridge, Knublauch, Rector, Stevens, & Wroe, 2004).

Travel Guides is designed so that all users contribute to the creation and updating of the knowledge base. Each group is contributing to the knowledge base in its own way:

- End users (tourists) feed the system with their personal data, which then get analyzed by the system in order to create/update user profiles. The system also uses logged data about each user's activities (mouse clicks) when updating the user's profile.
- Tourist agents are creating vacation packages and similar offers in tourist agencies. They feed and update the knowledge base with new information about destinations, arrangements, excursions, etc. To do this, they fill a form about a destination which includes fields like name, accommodation, hotel name, parking provided by the hotel, swimming pool inside the hotel, activities, transport service, etc.
- Portal administrators—they mediate the knowledge base updates with destinations not covered by the tourist agencies. The idea is that tourist agents can then use those updates as the basis for creating new vacation packages and other tourist offers. To alleviate the creation, extensions, and maintenance of this part of the knowledge base, Travel Guides exploits WordNet (Fellbaum, 1998), an open-source knowledge base that describes a number of concepts and terms. Some of these were copied to the Travel Guides knowledge base to avoid manual entrance of static (permanent) data about various destinations. A special tool is developed for copying instances of WordNet classes (concepts) and relations to instances of classes and relations of the Travel Guides World ontology.

FUTURE TRENDS

There is room for future improvements in several directions:

- The use of the Semantic Web services.
- The system is designed to possibly include information about all places in the world and all vacation packages. To achieve this, it is necessary to feed it and save a great amount of data. The system's prototype described here includes a limited collection of vacation packages, which must be extended and updated.
- Simplification of the document annotation process. Currently, it requires the knowledge and understanding of the GATE.
- Finally, Travel Guides supports only management of hotel accommodation. This should be expanded with hostels, campgrounds, and private apartments.

CONCLUSION

Artificial intelligence can play a significant role in improving e-tourism portals. The use of Semantic Web technologies can increase interoperability in the area of tourism, although the agreement of all involved parties about using the standards is essential. Without this agreement, the only useful thing that could be achieved with annotation process would be to analyze sites with content about countries, cities, beaches, and so forth. Most of the data regarding vacation packages are internally stored in the tourism portals, and hence only the usage of intelligent Web services would help their retrieval and representation in a machine readable form. Standardization of the way all tourist services are representing the data would speed up the process of their integration. This would ease searching for tourist deals from one place. The integration of geographical data would also decrease efforts of tourist agents who are responsible to feed the system and keep data up-to-date. If these data would be centralized in a repository available to tourist agents, this would significantly decrease the maintenance efforts.

The Travel Guides system is built to solve the problem of distributed tourist sources and to help users find a "perfect" vacation package quickly. The system includes intelligent components that perform reasoning and have some built-in heuristics. It is based on a number of ontologies, which support the process of adding semantics to data. The data are semantically enriched, which means that they can be understood by machines. The system is also personalized in order to adapt its content to each user. The more a user visits the portal, the more the system "knows" about him/her.

As this system is built using the latest Java technologies for building Web applications widely used in existing online tourism information systems nowadays, this prototype system is to show that such mainstream systems can benefit from integrating the Semantic Web components.

KEY TERMS

Dynamic Packaging: The combination of different travel components, bundled and priced in real time, in response to the requests of the consumer or booking agent.

Intelligent Agents: Software elements which help the user find information of specific interest to him/her without their explicit assistance.

Intelligent Reasoning: The act of using reason to derive a conclusion from certain premises using a given methodology.

Location Based Services: Services that provide context-sensitive information based on the mobile user's location.

Ontology: A controlled vocabulary that describes objects and the relations between them in a formal way, and has a grammar for using the vocabulary terms to express something meaningful within a specified domain of interest.

OWL-Based Web Service Ontology (OWL-S): An ontology which supplies Web service providers with a core set of constructs for describing the properties and capabilities of their Web services in unambiguous, computer-interpretable form.

Semantic Web Services: Self-contained, self-describing, semantically marked-up software resources that can be published, discovered, composed and executed across the Web in a task-driven semiautomatic way.

Web Service Modeling Ontology (WSMO): A data model that provides the conceptual underpinning and a formal language for semantically describing all relevant aspects of Web services in order to facilitate the automation of discovering, combining and invoking electronic services over the Web.

Web Portal: A Web site or service that offers a broad array of resources and services, such as e-mail, forums, search engines, and online shopping malls.

Semantic Web in E-Government

INTRODUCTION

Today, in many countries, looking for government information, filing taxes, renewing a driver's license, obtaining a certificate and notifying of a new address anytime, anywhere are becoming mundane online operations. For the satisfaction of their constituents, local governments are striving to deliver more effective and efficient online services through the use of innovative information and communications technologies.

E-government also known as "digital government" can be defined as the civil and political conduct of government using **information and communication technologies** (ICT) (McIver & Elmagarmid, 2002). The most accepted picture of e-government is that of a provider of online services to citizen (G2C), businesses (G2B) and the administration (G2G). The real value of an e-government rests on the effectiveness of its programs, the broad availability of its enhanced online services, the satisfaction of customers and the tangible savings in time, money and human resources (Koné, 2005).

E-government expansion and adoption by communities, citizens, businesses, and public administrations in most countries is generally seen as a four-step process: presence phase, interaction phase, transaction phase, and transformation phase. The goal of the last transformation phase is to integrate several internal services at the vertical and horizontal levels, into a one-stop, whole-of-government with innovative services operating seamlessly across departments, agencies and programs. To address the problems of **seamless integration** and **interoperability** (D'Auray, 2001), some actors in e-government are experimenting with the **semantic Web** promoted by **Tim Berners-Lee** (Berners-Lee et al., 1999, 2001), **Web service** technologies (McIlraith et al., 2001) as well as **service oriented architecture** (SOA) as a means for achieving integration and inter-operation in the service transformation phase.

Scope and Structure of the Article

This chapter aims at presenting the semantic Web technology applied to the transformation and advancement of e-government. After this introduction in the first section, we expose in the second section the nature of the semantic Web and e-government. Then, we explain in the fourth section, how semantic Web technologies can contribute to solving known issues in the transformation of e-government. Given this background, we are able to propose a simple illustration of our ideas: Web services and semantic Web-based architectures within the e-government project of Québec, Canada. We then give a glimpse of some future trends in the fourth section and the conclusion in the fifth and last section.

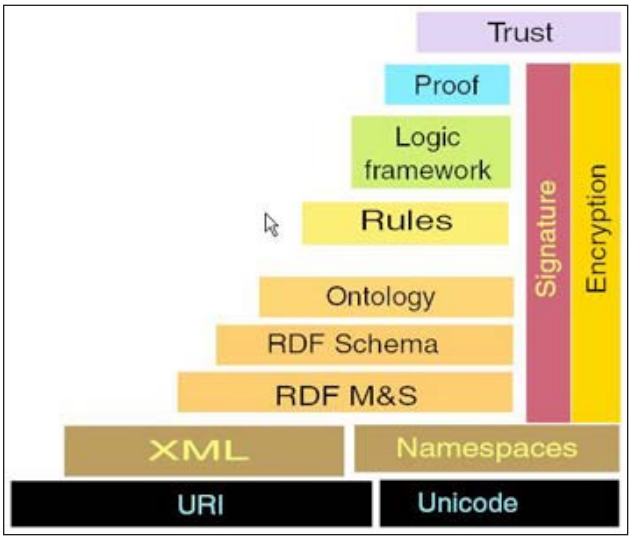
BACKGROUND

Semantic Web Technology

If the **Internet** is said to be "*the place where one can find anything,"* there are still concerns about really finding what one is looking for. In this context, Berners-Lee proposes (Berners-Lee et al., 1999, 2001) a whole new vision of the Web called the **semantic Web**. This semantic Web is "*an extension of the current Web, in which information is given well-defined meaning, better enabling computers and human to work in cooperation*" (Berners-Lee *et al.*, 2001). In line with this vision of the semantic Web, the **World Wide Web Consortium** (W3C) has developed a number of ontological languages for specific purposes. The following languages (Asuncion & Corcho, 2002) displayed in Figure 1 are called ontology languages because they can formally describe the meaning of terms and relations in Web documents.

- **The resource description framework** (RDF) is a flexible data model for resources described as objects and the relations among them. It provides a simple semantics for this data model, and these data models can be represented in XML syntax;
- **RDF schema** is a vocabulary for describing properties and classes of RDF resources, with semantics for hierarchies of such properties and classes;
- The **Darpa agent modeling language** (DAML) has been developed as an extension of XML and RDF. It

Figure 1. The Semantic Web 'layer cake' as proposed by Berners-Lee



is used to explicitly represent the meaning of terms in vocabularies and the relationships between these terms;

- The **ontology Web language** (OWL) is intended to provide a language suitable for describing the classes and relations inherent to Web documents. OWL has more facilities for expressing meaning than XML, RDF and RDF-S.

A more detailed and in-depth description of the semantic Web technology is given in "Semantic Web fundamentals" by Antoniou and Plexousakis in the Encyclopedia of Information Science and Technology, 2005.

E-Government

Considerable progress has been made in e-government over the past decade. A recent major study, in which 21 governments were surveyed, showed that e-government has created major changes along several dimensions: services, modes of operation, and organizational structures (Accenture, 2006). In particular, unified contact centers have been created to help government provide single entry points for citizen services.

Two broad classes of e-government technologies exist (Ashley, 1999). As seen in Table 1, one class comprises externalizing systems which provide interfaces to government entities through which citizens and other government entities can obtain services. The level of service of this range from one-way information delivery to complex transactional interactions, whereby legally-binding tasks, such as vehicle registration, can be completed. Another class comprises systems which provide:

Table 1. A summary of e-government characteristics

• Civil and political conduct of government using ICT; • Provision of online services to citizen (G2C), businesses (G2B) and the administration (G2G); • Two broad classes: externalizing and internalizing systems; • Evolution through presence, transaction and transformation phases.

1. Integrative communication functionality to improve intra-governmental workflows;
2. Domain-specific processing and knowledge management, such as data mining for public health or support for law enforcement investigations.

The needs and trends in e-government parallel those of the broader computing community with respect to semantic Web research. The current generation of research in e-government reflects an effort to make:

1. Services more widely accessible;
2. Services more integrated within organizations; and
3. Information more "intelligent" (Cencioni & Bertolo, 2006).

In a government context, the accessibility and integration of services is being addressed through Web services and business processes. Bringing intelligence to information has involved the injection of semantics into content as meta-data, largely XML-based, and corresponding processing techniques that allow those meta-data to be interpreted.

SEMANTIC WEB IN E-GOVERNMENT

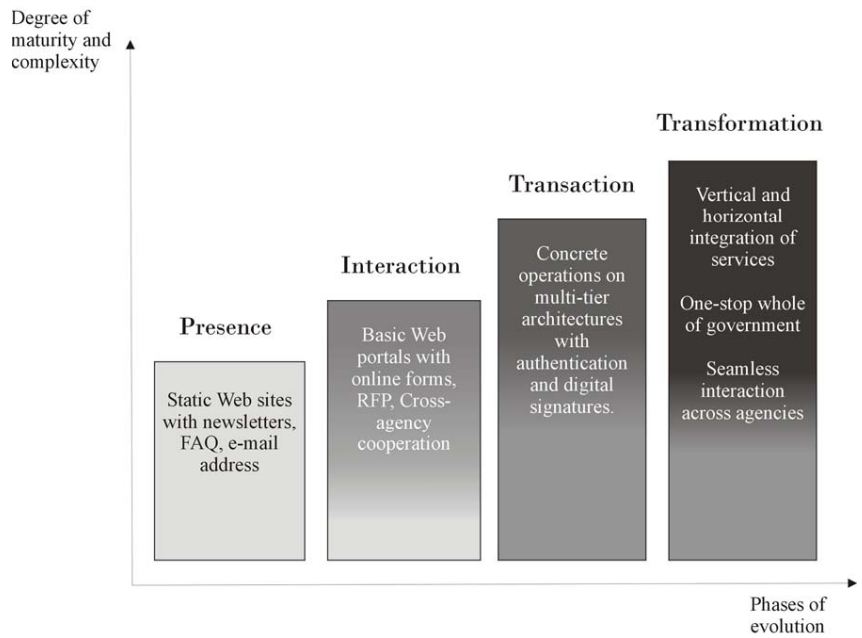
There is a need within e-government services to provide information whose format and methods of delivery are adapted to users and situations (Accenture, 2006). In its evolution, e-government is expected to format information from a given knowledge domain in different ways when presented to senior citizens, youth, or government officials.

E-Government Evolution

E-government expansion and adoption by communities, citizen, businesses and public administrations in most countries is generally seen (Government of Canada, 2003) as a four-step process: presence phase, interaction phase, transaction phase and transformation phase.

The initial **presence phase** is implemented through the publication on the Web of static information on government operations and services. Starting with few services, the initiative expands to a broad range of services with basic

Figure 2. E-government maturity model based on Gartner Research 2000



capabilities like official publications, newsletters, e-mail contact and a FAQ section.

The **interaction phase** appears through the building of basic Web portals containing online forms, requests for proposal and opinion surveys on critical issues of interest to citizen and local businesses. In addition, some kind of cross-agency cooperation appears: government agencies start to reach out to one another through links in their official Web sites.

The **transaction phase** offers online operations like a driver's license renewal, a car registration, a request for a new passport and requires payment of fees in a complete and secure online setting. The proper implementation of these online transactions draws much from the technical aspects of similar transactions in eCommerce. An e-government architecture, at this stage, uses complete multi-tier architectures with authentication and digital signatures.

The **transformation phase** aims at integrating several internal services at the vertical and horizontal levels, into a one-stop, whole-of-government with innovative services operating seamlessly across departments, agencies and programs. These services are therefore tailored to the needs of businesses, communities and citizens.

Current Challenges in E-Government

Significant challenges remain in e-government, for which S**emantic Web** technologies might offer solutions. The coming generation of research (Oreste, 2005) will focus on moving from intelligent information to information that is "actionable" (Bertolo, 2006). The Seventh Framework Programme of research of the European Commission has taken this view after extensive consultations with experts in this area. Semantic Web research directions that are relevant to e-government include:

1. Social networking;
2. Service composition and collaborative workflow;
3. Security and trust;
4. Automated collection and processing information; and
5. Adaptive information delivery.

As countries like United States, Denmark, Australia, Finland, United Kingdom, Germany, Ireland, and France are making remarkable progress in mature service delivery, questions arise about the appropriate technological platform for reaching the next level of service transformation. Until now, to design a platform for its service delivery, some government have quietly followed in the footsteps of the successful e-commerce where Web services technology with its Web services description language (WSDL), simple object access protocol (SOAP) and uniform description, discovery and integration (UDDI) protocols, appears to be the most popular. However, government providers not only have *different goals* in the design, organization, management and delivery of services than the private sector but face *massive challenges under different constraints*. According to D'Auray (2001), the most important of these challenges are safety, security, and integrity of online interactions

with government; privacy and confidentiality of personal and business information within government; information management with respect to accuracy and relevance when merging data across departments and agencies. Although security technology for Web services addresses the safety, integrity and confidentiality concerns through cryptography, digital certificates and trusted third-party authorities, it is neither convenient nor stable enough to inspire trust. In addition, current research has shown that it is possible to automatically discover, select and compose Web services on a syntactic, semantic and pragmatic (location, QoS, policy) levels. However, to date, no Web service infrastructure has the capability of dealing with laws (e.g., the *Privacy Act in Canada* mentioned in D'Auray, 2001) related to the use and sharing of personal information where the explicit written consent of a subject is required.

In Europe, there are a number of e-government projects using semantic Web technology. Access to e-government services employing semantic technologies (**Access-eGov**) is a project which aims at increasing the accessibility of public administration services for citizens and business users by supporting the interoperability among existing electronic and 'traditional' government services. Access-eGov is partially funded under the IST Programme of FP6 (e-government research). Its main objective according to the project designers is to create a server reference ontology covering basic domain knowledge and processes; rule-based editorial add-on component for Web sites and Web applications to insert semantic mark-up within public e-Gov applications.

SemanticGov (http://www.semantic-gov.org) is a project which aims at building the infrastructure (software, models, services) to support **semantic Web services** for interoperability across local or transborder public administrations (PA). It is based on the Service Oriented Architecture and Semantic Web Services technologies for enabling the discovery and execution of complex PA services.

e-govRTD2020 is a project co-funded by the European Commission under the 6th Framework Programme of IST. It aims at sketching e-government in 2020 through the identification of future strategic research fields in e-government. This project intends to use ontologies and well known knowledge management tools to provide information quality and economy.

The Online Address Change Service of Quebec

In Quebec, Canada, online services are organized according to visitors' profile (citizen or enterprise) and gathered according to specific topics such as finances, industry, business, education, employment, and legal matters. To have access to online government services, one must visit a constellation of Web sites whose architectures does not allow integrated service provision like a one-time change of address in several administrations. In addition, the personal data protection law requires each government organization in Québec to build and manage its own secure online database with no possibility of sharing personal information on citizen and businesses. Unfortunately, each of these organizations has its own concept of identification with rules and restrictions. The best example of this problem is the online address change Service of Quebec[1]. Here, the process of changing one's address has been made easy by a single online form which serves six ministries and agencies simultaneously. Then, each destination still bears the burden of validating the address changed. In the province of Québec, official records show that about 66 % of online address change requests through this traditional system is rejected during validation. Therefore, we proposed the design and implementation of an **e-government Web service** platform described in figure 3 (Ben Fadhel & Koné, 2005). This platform supports functionalities and modules made of a Web service-based portal which plays the role of online middle man; the services request folder, an emulation of an electronic commerce shopping cart system; the service search module as a channel to available government services and an online address change service.

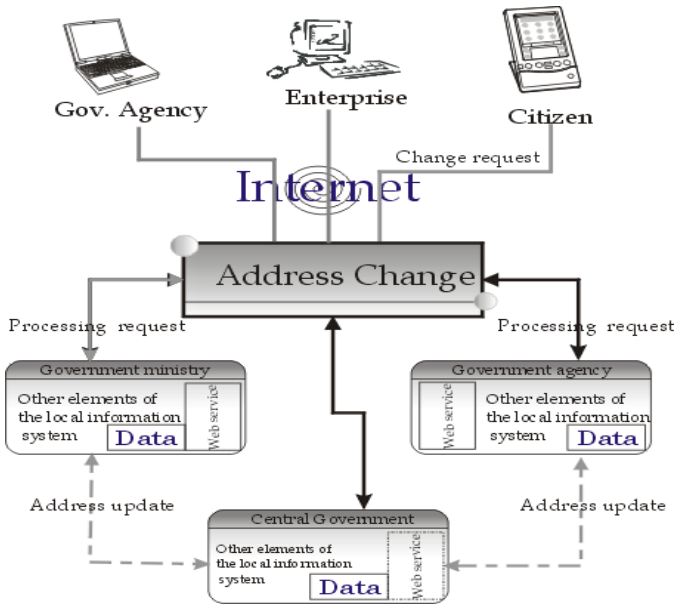
We designed an appropriate ontology for government services with the Protégé ontology editor to support these operations. With the local information at ministries and agencies being processed as Web services, our platform is able to efficiently collect and process data then display query results to consumers. Here, as required by the law, there is no need for interaction between the players.

A similar approach using semantic Web services technologies has been used by Medjahed, Bouguettaya, & Ouzzani (2003) for the automatic selection, interoperation and composition of e-government services in the context of the Family and Social Services Administration (FSSA) of their community.

FUTURE TRENDS

There are a number of semantic Web technologies which promises to bring significant innovations to the field of e-government. One remarkable example is the **service oriented architecture** or SOA based on semantic Web services (Erl, 2005). SOA is a reliable and relatively simple infrastructure which is flourishing and promises to spark greater data integration and interoperability between heterogeneous systems in administrations. It can articulate a process independent of any technology and allow the coordination and use of a collection of Web services. A number of e-government programmes (e.g., the state of Kentucky, in the United States, and Dubai Municipality) has already adopted this paradigm to support their ongoing effort in service transformation. Fortunately, SOA seems to help avoid the duplication of infrastructure and data across agencies and ministries. Therefore, coher-

Figure 3. Proposed structure of the online address change service



ence, accuracy of information, and trust among citizen are the first benefits in implementing this paradigm.

CONCLUSION

In this chapter, we first explained what e-government is and the state of its evolution. Then, we introduced the field of semantic Web applied to e-government to overcome the obstacles in achieving the last service transformation phase. As an illustration, we presented a couple of noteworthy ongoing projects in Europe called Access-eGov, SemanticGov and eGovRTD2020. Then, we presented an interesting online address change application that we suggested to the e-government of Québec in Canada to improve its architecture.

KEY TERMS

E-Government Web Services: E-government applications deployed over the Web within a Web service infrastructure. This technology becomes really useful only when an ensemble of related distributed e-government services are composed in order to create a new one.

Interoperability: The ability of several software components based on different platforms to interact, exchange services and cooperate in solving complex tasks. ISO TC204 defines interoperability as "*the ability of systems to provide services to and accept services from other systems and to use the services so exchanged to enabled them to operate effectively together."*

Ontology: Originally used in philosophy to refer to the kind of things that exist, an ontology is interpreted as "*a specification of a conceptualization*" (Tom R. Gruber) in the context of artificial intelligence. In practical terms, an ontology is the set of terms of a vocabulary about a given domain and all the relationships between these terms. It can be written as an RDF document with classes and properties available for creating instances and making assertions.

Semantic Web: The best and most well known definition of the semantic Web is given by its inventor, Tim Berners-Lee in the May, 2001 issue of Scientific American as "*The Semantic Web is not a separate Web but an extension of the current one, in which information is given well-defined meaning, better enabling computers and people to work in cooperation.*" To achieve this goal, a data model called resource description framework (RDF), several data interchange formats like RDF/XML and N3, notations called RDF schema (RDFS) and the Web ontology language (OWL) have been developed and proposed by the World Wide Web Consortium (W3C) to give formal descriptions of concepts, terms, and relationships in a domain.

Semantic Web Services: When Web services and their related messages are semantically described (capabilities, interfaces) with appropriate ontologies, they are called semantic Web services.

Service Oriented Architecture (SOA): is literally an architecture which relies on service-orientation. It is a reliable and relatively simple infrastructure which allows greater data integration, interoperability and the coordination of a collection of heterogeneous systems. OASIS (the Organization for the Advancement of Structured Information Standards) defines SOA as: "A paradigm for organizing and utilizing distributed capabilities that may be under the control of different ownership domains. It provides a uniform means to offer, discover, interact with and use capabilities to produce desired effects consistent with measurable preconditions and expectations."

Web Services: Web services are a set of protocols named Web services description language (WSDL), uniform description, discovery and integration (UDDI) and simple object access protocol (SOAP) used to exchange data between applications regardless of their platform, language or object model. In this interaction, there are three actors:

1. A service provider defines with the WSDL language the format for request and response of services it generates;
2. A UDDI registry stores the services descriptions published by the service provider;
3. A service consumer in need can make a request and find a particular service description in the UDDI registry. It subsequently calls this service through the SOAP protocol and requires it to perform some action at the provider's location and send back the result.

Current examples Web services are weather information service, authentication service, Foreign exchange service and Knowledge base service.

World Wide Web: A system of interlinked multimedia documents distributed over the Internet created by Tim Berners-Lee around 1990.

INTRODUCTION

Since the introduction of the *Semantic Web* vision (Berners-Lee, Hendler, & Lassila, 2001), attempts have been made for making Web resources more machine interpretable by giving them a well-defined meaning through semantic markups. One way to encode such semantic markups is to use ontologies. An *ontology* is "an explicit specification of a conceptualization" (Gruber, 1993, p. 199). Informally, an ontology consists of a set of terms in a domain, relationships between the terms, and a set of constraints on the way in which those terms can be combined. By explicitly defining the relationships and constraints among the terms, the semantics of the terms can be better defined and understood.

Over the last few years, a number of ontology languages have been developed, most of which use *Description Logics* (DLs) (Baader, McGuinness, Nardi, & Schneider, 2003) as the foundation. The family of DLs is a subset of first-order logic (FOL) and is considered to be attractive as it keeps a good compromise between expressive power and computational tractability.

Uncertainty is a form of deficiency or imperfection in the information/data, where the truth of information is not established definitely. Uncertainty modeling and reasoning have been challenging issues for over two decades in many disciplines, such as database and artificial intelligence. Most of the information in the real world is uncertain or imprecise, for example, classifications of genes in bioinformatics, schema matching in information integration, finding best matches in a Web search, and so forth. Therefore, uncertainty management is essential for the success of many such applications and in particular DLs and the Semantic Web.

Despite its popularity, it has been realized that classical DLs are inadequate to model uncertainty. For example, in the medical domain, one might want to express that: "It is very likely that an obese person would have heart disease," where "obese" is a vague concept that may vary across regions and "likely" shows the uncertain nature of this information. Such an expression cannot be expressed using classical DLs.

The importance of incorporating uncertainty in DLs has been recognized by the knowledge representation community: "modeling primitives such as … fuzzy/probabilistic definitions" could be the next step for extension (Horrocks et al., 2000, p. 3). For this, a number of frameworks have been proposed to incorporate uncertainty in DLs. This paper provides a survey of these proposals.

The rest of this paper is organized as follows. We first provide the background on the classical DL framework. We then study representative extensions of DLs with uncertainty. This follows by some possible research directions for incorporating uncertainty in the Semantic Web. We conclude with a summary and some remarks.

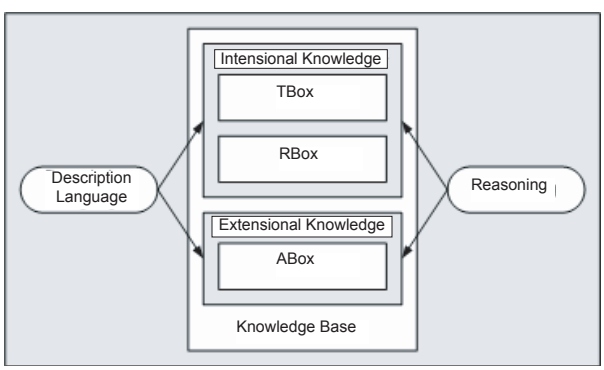
BACKGROUND

In this section, we review the basics of the classical DL framework, which provides facilities to represent knowledge bases and to reason about them.

As shown in Figure 1, the classical DL framework consists of three components:

1. **Description Language:** All description languages have elementary descriptions which include atomic

Figure 1. Classical DL framework



concepts (unary predicates) and atomic roles (binary predicates). Complex descriptions are built inductively from atomic ones using concept constructors. In this work, we focus on the description language $\mathcal{ALC}$ (Baader et al., 2003). Let C and D be concept descriptions. $\mathcal{ALC}$ includes atomic concepts A, atomic roles R, top/universal concept $\top$, bottom concept $\bot$, concept negation $\neg C$, concept conjunction $C \sqcap D$, concept disjunction $C \sqcup D$, role value restriction $\forall R.C$ (meaning $\forall y$: $R(x,y) \rightarrow C(y)$, for x in the domain), and role exists restriction $\exists R.C$ (meaning $\exists y$: $R(x,y) \wedge C(y)$, for x in the domain).

2. **Knowledge Base (KB):** The KB is composed of both intensional knowledge and extensional knowledge (see Figure 1). The former includes the Terminological Box (TBox or $\mathcal{T}$) consisting of a set of terminological axioms that could be concept subsumptions $C \sqsubseteq D$ and/or concept definitions $C \equiv D$ (where C and D are concepts), and the Role Box (RBox or $\mathcal{R}$) consisting of a set of role axioms that could be role subsumptions $R \sqsubseteq S$ and/or role definitions $R \equiv S$ (where R and S are roles). The extensional knowledge includes the Assertional Box (ABox or $\mathcal{A}$) consisting of a set of assertions/facts that could be concept assertions a: C (i.e., a is an instance of concept C) and/or role assertions (a,b):R (i.e., individuals a and b are related through relationship R).
3. **Reasoning Component:** A DL framework is equipped with reasoning services which allows that implicit knowledge be derived from explicit knowledge.

DESCRIPTION LOGICS WITH UNCERTAINTY

In this section, we study existing frameworks for DLs with uncertainty. We first provide a classification of the approaches of these frameworks. We then study representative extensions of DLs with uncertainty.

Approaches to Extend Description Logics with Uncertainty

On the basis of their mathematical foundation and the type of uncertainty modeled, we can classify existing proposals of DLs with uncertainty into three approaches: fuzzy, probabilistic, and possibilistic.

The fuzzy approach, based on fuzzy set theory (Zadeh, 1965), deals with vagueness in the knowledge, where a proposition is true only to some degree. For example, the statement: "Jason is obese with degree 0.4" indicates Jason is slightly obese. Here, the value 0.4 is the degree of membership that Jason belongs to the fuzzy concept obese.

The probabilistic approach, based on classical probability theory, deals with the uncertainty due to lack of knowledge, where a proposition is either true or false, but one does not know for sure which one is the case. Hence, the certainty value associated with the proposition refers to the probability that the proposition is true. For example, one could say: "The probability that Jason would have heart disease, given that he is obese, lies in the range [0.8,1]."

Finally, the possibilistic approach, based on possibility theory (Zadeh, 1978), allows both certainty (necessity measure) and possibility (possibility measure) to be handled in the same formalism. For example, by knowing that "Jason's weight is above 80 kg," the proposition "Jason's weight is 80 kg" is necessarily true with certainty 1, while "Jason's weight is 90 kg" is possibly true with certainty 0.5.

Description Logics with Uncertainty—Current State

To incorporate uncertainty into DLs, each component of the DL framework needs to be extended (Figure 2). In what follows, we survey how the description language, the KB, and the reasoning component have been extended with uncertainty using fuzzy, probabilistic, and possibilistic approaches.

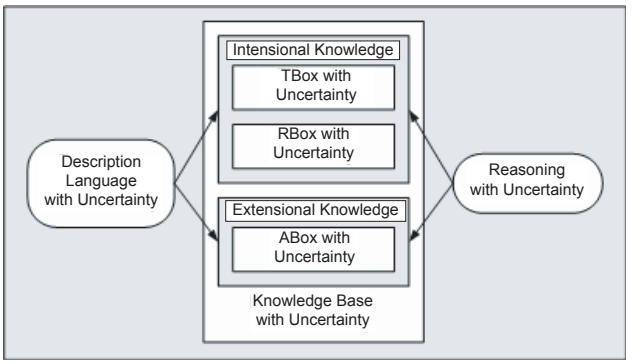
Description Languages with Uncertainty

The description languages contain a set of language constructors that serve as the building blocks of the description. In this section, we study how description languages have been extended using fuzzy and possibilistic approaches. To the best of our knowledge, no probabilistic extension of description languages has been proposed.

Fuzzy Description Languages

All existing proposals for fuzzy DL extend the semantics of the description language by fuzzifying their interpretation using fuzzy logic (Hölldobler, Khang, & Störr, 2002;

Figure 2. DL Framework with uncertainty



Sánchez & Tettamanzi, 2004; Straccia, 2001, 2004a, 2004b, 2005a, 2005b; Tresp & Molitor, 1998). In general, a fuzzy interpretation $\mathcal{I}$ is a pair $\mathcal{I} = (\Delta^{\mathcal{I}}, \cdot^{\mathcal{I}})$, where $\Delta^{\mathcal{I}}$ is the domain and $\cdot^{\mathcal{I}}$ is an interpretation function that maps language elements to some membership degree in [0,1]. For instance, the semantics of an atomic concept A is defined as $A^{\mathcal{I}}(a) \in [0,1]$ for all $a \in \Delta^{\mathcal{I}}$. That is, if individual a is an element of the domain, then the interpretation of the atomic concept A gives the membership degree that a belongs to A. The semantics of complex descriptions are defined in a straightforward way. For instance, the semantics of concept intersection is defined as $(C \sqcap D)^{\mathcal{I}}(a) = \min\{C^{\mathcal{I}}(a), D^{\mathcal{I}}(a)\}$, for all $a \in \Delta^{\mathcal{I}}$. That is, the certainty degree of concept C intersect D is the minimum of the certainty degrees of C and D.

In addition to the semantic extension, syntactic extensions to the description language are also proposed. The *manipulators/modifiers* (Hölldobler et al., 2002; Straccia, 2005a, 2005b; Tresp & Molitor, 1998) are unary operators that can modify the membership functions of the concepts they are applied to (e.g., "mostly," "very"), whereas *fuzzy quantifiers* (Sánchez & Tettamanzi, 2004) allow expressing vague quantities (e.g., "about 2") and quantity intervals (e.g., "roughly between 1 and 3").

Possibilistic Description Languages

Hollunder (1994) proposed a possibilistic extension to the description language. The idea is to keep the original description language syntax, while changing its interpretation using possibility theory. More specifically, the *possibility measure* Π for a concept (or event) C induced by a possibility distribution π on a set of interpretations $\Omega_{\perp}$ is defined as $\Pi(C) = sup\{\pi(\omega) \mid \omega \in \Omega_{\perp} \text{ and } \omega \vDash C\}$, characterizing the extent to which C is possible. On the other hand, the *necessity measure* N for a concept C is defined as $N(C) = inf\{1-\pi(\omega) \mid \omega \in \Omega_{\perp} \text{ and } \omega \nvDash C\}$, characterizing the extent to which this event is necessary or certain to occur. For example, the possibility that C and D are occurring at the same time is no more than the minimum of their possibilities, that is, $\Pi(C \sqcap D) \leq min\{\Pi(C), \Pi(D)\}$, but the necessity that both of them occur is $N(C \sqcap D) = min\{N(C), N(D)\}$.

Knowledge Base with Uncertainty

The fuzzy, probabilistic, and possibilistic extensions of KBs are defined in a similar way as the classical case, except that the interpretation $\mathcal{I}$ corresponds to the extension considered. An interpretation $\mathcal{I}$ *satisfies* (or is a *model* of) a KB Σ, denoted $\mathcal{I} \vDash \Sigma$, if it satisfies each element of Σ. Also, Σ is *satisfiable* if there exists an interpretation $\mathcal{I}$ that satisfies Σ. In this section, we study how each component of the KB can be extended with uncertainty.

Fuzzy Knowledge Base

Each component of the KB (i.e., the TBox, RBox, and ABox) has been extended with fuzzy logic.

For the TBox, two approaches are proposed. The first approach keeps the syntax the same as classical terminological axioms while extending only the semantics using fuzzy logic. Examples of this approach include Hölldobler et al. (2002), Sánchez & Tettamanzi (2004), and Straccia (2001, 2004a, 2004b, 2005b). A fuzzy interpretation $\mathcal{I}$ satisfies a fuzzy concept inclusion $C \sqsubseteq D$ if for all $a \in \Delta^{\mathcal{I}}$, we have that $C^{\mathcal{I}}(a) \leq D^{\mathcal{I}}(a)$. That is, the certainty of a subconcept C (e.g., *VeryTall*) is no more than the certainty value of a super-concept D (e.g., *Tall*). In the second approach, the TBox is extended both syntactically and semantically (Straccia, 2005a). Let C and D be concepts, $op \in \{\geq, \leq, >, <\}$, and $\alpha \in [0,1]$. A fuzzy terminological axiom is expressed as $\langle C \sqsubseteq D \text{ op } \alpha \rangle$. For example, $\langle C \sqsubseteq D \geq 0.8 \rangle$ indicates "the certainty that C is subsumed by D is at least 0.8."

Extension to RBox with fuzzy logic is proposed in Straccia (2005b). It is similar to the TBox counterparts, except that we have role axioms instead of terminological axioms.

In terms of the ABox, a fuzzy assertion can be represented as $\langle X \text{ op } \alpha \rangle$, where X is either a concept assertion $a{:}C$ or a role assertion $(a,b){:}R$, $op \in \{\geq, \leq, >, <, =\}$, and $\alpha \in [0,1]$ (Hölldobler et al., 2002; Sánchez & Tettamanzi, 2004; Straccia, 2001, 2004a, 2004b, 2005a, 2005b; Tresp & Molitor, 1998). For example, $\langle a{:}C \geq 0.5 \rangle$ means "the certainty that a is an instance of concept C is at least 0.5."

Probabilistic Knowledge Base

Several proposals extend TBox and ABox using probability theory as the mathematical basis.

A probabilistic TBox contains a set of classical terminological axioms and a set of probabilistic terminological axioms. The probabilistic information can either be embedded as part of the terminological axiom (Giugno & Lukasiewicz, 2002; Heinsohn, 1994; Jaeger, 1994) or be stored in Bayesian networks (Koller, Levy, & Pfeffer, 1997; Staker, 2002). For lack of space, we describe only the first approach here. A probabilistic terminological axiom is an expression of the form $P(C|D) \in [l,u]$, where C and D are concepts and $0 \leq l \leq u \leq 1$. This states that: "if an individual a is known to belong to concept D, then the probability that a belongs to concept C lies in $[l,u]$."

A probabilistic ABox (Giugno & Lukasiewicz, 2002; Jaeger, 1994) contains assertions of the form $P(a{:}C) \in [l,u]$, where C is a concept, a is an individual, and $l, u \in [0,1]$. Intuitively, this asserts that "the probability that an individual a belongs to concept C lies in $[l,u]$." The probabilistic assertions can also be applied to roles.

Possibilistic Knowledge Base

In Hollunder (1994), a possibilistic extension to TBox and ABox is proposed. Let X be an axiom or assertion, $\prod_\alpha$ be a possibility degree, and N_α be a necessity degree, where $\alpha \in (0,1]$. A possibilistic terminological axiom is either in the form $\langle X, \prod_\alpha \rangle$, meaning "$X$ is possibly true with degree at least α," or $\langle X, N_\alpha \rangle$, meaning "$X$ is necessarily true with degree at least α."

Reasoning with Uncertainty

The reasoning component provides inference services that enable implicit knowledge to become explicit. In this section, we study fuzzy, probabilistic, and possibilistic reasoning procedures.

Fuzzy Reasoning

For fuzzy reasoning, two main approaches are proposed. The first approach (Straccia, 2004a) transforms fuzzy DL into classical DL. The main advantage is that one can directly use existing reasoners developed for classical DL. The problem is that existing reasoners do not consider certainty values in fuzzy DL as something special, and hence no additional optimization techniques may be applied to inferences with certainty values involved.

The second approach extends existing reasoning procedure so that it takes into account the presence of certainty values during the reasoning process; hence, a reasoner has to be built from scratch. There are two variants of this approach. In the first one, certainty values are dealt with within the inference rules (Hölldobler et al., 2002; Straccia, 2001, 2004b). The basic idea is that, given a fuzzy ABox, a set of inference rules are applied to transform the ABox into simpler and satisfiability preserving equivalence, so that the implicit knowledge becomes explicit. For example, if we know that $\langle a{:}C \sqcap D \geq 0.5 \rangle$, then we could infer that $\langle a{:}C \geq 0.5 \rangle$ and $\langle a{:}D \geq 0.5 \rangle$. The inference rules are applied until either all branches in the extended ABox contain a contradiction/clash (meaning no model can be built), or there exists a clash-free completion of ABox (meaning the ABox is satisfiable). The second approach relies on integer programming and linear optimization to deal with certainty values (Straccia, 2005b). Here, a set of completion rules are applied to generate new assertions together with a set of constraints in the form of inequations over variables with values in [0,1]. The inference rules are applied until either the extended ABox contains a clash, or no rule can be further applied. If there is a clash, the ABox is unsatisfiable. Otherwise, an optimization technique is applied to solve the system of inequations to determine the satisfiability of the KB or the tightest bound such that an assertion is true.

Probabilistic Reasoning

The probabilistic reasoning procedure depends on how the probabilistic information is represented in the KB. In case Bayesian networks are used to express the probabilistic information, the inference procedure developed for Bayesian networks can be directly applied (Ding & Peng, 2004; Koller et al., 1997; Staker, 2002). On the other hand, if the probabilistic information is embedded in the KB (Baader et al., 2003, Giugno & Lukasiewicz, 2002), inference procedures similar to the fuzzy/linear optimization approach are applied to find the optimal bound for which, given a KB, a conditional probability $P(C|D)$ is satisfied.

Possibilistic Reasoning

The possibilistic reasoning is not well explored. No concrete calculus is provided in Hollunder (1994) for inferences on a given KB.

FUTURE TRENDS

In this section, we outline some possible directions for uncertainty management in the Semantic Web. First, it would be useful to have a generic framework that could handle various forms of uncertainty under a unifying umbrella. The first attempt has been made by Haarslev, Pai, and Shiri (2005), which is later extended with the reasoning component(2006). However, more work is required in this direction. For practical reasons, we also need to develop efficient tools that support DL with uncertainty. Finally, to handle real-life applications, more expressive fragments of DL (e.g., $\mathcal{SHOIN}$) should be extended with uncertainty.

CONCLUSION

We studied existing frameworks for DL with uncertainty which can form a basis for uncertainty management in the Semantic Web. Based on the mathematical foundations and the types of uncertainty modeled, we classified these frameworks into fuzzy, probabilistic, and possibilistic approaches. We also studied how these approaches extend the components of the DL framework, including description language, KB, and reasoning procedures. It is our hope that this survey would foster further research in incorporating uncertainty in the next generation of Web.

KEY TERMS

Description Logics: A decidable subset of first order logic.

Inference: The process of deriving conclusions from a knowledge base.

Knowledge Base: A collection of axioms and assertions.

Knowledge Representation: A formalism used for expressing knowledge stored in a knowledge base.

Ontology: An explicit formal specification of conceptualization that consists of a set of terms in a domain and the relations among them.

Semantic Web: An extension of the current Web by giving well-defined meaning to Web resources.

Uncertainty: A form of deficiency/imperfection in the information where the truth of information is not established definitely.

Service Description Ontologies

INTRODUCTION

Services can be Internet-based e-commerce services, business services that abstract company-level interactions, or any other software services that are provided by surrounding devices that are mobile or embedded in nearly any type of physical environment (e.g., home, office, or cars). In brief, services are ubiquitous and executed in heterogeneous environments.

Surrounding the definitions and technologies that describe services, there are some important features that are in common. First, services always have some actions that are performed by an entity, possibly on behalf of another. Second, there always exists service interaction, including a service provider, service requestor, and service registry. Finally, services have inherent value that is transferred from the service provider to the service requestor as a result of the service's execution.

To invoke and operate a service in the most efficient way, the service is to be described via essential types of knowledge: a) what the service requires from the user/agent(s) and then provides for them; b) where and when the service is available; c) what quality level is to be guaranteed; d) how to access and interact with the service; and e) what access rights are granted over the service.

An accurate service description, including the specifications of functional and nonfunctional properties, benefits and facilitates several important activities, such as service discovery, service composition, and service administration, including the monitoring and controlling of the service's execution. However, due to the diversity of service contexts, service technologies shall be generic and adaptable to different domains and heterogeneous environments. Service description ontologies solve this problem by enabling a rich representation of services and a common understanding about their respective features. The use of ontologies enables computational entities and services to have a common set of concepts and properties for representing knowledge about a domain of interest. The deployment and customization of existing and emerging service systems can also be considerably facilitated by a common set of ontologies that is developed in order to describe service semantics.

BACKGROUND

The studies on the data schema in XML, RDFs, OWL, and service description languages all form the basis for defining the service semantics. The eXtensible Markup Language (XML), as defined by the World Wide Web Consortium (W3C), is a well known, and industry accepted, way for representing flexible information. It is used to create information objects consisting of elements encoded by tags and attributes. XML schemas express shared vocabularies and allow machines to carry out those rules that are established by people.

The resource description framework (RDF) and Web ontology language (OWL) are built on XML and facilitate greater machine interpretability of content by providing additional vocabulary along with formal semantics.

XML, SOAP, WSDL, and UDDI form the core of Web service standards. Simple object access protocol (SOAP) is a lightweight protocol for exchanging XML-based information in a distributed environment. Web service description language (WSDL) is an XML format for describing services as a set of endpoints operating on messages. The operations and messages are described abstractly, and then bound to a concrete protocol and message format in order to define an endpoint. UDDI (universal description, discovery, and integration) is concerned with the publishing and discovery of Web services.

Service Level Agreements (SLAs) related quality information is described by:

- Web service level agreement (WSLA) language (Ludwig et al., 2002), which is based on an XML schema and defines the SLAs in three parts; i) contractual parties, ii) the characteristics of the service and its observable parameters, and ii) obligations to various guarantees and constraints that may be imposed on the SLA parameters, or
- Web services offerings language (WSOL) (Tosic, Paguredk, Patel, 2003), which is a formal specification language for defining the functional and QoS constraints and access rights for Web services. WSOL is XML-based and compatible with WSDL.

SERVICE ONTOLOGIES

In the following, the existing semantic approaches for describing the services, including their functional capabilities, QoS, and context are compared in Tables 1-3. This comparison aims at identifying the main benefits and shortcomings and the missing aspects in the service description ontologies that serve as a basis for the conclusion and future research trends that are to be identified in the remainder of the paper.

Service Functionality Descriptions

Several service ontologies contribute to the service creation, provision, and execution, to a varying extent, by using different description languages. Table 1 compares the main properties of four existing service description ontologies from the viewpoint of their completeness to describe the service related aspects. Web ontology language for services (OWL-S), Web service modeling ontology (WSMO) (Roman, Keller, Lausen, Lara, Bruijn, Stollberg, et al., 2005) and Internet reasoning service (IRS) (Domingue, Cabral, Hakimpour, Sell, & Motta 2004; Motta, Domingue, Cabral, & Gaspari, 2003;) provide specific ontology building blocks for particular purposes of use. Conversely, METEOR-S (LSDIS Lab, 2005) is an approach that targets the extension and integration of the existent Web services and semantic Web technologies. OWL-S is the most widely used approach concerning service semantic modeling. OWL-S combines the expressiveness of description logics, as it builds on OWL. The WSMO is a relatively new effort and is based on the Web service modeling framework (WSMF) (Fensel, Bussler, Ding, & Omelayenko, 2002). All of the approaches provide for specific advantages that are missing from another approach. However, the approaches do not individually provide complete description support for service semantics (see Table 1, Difference row).

Service Quality Descriptions

Table 2 compares a set of QoS ontologies that address their benefits and shortcomings. The difference that is in focus results in different ontology layers. A lack of completeness is common for all the approaches; only one or a few qualities are considered, and the vocabulary or/and metrics are missing. Moreover, there is no support for making tradeoffs between quality attributes or managing QoS at run-time.

In Zhou et al. (Zhou, Chia, & Lee, 2004), the QoS ontology with the three layers covers the matchmaking, QoS property definition layer with domain and range constraints, and metrics with the measurement details. A drawback of this approach is that the proposed ontology is rather limited, while the QoS ontology vocabulary is absent. The framework presented in Maximilien and Singh (2004) is based on agents that enable dynamic Web services selection. On the other hand, work in Tosic et al. (Tosic, Esfandiari, Pagurek, & Patel, 2002) has focused on metrics, measurement units, and currencies to support QoS semantic management. An extended matchmaking mechanism with the concept of the service broker is addressed in Tian et al. (Tian, Gramm, Naumowicz, Ritter, & Schiller, 2003). It also classifies the QoS parameters into network-related and server/client-related parameters. The MOQ (mid-level ontologies for quality) framework (Kim, Sengupta, & Evermann, 2005) aims to minimize the ambiguities in QoS evaluations by defining the ontologies for the requirements, measurement, traceability, and quality management.

Service Context Descriptions

Concerning the contextual characteristics of services, several ontologies have been designed, some of which are more elaborate and others more succinct, depending on their scope. The most popular of these are context ontology language (CoOL) (Strang, Linnhoff-Popien, & Frank, 2003), context broker architecture (CoBrA) (Chen, Finin, & Joshi, 2003), service-oriented context-aware middleware (SOCAM) (Gu, Wang, Pung, & Zhang, 2004), COntext MAnagement oNTOlogy (COMANTO) (Strimpakou, Roussaki, Pils, & Anagnostou, 2006), and the standard ontology for ubiquitous and pervasive applications (SOUPA) (Chen, Finin, & Joshi, 2005). Their main characteristics are shown in Table 3.

Most of the approaches presented address the vocabulary ontology needs in the domain of pervasive computing. The context ontologies that are designed include a set of vocabularies for describing people, agents, and places, as well as a set of properties and relationships that are associated with these basic concepts. However, rather little emphasis is placed on services, including their functional properties and related aspects, such as user interfaces and devices on which these services are deployed, along with temporal contextual information. No attempts have been made to align service and context ontologies.

Tools for Describing Service Semantics

Numerous freeware and commercial tools to support the development and use of ontologies are currently available: SWOOP is a hypermedia based OWL ontology editor; Protégé is a free, open source ontology editor and knowledgebase framework; TopBraid Composer™ is an enterprise class platform. The advancement in these tools has greatly improved the ability to test and build ontologies from scratch or to reuse existing ontologies.

Application programming interfaces (APIs) for ontology languages provide programming language dependent means to load ontologies, manipulate the ontology classes and relations, perform reasoning, and provide persistent storage for

the model. Jena and OWLS API are the most popular Java frameworks for building semantic Web applications. These tools provide an application developer with programming language level support for working with ontologies.

There are several tools that provide reasoning capabilities for ontology applications offering a language dependent API or DIG interface (i.e., a standardized XML interface to description logics systems). The examples of such are FaCT++, Pellet, and RacerPro. These tools help in ontology testing and in the development of application level intelligence that is based on ontologies. Domain ontology specific editors such as OWLS Editor and WSMO design studio help in order to create error free semantic descriptions based on a specific ontology.

From the service modeling perspective, what is missing in those tools are the features that would make the contextual semantic information related to service descriptions easier to understand and to be used by an application developer. The visualization support that is provided by generic ontology editors is limited to mainly showing the abstract structural relations of the ontology classes and their instances. These tools are not well suited for understanding and modeling the semantic relations and services in a complex dynamic physical world related to application scenarios. This leaves the step of adopting semantic approaches in service-oriented application development excessively high for most programmers.

FUTURE TRENDS
