Disc cartridges or caddies are required for both single- and double-sided discs. Double-sided discs must remain inside the caddy at all times for protection; however, single-sided discs can be taken out from the cartridge if necessary.

Figure 13.8 DVD-RAM wobbled land and groove recording.

DVD-RAM specifications are shown in Table 13.9.

Table 13.9 DVD-RAM Specifications

Storage capacity	2.6GB single-sided, 5.2GB double sided
Disc diameter	80–120mm
Disc thickness	1.2mm (0.6mm×2: bonded structure)
Recording method	Phase change
Laser wavelength	650nm
Numerical aperture of lens	0.6
Data bit length	0.41–0.43 microns
Recording track pitch	0.74 microns
Track format	wobbled land and groove

DVD-R

DVD-R is a write-once medium very similar to CD-R. As such, it is ideal for recording archival data or distribution discs. DVD-R discs can be played on a standard DVD-ROM drive.

DVD-R has a single-sided storage capacity of 3.95GB—about six times that of a CD-R, and double that for a two-sided disc—using an organic dye recording layer. The organic dye method also allows the low material cost, similar to CD-R.

To allow for positioning accuracy, DVD-R uses a wobbled groove recording, where special grooved tracks are pre-engraved on the disc during the manufacturing process. Data is recorded within the grooves only. The grooved tracks wobble slightly right and left, and the frequency of the wobble contains clock data for the drive to read, as well as clock data for the drive. The grooves are spaced more closely together than with DVD-RAM, but data is recorded only in the grooves and not on the lands (see Figure 13.9).

Figure 13.9 DVD-R wobbled groove recording.

Table 13.10 has the basic specifications for DVD-R drives.

Table 13.10 DVD-R Specifications

Storage capacity	3.95GB single-sided, 7.9GB double-sided
Disc diameter	80–120mm
Disc thickness	1.2mm (0.6mm×2: bonded structure)
Recording method	Organic dye layer recording method
Laser wavelength	635nm (recording), 635/650nm (playback)
Numerical Aperture of lens	0.6
Data bit length	0.293 microns
Recording track pitch	0.80 microns
Track format	Wobbled groove

DVD-RW (DVD-ReWritable)

The DVD Forum introduced DVD-RW (ReWritable) in March 1998. Created mainly by Pioneer, DVD-RW also uses a phase-change technology and is somewhat more compatible with standard DVD-ROM drives than DVD-RAM. Drives based on this technology began shipping in late 1999. Although newer DVD-type drives have become more compatible with the CD-R/CD-RW standards, there still exists a major problem in harmonizing the many different types of writable

DVD formats. As with the old Beta versus VHS battle, even the introduction of a superior specification complicates the process of accepting a single specification as an industry standard.

DVD-RW is analogous to CD-RW, using a similar phase-change technology to write and rewrite the disc. This is also similar in many ways to DVD-R, and it uses a similar wobbled groove recording technique as well. Just as a CD-RW drive can read and write CD-R discs, a DVD-RW drive will be able to read and write DVD-R discs. Also, DVD-RW discs can be played back on the DVD-Video players and DVD-ROM drives with only a small modification.

DVD+RW

DVD+RW, also called DVD Phase Change ReWritable, is a competing rewritable format championed by Philips, Sony, and Hewlett-Packard. It is more closely based on CD-RW and is incompatible with DVD-RAM, although DVD+RW drives can read DVD-ROMs and CDs. These drives began to ship in the summer of 1999. They are not officially endorsed by the DVD Forum, which is causing some problems with acceptance in the market.

With all these competing recordable DVD standards, one can only hope the companies involved will put aside their differences and one or two popular choices will emerge.

DVD Speed

Single-speed DVD-ROM drives provide a data transfer rate of 1.385MB/second, which means the data transfer rate from a DVD-ROM at 1x speed is roughly equivalent to a 9x CD-ROM (1x CD-ROM data transfer rate is 150 KB/s, or 0.15 MB/s). DVD drives actually spin at a rate which is about three times faster than a CD-ROM drive of the same speed; in other words, a 1x DVD spins at about the same rotational speed as a 3x CD. Many DVD drives list two speeds, one for reading DVD discs and another for reading CD discs. For example, a drive listed as a 16x/40x would indicate the performance when reading DVD/CD discs respectively.

DVD-ROM drives have been available in speeds up to 16x or more, but since virtually all are CAV (Constant Angular Velocity), they actually achieve the rated transfer speed only when reading the outer part of a disc. Table 13.11 shows the data rates for DVD drives reading DVD discs and how that rate compares to a CD-ROM drive.

Table 13.11 DVD Speeds

DVD Speed	Data Rate (Mbits/sec)	Data Rate (MB/sec)	Equivalent CD Speed
1x	11.08	1.385	9x
2x	22.16	2.77	18x
4x	44.32	5.54	36x
5x	55.40	6.925	45x
6x	66.48	8.31	54x
8x	88.64	11.08	72x
10x	110.80	13.85	90x
16x	177.28	22.16	144x

Mbits/sec = Millions of bits per second

MB/sec = Millions of bytes per second

The faster drives are useful primarily for data, not video. Having a faster drive may reduce or eliminate the pause during layer changes when playing a DVD video disc, but having a faster drive would have no effect on video quality.

Drive Compatibility—The MultiRead Specifications

When DVD drives first appeared on the market, they were touted to be fully backward compatible with CD-ROM drives. Although that may be the case when reading commercially pressed CD-ROM discs, that was not necessarily true when reading CD-R or CD-RW media. Fortunately the industry has responded with standards that allow you to know in advance how compatible your DVD drive will be.

The problem stems from the dyes used in the recording layer of CD-R and RW discs, which are very sensitive to the wavelength of light used to read them. At the proper wavelength of 780nm, they are very reflective, whereas at other wavelengths, the reflectivity falls off markedly. Normally CD-ROM drives use a 780nm (infrared) laser to read the data, whereas DVD drives use a shorter wavelength 650nm (red) laser. Although the shorter wavelength laser works well for reading commercial CD-ROM discs since the aluminum reflective layer they use is equally reflective at the shorter DVD laser wavelength, it doesn't work well at all for reading CD-R or RW discs. After an attempt at creating new CD-R and RW media that would work, a solution was first introduced by Sony and then similarly by all the other DVD drive manufacturers.

What they created was a dual-laser pickup that incorporated both a 650nm (DVD) and 780nm (CD) laser. Some of these used two discrete read units with separate optics mounted to the same assembly, whereas others eventually introduced dual laser units that use the same optics for both, making the pickup smaller and less expensive. Because most manufacturers wanted to make a variety of drives, including cheaper ones without the dual laser pickup, it was necessary to create a standard so that someone purchasing a drive would know the drive's capabilities.

To demonstrate the compatibility of a particular drive, the Optical Storage Technology Association (OSTA) created an industry standard test and label that would guarantee specific levels of compatibility. This is called the MultiRead specification. Currently there are two levels called MultiRead and MultiRead2. Table 13.12 shows the two levels of MultiRead capability that can be assigned to drives, and the types of media guaranteed to be readable in such drives.

Table 13.12 MultiRead and MultiRead2 Compatibility Standards for CD/DVD Drives

Media	MultiRead	MultiRead2
CD-DA (Digital Audio)	X	X
CD-ROM	X	X
CD-R	X	X
CD-RW	X	X
DVD-ROM	-	X
DVD-Video	-	X

(continues)

Table 13.12 Continued

Media	MultiRead	MultiRead2
DVD-Audio	-	X
DVD-RAM	-	X

X = Compatible, drive will read this media

- = Incompatible, drive won't read

To determine whether your drive meets either of these standards, merely look for the MultiRead or MultiRead2 logo on the drive. These logos are shown in Figure 13.10.

Figure 13.10 MultiRead and MultiRead2 logos.

The presence of these logos guarantees that particular level of compatibility. If you are purchasing a CD-ROM or DVD drive and want to be able to read recordable or rewritable discs, be sure to look for the MultiRead logo on your drive. Especially in the case of DVD drives, MultiRead versions will generally be more expensive due to the extra cost of the dual-mode laser pickup required.

Adding a DVD Drive to Your System

A DVD drive installs in a manner similar to that of a CD-ROM or any other type of drive. See Chapter 14, “Physical Drive Installation and Configuration,” to learn how to install a 5 1/4-inch DVD drive.

Following are some basic principles to keep in mind when installing a DVD drive:

- Most DVD drives are IDE/ATAPI devices, meaning that you have the issue of master/slave setups on the dual-connector 40-pin IDE cable. If you're replacing an old CD-ROM drive, simply note its master/slave configuration when you remove it from your system, set the new DVD drive the same way, attach it to the data cable, connect the power, and you're finished.
- Many current DVD drives require that you connect them to a bus-mastering IDE interface. If your drive requires a bus-mastering interface, check out the tips earlier in this chapter.
- The other half of DVD, the MPEG decoder card, can be tougher. You must have an open PCI expansion slot, the card usually requires an IRQ (which might force you to disable an existing port to free up an IRQ), and you must connect the decoder card to your existing VGA card. Because of the high hardware demands that MPEG decoder cards place on many users' systems, new VGA video cards with high-quality MPEG movie playback are looking more and more interesting to users. Table 13.13 compares MPEG decoder cards to video cards with built-in MPEG players.

Table 13.13 MPEG Decoder Cards Versus Video Cards with MPEG Players

Consideration	MPEG Decoder	MPEG Player
PCI slot usage	one for decoder; one for VGA	one slot only
Movie image quality	High	Varies
Playback speed	High	Varies
MPEG game compatibility	Yes	No

Note that as processors have become more powerful, many DVD drives now ship with MPEG-2 software decoders. These eliminate the need for an MPEG-2 decoder card, and if your processor is fast enough, allow for adequate performance when playing DVD video discs. Although the software decoders can work well, in most cases if you really plan on using your PC to watch DVD movies, it is worth the extra cost for a hardware MPEG-2 decoder card.

Another performance issue is related to data transfer. Most ATAPI/IDE DVD drives support DMA transfers. Make sure you enable DMA transfers in your BIOS setup and in the DVD driver installed in your operating system. Most installation programs automatically enable DMA support in the driver, but it's a good idea to check anyway. Enabling DMA dramatically reduces the load on your processor and greatly enhances system performance when playing or reading DVDs.

CD-ROM Software on Your PC

After you've physically installed the drive, you're ready for the last step—installing the drivers and other CD-ROM/DVD-ROM software. As usual, this process can be simple with a PnP operating system such as Windows 9x or rather painful with DOS and Windows 3.1. The optical drive needs the following three software components for it to operate on a PC:

- A SCSI adapter driver (not needed for ATAPI IDE CD-ROM drives). Most popular SCSI adapter drivers are built in to Windows 9x.
- A SCSI driver for the specific CD-ROM drive you've installed. An ASPI driver is built into Windows 9x, as is an ATAPI IDE CD-ROM driver.
- MSCDEX—Microsoft CD Extensions for DOS, which is built into Windows 9x as the CDFS VxD.

If you still use DOS, you can have the first two drivers—the SCSI adapter driver and CD-ROM driver—load into your system at startup by placing command lines in your CONFIG.SYS file. The MSCDEX, or DOS extension, is an executable file added into your system through your AUTOEXEC.BAT file. This is not required in Windows 9x; the operating system will autodetect the drive on startup and prompt you to install the correct drivers if it can't find them in its standard arsenal of device drivers.

Using Windows 9x along with a CD-ROM or DVD-ROM drive that conforms to the ATAPI (AT Attachment Packet Interface) IDE specification does not require you to do anything. All the driver support for these drives is built into Windows 9x, including the ATAPI driver and the CDFS VxD driver.

If you are running a SCSI CD-ROM drive under Windows 9x, you will still need the ASPI (Advanced SCSI Programming Interface) driver that goes with your drive. The ASPI driver for your

drive will normally come from the drive manufacturer and is included with the drive in most cases. However, by arrangement with hardware manufacturers, Windows 9x usually includes the ASPI driver for most SCSI host adapters, and also automatically runs the CDFS VxD virtual device driver. In some rare cases, you might have to install an updated driver that you have obtained from the manufacturer.

When you install a PnP SCSI host adapter in a Windows 9x system, simply booting the computer should cause the operating system to detect, identify, and install drivers for the new device. When the driver for the host adapter is active, the system should detect the SCSI devices connected to the adapter and again load the appropriate drivers automatically.

The only problem you might encounter is if you are installing a new device, such as a DVD-ROM drive, on an older version of Windows. Windows 98 includes drivers for most of the DVD-ROM drives on the market, but Windows 95 was released before these devices existed. In this case, you will probably have to supply a device driver on floppy disk, in response to a request from the OS, during the installation process.

DOS SCSI Adapter Driver

For DOS users, of course, the installation process is not so easy. Each SCSI adapter model has a specific driver that enables communication between the PC and the SCSI interface. Normally, these drivers conform to the ASPI. The ASPI driver for the drive connects with the ASPI driver for the SCSI host adapter; this is how the adapter and the drive communicate. An ASPI driver should be provided both with your SCSI drive and with the host adapter. Documentation should also have been included that walks you through the installation of the software.

Most SCSI adapters come with an installation program that automates the process of installing the appropriate ASPI drivers, both for the adapter and for the devices connected to the SCSI bus. However, you can manually add the SCSI device driver to your CONFIG.SYS file. In the CONFIG.SYS file, add the name and path of the appropriate driver with the `DEVICE=` command (replace `C:\DRIVERS` with the actual location of your files, and `MYSCSI.SYS` with the actual name of your SCSI driver):

```
DEVICE=C:\DRIVERS\MYSCSI.SYS
```

`C:\DRIVERS` is the subdirectory into which you copied the SCSI ASPI device drivers. Some drivers have option switches or added commands that, for example, enable you to view the progress of the driver being loaded.

DOS CD-ROM Device Driver

This driver should be a part of your basic installation kit as well. If not, contact the drive's manufacturer for the proper device driver for your SCSI card.

The device driver should come with an installation program that prompts you for the memory I/O address for the SCSI adapter to which you've connected the CD-ROM drive. This device driver enables the adapter to communicate with the drive through the SCSI bus. Installation programs

add a line similar to the following to your CONFIG.SYS file (replace MYCDROM.SYS with the actual name of your CD-ROM driver file, and C:\DRIVERS with the actual location of your files):

```
DEVICE=C:\DRIVERS\MYCDROM.SYS /D:mscd001
```

C:\DRIVERS is the subdirectory that contains the driver MYCDROM.SYS, the driver for your specific CD-ROM drive.

Note the /D:mscd001 option after the preceding statement. This designation, called the device signature, identifies this CD-ROM driver as controlling the first (001), and only, CD-ROM drive on the system. This portion of the device driver statement is for the Microsoft DOS Extensions driver, which designates CD-ROM drives in this fashion. In fact, you could use any designation here, as long as the MSCDEX command line uses the same one.

MSCDEX: Adding CDs to DOS

The Microsoft CD Extensions for DOS allow the DOS operating system (and by extension, Windows 3.1) to identify and use data from CD-ROMs attached to the system. The original DOS operating system had no provisions for this technology, so “hooks” or handling of this unique media are not part of the basic operating environment. Using these extensions is convenient for all involved, however. As CD-ROM technology changes, the MSCDEX can be changed, independently of DOS. For example, most PhotoCD, multiple-session CD-ROM drives require MSCDEX.EXE version 2.21 or higher, which has been modified from earlier versions to accommodate the newer CD-ROM format.

MSCDEX.EXE should be in your software kit with your drive. If not, you can obtain the latest copy directly from Microsoft. If you are a registered user of DOS or Windows 3.1, MSCDEX.EXE is free. Read the licensing agreement that appears on the disc or in your manual concerning the proper licensing of the MSCDEX files.

Your installation software should add a line similar to the following to your AUTOEXEC.BAT file:

```
C:\WINDOWS\COMMAND\MSCDEX.EXE /d:mscd001
```

C:\WINDOWS\COMMAND is the directory in which the MSCDEX.EXE file is located by default with Windows 95 and 98; with MS-DOS and Windows 3.1, it could be located in the \DOS directory, or in the directory containing the CD-ROM drivers. The /d:mscd001 portion of the command line supplies the MSCDEX extension with the device signature defined in the CD-ROM device driver of your CONFIG.SYS file.

Note

The MSCDEX and CD-ROM device signatures must match. The defaults that most installations provide are used in this example. As long as the two names are the same, the drivers can find one another.

As long as you have these three drivers—the SCSI adapter driver, the CD-ROM driver, and the DOS CD extensions—loaded properly in your system, the CD-ROM drive will operate as transparently as any other drive in your system.

Table 13.14 lists the options that you can add to the MSCDEX.EXE command line.

Table 13.14 MSCDEX Command-Line Options

Switch	Function
/V	Called Verbose; when this option is added to the command line, it displays information about memory allocation, buffers, drive letter assignments, and device driver names on your screen at boot time.
/L:<letter>	Designates which DOS drive letter you want to assign to the drive. For example, /L:G assigns the drive letter G: to your CD-ROM drive. Two conditions apply: First, you must not have another drive assigned to that letter; and second, your lastdrive= statement in your CONFIG.SYS file must be equal to or greater than the drive letter you're assigning. LASTDRIVE=G would be fine. LASTDRIVE=F would cause an error if you attempt to assign the CD-ROM drive to the G: drive with the /L: switch.
/M:<buffers>	Enables you to buffer the data from the CD-ROM drive. This is useful if you want faster initial access to the drive's directory. Buffers of 10 to 15 are more than enough for most uses. Any more is overkill. Each buffer, however, is equal to 2KB of memory. So a /M:10 buffer argument, for example, would take 20KB of memory. Note that this does not significantly increase the overall performance of the drive, just DOS's initial access to the drive and the access of large data blocks when the drive is reading live-motion video files, for example. You can't turn a 400ms drive into a speed demon by adding a 200KB buffer. With no /M: argument added, MSCDEX will add six buffers as a default. That might be fine for most PCs and CD-ROM drives.
/E	Loads the aforementioned buffers into DOS high memory, freeing up space in the conventional 640KB. Early versions of MSCDEX—anything below version 2.1—do not load into extended memory. You must have DOS 5.0 for this option to load.
/K	Provides Kanji (Japanese) language support.
/S	Enables you to share your CD-ROM drive on a peer-to-peer network, such as Windows for Workgroups.

Note that Windows 9x uses a built-in CDFS (CD File System) driver that takes the place of MSCDEX. It is configured through the Windows 9x Registry and requires no AUTOEXEC.BAT command. USB-based CD-ROM/CD-R/CD-RW drives are also configured through the Windows 9x Registry and use no CONFIG.SYS or AUTOEXEC.BAT commands.

Loading CD-ROM Drivers

As mentioned earlier, your drive should come with installation software that copies the device driver files to your hard drive. It should also add the necessary command lines to your CONFIG.SYS and AUTOEXEC.BAT files.

When the process is complete, you can reboot your machine and look for signs that all went smoothly in the software installation.

Following is a series of sample portions of your startup screens to give you an idea of what messages you'll receive when a given driver is properly loaded into the system.

When you're sure that the software is loaded correctly, try the drive by inserting a disc into the drive. Then get a directory of the disc from the DOS prompt by issuing the following command:

```
DIR/w G:
```

This command gives you a directory of the CD you've inserted, if your CD has been assigned the drive letter G.

You can log in to the CD-ROM drive, as you would any DOS drive. The only DOS commands not possible on a CD-ROM drive are those that write to the drive. Remember that CDs are media that cannot be overwritten, erased, or formatted.

If you logged in to the CD-ROM and received a directory of a sample CD, you're all set.

Now you can power down the PC and replace the cover.

CD-ROM in Microsoft Windows 3.x

When your drive is added to your system, Windows already knows about it through the device drivers and DOS. The CD-ROM drive is accessible through File Manager by double-clicking its file cabinet icon. You see your CD-ROM drive among the drive icons across the top. Windows knows that the drive is a CD-ROM drive through the DOS extensions discussed earlier.

You can set your CD-ROM player to play audio CDs while you are working in Windows. You need to hook up your drive to a sound card and speakers or connect the CD's audio ports to a stereo first. Go to the Windows Control Panel and select Drivers. If you do not see [MCI] CD Audio among the files in the driver's list, choose Add. Insert the Windows installation disk that contains the CDAUDIO driver and add the driver. When the driver appears on the list, close the Drivers and control panel windows.

Double-click the Media Player icon. Under Devices, select CD. A listing of the track numbers on your audio CD appears along the bottom edge of the Media Player. The controls on Media Player are similar to those of an audio CD player, including track select, continuous play, and pause.

Many drive manufacturers supply DOS-based CD audio players with their systems. Check your installation manual and software discs for these utilities.

Optical Drives in Windows 9x and Windows NT 4.0

As stated earlier, Windows 9x and Windows NT include virtually all the drivers you will need to run your optical drive, making the software installation automatic. Windows automatically recognizes most IDE drives, and with the addition of the appropriate drive-specific ASPI driver, most SCSI drives as well.

There are several new capabilities with CDs and DVDs in Windows 9x/NT. The most dramatic is the Autoplay feature, which is available on Windows 95/98 and some versions of Windows NT 4.0.

Autoplay is a feature integrated into Windows 9x that enables you to simply insert a disc into the drive, and Windows will automatically run it without any user intervention. It will also detect whether that particular disc has already been installed on your system, and if not, it will automatically start the install program. If the disc has already been installed, it will start the application program on the disc.

The Autoplay feature is simple. When you insert a disc, Windows 9x automatically spins it and looks for a file called AUTORUN.INF. If this file exists, Windows 9x opens it and follows the instructions contained within. As you can see, this Autoplay feature will only work on discs that have this file. Most software companies are now shipping CD-ROM and DVD-ROM titles that incorporate the Autoplay feature.

Tip

You can disable the Autoplay feature for all CD-ROMs by opening the Windows 9x System control panel to the Device Manager page, highlighting your CD-ROM drive, and clicking the Properties button. The Properties dialog box for the drive has a Settings page that contains an Auto Insert Notification checkbox. Clearing this box prevents the operating system from processing the AUTORUN.INF file.

If you want to use Autoplay for some CDs, but not others, hold down the Shift key when inserting a CD you don't want to Autoplay.

Windows 9x/NT includes a new version of the Media Player found in Windows 3.x called the CD Player. This application allows you to play audio CDs in your drive while you work at the computer. The CD Player features graphical controls that look like a standard audio CD-ROM drive and even has advanced features found in audio drives, such as random play, programmable playback order, and the capability to save play list programs.

MS-DOS Drivers and Windows 9x

Many users have discovered that their CD-ROM drives didn't come with MS-DOS drivers at a very unfortunate time: when their Windows 9x system wouldn't start up. All too often, the "cure" for a "dead" Windows 9x system is a complete reinstallation from the Windows 9x CD, to replace defective files and settings with new copies. Of course, if Windows isn't working, its 32-bit CD-ROM device drivers aren't working either. And, if you don't have your CONFIG.SYS and AUTOEXEC.BAT files and the files listed earlier either, you can't reload Windows! You should have a bootable disk ready that has the appropriate drivers included to allow you to rebuild your Windows 9x installation in case of emergencies.

If you have Windows 98, the Emergency Startup disk that you create during installation or later already has the appropriate drivers, AUTOEXEC.BAT, and CONFIG.SYS included to run most popular SCSI and ATAPI/IDE-based CD-ROMs. However, a Windows 95 bootable disk doesn't include the AUTOEXEC.BAT, CONFIG.SYS, or drivers; you'll have to add these yourself (see the next section).

Note

If you can't find any references to the MS-DOS drivers needed for your CD-ROM drive on your Windows 9x computer, check for an installation disk that might have been shipped with the drive. To install the CD-ROM device driver files you need, use that disk to perform an MS-DOS/Windows 3.1 installation, which will add the appropriate lines to your CONFIG.SYS and AUTOEXEC.BAT files and copy the drivers to your system.

Creating a Bootable Disk with CD-ROM Support

If you use Windows 95 (any version), take a moment and create a bootable disk.

Tip

Optionally you can use a Windows 98/Me startup floppy, as these have the CD-ROM support already configured and installed. You can even use a Windows 98/Me startup disk to boot a Windows 95 system, so getting a disk from a 98/Me system is definitely the easiest way to proceed. If that is not an option, you can add the CD-ROM support to the Windows 95 startup disk.

I'll assume that your CD-ROM drive uses the following CD-ROM device driver: MYCDROM.SYS, located in C:\CDROM.

Note

Your actual CD-ROM device driver will have a different name, but it almost always has *CD* or *CD-ROM* in the name somewhere!

You need to copy the following files to your bootable disk in A: drive:

- MYCDROM.SYS

Use the actual driver name for your CD-ROM drive and copy it from the file's actual location.

- MSCDEX.EXE

Copy from C:\WINDOWS\COMMAND; same file for any CD-ROM drive.

Then, you need to create a CONFIG.SYS file that loads the CD-ROM device driver and an AUTOEXEC.BAT that loads the MSCDEX.EXE CD-ROM extensions for MS-DOS program. Use a text editor such as the Windows Notepad.

- Contents of CONFIG.SYS:

```
DEVICE=MYCDROM.SYS /D:miscd001
```

- Contents of AUTOEXEC.BAT:

```
MSCDEX.EXE /d:miscd001 (other optional switches if you like as noted earlier)
```

Note

Note that the */d:* switch refers to the same device name, which could be "Charlie" or "Kumquat" or anything that matches! A mismatch would cause the loading process to fail.

Copy the following four files to your bootable floppy (listed again here for clarity):

- MYCDROM.SYS (or whatever your CD-ROM driver is called)

- MSCDEX.EXE

- AUTOEXEC.BAT (references MSCDEX.EXE)

- CONFIG.SYS (references MYCDROM.SYS)

Also, copy the COMMAND.COM file and the hidden boot files to the disk to complete your bootable disk that can both start your computer and give you access to the CD-ROM drive.

With the disk still in the A: drive, check your BIOS setup, change the drive boot order to allow A: to be first if needed, and then save any changes if necessary. The computer reboots, and if you've done your work properly, you should boot up to an A: prompt and be able to access your CD-ROM drive at whatever drive letter was displayed when MSCDEX.EXE ran. This will be the next drive letter after your last hard drive letter. If your latest hard drive letter is C:, the CD-ROM is D:.

Put your Windows 95 CD-ROM in the CD-ROM drive and see whether you can display a directory listing. If you can, your bootable disk is a success! Put the disk away for a rainy day. Sooner or later, you'll need it.

Note

The same basic procedure works for MS-DOS and Windows 3.1 users.

Windows 98/Me users can normally use their Emergency Startup disk created during upgrade installation or through the Windows Programs tab in the Add/Remove Software dialog box. Unlike the Windows 95 version, the Windows 98/Me version has an elaborate multipart CONFIG.SYS file that tries the most common IDE and SCSI CD-ROM drivers to find one that works with your drive.

If you did not create an emergency disk when installing Windows 98/Me or have misplaced the disk, you can create one at any time by opening the Add/Remove Programs control panel, selecting the Startup Disk tab and choosing Create Disk.

If you use an OEM version of Windows 98/Me or any version of Windows 2000, your CD is bootable. Be sure to set the boot order in your BIOS so that your system scans your CD-ROM before your hard drive. See Chapter 5, "BIOS," for more information on accessing the BIOS Setup utility.

Making a Bootable CD-ROM for Emergencies

With the rise of low-cost CD-R/CD-RW drives and low-cost drive imaging products such as Norton's Ghost and PowerQuest's Drive Image, it's now possible for individual PC owners to create their own version of what is standard with more and more new computers: a bootable CD-ROM that can be used to start up a system and restore it to a previously saved state. This is a step beyond the rescue CD that I discussed earlier, in which the image file was placed on a standard data CD-R. To recover from a system crash with that type of CD, you'd need to boot your system with a boot disk similar to the one I described making in the previous section.

But wouldn't it be great if you didn't need a bootable disk? They're easy to erase, damage, or lose. What if the CD-R itself could be bootable? You might have even seen a computer manufacturer's recovery CD boot itself before restoring a drive. With most CD-R mastering software, you can make one too.

Bootable CDs contain a special version of the boot files found on any disk or hard drive used to start a system. Because these files take less than 100KB (in the case of Windows 95B), the remainder of the 650MB can be used to store a compressed image of the system hard drive (made with Ghost, Drive Image, or similar products), a copy of the original operating system installation files, or anything else that you'd find useful.

By creating a bootable CD, you can

- Have a bootable “super-sized floppy” that can’t be erased or altered (if you write-protect it during creation).
- Create your own recovery CD by creating a compressed image file of your system when it’s in top working condition and placing the image file on the CD along with the restore program. In the event of disaster, boot with the CD and restore the image file.
- Switch between operating systems by creating compressed image files of each operating system after you install it and copying each to a separate CD along with the recovery utility. It isn’t necessary to make the CD bootable with the same operating system because you’ll need to restart the computer after restoring the image file.

Files Needed for a Bootable CD

The minimum requirements for a bootable CD include

- A system in which the CD-ROM can be designated as a boot drive

Note

Check your BIOS under Advanced Setup or similar options. Recent and current BIOS code supplied by AMI, Award Software, and Phoenix Technologies typically support the CD-ROM as a bootable device.

- A CD-ROM drive which can be treated as a bootable device (see the following sidebar)
- A CD-R or CD-RW drive (you’ll use CD-R media in either case)
- Mastering software that allows creation of a bootable CD

Note

If your current CD-mastering software lacks this option, consider changing to Adaptec’s Easy CD-Creator Pro. This low-cost software program supports most CD-R/CD-RW drives, offers high performance, many features for creating music as well as data CDs, and can make bootable CD-Rs.

- A floppy disk containing your operating system boot files

Note

You can use the ERU disk created by Windows 95, the startup disk created by Windows 95/98, or any bootable disk made by your operating system. Note that you’ll need to add the CD-ROM drivers to the disk, or verify that the Windows 98 startup disk will work with your CD-ROM drive (discussed later in this chapter).

ATAPI/IDE Drives Are Bootable

Most ATAPI/IDE drives connected to a motherboard IDE interface can be used as a bootable device if the BIOS permits it. If your CD-ROM is connected to a sound card, this procedure won’t work. If your CD-ROM is connected to an SCSI interface, you’ll need an SCSI interface with a BIOS chip that permits booting as well as a bootable CD.

(continues)

(continued)

Here's a quick test to see whether your system can handle treating an IDE/ATAPI CD as a bootable device:

1. Place a data CD into your CD-ROM drive.
 2. Start your computer.
 3. Enter the BIOS Setup program.
 4. Go to the appropriate screen (as mentioned earlier) and select CD-ROM as first boot device.
 5. Select first hard disk (a.k.a. C:) as second boot device.
 6. Exit BIOS setup screens and save changes.
 7. On computer restart, see whether the CD-ROM drive is being read for boot files. If so, eject data CD and allow computer to boot from hard disk. You should be able to boot from a bootable CD if your system tries to read the boot files from the CD-ROM drive.
-

The basic procedure for creating a bootable CD is as follows:

1. Create a bootable floppy for the operating system you want to install on the CD.
2. Get a blank CD-R and place it into your CD-R/CD-RW drive.
3. Start your mastering software.
4. Under disc layout, make sure that ISO 9660 is selected. This CD format doesn't permit long filenames, so make sure that any additional files you add to the CD have no more than eight characters plus up to three characters for the filename extension.
5. Make sure that the bootable option is enabled in the disc layout.
6. When prompted, insert the disk containing boot files into A: drive.
7. These files are copied to your CD layout. Note that the names of these files are not the same as the normal operating system boot files. The files are called BOOTCAT.BIN and BOOTIMG.BIN.
8. Add any additional files (image files, operating system install files, and so on) you want to the layout.
9. Start the CD Creation process.
10. When the process is completed, view the contents of the finished CD-R.
11. Close your mastering program, saving the layout if you desire.
12. Insert the bootable CD you just created into your CD-ROM drive.
13. Restart the computer and see whether your system boots from the CD.

If you follow these directions, you will discover two interesting things when you reboot:

- Your CD-ROM drive is called drive A:.
- You won't be able to see any of your files on drive A: (the CD-ROM) except for COMMAND.COM if you made the CD-R with Windows 9x boot files.

Even though the bootable CD was able to start the computer, a CD-ROM, regardless of BIOS version, is still primarily a software-controlled peripheral. Without the appropriate driver software (the CD-ROM device driver in CONFIG.SYS and the MSCDEX.EXE program in AUTOEXEC.BAT),

the CD-ROM drive cannot function at all (normal mode) or cannot do any more than boot the computer as if it's a 650MB shiny round floppy disk (bootable CD mode).

The CONFIG.SYS and AUTOEXEC.BAT statements needed on a bootable CD are similar to the standard examples you saw earlier, but with special modifications that allow them to work on a CD and change the drive letter assignments back to normal.

1. Start with a bootable disk containing the AUTOEXEC.BAT, CONFIG.SYS, MYCDROM.SYS (substitute your driver for this one), and MSCDEX.EXE as I discussed earlier.

2. Edit the CONFIG.SYS to read

```
Lastdrive=Z
Device=mycdrom.sys /d:mscd001
```

3. Edit the AUTOEXEC.BAT to read

```
MSCDEX /d:mscd001 /l:z
```

The /l:z statement “locks” your CD-ROM drive letter at Z.

4. Boot the computer with the modified boot disk, and make sure the CD-ROM drive is accessible as Z:.
5. Start the CD-R mastering software program.
6. Create your CD-layout. If you're trying to make a rescue CD from an image file made with Norton Ghost, Drive Image, and so on, place the image file into the CD layout, along with the image-file-restore program.
7. Open the File menu and select CD Properties. Check mark the box that says Bootable CD.
8. Under Data type, select ISO 9660 and select Any 8+3 Character MS-DOS Filename under Properties.

Note that with ISO 9660 any Windows 9x-style long file names are shortened to their MS-DOS alias names (“Program Files” = “Progra~1”, and so on).

9. Create the CD. Insert the bootable disk you created in steps 1–4 when prompted.
10. Note that even though the bootable floppy contains four additional files, the two files in the CD layout are still called BOOTCAT.BIN and BOOTIMG.BIN. These files contain all bootable information from the floppy.
11. Remove the bootable floppy, and restart the computer (change the boot sequence to CD-ROM first and hard disk second).
12. Success means the system boots from CD-ROM and CD-ROM drivers load to allow access to entire CD.

Caring for Optical Media

Some people believe that optical discs and drives are indestructible when compared to their magnetic counterparts. Actually, modern optical drives are far less reliable than modern hard disk drives. Reliability is the bane of any removable media, and CD-ROMs and DVD-ROMs are no exception.

By far the most common causes of problems with optical discs and drives are scratches, dirt, and other contamination. Small scratches or fingerprints on the bottom of the disc should not affect performance because the laser focuses on a point inside the actual disc, but dirt or deep scratches can interfere with reading a disc.

To remedy this type of problem, you can clean the bottom surface of the CD with a soft cloth, but be careful not to scratch the surface in the process. The best technique is to wipe the disc in a radial fashion, using strokes that start from the center of the disc and emanate toward the outer edge. This way, any scratches will be perpendicular to the tracks rather than parallel to them, minimizing the interference they might cause. You can use any type of solution on the cloth to clean the disc, so long as it will not damage plastic. Most window cleaners are excellent at removing fingerprints and other dirt from the disc and will not damage the plastic surface.

If there are deep scratches, they can often be buffed or polished out. A commercial plastic cleaner such as that sold in auto parts stores for cleaning plastic instrument cluster and tail-lamp lenses is very good for removing these types of scratches. This type of plastic polish or cleaner has a very mild abrasive that polishes scratches out of a plastic surface. Products labeled as cleaners are usually designed for more serious scratches, whereas those labeled as polishes are usually milder and work well as a final buff after using the cleaner. Polishes can be used alone if the surface is not scratched very deeply.

Read errors can also occur when dust accumulates on the read lens of your CD-ROM drive. You can try to clean out the drive and lens with a blast of “canned air,” or by using a drive cleaner (which can be purchased at most music stores that sell audio CDs).

If your discs and your drive are clean, but you still can't read a particular disc, your trouble might be due to disc capacity. Early CD-ROM discs had a capacity of about 550MB (equivalent to about 60 minutes of CD audio). More recently, the capacity of a standard CD has been pushed to 650MB (74 minutes of CD audio). Many older CD-ROM drives are unreliable when they try to read the outermost tracks of newer discs where the last bits of data are stored. You're more likely to run into this problem with a CD that has lots of data—including some multimedia titles. If you have this problem, you might be able to solve it with a firmware or driver upgrade for your CD-ROM drive, but it's possible that the only solution will be to replace the drive.

Sometimes too little data on the disc can be problematic as well. Some older CD-ROM drives use an arbitrary point on the disc's surface to calibrate their read mechanism, and if there happens to be no data at that point on the disc, the drive will have problems calibrating successfully. Fortunately, this problem can usually be corrected by a firmware or driver upgrade for your drive.

Many older drives have had problems working under Windows 9x. If you are having problems, contact your drive manufacturer to see whether there is a firmware or software-driver upgrade that might take care of your problem. With new high-speed drives available for well under \$100, it might not make sense to spend any time messing with an older drive that is having problems. It would be more cost-effective to upgrade to a new drive instead.

If you are having problems with only one particular disc and not the drive in general, you might find that your difficulties are in fact caused by a defective disc. See whether you can exchange the disc for another to determine whether that is indeed the cause.

Troubleshooting Optical Drives

Failure Reading a CD

If your CD fails to read a CD, try the following solutions:

- Check for scratches on CD data surface.
- Check drive for dust, dirt; use cleaning CD.
- Make sure drive shows up as working device in System Properties.
- Try a CD that you know to work.
- Restart computer (the magic cure-all).
- Remove drive from Device Manager in Windows 9x; allow system to redetect drive and reinstall drivers (if PnP-based system).

Failure to Read CD-R, CD-RW Discs in CD-ROM or DVD Drive

If your CD-ROM or DVD drive fails to read CD-R and CD-RW discs, try the following solutions:

- Check compatibility; some very old 1x CD-ROM drives can't read CD-R media. Replace drive with newer, faster, cheaper model.
- Many early-model DVD drives can't read CD-R, CD-RW media; check compatibility.
- CD-ROM drive must be MultiRead compatible to read CD-RW due to lower reflectivity of media; replace drive.
- If some CD-Rs but not others can be read, check media color combination to see whether some color combinations work better than others; change brand of media.
- Packet-written CD-Rs (from Adaptec DirectCD and backup programs) can't be read on MS-DOS/Windows 3.1 CD-ROM drives due to limitations of operating system.

IDE/ATAPI CD-ROM Drive Runs Slowly

If your IDE/ATAPI CD-ROM drive performs poorly, check the following items:

- Check cache size in the Performance tab of the System Properties control panel. Select the quad-speed setting (largest cache size).
- Check to see whether the CD-ROM drive is set as the slave to your hard disk; move CD-ROM to the secondary controller if possible.
- Your PIO or UDMA mode might not be set correctly for your drive in the BIOS; check drive specs and use autodetect in BIOS for best results (see Chapter 5).
- Check to see that you are using bus-mastering drivers on compatible systems; install appropriate drivers for motherboard's chipset and operating system in use. See "DMA (Direct Memory Access)" earlier in this chapter.
- Check to see whether you are using the CD-ROM interface on your sound card instead of IDE connection on motherboard. Move drive connection to the IDE interface on motherboard and disable sound card IDE if possible to free up IRQ and I/O port address ranges.

- Open the System Properties control panel and select the Performance tab to see whether system is using MS-DOS Compatibility Mode for CD-ROM drive. If all IDE drives are running in this mode, see www.microsoft.com and query on “MS-DOS Compatibility Mode” for a troubleshooter. If only the CD-ROM drive is in this mode, see whether you’re using CD-ROM drivers in CONFIG.SYS and AUTOEXEC.BAT. Remove the lines containing references to the CD-ROM drivers (don’t actually delete the lines—REM them), reboot the system, and verify that your CD-ROM drive still works and that it’s running in 32-bit mode. Some older drives require at least the CONFIG.SYS driver to operate.

Poor Results When Writing to CD-R Media

If you are having problems successfully writing data to a CD-R disc, see “How to Reliably Make CD-Rs” earlier in this chapter.

Trouble Reading CD-RW Discs on CD-ROM

If you cannot read CD-RW discs in your CD-ROM, check the vendor specifications to see whether your drive is MultiRead compliant. Some drives are not compliant.

If your drive is MultiRead compliant, try the CD-RW disc on known-compliant CD-ROM drive (drive with MultiRead feature).

Trouble Reading CD-R Discs on DVD Drive

If your DVD drive cannot read a CD-R disc, check drive compliance—original DVDs cannot read CD-R media. Newer, faster DVD drives support CD-R media.

Trouble Making Bootable CDs

If you are having problems creating a bootable CD, try these possible solutions:

- Check the contents of bootable floppy disk from which you copied the boot image. To access entire contents of a CD-R, a bootable disk must contain CD-ROM drivers, AUTOEXEC.BAT, and CONFIG.SYS.
- Use ISO 9660 format. Don’t use Joliet format because it is for long-filename CDs and can’t boot.
- Check your system’s BIOS for boot compliance and boot order; CD-ROM should be listed first.
- Check drive for boot compliance.
- SCSI CD-ROMs need SCSI card with BIOS and bootable capability as well as special motherboard BIOS settings.

CHAPTER 14

Physical Drive Installation and Configuration

This chapter covers the actual installation of hard drives, optical drives (CD/DVD), floppy drives, and tape drives. This includes everything from preparing the components to setting jumpers to installing the actual cabling and physical installation. Also the initial system software configuration issues will be covered as well, right up until the start of the operating system installation. From that point on, the steps you take would depend on which operating system you are installing.

For more information on drive interfaces, magnetic storage, drive operation, and operating system issues, see the following chapters:

- Chapter 7, “The IDE Interface”
- Chapter 8, “The SCSI Interface”
- Chapter 9, “Magnetic Storage Principles”
- Chapter 10, “Hard Disk Storage”
- Chapter 11, “Floppy Disk Storage”
- Chapter 12, “High-Capacity Removable Storage”
- Chapter 13, “Optical Storage”

Although most of the drives you would install in a PC are covered here, the primary emphasis is on hard disks.

Hard Disk Installation Procedures

This section describes the hard disk drive installation process, particularly the configuration, physical installation, and formatting of a hard disk drive.

To install a hard drive in a PC, you must perform some or all of the following procedures:

- Configure the drive
- Configure the host adapter (if used)
- Physically install the drive
- Configure the system
- Partition the drive
- High-level format the drive

As you perform the setup procedure, you might need to know various details about the hard disk drive, the host adapter (if used), and the system ROM BIOS, as well as many of the other devices in the system. This information usually appears in the various OEM manuals that come with these devices. Make sure when you purchase these items that the vendor includes these manuals. (Many do not include the manuals unless you ask for them.) For most equipment sold today, you will get enough documentation from the vendor or reseller of the equipment to enable you to proceed.

If you are like me, however, and want all the technical documentation on the device, you will want to contact the original manufacturer of the device and order the technical specification manual. For example, if you purchase a system that comes with an IBM ATA (IDE) hard disk, the

seller probably will give you some limited information on the drive, but not nearly the amount that the actual IBM technical manual provides. To get this documentation, you normally download it from the drive manufacturer's Web site. The same rule applies for any of the other components in most of the systems sold today. I find the OEM technical manuals to be essential in providing the highest level of technical support possible.

For reference, you can look up the hard disk manufacturer names in the Vendor List on the CD, and you will find numbers to call for technical support, as well as URLs for their Web sites.

Note

You'll also find a drive specification database on the CD. This database, from BluePlanet.com, contains an exhaustive list of drive specs for thousands of drives. If you don't have ready access to your drive specs, check out this searchable database.

Drive Configuration

Before you physically install a hard disk drive into the computer, you must be sure that it is properly configured. For an ATA/IDE drive, this generally means designating the drive as a master/slave or using the Cable Select (CS) feature and a special cable to determine the relationship. For SCSI drives, you must set the device's SCSI ID and possibly its SCSI bus termination state.

◀◀ These procedures are covered in "The IDE Interface," p. 515, and "The SCSI Interface," p. 545.

Host Adapter Configuration

Older hard disk drive types used separate disk controller cards that you had to install in a bus slot. The IDE and SCSI hard disk drives used in today's PCs have the disk controller integrated into the drive assembly. For IDE drives, the I/O interface is nearly always integrated into the system's motherboard, and you configure the interface through the system BIOS. There is no separate host adapter; therefore, if you have an IDE drive you can proceed to "Physical Installation," later in this chapter. Some systems might use ATA/IDE adapters in lieu of the built-in interface, because some of the motherboard-integrated ATA interfaces will not support the faster modes some newer drives (such as Ultra-ATA/33 and Ultra-ATA/66) are capable of achieving. In most cases, I would recommend upgrading the motherboard rather than getting an IDE host adapter, because there are other benefits to a new motherboard and the cost isn't much higher.

SCSI drives, however, usually require a host adapter card that you must install in a bus slot like any other card. A few motherboards have integrated SCSI adapters, but these are rare. Configuring a SCSI host adapter card involves setting the different system resources that the adapter requires. As with most expansion cards, a SCSI host adapter will require some combination of the following system resources:

- Boot ROM addresses
- Interrupt request (IRQ)
- DMA (Direct Memory Access) channel (DRQ)
- I/O port addresses

Not all adapters use every one of these resources, but some might use them all. In most cases with modern plug-and-play adapters and systems, these resources will be automatically configured by the BIOS and your operating system. The computer sets the required hardware resource settings to values that do not conflict with other devices in the computer.

◀◀ See "Plug-and-Play BIOS," p. 424.

Note

A detailed list of PnP device IDs is included in the Technical Reference section of the CD included with this book.

If your hardware or operating system does not support Plug and Play, you have to manually configure the adapter to use the appropriate resources. Some adapters provide software that enables you to reconfigure or change the hardware resources, whereas others use jumpers or DIP switches.

◀◀ See "System Resources," p. 340.

The IDE interface driver is part of the standard PC BIOS, which makes it possible to boot from an IDE drive. The BIOS provides the device driver functionality that the system needs to access the drive before any files can be loaded from disk. A SCSI interface driver is not part of the standard PC BIOS, so most SCSI host adapters have their own on-board ROM BIOS that enables SCSI drives to function as bootable devices.

Use of the SCSI BIOS is usually optional. If you are not booting from a SCSI drive, you can load a standard device driver to access the SCSI devices. Most host adapters have switches, jumpers, or configuration software that you use to enable or disable SCSI BIOS support.

In addition to providing boot functionality, the SCSI BIOS can provide many other functions, including any or all of the following:

- Low-level formatting
- Drive-type (parameter) control
- Host adapter configuration
- SCSI diagnostics
- Support for nonstandard I/O port addresses and interrupts

If the adapter's onboard BIOS is enabled, it will use specific memory address space in the upper memory area (UMA). The UMA is the top 384KB in the first megabyte of system memory. The UMA is divided into three areas of two 64KB segments each, with the first and last areas being used by the video adapter circuits and the motherboard BIOS, respectively. Segments C000h and D000h are reserved for use by adapter ROMs such as those found on disk controllers or SCSI host adapters.

Note

You must ensure that any adapters using space in these segments of the HMA (high memory area) do not overlap with another adapter that uses this space. No two adapters can share this memory space. Most adapters have software, jumpers, or switches that can adjust the configuration of the board and change the addresses it uses to prevent conflict.

Physical Installation

The procedure for the physical installation of a hard disk drive is much the same as that for installing any other type of drive. You must have the correct screws, brackets, and faceplates for the specific drive and system before you can install the drive.

Some computer cases require plastic or metal rails that are secured to the sides of a hard disk drive so it can slide into the proper place in the system (see Figure 14.1). Other case designs have drive bays that directly accept the drive via screws through the side supports and no other hardware is necessary, whereas others use a cage arrangement where you first install the drives into a cage, and then slide the cage into the case (see Figure 14.2). If your case uses rails or a cage, these will be included with the case. With the proper mounting mechanism supplied via the case, all you need is the bare drive to install.

Because cables can vary for both IDE and SCSI interfaces, be sure you have the proper cable for both your drive and controller. For example, to run the newer Fast-ATA/66 modes, you need a special 80-conductor cable which supports the Cable Select (CS) feature. This cable is also recommended if you are running Fast-ATA/33; it will work for all slower modes as well.

Figure 14.1 A typical hard disk with mounting rails.

If you need additional drive mounting hardware not included with either your case or the drive, there are several companies listed in the Vendor List (on the CD) that specialize in drive-mounting brackets, cables, and other hardware accessories. Most 3 1/2-inch hard drives sold in boxed packaging in retail outlets do include the mounting bracket required to mount a 3 1/2-inch drive in a 5 1/4-inch bay (as shown in Figure 14.3).

Note

You should also note the length of the drive cable itself when you plan on adding a hard disk drive. It can be very annoying to assemble everything that you think you'll need to install a drive, and then find that the drive cable is not long enough to reach the new drive location. You can try to reposition the drive to a location closer to the

(continues)

(continued)

interface connector on the host adapter or motherboard, or just get a longer cable. ATA/IDE cables are limited to 18 inches in overall length; if they are shorter, that is all the better. This is most important if your drive is going to use the faster ATA/33 and ATA/66 modes. Using a cable that is too long will cause timing errors and signal degradation, possibly corrupting the data on your drive. I see many 24-inch long cable assemblies being sold or used in systems; you are asking for trouble if you violate the 18-inch maximum-length specification.

Figure 14.2 A typical hard disk mounted in a removable drive cage.

Figure 14.3 A typical bracket used to mount a 3 1/2-inch drive in a 5 1/4-inch drive bay. The bracket is screwed to the drive and then mounted in the bay by using screws or rails as determined by the case.

Different faceplate, or bezel, options are also available. Make sure that you have the correct bezel for your application. Some systems, for example, do not need a bezel; if there is a bezel on the drive, you must remove it.

Caution

Make sure you use only the screws that come with your new drive. Many drives come with special short-length screws that might have the same size thread as other screws you might use in your system, but that should not be interchanged. If you use screws that are too long, they might protrude too far into the drive casing and cause problems.

Hard Drive Physical Installation—Step by Step

The step-by-step procedures for installing a hard drive are as follows:

Note

Be sure to see the step-by-step instructions and photos for installing a hard drive in Chapter 24, “Building or Upgrading Systems.”

1. Check your computer for an unused ATA/IDE connector. Typical Pentium-class and newer PCs have two ATA/IDE connectors, allowing for up to four ATA/IDE devices.

Tip

Normally it is best for performance to keep hard drives on the primary IDE cable and other types of drives (CD-ROM/DVD/tape/SuperDisk and so on) on the secondary.

You might need an additional cable if both master and slave connectors are used on the primary and you are adding a third device.

2. Double-check the pin configuration and cable type. The colored (normally red or red-flecked) stripe on one edge of the cable goes to pin 1 of the hard drive’s data connector. Most cables and drive connectors will be keyed to prevent improper (backward) installation, but many are not. Keying can be done via missing and plugged pins, a ridge on one side of the connector, or both. One tip is that on the drive connector pin 1 is almost always oriented nearest to the power connector.

Tip

Newer ATA drives that operate in Ultra-DMA modes require a special 80-conductor cable whereas lesser drives can use a 40-conductor cable. Note that you can always use the superior 80-conductor cable for slower drives, so normally that is all I recommend purchasing anymore. SCSI drives use either 50-pin or 68-pin (wide) cables. Often, these 80-conductor cables are identified with a conductor of a different color (blue is common).

3. Configure the drive jumpers. If the drive is ATA/IDE and you are using a cable that supports Cable Select (CS), you must set the CS jumper on any drives connected to that cable. Otherwise you must set the drives on the cable as either master or slave. Note that some

older drives also required a slave-present jumper be set if the drive was configured as a master with a slave drive on the same cable. You'll find more detail on the drive configuration procedures, later in this chapter.

4. Slide the drive carefully into a drive bay of the correct size. Most hard drives, except for a few very high-capacity SCSI drives meant for servers and the Quantum Bigfoot series, are 3 1/2-inch wide and one-inch high. If you have no 3 1/2-inch drive bays left for your hard disk, attach a drive-adapter kit to the sides of the drive to make it wide enough to fit into a 5 1/4-inch wide drive bay (refer to Figure 14.3). Some case designs require that you attach rails to the side of the hard drive. If so, attach them to the drive using the screws supplied with either the case or the drive. Be sure the screws aren't too long; if you bottom the screws in the drive, you can damage it. Then slide the drive into the bay in the case until the rails latch into place. Note that most cases include the screws and rails to install drives, but if not you might have to purchase them separately.
5. Attach the data cable connector to the back of the drive, unless you are adding the drive and cable at the same time. In that case, attach the cable to the drive before you slide it into the drive bay and fasten it into place (step 2).
6. Attach the appropriate power connector to the drive. Most hard drives use the larger, or "Molex" four-wire power connector. If necessary, purchase a Y-splitter cable to create two power connectors from one (many computers have fewer power connectors than drive bays).
7. Turn on the computer and listen for the new hard disk to spin up. While today's drives are very quiet compared to early hard disks, you should still hear a faint rattling or clicking as the new hard disk starts to run. If you don't hear anything from the drive, double-check the data and power cables.
8. Restart the computer and access the BIOS setup screens to configure the new hard disk. At a minimum, you'll need to detect (or set) the following parameters: cylinders, heads, sectors per track, and write precompensation. If your BIOS has an autodetect or auto type setting, I recommend you use it as it will configure most parameters automatically. For IDE hard drives above 528MB (504 megabytes), you'll also need to set LBA translation to access the drive's full capacity. If autodetect was selected, LBA translation should already be set correctly. Many systems have a Peripherals Configuration screen, which also allows you to set transfer speeds for maximum drive performance, but again these should be configured automatically if you had enabled auto-detect. See your drive's documentation for the correct settings. Save the BIOS configuration, and exit the BIOS setup screen to continue. The following section has more information on this step, as it can be complicated.
9. Restart the computer, and prepare to run FDISK to prepare the hard drive for formatting and use. Or, you can use drive partitioning software, such as PowerQuest's PartitionMagic to automatically create and manage disk partitions. Normally, FDISK can be found on the operating system start disk such as the Windows startup disk. Simply insert the startup disk in the floppy drive, boot from it, and type the FDISK command at the A: prompt.

◀ See "The IDE Interface," p. 515, and "The SCSI Interface," p. 545.

System Configuration

After your drive is physically installed, you have to provide the computer with basic information about the drive so the system can access it and boot from it. How you set and store this information depends on the type of drive and system you have. Standard (IDE) setup procedures apply

for most hard disks except SCSI drives. SCSI drives normally follow a custom setup procedure that varies depending on the host adapter that you are using. If you have a SCSI drive, follow the instructions included with the host adapter to configure the drives.

Automatic Drive Typing

For IDE drives, virtually all new BIOS versions in today's PCs have automatic typing. The BIOS sends a special Identify Drive command to all the devices connected to the IDE interface during the system startup sequence; the drives are intelligent enough to respond with the correct parameters. The BIOS then automatically enters the parameter information returned by the drive. This procedure eliminates errors or confusion in parameter selection. However, even with automatic drive typing, some BIOSes will alert you that you need to enter the system Setup program and configure the drive. In these situations, just enter the system BIOS configuration utility and save the settings that the BIOS has detected for the drive. You don't need to enter any settings yourself.

If your system supports automatic drive typing but no drive information appears onscreen, you might have forgotten to attach the power cable to the drive, or you might have reversed the IDE interface cable at either the motherboard or the hard drive connections. The red stripe on the 40-pin IDE cable is supposed to be aligned with pin 1 at both ends. Without power or proper data connection the drive will never spin up and, therefore, cannot be detected.

Even though most new BIOSes support automatic drive typing at startup, there are a couple of benefits to performing this task within the BIOS configuration screen:

- In the event that you need to move the drive to another system, you'll know the drive geometry and translation scheme (such as LBA) that was used to access the drive. If the drive is moved to another computer, the identical drive geometry (cylinder, head, sectors per track) and translation scheme must be used in the other computer, or the data on the drive will not be accessible and can be lost. Because many systems with auto-configuration don't display these settings during the startup process, performing the drive-typing operation yourself might be the only way to get this information.
- Even if you never expect to move the drive, you'll gain several seconds on every startup by detecting the drive in the BIOS configuration screens and saving the setting there. You can also save time by setting unused drive interfaces to Not Installed. Otherwise, the computer will try to detect devices on all four IDE ports (primary master, primary slave, secondary master, and secondary slave) each time you start the computer.

Manual Drive Typing

If you are dealing with a motherboard that does not support automatic typing, you must enter the appropriate drive information in the system BIOS manually. The BIOS has a selection of pre-configured drive types, but these are woefully outdated in most cases, providing support only for drives holding a few hundred megabytes or less. In nearly every case, you will have to select the user-defined drive type and provide values for the following settings:

- Cylinders
- Heads
- Sectors per track
- Write precompensation

The values that you use for these settings should be provided in the documentation for the hard disk drive, or they might be printed on the drive itself. It's a good idea to check for these settings and write them down, because they might not be visible after you've installed the drive. You should also maintain a copy of these settings in case your system BIOS should lose its data due to a battery failure. One of the best places to store this information is inside the computer itself. Taping a note with vital settings like these to the inside of the case can be a lifesaver.

In the event that you are unable to determine the correct settings for your hard drive from either the drive case or from the Technical Reference, there are utility programs available from the Internet that can query the drive for this information. Western Digital's TBLCHK.EXE has been updated to handle LBA-mode hard drives, unlike many older utilities, and can be obtained from Western Digital's Web site.

Note

The setup parameters for over 1,000 popular drive models are included in the Technical Reference on the CD. Additionally, there is a generic table of parameters included in the appendix that will work (although they might not work optimally) with any IDE drive up to 528MB.

Depending on the maker and the version of your system BIOS, there might be other settings to configure as well, such as what transfer mode to use, and whether the BIOS should use logical block addressing.

Formatting

Proper setup and formatting are critical to a drive's performance and reliability. This section describes the procedures used to format a hard disk drive correctly. Use these procedures when you install a new drive in a system or immediately after you recover data from a hard disk that has been exhibiting problems.

There are three major steps in the formatting process for a hard disk drive subsystem:

1. Low-level formatting
2. Partitioning
3. High-level formatting

Low-Level Formatting

All new hard disk drives are low-level formatted by the manufacturer, and you do not have to perform another LLF before you install the drive. In fact, under normal circumstances, you should not ever have to perform a low-level format on an IDE or SCSI drive. Most manufacturers no longer recommend that you low-level format any IDE type drive.

This recommendation has been the source of some myths about IDE. Many people say, for example, that you cannot perform a low-level format on an IDE drive, and that if you do, you will destroy the drive. This statement is untrue! What can happen is that you might lose the optimal head and cylinder skew factors for the drive that were set by the manufacturer, as well as the map

of drive defects. This situation is not good and will definitely have a negative effect on the drive's performance, but you still can use the drive with no problems.

However, there might be times when you must perform a low-level format on an IDE or SCSI drive. The following sections discuss the software that you can use to do this.

SCSI Low-Level Format Software

If you are using an SCSI drive, you must use the LLF program provided by the manufacturer of the SCSI host adapter. The design of these devices varies enough that a register-level program can work only if it is tailored to the individual controller. Fortunately, all SCSI host adapters include low-level format software, either in the host adapter's BIOS or in a separate disk-based program.

The interface to the SCSI drive is through the host adapter. SCSI is a standard, but there are no true standards for what a host adapter is supposed to look like. This means that any formatting or configuration software will be specific to a particular host adapter.

Note

Notice that SCSI format and configuration software is keyed to the host adapter and is not specific in any way to the particular SCSI hard disk drive that you are using.

IDE Low-Level Format Software

IDE drive manufacturers have defined extensions to the standard WD1002/1003 AT interface, which was further standardized for IDE drives as the ATA (AT Attachment) interface. The ATA specification provides for vendor-unique commands, which are manufacturer proprietary extensions to the standard. To prevent improper low-level formatting, many of these IDE drives have special codes that must be sent to the drive to unlock the format routines. These codes vary among manufacturers. If possible, you should obtain LLF and defect-management software from the drive manufacturer; this software usually is specific to that manufacturer's products, and often is model-specific. Check the brand and model number of your hard disk to determine the utility program you need.

Most ATA IDE drives are protected from any alteration to the skew factors or defect map erasure because they are in a translated mode. Zoned bit recording drives are always in translation mode and are fully protected. Most ATA drives have a custom command set that must be used in the format process; the standard format commands defined by the ATA specification usually do not work, especially with intelligent or zoned bit recording IDE drives. Without the proper manufacturer-specific format commands, you can't perform the defect management by the manufacturer-specified method, in which bad sectors often can be spared.

Most manufacturers supply low-level format programs for their drives. Here are a few examples:

- *Seagate*. ftp://ftp.seagate.com/techsuppt/seagate_utils/sgatfmt4.zip
- *IBM*. <http://www.storage.ibm.com/techsup/hddtech/welcome.htm>
- *Quantum*. http://www.quantum.com/support/csr/software/csr_software.htm
- *Western Digital*. http://www.wdc.com/service/ftp/wddiag/wd_diag.exe
- *Maxtor*. <http://www.maxtor.com/library/ide.html>

I would try the manufacturer-specific format programs first. They are free and can often work at a lower level and handle defects in ways that the more generic ones can't. If formatting software is not available from your drive's manufacturer, I recommend Disk Manager by Ontrack and the MicroScope program by Micro 2000. Another excellent, inexpensive, general-purpose PC hardware diagnostic that includes low-level format capability is #1 TuffTEST Pro from #1-PC Diagnostics. These programs can format many IDE drives because they know the manufacturer-specific IDE format commands and routines. They also can perform defect-mapping and surface-analysis procedures.

Note

While Ontrack Disk Manager can be purchased in a "generic" version that works with any manufacturer's hard drives, brand-specific OEM versions are often available free of charge on the utility disks or CD-ROMs shipped with new retail-packaged hard disk drives. You should also check your drive maker's Web site for updated versions of Disk Manager. These OEM versions are designed to check for a particular brand's drive firmware and will not work on any other brand than the one for which they were modified.

Nondestructive Formatters

General-purpose, BIOS-level, nondestructive formatters, such as Calibrate and SpinRite, are not recommended in most situations where a real LLF is required. These programs have several limitations and problems that limit their effectiveness; in some cases, they can even cause problems with the way that defects are handled on a drive. These programs attempt to perform a track-by-track LLF by using BIOS functions, while backing up and restoring the track data as they go. These programs do not actually perform a complete LLF, because they do not even try to low-level format the first track (Cylinder 0, Head 0) due to problems with some controller types that store hidden information on the first track.

These programs also do not perform defect mapping in the way that standard LLF programs do, and they can even remove the carefully applied sector header defect marks during a proper LLF. This situation potentially allows data to be stored in sectors that originally were marked defective and might actually void the manufacturer's warranty on some drives. Another problem is that these programs only work on drives that have already been formatted and can format only drives that are formattable through BIOS functions.

Note

SpinRite is useful for recovering data found on drives with read errors, because of its thorough method of repeatedly rereading the errors and analyzing the results to reconstruct the missing data.

A true LLF program bypasses the system BIOS and sends commands directly to the disk controller hardware. For this reason, many LLF programs are specific to the disk controller hardware for which they are designed. It is virtually impossible to have a single format program that will run on all different types of controllers. Many hard drives have been incorrectly diagnosed as being defective because the wrong format program was used and the program did not operate properly.

Drive Partitioning with FDISK

Partitioning a hard disk is the act of defining areas of the disk for an operating system to use as a volume.

When you partition a disk, the partitioning software writes a master partition boot sector at Cylinder 0, Head 0, Sector 1—the first sector on the hard disk. This sector contains data that describes the partitions by their starting and ending cylinder, head, and sector locations. The partition table also indicates to the ROM BIOS which of the partitions is bootable and, therefore, where to look for an operating system to load.

▶▶ See “File Systems and Data Recovery,” p. 1433.

The FDISK program is the accepted standard for partitioning hard disk drives for use with all operating systems. The program is included with your operating system and although it has the same name and basic functions with any OS, you should normally use the one that specifically came with your OS. Partitioning prepares the boot sector of the disk in such a way that the FORMAT.COM program or the Windows GUI format utility can operate correctly. FDISK also makes it possible for different operating systems to coexist on a single hard disk. No matter which operating system you use, it should come with an FDISK program that can be used to partition the drive.

Note

Because FDISK depends on BIOS information about the hard disk to determine the size and drive geometry of the hard disk, having correct BIOS settings saved in the BIOS Setup is vital to the correct operation of FDISK. If a 10GB hard drive is defined in the BIOS as a 10MB hard drive, for example, all that FDISK will prepare for use, and all that FORMAT will ultimately prepare, is 10MB.

With any version of Windows, as with MS-DOS, FDISK allows you to create two different types of disk partitions: primary and extended. A primary partition can be bootable but an extended partition cannot. If you have only a single hard disk in your system, at least part of the drive must be prepared as a primary partition if you want to start your computer from the hard disk (and who doesn't?). A primary partition is seen as a single volume or drive letter (C: on one-drive systems), whereas an extended partition acts as a sort of logical container for additional volumes (drive letters D: and beyond). A single extended partition can contain a single volume (also referred to by FDISK as a *logical DOS drive*), or several volumes (logical DOS drives) of different sizes.

Don't get hung up on the fact that FDISK calls partitions “DOS” partitions or “DOS” drives. This is true even though the operating system you are installing is Windows 95, 98, Me, NT, 2000, Linux, and so on.

Depending on the version of Windows in use (and with any version of MS-DOS), it might be necessary to subdivide a hard drive through the use of FDISK. The original release of Windows 95 and MS-DOS supports a file system known as FAT16, which allows no more than 65,536 files per drive and a single drive letter or volume size of no more than 2.1GB in size. Thus, a 10.1GB hard disk prepared with MS-DOS or the original Windows 95 (or 95A) must have at a minimum of five drive letters, and could have more. See Figure 14.4.

Figure 14.4 Adding a hard drive above 2.1GB in size to an MS-DOS or original Windows 95A computer forces the user to create multiple drive letters to use the entire drive capacity. The logical DOS drives are referenced like any other drive, although they are portions of a single physical hard disk.

Another reason for subdividing a single drive into multiple volumes is for increased data security. For example, PowerQuest (the creators of PartitionMagic) suggests a three-volume partitioning scheme that looks like this:

- C: for the operating system and utilities
- D: for applications
- E: and above for data

In this example, primary and extended partitions would be assigned as shown here:

- C: the primary partition
- D: and E: in the extended partition as logical DOS drives (volumes)

If a catastrophic failure to the disk structure wipes out C: or D:, Drive E:, which contains the data, will normally still be intact. This method also makes backing up the data easier; just set the backup program to back up all of E:, or all the changed files on E:.

Large Hard Disk Support

If you use the Windows 95B or above (Win95 OSR 2.x), Windows 98, Windows Me, or Windows 2000 versions of FDISK with a hard drive greater than 512MB, FDISK will offer to enable large disk support.

Choosing to enable large disk support provides several benefits:

- You can use a large hard disk (greater than 2.1GB) as a single drive letter; in fact, your drive can be as large as 2TB and still be identified by a single drive letter. This is due to the FAT32 file system, which allows for many more files per drive than FAT16.

▶▶ See “FAT32,” p. 1453.

- Because of the more efficient storage methods of FAT-32, your files will use less hard disk space overall.

However, keep in mind that all disk operations must be done through an operating system with FAT32 support (Windows 95B or later, Windows 98, Windows Me, or Windows 2000). If you have old MS-DOS games or applications that require you to boot with MS-DOS rather than with Windows’s command-prompt mode, they can’t access a FAT32 drive.

A drive prepared with the large hard disk support (FAT32) option enabled can still be partitioned into primary and secondary partitions with FDISK, as with FAT16 for the data-security reasons listed earlier.

Another type of file system is NTFS, which is supported only by Windows NT and Windows 2000. This is a high-performance file system with additional security and networking features. NTFS was revised to NTFS5 in Windows NT 4.0 with Service Pack 4 and later, as well as Windows 2000. It is discussed in more detail in Chapter 26, “File Systems and Data Recovery”. Note that Windows 9x cannot read NTFS partitions, and Windows NT cannot read FAT32 partitions. Windows 2000 can handle both FAT32 and NTFS.

Assigning Drive Letters with FDISK

There are many ways to use FDISK, depending on the number of hard drives you have in your system and the number of drive letters you want to create.

With a single drive, creating a primary partition (C:) and an extended partition with two logical DOS drives within it will result in the following drive letters:

Partition Type	Drive letter(s)
Primary	C:
Extended	D: and E:

Most people would think that a second physical drive added to this system should have drive letters that follow the E: drive.

However, you need to understand how drive letters are allocated by the system to know how to use FDISK correctly in this situation. Table 14.1 shows how FDISK assigns drive letters by drive and partition type.

Table 14.1 Drive Letter Allocations by Drive and Partition Type

Drive	Partition	Order	Drive Letter
1st	Primary	1st	C:
1st	Extended	3rd	E:
2nd	Primary	2nd	D:
2nd	Extended	4th	F:

How does this affect you when you add another hard drive? If you prepare the second hard drive with a primary partition and your first hard drive has an extended partition on it, the second hard drive will take the primary partition's D: drive letter. This moves all the drive letters in the first hard drive's extended partition up one drive letter.

In the first example, we listed a drive with C: (primary partition), D:, and E: (extended partition volumes) as the drive letters (D: and E: were in the extended partition). Table 14.2 indicates what happens if a second drive is added with a primary partition and an extended partition with two volumes (same setup as the first drive):

Table 14.2 Drive Letter Changes Caused by Addition of Second Drive with Primary Partition

Drive	Partition Type	Order	Original Drive Letters (First Drive Only)	New Drive Letters After Adding Second Drive
1st	Primary	1st	C:	C:
1st	Extended	3rd	D:, E:	E:, F:
2nd	Primary	2nd		D:
2nd	Extended	4th		G:, H:

After adding the second drive, the original drive letters D: and E: have now become E: and F:. The primary partition on the new drive has become D:, and the extended partition volumes on the second drive are G: and H:. Confused? Well you better not be or you'll find yourself deleting or copying data to or from the wrong drive.

This principle extends to third and fourth physical drives as well: the primary partitions on each drive get their drive letters first, followed by logical DOS drives in the extended partitions.

One way to affect this is to only partition additional drives with extended partitions, in other words, do not create primary partitions on them. That way the new drive's partitions will be seen only as additional letters, and the letters used by the first drive's partitions will remain unchanged.

If you're *adding* a drive to your system, you should now understand why preparing that second, third, or fourth drive with a primary partition is a bad idea. If you're installing an additional hard drive (not a replacement), remember that it can't be a bootable drive. If it can't be bootable, there's no reason to make it a primary partition. FDISK will allow you to create an extended partition using 100 percent of the space on any drive. Table 14.3 shows the same example used in the Table 14.2 with the second drive installed as an extended partition:

Table 14.3 Drive Letter Allocations After Addition of Second Drive with Extended Partition Only

Drive	Partition Type	Order	Original Drive Letters (First Drive Only)	New Drive Letters After Adding Second Drive
1st	Primary	1st	C:	C:
1st	Extended	3rd	D:, E:	D:, E:
2nd	Primary	2nd	—	—
2nd	Extended	4th		F:

When a new drive is added with only extended partition volumes, you can see that the original drive letters remain undisturbed. This is a much easier to understand arrangement, and prevents accidents with data due to drive letters changing. This operating-system behavior also explains why some of the first computers with IDE-based (ATAPI) Iomega Zip drives had the Zip drive as D:, with a single hard disk identified as C: and E;; the Zip drive was treated as the second hard drive with a primary partition.

Running FDISK

When you run newer versions of FDISK, the first thing that will happen is you will be prompted:

```
Do you wish to enable large disk support (Y/N).....? [Y]
```

If you answer Yes to this question, FDISK will create FAT32 volumes for all volumes created that are larger than 512MB. Answering No to this question forces FDISK to create only FAT16 volumes, which will be limited to 2GB maximum size, and will waste more space on the disk due to larger cluster sizes.

Normally in a modern system you would answer Yes, allowing the use of FAT32. After answering the question, FDISK will show a menu like the following:

```
Current fixed disk drive: 1
  Choose one of the following:
    1. Create DOS partition or Logical DOS Drive
    2. Set active partition
    3. Delete partition or Logical DOS Drive
    4. Display partition information
    5. Change current fixed disk drive
Enter choice: [1]
```

Option 5 will only be shown if FDISK detects more than one drive on your system (if more than one is entered via your BIOS Setup). In that case, FDISK will default to the first drive, and via option 5 you can cause FDISK to work with any of the other hard disks on the system.

To create partitions you would select option 1. If the drive is already partitioned, you can use option 4 to display the current layout of the drive.

After selecting option 1, the menu changes to allow you to create primary or extended partitions on a drive as follows:

```
Create DOS Partition or Logical DOS Drive
  Current fixed disk drive: 1
  Choose one of the following:
    1. Create Primary DOS Partition
    2. Create Extended DOS Partition
    3. Create Logical DOS Drive(s) in the Extended DOS Partition
Enter choice: [1]
```

The rules require that you must create a primary partition first on the boot drive, but on a secondary or non-boot drive you can create just an extended partition if you choose. So if you are partitioning the first drive in a system and it will be bootable, you would choose option 1.

At this point you will be prompted to decide if you want to use the maximum available size for a Primary DOS Partition. If you say Yes and you are using FAT32, the primary partition will use the entire drive; if you say Yes and you did not enable large drive support (meaning you are using FAT16), the partition will use the entire drive or 2GB, whichever is smaller.

If you decide to create a primary partition that is not the full drive, you should go back through the menus and create an extended partition using the rest of the drive, and then further divide it into logical drives. Normally I recommend making the primary partition the full size of the drive, keeping all of the drive as one letter, but there are various reasons one might want to split the drive into multiple partitions such as for different operating systems, different file systems, applications, and so on.

After all the partitions are created, the final operation is to make one of them active (bootable), which is option 2 from the main FDISK menu. Normally the only one that can be active is the primary partition. After that is done, all FDISK operations are complete, and you can exit the program.

When exiting FDISK after making partition changes, the system must be rebooted before these changes will be recognized. After rebooting, you must then high-level format each of the volumes with the operating system FORMAT command, which will then allow the operating system to store files on them.

The C: volume must normally be formatted with the system files, although when you install Windows via the Windows Setup command, it will detect if the system files are not present and will offer to install them for you.

Drive Partitioning with PartitionMagic

PowerQuest's PartitionMagic allows you to take an existing hard drive and perform the following changes to it without loss of data:

- Change primary partition size (larger or smaller)
- Turn empty space on hard drive into additional drive letters
- Convert the inefficient FAT16 partition type into efficient FAT32 on systems with Windows 95B or Windows 98
- Move programs to new drive letters created with PM and change Registry keys and other information automatically with Magic Mover (included with retail versions of PartitionMagic)

Note

I still recommend FDISK be used for initial partitioning and setup of any drive, but PartitionMagic can be very useful for reconfiguring a system that is already partitioned.

While the program recommends a full backup before starting, I've used PartitionMagic many times to turn a single "big drive" into two or more drive letters in less than 10 minutes. Performing the same task with backup software and FDISK/FORMAT can take several hours.

High-Level (Operating System) Formatting

The final step in the installation of a hard disk drive is the high-level format. Like the partitioning process, the high-level format is specific to the file system you've chosen to use on the drive. On Windows 9x and DOS systems, the primary function of the high-level format is to create a FAT and a directory system on the disk so the operating system can manage files. You must run FDISK before formatting a drive. Each drive letter created by FDISK must be formatted before it can be used for data storage.

Usually, you perform the high-level format with the FORMAT.COM program or the formatting utility in Windows 9x Explorer. FORMAT.COM uses the following syntax:

```
FORMAT C: /S /V
```

This command high-level formats drive C:, writes the hidden operating system files in the first part of the partition, and prompts for the entry of a volume label to be stored on the disk at the completion of the process.

The FAT high-level format program performs the following functions and procedures:

1. Scans the disk (read only) for tracks and sectors marked as bad during the LLF, and notes these tracks as being unreadable.
2. Returns the drive heads to the first cylinder of the partition, and at that cylinder (Head 1, Sector 1) writes a DOS volume boot sector.
3. Writes a FAT at Head 1, Sector 2. Immediately after this FAT, it writes a second copy of the FAT. These FATs essentially are blank except for bad-cluster marks noting areas of the disk that were found to be unreadable during the marked-defect scan.
4. Writes a blank root directory.
5. If the /S parameter is specified, copies the system files, IO.SYS and MSDOS.SYS (or IBM-BIO.COM and IBMDOS.COM, depending on which DOS you run) and COMMAND.COM to the disk (in that order).
6. If the /V parameter is specified, prompts the user for a volume label, which is written as the fourth file entry in the root directory.

Now, the operating system can use the disk for storing and retrieving files, and the disk is a bootable disk.

During the first phase of the high-level format, the program performs a marked defect scan. Defects marked by the LLF operation show up during this scan as being unreadable tracks or sectors. When the high-level format encounters one of these areas, it automatically performs up to five retries to read these tracks or sectors. If the unreadable area was marked by the LLF, the read fails on all attempts.

After five retries, the DOS FORMAT program gives up on this track or sector and moves to the next one. Areas that remain unreadable after the initial read and the five retries are noted in the FAT as being bad clusters.

Note

Because the high-level format doesn't overwrite data areas beyond the root directory of the hard disk, it's possible to use programs such as Norton Utilities to unformat the hard disk that contains data from previous operations, provided no programs or data has been copied to the drive after high-level formatting. Unformatting can be performed because the data from the drive's previous use is still present.

If you create an extended partition, the logical DOS drive letters found there need a simpler `FORMAT` command, because system files aren't necessary. For example, `FORMAT D: /V` for drive D:, `FORMAT E: /V` for drive E:, and so on.

FDISK and FORMAT Limitations

The biggest problem with FDISK is that it is destructive. If you change your mind about disk structure, you must back up your system and start over again. That alone is cause for using FDISK with care, but there are other limitations you should keep in mind:

- FDISK doesn't provide any help with issues of drive letter changes.
- FDISK requires `FORMAT` before the drive is ready for use.
- `FORMAT` must check the entire drive before making it ready for use. Its error management is rudimentary and can waste a lot of disk space with older drives that have disk errors.
- FDISK and `FORMAT` are designed for a single operating system environment, with no provision for multiboot options (Windows 9x and NT or Windows 9x and Linux, for example).
- FDISK and `FORMAT` offer no procedure for migrating data to a new drive, and `XCOPY` is tricky to use.
- FDISK and `FORMAT` might cause conflicts with existing CD-ROM drives, which often use the next available drive letter after the existing hard drive.

For these reasons, many drive vendors offer some sort of automatic disk installation software with their hard drives. These routines can make the task of disk migration a fast, easy, reliable operation.

Typical features of automatic disk installation programs include the following:

- *Replacement for FDISK and FORMAT.* A single program performs both functions more quickly than FDISK and `FORMAT` separately.
- *Database of drive jumpers for major brands and models.*
- *Drive copy function.* Copies contents of old MS-DOS or Windows 9x drive to new drive, retaining long filenames, file attributes, and so on.
- *CD-ROM drive letter relocation utility.* Moves CD-ROM to new drive letter (to make room for new hard drive letters) and resets Windows Registry and INI file references to new drive letter so CD-ROM software works without reinstallation.
- *Menu-driven or wizard-driven process for installing new hard drive.*
- *Optional override of BIOS limitations for installation of large hard drives (>504MB, 2.1GB, 8.4GB, and so on).*

The two major vendors in the automated disk-utility business are Ontrack Data International, Inc. and StorageSoft. These companies sell their disk-installation products to OEM hard drive vendors for use with particular brands of drives. They also sell to the public “generic” versions that can be purchased for use with any brand or model of hard disk. Table 14.4 provides a basic overview of the most popular disk installation programs.

Table 14.4 Overview of Automatic Disk-Installation Programs

Vendor	Software	Current Version	OEM	Retail
Ontrack	Disk Manager	9.xx	Yes	Yes
	Disk Manager DiskGo!	2.5x	Yes	Yes
StorageSoft	EZ Drive	9x	Yes	Yes
	DrivePro	3.x	No	Yes
Seagate ¹	DiscWizard	2.4x	Yes	No
Maxtor ²	MaxBlast!	9.x	Yes	No

1 Seagate's DiscWizard was codeveloped with Ontrack and contains Ontrack Disk Manager v9.x.

2 Maxtor's MaxBlast! Software v9.x is a customized version of EZ-Drive. Version 7.x and 8.x of MaxBlast! were customized versions of Ontrack Disk Manager.

Disk Manager and EZ-Drive are DOS-based utility programs, whereas DiscWizard and Disk Manager DiskGo! offer a Windows-like interface. Seagate's DiscWizard actually analyzes the system, asks the user questions about the intended installation, and prepares a customized procedure based on the user's responses.

OEM versions of disk-installation programs are available from the drive makers' Web sites; retail versions usable with any combination of drives can be purchased from retail stores or at the vendors' online stores.

Replacing an Existing Drive

Previous sections discuss installing a single hard drive or adding a new hard drive to a system. While formatting and partitioning a new hard disk can be challenging, replacing an existing drive and moving your programs and files to it can be a lot more challenging.

Drive Migration for MS-DOS Users

When MS-DOS 6.x was dominant, many users used this straightforward method to transfer the contents of their old hard drive to their new hard drive:

1. The user created a bootable disk containing FDISK, FORMAT, and XCOPY.
2. The new hard drive was prepared with a primary partition (and possibly an extended partition, depending on the user's desires).
3. The new hard drive was formatted with system files, although the operating system identified it as D:.

4. The XCOPY command was used to transfer all non-hidden files from C:\ (the old hard drive) to D:\ thus:

```
XCOPY C:\ D:\ /S/E
```

The XCOPY command also was used as necessary to transfer files from any remaining drive letters on the old hard drive to the corresponding drive letters on the new drive.

Because the only hidden files such a system would have were probably the operating system boot files (already installed) and the Windows 3.1 permanent swap file (which could be recreated after restarting Windows), this “free” data transfer routine worked well for many people.

After the original drive was removed from the system, the new drive would be jumpered as master and assigned C:. You would need to run FDISK from a floppy and set the primary partition on the new C: drive as Active. You’d then exit FDISK and the drive will boot.

Drive Migration for Windows 9x/Me Users

Windows 9x/Me have complicated the once-simple act of data transfer to a new system by their frequent use of hidden files and folders (such as \Windows\Inf, where Windows 9x hardware drivers are stored). The extensive use of hidden files was a major reason for a greatly enhanced version of XCOPY to be included in Windows 9x/Me.

Note

XCOPY32 is automatically used in place of XCOPY when XCOPY is started within a DOS session under Windows.

XCOPY32 for Windows 9x Data Transfer

Compared to “classic” XCOPY, XCOPY32 can copy hidden files; can preserve file attributes such as system, hidden, read-only, and archive; can automatically create folders; and is compatible with long filenames. Thus, it is possible to use it to duplicate an existing drive, but with these cautions:

1. The XCOPY32 command is much more complex.
2. There might be errors during the copy process because of Windows’s use of temporary files during normal operation, but XCOPY32 can be forced to continue.

This command line will call XCOPY32 and transfer all files and folders with their original attributes intact from the original drive (C:) to the new drive (D:). This command must be run from an MS-DOS session under Windows 95 or 98.

```
xcopy32 c:\. d:\ /e/c/h/r/k
```

The command switches are explained here:

- /e. Copies folders, even if empty; also copies all folders beneath the starting folder
- /c. Continues to copy after errors (The Windows swap file can’t be copied due to being in use.)
- /h. Copies hidden and system files

- /r. Overwrites read-only files
- /k. Preserves file attributes

Repeat the command with appropriate drive-letter changes for any additional drive letters on your old drive.

After the original drive is removed from the system, the new drive needs to be jumpered as master (or single) and the operating system will assign it C:. You will need to run FDISK from a floppy and set the primary partition on the new C: drive as Active. Then exit FDISK, and the drive will boot.

Note that although the XCOPY method has worked for me, some people have problems with it. A much more automated and easy approach to cloning drives is to use commercial software designed for that purpose, such as Drive Copy by PowerQuest or Norton Ghost by Symantec.

While many users have prepared new hard drives for use with nothing but FDISK and FORMAT, today's more complex systems are presenting increasingly good reasons for looking at alternatives.

Interfacing to Disk Drives

DOS uses a combination of disk management components to make files accessible. These components differ slightly between floppies and hard disks and between disks of different sizes. They determine how a disk appears to DOS and applications. Each component used to describe the disk system fits as a layer into the complete system. Each layer communicates with the layer above and below it. When all the components work together, an application can access the disk to find and store data.

There are four primary interface layers between an application program running on a system and the disk drives attached to the system. They consist of software routines that can perform various functions, usually to communicate with the adjacent layers. These layers are as follows:

- DOS Interrupt 21h (Int 21h) routines
- DOS Interrupt 25/26h (Int 25/26h) routines
- ROM BIOS disk Interrupt 13h (Int 13h) routines
- Disk controller I/O port commands

Each layer accepts various commands, performs different functions, and generates results. These interfaces are available for both floppy disk drives and hard disks, although the floppy disk and hard disk Int 13h routines differ widely. The floppy disk controllers and hard disk controllers are very different as well, but all the layers perform the same functions for both floppy disks and hard disks.

Interrupt 21h

The DOS Int 21h routines exist at the highest level and provide the most functionality with the least amount of work. For example, if an application program needs to create a subdirectory on a disk, it can call Int 21h, Function 39h. This function performs all the operations necessary to

create the subdirectory, including updating the appropriate directory and FAT sectors. The only information this function needs is the name of the subdirectory to create. DOS Int 21h would do much more work by using one of the lower-level access methods to create a subdirectory. Most applications access the disk through this level of interface.

Interrupt 25h and 26h

The DOS Int 25h and Int 26h routines provide much lower level access to the disk than the Int 21h routines. Int 25h reads only specified sectors from a disk, and Int 26h only writes specified sectors to a disk. If you were to write a program that used these functions to create a subdirectory on a disk, the amount of work would be much greater than that required by the Int 21h method. For example, your program would have to perform all these tasks:

- Calculate exactly which directory and FAT sectors need to be updated
- Use Int 25h to read these sectors
- Modify the sectors appropriately to add the new subdirectory information
- Use Int 26h to write the sectors back to the disk

The number of steps is even greater when you factor in the difficulty in determining exactly what sectors have to be modified. According to Int 25/26h, the entire DOS-addressable area of the disk consists of sectors numbered sequentially from 0. A program designed to access the disk using Int 25h and Int 26h must know the correct disk locations by sector number. A program designed this way might have to be modified to handle disks with different numbers of sectors or different directory and FAT sizes and locations. Because of all the overhead required to get the job done, most programmers do not choose to access the disk in this manner and instead use the higher level Int 21h, which does all the work automatically.

Typically, only disk- and sector-editing programs access disk drives at the Int 25h and Int 26h level. Programs that work at this level of access can edit only areas of a disk that have been defined to DOS as a logical volume (drive letter). For example, the DOS DEBUG program can read sectors from and write sectors to disks with this level of access.

Interrupt 13h

The next lower level of communications with drives, the ROM BIOS Int 13h routines, usually are found in ROM chips on the motherboard or on an adapter card in an expansion slot. However, an Int 13h handler also can be implemented by using a device driver loaded at boot time. Because DOS requires Int 13h access to boot from a drive (and a device driver cannot be loaded until after boot-up), only drives with ROM BIOS-based Int 13h support can be bootable. Int 13h routines communicate directly with the controller using the I/O ports on the controller.

Note

The CD accompanying this book contains a list of functions available at the Interrupt 13h BIOS interface, as well as the error codes that might be returned by the BIOS INT 13h routines. See the Technical Reference section of the CD.

Few high-powered disk utility programs, other than some basic disk-formatting applications, can talk to the disk at the Int 13h level. The DOS FDISK program communicates at the Int 13h level, as does the Norton Utilities' DISKEDIT program when it is in its absolute sector mode; these are some of the few disk-repair utilities that can do so. These programs are important because you can use them for the worst data recovery situations in which the partition tables have been corrupted. Because the partition tables, and any non-DOS partitions, exist outside the area of a disk that is defined by DOS, only programs that work at the Int 13h level can access them. Most utility programs for data recovery work only at the DOS Int 25/26h level, which makes them useless for accessing areas of a disk outside of DOS's domain.

Disk Controller I/O Port Commands

At the lowest interface level, programs communicate directly with the disk controller in the controller's own specific native language. To do this, a program must send controller commands through the I/O ports to which the controller responds.

◀◀ See "IDE Origins," p. 519.

Most applications work through the Int 21h interface. This interface passes commands to the ROM BIOS as Int 13h commands; the ROM BIOS then converts these commands into direct controller commands. The controller executes the commands and returns the results through the layers until the desired information reaches the application. This process enables developers to write applications without worrying about such low-level system details, leaving them instead up to DOS and the ROM BIOS. This also enables applications to run on widely different types of hardware, as long as the correct ROM BIOS and DOS support is in place.

Any software can bypass any level of interface and communicate with the level below it, but doing so requires much more work. The lowest level of interface available is direct communication with the controller using I/O port commands. Each type of controller has different I/O port locations. With different controllers there are also differences among the commands presented at the ports. Only the controller can talk directly to the disk drive.

If not for the ROM BIOS Int 13h interface, a unique DOS would have to be written for each available type of hard and floppy disk drive. Instead, DOS communicates with the ROM BIOS using standard Int 13h function calls translated by the Int 13h interface into commands for the specific hardware. Because of the standard ROM BIOS interface, DOS is relatively independent from the disk hardware and can support many different types of drives and controllers.

Hard Disk Drive Troubleshooting and Repair

If a hard drive has a mechanical problem inside the sealed HDA (head disk assembly), repairing the drive is usually unfeasible. It might be doable, but financially it will be far less expensive to purchase a new drive. If the failure is in the logic board, that board can be replaced with one from a donor drive. Normally this is done only for the purposes of reading the information on the failed drive, because you will have to purchase a complete second drive to cannibalize for the logic board. None of the drive manufacturers normally sell spare parts for their drives anymore.

Most hard disk drive problems are not mechanical hardware problems; instead, they are “soft” problems that can be solved by a new LLF and defect-mapping session. Soft problems are characterized by a drive that sounds normal but produces various read and write errors.

Hard problems are mechanical, such as when the drive sounds as though it contains loose marbles. Constant scraping and grinding noises from the drive, with no reading or writing capability, also qualify as hard errors. In these cases, it is unlikely that an LLF will put the drive back into service. If a hardware problem is indicated, first replace the logic-board assembly. You can make this repair yourself and, if successful, you can recover the data from the drive.

If replacing the logic assembly does not solve the problem, contact the manufacturer or a specialized repair shop that has clean-room facilities for hard disk repair. (See the Vendor’s List on the CD for a list of drive manufacturers and companies that specialize in hard disk drive repair.) Because of the costs, it will probably be more economical to simply purchase a new drive.

Testing a Drive

When accessing a drive, it is easy to tell if the drive has been partitioned and formatted properly. A simple test will tell you if a stored drive is in its “raw” condition or has been partitioned and formatted properly. These tests work best if you have a boot disk available and if the spare hard drive is the only hard drive attached.

First, attach the drive to your system. If you can attach power and data cables to it, you need not install it into a drive bay unless you are planning to use it immediately. If the drive will be run loose, I recommend placing it on a non-conductive foam pad or other soft surface. This will insulate the drive from potential shocks and other hazards. After detecting the drive in the BIOS and saving the changes, start your operating system from the boot disk.

Then, from the A: prompt, enter the following command:

```
DIR C:
```

This will produce one of the following responses:

- *Invalid Drive Specification.* This indicates the drive does not have a valid partition (created by FDISK) or that the existing Master Boot Sector or partition tables have been damaged. No matter what, the drive must be partitioned and FORMatted before use. You will also get this warning on a FAT32 or NTFS partitioned drive if you use a Windows 95 (original version) or MS-DOS boot disk when checking. Use a Windows 95B, Windows 98, or Windows 2000 boot disk to avoid this false message from FAT32 partitions. Or use a Windows NT or Windows 2000 boot disk to detect NTFS partitions.
- *Invalid media type.* This drive has been partitioned but not FORMatted, or the format has been corrupted. You will want to use FDISK’s #4 option to examine the drive’s existing partitions, and either delete them and create new ones or keep the existing partitions and run FORMAT on each drive letter.
- *Directory of C:.* The contents of C: drive are listed, indicating the drive was stored with a valid FDISK and FORMAT structure and data.

Installing an Optical Drive

Installation of a CD-ROM or DVD-ROM drive can be as difficult or as easy as you make it. If you plan ahead, the installation should go smoothly.

This section walks you through the installation of a typical internal (SCSI or IDE) and external (SCSI only) optical drive, with tips that often aren't included in the manufacturer's installation manuals. After you install the hardware, your job might be finished if you are running Windows 9x and using a Plug-and-Play drive, or you might have to manually load the software needed to access the drive.

Note

CD-ROM and DVD-ROM drives use the same IDE and SCSI system interfaces and can be installed using the same basic procedures. Some DVD-ROM drives come with an MPEG-2 decoder board or MPEG decoder software that enables you to view DVD movies and video on your PC. If a board is included, it normally installs in a PCI bus slot like any other expansion card and performs the video decoding process that would otherwise fall to the system processor. Software decoding does not require a board and instead uses your processor to do the decoding work. Software decoding normally requires a fast processor (see the software manufacturer's recommendations for how fast) or else the video will appear jumpy, jerky, or unsynchronized with the sound. Premium DVD setups almost always include hardware decoding for this reason.

Note that there will usually be a separate analog or digital audio connection between the drive and the sound card as well, used primarily for playing audio CDs.

Avoiding Conflict: Get Your Cards in Order

Regardless of the type of installation—internal or external drive—you must have a functioning IDE or SCSI host adapter before the drive can function. In most cases, you will be connecting the optical drive to an existing IDE or SCSI adapter. If so, the adapter should already be configured not to conflict with other devices in your system. All you have to do is connect the drive with the appropriate cable and proceed from there.

Most computers today have an IDE adapter integrated into the motherboard. However, if you are adding SCSI to your system for the first time, you must install a SCSI host adapter into an expansion slot and make sure it is configured to use the appropriate hardware resources, such as the following:

- IRQ
- DMA channel
- I/O port address

As always, Windows 9x and PnP hardware can completely automate this process, but if you're using another operating system, you might have to configure the adapter manually.

Drive Configuration

Configuration of your new optical drive is paramount to its proper functioning. Examine your new drive (see Figure 14.5) and locate any jumpers. For an IDE drive, here are the typical ways to jumper the drive:

- As the primary (master) drive on the secondary IDE connection
- As the secondary (slave) drive to a current hard disk drive
- Using Cable Select (CS), where the cable connector determines which drive is master or slave automatically

Figure 14.5 The rear connection interfaces of a typical IDE internal CD-ROM drive.

If the drive is to be the only device on your secondary EIDE interface, the factory settings are usually correct. Consult the manual to make sure this is so.

When you use the CD-ROM or DVD-ROM as a secondary drive—that is, the second drive on the same ribbon cable with another device—make sure it is jumpered as the slave drive, and configure the other device so it is the master drive (see Figure 14.6). In most cases, the drive will show up as the next logical drive, or the D: drive.

Caution

Whenever possible, you should not connect a CD-ROM or DVD-ROM drive to the same channel as a hard disk drive, as sharing the channel can slow down both devices. If your computer has the two IDE channels standard in systems today, you should connect the optical drive to the secondary channel, even if you only have one hard disk drive on the primary.

◀ These procedures are covered in “The IDE Interface,” p. 515, and “The SCSI Interface,” p. 545.

Depending on how you look at it, SCSI drives can be a bit easier to configure, because you need only to select the proper SCSI ID for the drive. By convention, the boot disk (the C: drive) in a SCSI system is normally set as ID0, and the host adapter has the ID of 7. You are free to choose any ID in between that is not being used by another device. Most SCSI devices use some sort of rotating or pushbutton selector to cycle between the SCSI IDs, but some might use jumpers.

Figure 14.6 An embedded EIDE interface with a primary and secondary IDE connection.

SCSI devices are cabled together in a bus configuration. If your new SCSI drive falls at the end of the SCSI bus, you will also need to terminate the drive. Note that the SCSI bus refers to the physical arrangement of the devices, and not the SCSI IDs selected for each one.

Note

IDE/EIDE discs and SCSI optical drives can easily coexist in the same system. The optical drive will need to be connected to a SCSI host adapter separate from the IDE subsystem. Some audio adapters have a SCSI interface built in.

External (SCSI) Drive Hook-Up

Unpack the drive carefully. With the purchase of an external drive, you should receive the following items:

- CD-ROM or DVD-ROM drive
- SCSI adapter cable

With the exception of the SCSI host adapter, this is the bare minimum you need to get the drive up and running. You'll probably also find a CD caddy, documentation for the drive, driver software, a SCSI terminator plug, and possibly a sampling of CDs to get you started. SCSI drives almost never come with the SCSI host adapter that you need to connect them to the system. Because SCSI is designed to support up to seven devices on the same system (or up to 15 devices for Ultra2 SCSI), it would be impractical to include a host adapter with every peripheral. Although a few computers have SCSI interfaces integrated into the motherboard, in most cases you have to purchase a SCSI adapter as a separate expansion card.

To begin the installation, take a look at your work area and the SCSI cable that came with the drive. Where will the drive find a new home? You're limited by the length of the cable. Find a spot for the drive, and insert the power cable into the back of the unit. Make sure that you have an outlet or, preferably, a free socket in a surge-suppressing power strip to plug in the new drive.

SCSI devices generally use one of two cable types. Some older drives use a 50-pin Centronics cable, referred to as an A-cable, whereas most drives today use a 68-connector D-shell cable called a P-cable. Plug one end of the supplied cable into the connector socket of the drive, and one into the SCSI connector on the adapter card. Most external drives have two connectors on the back—either connector can be hooked to the PC (see Figure 14.7). You use the other connector to attach another SCSI device or, if the drive is at the end of the bus, to connect a terminator plug. Secure the cable with the guide hooks on both the drive and adapter connector, if provided.

Note

A SCSI device should include some means of terminating the bus, when necessary. The terminator may take the form of a cableless plug that you connect to the second SCSI connector on the drive, or the drive may be self-terminating, in which case there should be a jumper or a switch that you can set to activate termination.

Figure 14.7 Older Centronics-style external CD-ROM drive SCSI connectors.

Finally, your external drive should have a SCSI ID select switch on the back. This switch sets the identification number that the host adapter uses to distinguish the drive from the other devices on the bus. The host adapter, by most manufacturers' defaults, should be set for SCSI ID 7, and some (but not all) manufacturers reserve the IDs 0 and 1 for use by hard disk drives. Make sure you set the SCSI ID for the CD-ROM or DVD-ROM drive to any other number—6, 5, or 4, for example. The only rule to follow is to make sure that you do not set the drive for an ID that is already occupied—by either the adapter or any other SCSI peripheral on the bus.

Internal Drive Installation

Unpack your internal drive kit. You should have the following pieces:

- The drive
- Internal CD-audio cable
- Floppy disks/CD-ROM with device driver software and manual
- Drive rails and mounting screws

Your manufacturer also might have provided a power cable splitter—a bundle of wires with plastic connectors on each of three ends. A disc caddy and owner's manual might also be included. If you do not already have one in the computer, you will also need a SCSI host adapter to connect SCSI peripherals.

Make sure the PC is turned off, and remove the cover from the case. Before installing a SCSI adapter into the PC's expansion bus, connect the SCSI ribbon cable onto the adapter card (see Figure 14.8).

Figure 14.8 Connecting a ribbon cable to a SCSI adapter.

Ribbon Cable and Card Edge Connector

The ribbon cable should be identical on both ends. You'll find a red stripe or dotted line down one side of the outermost edge of the cable. This stripe indicates a pin-1 designation and ensures that the SCSI cable is connected properly into the card and into the drive. If you're lucky, the manufacturer supplied a cable with notches or keys along one edge of the connector. With such a key, you can insert the cable into the card and drive in only one way. Unkeyed cables must be hooked up according to the pin-1 designation.

Along one edge of your SCSI adapter, you'll find a double row of 50 brass-colored pins. This is the card edge connector. In small print along the base of this row of pins you should find at least two numbers next to the pins—1 and 50. Aligning the ribbon cable's marked edge over pin 1, carefully and evenly insert the ribbon cable connector.

Now insert the adapter card into a free bus slot in the computer, leaving the drive end of the cable loose for the time being.

Choose a bay in the front of your computer's case for your internal drive. Make sure it's easily accessible from outside and not blocked by other items on your desk. You'll be inserting the CDs or DVDs here, and you'll need the elbow room.

Remove the drive bay cover from the computer case. You might have to loosen some screws to do this, or the cover might just pop out. Inside the drive bay, you should find a metal enclosure with screw holes for mounting the drive. If the drive has mounting holes along its side and fits snugly into the enclosure, you won't need mounting rails. If it's a loose fit, however, mount the rails along the sides of the drive with the rail screws, and then slide the drive into the bay. Secure the drive into the bay with four screws—two on each side. If the rails or drive don't line up evenly with four mounting holes, make sure that you use at least two—one mounting screw on each side. Because you'll be inserting and ejecting many discs over the years, mounting the drive securely is a must.

Once again, find the striped side of the ribbon cable and align it with pin 1 on the drive's edge connector. Either a diagram in your owner's manual or a designation on the connector itself tells you which is pin 1.

The back of the drive has a four-pin power connector outlet. Inside the case of your PC, at the back of your floppy or hard disk, are power cords—bundled red and yellow wires with plastic connectors on them. You might already have an open power connector lying open in the case. Take the open connector and plug it into the back of the power socket on the CD-ROM or DVD-ROM drive. These connectors can only go in one way. If you do not have an open connector, use a drive power splitter (see Figure 14.9). Disconnect an existing drive power cord from the device that uses the least power. Attach the splitter to the detached power cord. Plug one of the free ends back into the drive you removed the power from and the other into the CD-ROM or DVD-ROM drive.

Note

It's preferable to "borrow" power from the drive that consumes the least power so as not to overload the connection. If you have no choice—if the splitter and ribbon cable won't reach, for example—you can split off any power

cord that hasn't already been split. Check the power cable to ensure that you have a line not already overloaded with another splitter.

Figure 14.9 Power cord splitter and connector.

Do not replace the PC cover yet—you need to make sure that everything is running perfectly before you seal the case. You're now ready to turn on the computer.

SCSI Chains: Internal, External, or Both

Remember, one of the primary reasons for using the SCSI interface for your CD-ROM or DVD-ROM drive is the ability to connect a string of peripherals from one adapter, thus saving card slots inside the PC and limiting the nightmare of tracking IRQs, DMAs, and I/O memory addresses.

You can add hard drives, scanners, tape backup units, and other SCSI peripherals to this chain (see Figure 14.10). You must keep a few things in mind, however, and chief among them is SCSI termination.

◀◀ See "Termination," p. 565.

Example One: All External SCSI Devices. Say that you installed your CD-ROM or DVD-ROM drive and added a tape device to the SCSI bus with the extra connector on the back of the optical drive. The first device in this SCSI bus is the adapter card itself. Most modern host adapters are *auto terminating*, meaning they will terminate themselves without your intervention if they are at the end of the bus.

From the card, you ran an external cable to the optical drive, and from the optical drive, you added another cable to the back of the tape unit. You must now terminate the tape unit as well. Most external units are terminated with a SCSI cap—a small connector that plugs into the unused external SCSI connector. These external drive connectors come in two varieties: a SCSI cap and a pass-through terminator. The cap is just that; it plugs over the open connector and covers it. The pass-through terminator, however, plugs into the connector and has an open end into which you

can plug the SCSI cable. This type of connector is essential if your external drive has only one SCSI connector; you can plug the drive in and make sure that it's terminated—all with one connector.

Figure 14.10 An SCSI chain of devices on one adapter card.

Example Two: Internal Chain and Termination. On an internal SCSI bus, the same rules apply: All the internal devices must have unique SCSI ID numbers, and the first and last devices must be terminated. In the case of internal devices, however, you must check for termination. Internal devices typically have DIP switches or terminator packs similar to those on your adapter card. If you install a tape unit as the last device on the chain, it must have some means of terminating the bus. If you place your optical drive in the middle of the bus, you must deactivate its termination. The host adapter at the end of the chain must still be terminated.

Note

Most internal SCSI devices ship with terminating resistors or DIP switches on board, usually the latter. Check your user's manuals for their locations. Any given device may have one, two, or even three such resistors.

Example Three: Internal and External SCSI Devices. If you mix and match external as well as internal devices, follow the same rules. The bottom example shown in Figure 14.11 has an internal CD-ROM drive, terminated and set for SCSI ID 6; the external hard drive also is terminated, and it is using SCSI ID 5. The SCSI adapter itself is set for ID 7 and, most importantly, its termination has been disabled, because it is no longer at the end of the bus.

Note

As with any adapter card, be careful when handling the card itself. Make sure that you ground yourself first.

To help you determine whether your SCSI interface card and devices are functioning properly, Adaptec supplies a utility program called SCSI Interrogator. Use it to determine which LUN (Logical Unit Numbers) are available for new devices.

Figure 14.11 Examples of various SCSI termination scenarios.

If you don't see any devices listed, you might have a termination problem. Shut down your system and your devices. Then, check terminator plugs, switches, or resistor packs. If they appear correct, turn on the external devices about five seconds before you start the system. A multi-switch power director with high-quality surge protection works well for this, since it allows you to turn on individual devices. If the devices fail to show up after you restart the system, you might have a problem with the SCSI device driver software, as explained later in the chapter.

One peculiarity of the Adaptec SCSI Interrogator is that it lists a “host adapter #1” that’s actually your IDE interface! If your SCSI card isn’t working, both “host adapter #0” and “host adapter #1” will actually be IDE. You can tell whether this is happening with Windows 9x because it will list “ESDI_506” as the driver version.

Floppy Drive Installation Procedures

A floppy drive is one of the simplest types of drives to install. In most cases, installing a floppy disk drive is a matter of attaching the drive to the computer chassis or case and then plugging the power and signal cables into the drive. Some type of bracket and screws are normally required to attach the drive to the chassis; however, some chassis are designed to accept the drive with no brackets at all. Any brackets, if needed, are normally included with the chassis or case itself. Several companies listed in the Vendor List on the CD specialize in cases, cables, brackets, screw hardware, and other items useful in assembling systems or installing drives.

Note

Because floppy disk drives are generally installed into the same half-height bays as hard disk drives, the physical mounting of the drive in the computer case is the same for both units. See “Hard Disk Installation Procedures,” earlier in this chapter, for more information on the process.

When you connect the drive, make sure the power cable is installed properly. The cable is normally keyed so you cannot plug it in backward, but the keying can be defeated by somebody forcing the connection. If that is done, the drive will be fried the instant the power is turned on.

Next install the interface cable. A floppy interface cable is a 34-pin cable that normally has a twist in it. What I mean is that pins 10–16 are twisted around before they reach the last (A:) drive connector. Normally the A: drive must be plugged in after this twist; any drive plugged in to a connector before the twist will be seen by the system as drive B:. The twist reverses the drive select and motor enable signals allowing A: and B: drives to coexist without rejumping. This is similar to the way Cable Select works for ATA/IDE drives. For more information on floppy drives and interfacing, see Chapter 11.

The interface cable is normally keyed to prevent backward installation. If there is no key in this cable, use the colored wire in the cable as a guide to the position of pin 1. Normally pin 1 would be oriented closest to the power connector, which is the same as other drives. If the drive LED stays on continuously when you power up the system or when the system is running, that is a sure sign you have the floppy cable on backward either at the drive end or at the controller (motherboard) end.

CHAPTER 15

Video Hardware

Video Display Technologies

As much as the mouse and keyboard, the video display is a vital part of the “user interface” of any computer. The video display is actually a latecomer to computing; before CRT monitors came into general use, the teletypewriter was the standard computer interface—a large, loud device that printed the input and output characters on a roll of paper. The first CRT displays were primitive by today’s standards; they displayed only text in a single color (usually green), but to users at the time they were a great improvement, allowing real-time display of input and output data.

Today, PC video displays are much more sophisticated, but you must be careful when selecting video hardware for your computer. Working with even the fastest and most-powerful PC can be a chore when the display slows the system down, causes eyestrain, or is unsuitable for the tasks you want to accomplish.

The video subsystem of a PC consists of two main components:

- Monitor (or video display)
- Video adapter (also called the video card or graphics adapter)

This chapter explores the range of PC video adapters on the market today and the displays that work with them.

Note

The term *video*, as it is used in this context, does not necessarily imply the existence of a moving image, such as on a television screen. All adapters that feed signals to a monitor or other display are video adapters, whether or not they are used with applications that display moving images, such as multimedia or video-conferencing software.

How CRT Display Technology Works

A monitor can use one of several display technologies. The most popular continues to be cathode ray tube (CRT) technology, the same technology used in television sets. CRTs consist of a vacuum tube enclosed in glass. One end of the tube contains an electron gun; the other end contains a screen with a phosphorous coating.

When heated, the electron gun emits a stream of high-speed electrons that are attracted to the other end of the tube. Along the way, a focus control and deflection coil steer the beam to a specific point on the phosphorous screen. When struck by the beam, the phosphor glows. This light is what you see when you watch TV or your computer screen.

The phosphor chemical has a quality called persistence, which indicates how long this glow remains onscreen. Persistence is what causes a faint image to remain on your TV screen for a few seconds after you turn the set off. The scanning frequency of the display specifies how often the image is refreshed. You should have a good match between persistence and scanning frequency so that the image has less flicker (which occurs when the persistence is too low) and no ghost images (which occurs when the persistence is too high).

The electron beam moves very quickly, sweeping the screen from left to right in lines from top to bottom, in a pattern called a raster. The horizontal scan rate refers to the speed at which the electron beam moves laterally across the screen.

During its sweep, the beam strikes the phosphor wherever an image should appear onscreen. The beam also varies in intensity to produce different levels of brightness. Because the glow begins to fade almost immediately, the electron beam must continue to sweep the screen to maintain an image—a practice called redrawing or refreshing the screen.

Most current CRT displays have an ideal refresh rate (also called the vertical scan frequency) of about 85 hertz (Hz), which means that the screen is refreshed 85 times per second. Refresh rates that are too low cause the screen to flicker, contributing to eyestrain. The higher the refresh rate, the better for your eyes. Low-cost monitors often have flicker-free refresh rates available only at 640 by 480 and 800 by 600 resolutions; you should insist on high refresh rates at resolutions such as 1024 by 768.

It is important that the refresh rates expected by your monitor match those produced by your video card. If you have mismatched rates, you will not see an image and can actually damage your monitor.

Multiple Frequency Monitors

Although a few monitors have a fixed refresh rate, most monitors support a range of frequencies; this support provides built-in compatibility with a wide range of current and future video standards (described in the “Video Display Adapters” section later in this chapter). A monitor that supports many video standards is called a multiple-frequency monitor. Virtually all monitors sold today are multiple frequency, which means they support operation with a variety of popular video signal standards. Different vendors call their multiple-frequency monitors by different trade names, including multisync, multifrequency, multiscan, autosynchronous, and autotracking.

Curved Versus Flat Picture Tubes

Phosphor-based screens come in two styles: curved and flat. Until recently, the typical display screen has been curved; it bulges outward from the middle of the screen. This design is consistent with the vast majority of CRT designs (the same as the tube in most television sets).

The traditional screen is curved both vertically and horizontally. Some monitor models use the Sony Trinitron CRT, some versions of which are curved only horizontally but flat vertically; these are referred to as flat square tube (FST) designs.

Many manufacturers are now selling monitors featuring CRTs that are flat both horizontally and vertically. Sony’s FD Trinitron and Mitsubishi’s DiamondTron NF are two of these new CRT designs, the first such screens for PCs since the short-lived Zenith FTM monitors of the late 1980s. Many people prefer this type of flatter screen because these picture tubes show less glare and provide a higher-quality, more-accurate image. Although flat-screen CRTs are slightly more expensive than conventional curved CRTs, they are only one-third to one-half the price of flat-panel LCD displays.

DVI—Digital Signals for CRT Monitors

The latest trend in CRT monitor design is the use of digital input signals using the same DVI (Digital Video Interface) standard used for LCD flat-panel displays. Major monitor vendors such as ViewSonic, NEC, ADC, Acer, and Samsung announced support for this standard in the late summer of 1999, with CRT monitors supporting DVI being introduced during the first half of 2000. These monitors, unlike the TTL digital displays of the 1980s which supported only a few colors, support the same unlimited color spectrum as analog CRTs. Users benefit from digital displays because they can feature better picture quality, better signal reception, and precise auto setup.

Because most video cards still feature only analog (DB-15) VGA connectors, these monitors feature both analog and 20-pin DVI interfaces. However, if the use of DVI video cards becomes widespread, sometime in this decade we might see the end of analog VGA, just as VGA replaced the original TTL digital displays used in the first decade of personal computers.

An increasingly popular alternative to CRTs are flat-panel LCD displays.

- ▶▶ See “Flat-Panel LCD Displays,” p. 853.

CRT Monitors

A monitor requires a source of input. The signals that run to your monitor come from a video adapter inside or plugged into your computer. Some computers—such as those that use the low profile (LPX) or new low profile (NLX) motherboard form factor—contain this adapter circuitry on the motherboard. Most systems, however, use Baby-AT or ATX-style motherboards and usually incorporate the video adapter on a separate circuit board that is plugged into an expansion or bus slot. The expansion cards that produce video signals are called video cards, or graphics cards. The term *video adapter* applies to either integrated or separate video circuitry. Whether the video adapter is built into the motherboard or found on a separate card, the circuitry operates the same way and generally uses the same components.

All-in-One Technologies

Several chipset families for integrated motherboards have incorporated video display features into the chipset. The pioneer product was the two-chip Cyrix MediaGX, with two chips that incorporate the functions of a CPU, memory controller, sound, and video. Although Cyrix was sold to Via Technologies, National Semiconductor retained rights to the MediaGX and has repositioned this relatively low-performance chipset for Internet appliances and other embedded processor uses.

Intel has also developed its own version of this technology, the Intel 810 chipset, a three-chip set which works with its Pentium II, III, and Celeron family of CPUs to provide integrated AGP 3D graphics with DVD playback, sound, USB ports, and other features on a highly integrated motherboard. Via Technologies' Apollo MVP 4 is a two-chip chipset designed to work with Socket 7 CPUs from Intel, AMD, and others. Acer Labs' Aladdin TNT2/M1535D combo uses nVidia's RIVA TNT2 graphics technology.

The latest development is Silicon Integrated System's (SiS) SiS630 single-chip chipset for Pentium II, III, and Celeron CPUs and SiS 540 single-chip chipset for AMD K6 family CPUs. A single chip incorporates AGP 4x (630) and 2x

(540) functionality, dual display for LCD or CRT monitors, TV-out, full peripheral control, UDMA 66 IDE, PC 133 memory, ACPI power management, and more.

All versions of the Cyrix/NSC MediaGX and most, if not all, motherboards based on the other chipsets listed earlier use a shared memory technique for frame buffer RAM, using some of the system's memory for video operations. The amount of memory used by video operations can vary with the amount of video memory required for the current image or can be fixed by the user in the BIOS configuration program.

This memory-sharing technique is called Unified Memory Architecture (UMA); it reduces system cost, but also reduces system performance.

►► See "The Digital-to-Analog Converter (RAMDAC)," p. 887.

LCD Displays

Borrowing technology from laptop manufacturers, more and more monitor makers market monitors with liquid crystal displays (LCDs). LCDs have low-glare, completely flat screens and low power requirements (five watts versus nearly 100 watts for an ordinary monitor). The color quality of an active-matrix LCD panel actually exceeds that of most CRT displays.

At this point, however, LCD screens usually are more limited in resolution than typical CRTs and are more expensive; for example, a 15-inch LCD screen can cost more than \$900—more than twice the cost of a high-quality 17-inch CRT monitor. However, it is important to consider that an LCD screen provides a larger viewable image than a CRT monitor of the same size. Three basic LCD choices are available today on notebook computers and in desktop display panels: passive-matrix color, active-matrix analog color, and the latest—active-matrix digital. Monochrome LCD displays are obsolete for PCs, although they remain popular for Palm and similar organizer devices and are sometimes used for industrial display panels. Virtually all passive-matrix designs sold today use dual-scan technology, with the dimmer single-scan versions again being relegated to handheld organizers. The passive-matrix color panels are primarily found in low-cost notebook computer displays or in industrial-use desktop display panels because of their relatively low cost and enhanced durability compared to active-matrix models. Desktop LCD panels are analog or digital units.

Note

The most common type of passive-matrix display uses a supertwist nematic design, so these panels are often referred to as STNs. Active-matrix panels usually use a thin-film transistor design and are thus referred to as TFTs.

In an LCD, a polarizing filter creates two separate light waves. The polarizing filter allows light waves that are aligned only with the filter to pass through. After passing through the polarizing filter, the remaining light waves are all aligned in the same direction. By aligning a second polarizing filter at a right angle to the first, all those waves are blocked. By changing the angle of the second polarizing filter, the amount of light allowed to pass can be changed. It is the role of the liquid crystal cell to change the angle of polarization and control the amount of light that passes. In a color LCD, an additional filter has three cells for each pixel—one each for displaying red, green, and blue.

The light wave passes through a liquid-crystal cell, with each color segment having its own cell. The liquid crystals are rod-shaped molecules that flow like a liquid. They enable light to pass straight through, but an electrical charge alters their orientation and the orientation of light passing through them. Although monochrome LCDs do not have color filters, they can have multiple cells per pixel for controlling shades of gray.

In a passive-matrix LCD, each cell is controlled by the electrical charges of two transistors, determined by the cell's row and column positions on the display. The number of transistors along the screen's horizontal and vertical edges determines the resolution of the screen. For example, a screen with a 1024×768 resolution has 1024 transistors on its horizontal edge and 768 on the vertical, for a total of 2,000. As the cell reacts to the pulsing charge from its two transistors, it twists the light wave, with stronger charges twisting the light wave more. Supertwist refers to the orientation of the liquid crystals, comparing on mode to off mode—the greater the twist, the higher the contrast.

Charges in passive-matrix LCDs are pulsed; therefore, the displays lack the brilliance of active-matrix, which provides a constant charge to each cell. To increase the brilliance, virtually all vendors have turned to a technique called double-scan LCD, which splits passive-matrix screens into a top half and bottom half, reducing the time between each pulse. In addition to increasing the brightness, dual-scan designs also increase the response time and therefore the perceptible speed of the display, making this type more usable for full-motion video or other applications where the displayed information changes rapidly.

In an active-matrix LCD, each cell has its own dedicated transistor behind the panel to charge it and twist the light wave. Thus, a 1024×768 active-matrix display has 786,432 transistors. This provides a brighter image than passive-matrix displays because the cell can maintain a constant, rather than a momentary, charge. However, active-matrix technology uses more energy than passive-matrix, leading to shorter battery life on portable systems. With a dedicated transistor for every cell, active-matrix displays are more difficult and expensive to produce.

Note

Because an LCD display requires a specified number of transistors to support each cell, there are no multiple frequency displays of this type. All the pixels on an LCD screen are of a fixed size, although CRT pixels are variable. Thus, LCD displays are designed to be operated at a specific resolution, although newer notebook display panels might offer onboard scaling. Before purchasing this type of display, be sure your video adapter supports the same resolution as the screen and that the resolution will be sufficient for your needs throughout the life of the monitor.

High-quality LCD displays for desktop computers and their matching video controllers usually feature onboard image scalars to allow different resolutions on the LCD display. This is an important feature to check for before purchasing a flat panel (FP) LCD display.

►► See "FlatPanel LCD Displays," p. 853.

In both active- and passive-matrix LCDs, the second polarizing filter controls how much light passes through each cell. Cells twist the wavelength of light to closely match the filter's allowable wavelength. The more light that passes through the filter at each cell, the brighter the pixel.

Monochrome LCDs achieve grayscales (up to 64) by varying the brightness of a cell or dithering cells in an on-and-off pattern. Color LCDs, on the other hand, dither the three-color cells and control their brilliance to achieve different colors on the screen. Double-scan passive-matrix LCDs (also known as DSTN) have recently gained in popularity because they approach the quality of active-matrix displays but do not cost much more to produce than other passive-matrix displays. Although DSTN panels offer better on-axis (straight-ahead) viewing quality than straight passive-matrix panels, their off-axis (viewing at an angle) performance is still poor when compared to active-matrix (TFT) panels.

The big problem with active-matrix LCDs has been that the manufacturing yields are lower than for passive-matrix LCDs, forcing higher prices. This means many of the panels produced have more than a certain maximum number of failed transistors. The resulting low yields limit the production capacity and incurs somewhat higher prices.

In the past, several hot, miniature CRTs were needed to light an LCD screen, but portable computer manufacturers now use a single tube the size of a cigarette. Fiber-optic technology evenly spreads light emitted from the tube across an entire display.

Thanks to supertwist and triple-supertwist LCDs, today's screens enable you to see the screen clearly from more angles with better contrast and lighting. To improve readability, especially in dim light, some laptops include backlighting or edgelighting (also called sidelighting). Backlit screens provide light from a panel behind the LCD. Edgelit screens get their light from small fluorescent tubes mounted along the sides of the screen. Some older laptops excluded such lighting systems to lengthen battery life. Most modern laptops enable you to run the backlight at a reduced power setting that dims the display but that allows for longer battery life.

The best color displays are active-matrix or thin-film transistor (TFT) panels, in which each pixel is controlled by three transistors (for red, green, and blue). Active-matrix screen refreshes and redraws are immediate and accurate, with much less ghosting and blurring than in passive-matrix LCDs (which control pixels via rows and columns of transistors along the edges of the screen). Active-matrix displays are also much brighter and can easily be read at an angle.

Note

An alternative to LCD screens is gas-plasma technology, typically known for its black and orange screens in some of the older Toshiba notebook computers. Some companies are incorporating full-color gas-plasma technology for desktop screens and possibly color high-definition television (HDTV) flat-panel screens, such as the Philips Flat TV.

Flat-Panel LCD Displays

LCD desktop monitors, once seen mainly on the office sets of futuristic TV shows, are now becoming an increasingly reasonable choice for use in today's office computing environment.

LCD desktop monitors offer the following benefits over conventional CRT (Cathode Ray Tube) "glass tube" monitors:

- Virtually 100 percent of LCD size is viewable area, compared to a loss of 1 to 1 1/2-inches of viewable area versus the diagonal tube measurement on CRT monitors. Thus, a 15-inch LCD provides a viewable area roughly equal to a typical 17-inch CRT monitor.

- Small front-to-back dimensions free up desk space.
- Direct addressing of display (each pixel in the picture corresponds with a transistor) and always perfect alignment provide a high-precision image that lacks CRT's problems with pincushion or barrel distortion or convergence errors (halos around the edges of onscreen objects).
- Low power consumption and less heat buildup make LCD units less expensive to operate.
- Because LCD units lack a CRT, no concerns exist about electromagnetic VLF or ELF emissions.
- A number of LCD panels offer a pivoting feature, enabling the unit to swivel 90°, allowing a choice of the traditional “landscape” horizontal mode for Web surfing and the “portrait” vertical mode for word processing and page-layout programs.

Before you rush to the store to purchase an LCD desktop monitor, you should consider several potential drawbacks:

- If you routinely switch display resolutions (as Web developers do to preview their work), LCD monitors must take one of two approaches to change resolutions: reduce the onscreen image to occupy only the pixels of the new resolution, thus using only a portion of a typical 1024×768 LCD panel to display a 640×480 image, or scale the image to occupy the entire screen. Scaling is becoming more common because the Digital Display Work Group (DDWG) standard for LCD desktop displays specifies that the scaling must take place in the display panel, the graphics controller, or both places. Look at the quality of a scaled image if using different resolutions is important to you.
- You have a choice between digital and analog LCD panels. Digital LCD panels generally offer higher image quality because no conversion of analog to digital signals occurs, but they require a special digital display card. These display cards might be included in the price of the panel, or they might be an extra-cost item.

Note

Video card and chipset makers such as 3Dfx, nVidia, S3, ATI, and others are rapidly adding support for digital and analog display panels to their newest 3D chipsets and video cards. See the illustrations of typical video cards in Figures 15.7 and 15.8 to see what a typical digital display panel connector looks like.

- If you choose an analog LCD panel, you'll usually save money and be able to use your existing video card, but image quality for both text and graphics can suffer because of the conversion of the computer's digital signal to analog (at the video card) and back to digital again (inside the LCD panel). The conversion can lead to “pixel jitter” or “pixel swim,” in which adjacent LCD cells are turned on and off by the display's inability to determine which cells should stay on and stay off. Most panels come with adjustment software to reduce this display-quality problem, but you might not be able to eliminate it entirely.
- High-quality LCD display panels of either digital or analog type are great for displaying sharp text and graphics, but they often can't display as wide a range of very light and very dark colors as CRTs.
- LCD displays don't react as quickly as CRTs, which can cause full-motion video, full-screen 3D games, and animation to look smeared onscreen.

With prices dropping, sizes increasing, and computer companies such as Compaq and video card makers already including built-in video connectors especially designed for LCD panels on some products, now is a great time to consider buying an LCD panel for your desktop. Make sure that you use the following criteria when you consider purchasing an LCD monitor:

- Evaluate the panel both at its native resolution and at any other resolutions you plan to use.
- If you're considering an analog LCD panel, try it with the video cards you plan to use and be sure to check the panel maker's list of suggested video cards for each model.
- If you're considering a digital LCD panel, determine whether the bundled video card (if any) supports the features you need if your existing video card lacks digital panel support: For example, OpenGL and high-speed 3D support are important for game players; VGA-to-TV support is important for video producers. If the bundled card lacks the features you need, can you get the features in another card? Because several rival standards exist, make sure any alternative digital display cards support the particular panel you want to buy.

Note

Although VESA (the Video Electronic Standards Association) approved the Digital Flat Panel (DFP) standard (previously known as Panellink) in February 1999, the Digital Visual Interface (DVI) standard supported by the Digital Display Working Group (DDWG) is much more popular with hardware vendors, and should be regarded as a de facto standard.

- Make sure your system has a suitable expansion slot for the recommended or bundled video-card type. Many low-cost systems today feature onboard AGP video but no AGP slot, which can't be upgraded unless the user opts for the obsolescent (for video) PCI slot. As the move to LCD panels continues, more of these systems should feature built-in support for LCD displays, but this could be a problem for some time to come.
- Evaluate the panel and card combo's performance on video clips and animation if you work with full-motion video or animated presentation programs.
- Because most video cards aren't optimized for the pivoting feature found in many LCD panels, the portrait mode's performance is often as much as 10–45 percent slower than the default landscape mode.
- Although active-matrix (analog) and digital LCD monitors have much wider viewing areas than do passive-matrix and dual-scan LCD panels used in low-cost notebook computers, their viewing angles are still usually much less than CRTs. This is an important consideration if you're planning to use your LCD monitor for group presentations. In a test of 29 different 15-inch LCD panels in *PC Magazine's* April 20, 1999 issue, horizontal viewing angles without noticeable color shift ranged from as little as 50° to as much as 115° (higher is better). Most panels tested had viewing angles between 50° and 75°, a very narrow viewing angle compared to CRTs. A typical CRT monitor allows viewing up to 120° without noticeable color shift.
- A high-contrast ratio (luminance difference between white and black) makes for sharper text and vivid colors. A typical CRT has a contrast ratio of about 245:1. LCD panels in the April 20, 1999 *PC Magazine* test had contrast ratios ranging from a low of 129:1 to a high of 431:1, with more than half of the units tested exceeding the 245:1 contrast ratio of typical CRTs.
- Features such as integrated speakers and USB (Universal Serial Bus) hubs are pleasant additions, but your eyes should make the final decision about which panel is best for you.

All-in-One Desktop PCs

Spurred by the popularity of the Apple iMac, several major PC vendors, including NEC and Gateway, have introduced their own version of an all-in-one desktop PC. These units integrate a CRT or LCD with the normal features of a desktop computer.

The key benefit is that they're sleek and occupy little room on your desk, compared with the usual mid-tower computer and separate monitor. On the other hand, you lose the ability to mix and match components, you can't upgrade the monitor or the video, and if the monitor goes down, your entire unit is disabled.

I recommend these units only when minimum system size is the overriding requirement.

Monitor Selection Criteria

Stores offer a dizzying variety of monitor choices, from the low-cost units bundled with computers to large-screen tubes that cost more than many systems. Because a monitor can account for a large part of the price of your computer system, you need to know what to look for when you shop for a monitor.

Monochrome displays were the first display type used and were common throughout most of the 1980s. After the advent of VGA displays in 1987, monochrome displays based on the original MDA (Monochrome Display Adapter) and HCG (Hercules Graphics Card) standards fell out of favor, and very few monochrome VGA displays were ever produced. Today, except for surplus and used equipment and a few industrial LCD panels, monochrome is dead as a display technology.

Note

You can learn more about the old monochrome standards in "Monochrome Versus Color" in the Technical Reference section of the CD accompanying this book.

The Right Size

CRT-based monitors come in different sizes ranging from 9-inch to 42-inch diagonal measure. The larger the monitor, the higher the price tag—after you get beyond 19-inch displays, the prices skyrocket. The most common CRT monitor sizes are 15, 17, 19, and 21 inches. These diagonal measurements, unfortunately, often represent not the size of the actual image that the screen displays, but the size of the tube.

As a result, comparing one company's 17-inch monitor to that of another might be unfair unless you actually measure the active screen area. The active screen area refers to the diagonal measure of the lighted area on the screen. In other words, if you are running Windows, the viewing area is the actual diagonal measure of the desktop.

This area can vary widely from monitor to monitor, so one company's 17-inch monitor can display a 15-inch image, and another company's 17-inch monitor can present a 15 1/2-inch image.

Table 15.1 shows the monitor's advertised diagonal screen size, along with the approximate diagonal measure of the actual active viewing area for the most common display sizes. Use the

following chart as a guideline; most monitor packaging and advertising provides precise information for a given model.

Table 15.1 Advertised Screen Size Versus Actual Viewing Area

Monitor CRT Size (in Inches)	Actual Viewing Area (in Inches)
12	10 1/2
14	12 1/2
15	13 1/2
16	14 1/2
17	15 1/2
18	16 1/2
19	17 1/2
20	18 1/2
21	19 1/2

The size of the actual viewable area varies from manufacturer to manufacturer but tends to be approximately 1 1/2-inches less than the actual screen size. However, you can adjust many better-quality monitors to display a high-quality image that completely fills the tube from edge to edge. Less-expensive monitors can fill the screen also, but some of them do so only by pushing the monitor beyond its comfortable limits. The result is a distorted image that is worse than the monitor's smaller, properly adjusted picture.

In most cases, the 17-inch monitor is currently the best bargain in the industry. A 17-inch monitor is recommended for new systems, especially when running Windows and is not much more expensive than a 15-inch display. I recommend a 17-inch monitor as the minimum you should consider for most normal applications. Low-end applications can still get away with a 15-inch display, but you will be limited in the screen resolutions that you can view comfortably. Displays of 18 to 21 inches or larger are recommended for high-end systems, especially where graphics applications are the major focus.

Larger monitors are particularly handy for applications such as CAD and desktop publishing, in which the smallest details must be clearly visible. With a 17-inch or larger display, you can see nearly an entire 8 1/2×11-inch print page in 100 percent view; in other words, what you see onscreen virtually matches the page that will be printed. This feature is called WYSIWYG—short for “what you see is what you get.” If you can see the entire page at its actual size, you can save yourself the trouble of printing several drafts before you get it right.

With the popularity of the Internet, monitor size and resolution become even more of an issue. Many Web pages are being designed for 1,024×768 resolution, which requires a 17-inch CRT display as a minimum to handle without eyestrain and inadequate focus. Because of their much tighter dot pitch, LCD displays in laptop computers can handle that resolution easily on 13.3- or even some 12.1-inch displays. Using 1,024×768 resolution means you will be able to view most Web pages without scrolling sideways, which is a major convenience.

Note

Although many monitors smaller than 17 inches are physically capable of running at 1,024×768 and even higher resolutions, most people have trouble reading print at that size.

If you have Windows 98, a partial solution is to enable the larger icons by opening the Display control panel, clicking the Settings tab, clicking Advanced, and selecting Large Icons. With either Windows 95 or 98, you can also use Large Fonts, but many programs have problems with font sizes larger than the default Small Fonts setting.

Monitor Resolution

Resolution is the amount of detail a monitor can render. This quantity is expressed in the number of horizontal and vertical picture elements, or pixels, contained in the screen. The greater the number of pixels, the more detailed the images. The resolution required depends on the application. Character-based applications (such as DOS command-line programs) require little resolution, whereas graphics-intensive applications (such as desktop publishing and Windows software) require a great deal.

It's important to realize that CRTs are designed to handle a range of resolutions natively, but LCD panels (both desktop and notebook) are built to run a single native resolution and must scale to other choices.

As PC video technology developed, the screen resolutions supported by video adapters grew at a steady pace. The following list shows standard resolutions used in PC video adapters and the terms commonly used to describe them:

Resolution	Abbreviation	Standard Designation
640×480	VGA	Video Graphics Array
800×600	SVGA	Super VGA
1,024×768	XGA	eXtended Graphics Array
1,280×1,024	UVGA	Ultra VGA

Today, the term *VGA* is still in common usage as a reference to the standard 640×480 16-color display that the Windows operating systems use as their default. The 15-pin connector to which you connect the CRT monitor on most video adapters is also often called a *VGA* plug. A 20-pin connector is used for DFP-compatible and DVI-compatible LCD display panels and the new DVI-compatible digital CRTs.

However, the terms *SVGA*, *XGA*, and *UVGA* have fallen into disuse. The industry now describes screen resolutions simply by citing the number of pixels. Nearly all the video adapters sold today support the 640×480, 800×600, and 1,024×768 pixel resolutions at several color depths, and many support 1,280×1,024 and higher as well.

Because all CRT and most new and upcoming LCD displays can handle different resolutions, you have a choice. As you'll see later in this chapter, the combinations of resolution and color depth (number of colors onscreen) that you can choose can be limited by how much RAM your graphics adapter has onboard. But, if your graphics adapter has at least 4MB or more, you're free to choose from many settings based on your needs.

What resolution do you want for your display? Generally, the higher the resolution, the larger the display you will want.

Note

To understand this issue, you might want to try different resolutions on your system. As you change from 640×480 to 800×600 and 1024×768, you'll notice several changes to the appearance of your screen.

At 640×480, text and onscreen icons are very large. Because the screen elements used for the Windows 9x desktop and software menus are at a fixed pixel width and height, you'll notice that they shrink in size onscreen as you change to the higher resolutions. You'll be able to see more of your document or Web page onscreen at the higher resolutions because each object requires less of the screen.

Tip

With Windows 98, Millennium, and 2000, you can use a higher screen resolution and still have acceptably sized icons by selecting the "Use Large Icons" option in the Display properties sheet.

If you are operating at 640×480 resolution, for example, you should find a 14- or 15-inch monitor to be comfortable. At 1,024×768, you probably will find that the display of a 15-inch monitor is too small; therefore, you will prefer to use a larger one, such as a 17-inch monitor. The following list shows the minimum-size monitors I recommend to properly display the resolutions that users typically select:

Resolution	Minimum Recommended Monitor
640×480	13-inch
800×600	15-inch
1,024×768	17-inch
1,280×1,024	21-inch

These minimum recommended display sizes are the advertised diagonal display dimensions of the monitor. Note that these are not necessarily the limits of the given monitors' capabilities, but they are what I recommend. In other words, most 15-inch monitors are able to display resolutions at least up to 1,024×768, but the characters, icons, and other information are too small for most users and can cause eyestrain if you try to run beyond the recommended 800×600 resolution.

One exception to this rule is with the LCD displays used in portable systems and a few desktop monitors. LCD-type displays are always crisp and perfectly focused by nature. Also, the dimensions advertised for the LCD screens represent the exact size of the viewable image, unlike most conventional CRT-based monitors. So, the 12.1-inch LCD panels found on many notebook systems today actually have a viewable area with a 12.1-inch diagonal measurement. This measurement is comparable to a 14-inch or even a 15-inch CRT display in most cases. In addition, the LCD is so crisp that screens of a given size can easily handle resolutions that are higher than what would otherwise be acceptable on a CRT. For example, many of the high-end notebook systems now use 13.3-inch LCD panels that feature 1,024×768 resolution. Although this resolution

would be unacceptable on a 14-inch or 15-inch CRT display, it works well on the 13.3-inch LCD panel due to the crystal-clear image.

Dot Pitch

Another important specification that denotes the quality of a given CRT monitor is its dot pitch. In a monochrome monitor, the picture element is a screen phosphor, but in a color monitor, the picture element is a phosphor triad. Dot pitch, which applies only to color monitors, is the distance (in millimeters) between phosphor triads. Screens with a small dot pitch have a smaller space between the phosphor triads. As a result, the picture elements are closer together, producing a sharper picture on the screen. Conversely, screens with a large dot pitch tend to produce images that are less clear. Figure 15.1 illustrates dot pitch.

Figure 15.1 Dot pitch is the distance between each group (triad) of red, green, and blue (RGB) phosphors. A smaller dot pitch helps produce sharper, clearer images.

Note

Dot pitch is not an issue with LCD portable or desktop display panels because of their design.

The original IBM PC color monitor had a dot pitch of 0.43mm, which is considered to be poor by almost any standard. Smaller pitch values indicate sharper images. Most monitors have a dot pitch between 0.25 and 0.30mm, with state-of-the-art monitors at the lower end of the scale. To avoid grainy images, look for a dot pitch of 0.26mm or smaller. Be wary of monitors with anything larger than a 0.28mm dot pitch; they lack clarity for fine text and graphics. Although you can save money by buying monitors with smaller tubes or a higher dot pitch, the tradeoff isn't worth it.

Monitors based on Sony's Trinitron picture tubes and Mitsubishi's DiamondTron picture tubes use an aperture grille, which uses vertical strips to separate red, green, and blue phosphors, rather than a shadow mask. This produces a brighter picture, although the stabilizing wire shown in

Figure 15.2 is visible on close examination. Monitors using an aperture grille-type picture tube use a “stripe pitch” measurement instead of dot pitch.

Figure 15.2 Aperture-grille picture tubes have their phosphors arranged in vertical stripes with one or two reinforcing wires, depending on CRT size.

NEC's monitors use a variation on aperture grille called the slotted mask, which is brighter than standard shadow-mask monitors and more mechanically stable than aperture grille-based monitors, as in Figure 15.3.

Figure 15.3 NEC's slotted mask picture tube design provides many of the benefits of both shadow-mask and aperture grille designs.

The dot pitch or stripe pitch measurement is one of the most-important specifications of any monitor, but it is not the only specification. It is entirely possible that you might find the image on a monitor with a slightly higher dot pitch superior to that of a monitor with a lower dot

pitch. There is no substitute for actually looking at images and text on the monitors you're considering purchasing.

Image Brightness and Contrast (LCD Panels)

As previously mentioned, dot pitch is not a factor in deciding which LCD panel to purchase. A corresponding consideration that applies both to LCDs and CRTs, but that is more important on LCDs, is the brightness of the display.

Although a dim CRT display is almost certainly a sign either of improper brightness control or a dying monitor, brightness in LCD displays can vary a great deal from one model to another. Brightness for LCD panels is measured in candelas per square meter, which for some reason is referred to as a "nit." Typical ratings for analog and digital display panels range from 150–250 nits. A good combination is a high nit rating and a high contrast rating.

Interlaced Versus Noninterlaced

Monitors and video adapters can support interlaced or noninterlaced resolution. In noninterlaced (conventional) mode, the electron beam sweeps the screen in lines from top to bottom, one line after the other, completing the screen in one pass. In interlaced mode, the electron beam also sweeps the screen from top to bottom, but it does so in two passes—sweeping the odd lines first and the even lines second. Each pass takes half the time of a full pass in noninterlaced mode. Thus, a monitor such as IBM's 8514/A unit, which offered an 87Hz interlaced mode, could redraw the screen twice in the same time as a monitor running at a noninterlaced mode of 43.5Hz ($43.5 \times 2 = 87$).

Note

Hz (hertz) refers to how many times the monitor can refresh (redraw) the picture per second. For example, a monitor rated at 85Hz would redraw the picture 85 times per second.

This technique redraws the screen faster and provides more stable images, but it also produces what is often a very noticeable flicker. If you switch your video adapter to a higher screen resolution and you find that your solid, satisfactory picture suddenly seems flickery, you have probably switched to a resolution that your hardware only supports in interlaced mode. Different users react to interlaced displays differently. To some people, it is hardly noticeable, whereas to others, looking at the screen is unbearable.

Caution

It's not unheard of for people with neurological disorders such as epilepsy to be profoundly affected by the flicker produced by monitors running in interlaced mode or at low refresh rates. These people should take adequate precautions before adjusting their video display setting and, if possible, be aware of their physical limitations.

Monitors that use interlacing can use lower refresh rates, thus lessening their cost. The drawback is that interlacing depends on the ability of the eye to combine two nearly identical lines, separated by a gap, into one solid line. If you are looking for high-quality video, however, you should avoid interlacing at all costs and get a video adapter and monitor that support high-resolution,

noninterlaced displays. With recent price drops, virtually any user can afford to replace the older high-resolution interlaced displays with monitors that can display 1024×768 or higher resolutions without interlacing.

If you must use an interlaced display, try using a high-quality, dark-glass, antiglare filter on the front of the monitor. This reduces the apparent flicker as well as the glare, and it improves your vision and your comfort.

Energy and Safety

A properly selected monitor can save energy. Many PC manufacturers are trying to meet the Environmental Protection Agency's Energy Star requirements. Any PC-and-monitor combination that consumes less than 60 watts (30 watts apiece) during idle periods can use the Energy Star logo. Some research shows that such "green" PCs can save each user about \$70 per year in electricity costs.

Power Management

Monitors, one of the most power-hungry computer components, can contribute to those savings. One of the first energy-saving standards for monitors was VESA's Display Power-Management Signaling (DPMS) spec, which defines the signals that a computer sends to a monitor to indicate idle times. The computer or video card decides when to send these signals.

In Windows 9x or 2000, you need to enable this feature if you want to use it because it's turned off by default. To enable it, open the Display properties in the control panel, switch to the Screen Saver tab and make sure the Energy Star low-power settings and Monitor shutdown settings are checked. You can adjust how long the system remains idle before the monitor picture is blanked or the monitor shuts down completely. Use the Power icon in Windows 2000 to set power management for the monitor and other peripherals.

Intel and Microsoft have jointly developed the Advanced Power Management (APM) specification, which defines a BIOS-based interface between hardware that is capable of power-management functions and an operating system that implements power-management policies. In short, this means that you can configure an OS such as Windows 9x to switch your monitor into a low-power mode after an interval of nonuse and even to shut it off entirely. For these actions to occur, however, the monitor, the system BIOS, and the operating system must all support the APM standard.

With Windows 98 and Windows 2000, Microsoft introduced a more comprehensive power management method called Advanced Configuration and Power Interface, or ACPI for short. ACPI also works with displays, hard drives, and other devices supported by APM, as well as allowing the computer to "automatically turn peripherals on and off, such as CD-ROMs, network cards, hard disk drives, printers, as well as consumer devices connected to the PC such as VCRs, televisions, telephones, and stereos."

Although APM compatibility has been standard in common BIOSes for several years, a number of recent-model computers from major manufacturers required BIOS upgrades to add this feature when Windows 98 was introduced.

Note

ACPI support is installed on Windows 98 and Windows 2000 computers if an ACPI-compliant BIOS is present when either version of Windows is first installed. If an ACPI-compliant BIOS is installed after the initial Windows installation, it will be ignored. Fortunately, both versions of Windows still support APM as well. See Microsoft's FAQ for ACPI on the Microsoft Web site.

For displays, power management is implemented when DPMS signals the monitor to enter into the various APM modes. The basis of the DPMS standard is the condition of the synchronization signals being sent to the display. By altering these signals, a DPMS-compatible monitor can be forced into the various APM modes by an operating system that supports the power-management standard. You can configure the monitor to enter the standby and suspend modes at predefined intervals when the computer is not in use, and even shift back to the on mode when certain events occur, such as when a modem phone line rings.

The defined monitor states in DPMS are as follows:

- *On*. Refers to the state of the display when it is in full operation.
- *Stand-By*. Defines an optional operating state of minimal power reduction with the shortest recovery time.
- *Suspend*. Refers to a level of power management in which substantial power reduction is achieved by the display. The display can have a longer recovery time from this state than from the Stand-By state.
- *Off*. Indicates that the display is consuming the lowest level of power and is nonoperational. Recovery from this state can optionally require the user to manually power on the monitor.

Table 15.2 summarizes the DPMS modes.

Table 15.2 Display Power Management Signaling

State	Horizontal	Vertical	Video	Power Savings	Recovery Time
On	Pulses	Pulses	Active	None	n/a
Stand-By	No Pulses	Pulses	Blanked	Minimal	Short
Suspend	Pulses	No Pulses	Blanked	Substantial	Longer
Off	No Pulses	No Pulses	Blanked	Maximum	System Dependent

Emissions

Another trend in green monitor design is to minimize the user's exposure to potentially harmful electromagnetic fields. Several medical studies indicate that these electromagnetic emissions can cause health problems, such as miscarriages, birth defects, and cancer. The risk might be low, but if you spend a third of your day (or more) in front of a computer monitor, that risk is increased.

The concern is that VLF (very low frequency) and ELF (extremely low frequency) emissions might affect the body. These two emissions come in two forms: electric and magnetic. Some research

indicates that ELF magnetic emissions are more threatening than VLF emissions because they interact with the natural electric activity of body cells. Monitors are not the only culprits; significant ELF emissions also come from electric blankets and power lines.

Note

ELF and VLF are a form of electromagnetic radiation; they consist of radio frequencies below those used for normal radio broadcasting.

The standards shown in Table 15.3 have been established to regulate emissions and other aspects of monitor operations. Even though these standards originated with Swedish organizations, they are recognized and supported throughout the world.

Table 15.3 Monitor Emissions Standards

Standard Name	Established by	Date Established	Regulates	Notes
MPR I	SWEDAC ¹	1987	Monitor emissions	Replaced by MPR II
MPR II	SWEDAC ¹	1990	Monitor emissions	Added maximums for ELF and VLF; minimum standard in recent monitors
TCO ²	TCO ²	1992	Tighter monitor emissions limits than MPR II; power management	TCO 95 and TCO 99 add other classes of devices to the TCO standard

1. The Swedish Board for Accreditation and Conformity Assessment

2. Swedish abbreviation for the Swedish Confederation of Professional Employees

Today, virtually all monitors on the market support TCO standards.

If you aren't using a low-emission monitor yet, you can take other steps to protect yourself. The most important is to stay at arm's length (about 28 inches) from the front of your monitor. When you move a couple of feet away, ELF magnetic emission levels usually drop to those of a typical office with fluorescent lights. Likewise, monitor emissions are weakest at the front of a monitor, so stay at least three feet from the sides and backs of nearby monitors and five feet from any photocopiers, which are also strong sources of ELF.

Electromagnetic emissions should not be your only concern; you also should be concerned about screen glare. In fact, some of the antiglare panels that fit in front of a monitor screen not only reduce eyestrain, but also cut ELF and VLF emissions.

Frequencies

One essential buying decision is to choose a monitor that works with your selected video adapter. Today, virtually all monitors are multiple-frequency (also called multiscanning and multifrequency) units that accommodate a range of standards, including those that are not yet standardized. However, big differences exist in how well different monitors cope with different video adapters.

Tip

High-quality monitors retain their value longer than most other computer components. Although it's common for a newer, faster processor to come out right after you have purchased your computer, or to find the same model with a bigger hard disk for the same money, a good quality monitor should outlast your computer. If you purchase a unit with the expectation that your own personal requirements will grow over the years, you might be able to save money on your next system by reusing your old monitor.

Two essential features are front-mounted controls, which can memorize screen settings, and built-in diagnostics. Built-in diagnostics can save you unnecessary trips to the repair shop.

With multiple-frequency monitors, you must match the range of horizontal and vertical frequencies the monitor accepts with those generated by your video adapter. The wider the range of signals, the more expensive—and more versatile—the monitor. Your video adapter's vertical and horizontal frequencies must fall within the ranges supported by your monitor. The vertical frequency (or refresh/frame rate) determines how stable your image will be. The higher the vertical frequency, the better. Typical vertical frequencies range from 50Hz to 160Hz, but multiple-frequency monitors support different vertical frequencies at different resolutions. You might find that a bargain monitor has a respectable 100Hz vertical frequency at 640×480, but drops to a less desirable 60Hz at 1,024×768. The horizontal frequency (or line rate) typically ranges from 31.5KHz to 90KHz or more.

Refresh Rates

The refresh rate (also called the vertical scan frequency) is the rate at which the screen display is rewritten. This is measured in hertz (Hz). A refresh rate of 72Hz means that the screen is refreshed 72 times per second. A refresh rate that is too low causes the screen to flicker, contributing to eyestrain. The higher the refresh rate, the better for your eyes and your comfort during long sessions at the computer.

A *flicker-free refresh rate* is a refresh rate high enough to prevent you from seeing any flicker. The flicker-free refresh rate varies with the resolution of your monitor setting (higher resolutions require a higher refresh rate) and must be matched by both your monitor and your display card. Because a refresh rate that is too high can slow down your video display, use the lowest refresh rate that is comfortable for you.

One factor that is important to consider when you purchase a monitor is the refresh rate, especially if you are planning to use the monitor at 1,024×768 or higher resolutions. Low-cost monitors often have refresh rates that are too low to achieve flicker-free performance for most users, and thus can lead to eyestrain.

Table 15.4 compares two typical 17-inch CRT monitors and a typical midrange graphics card.

Note the differences in the refresh rates supported by the Matrox Millennium G200 and two different 17-inch CRT monitors from LG-Goldstar.

The LG 760SC is a typical, under-\$300 monitor, and the LG 790SC sells for about \$80 more. Note the 790SC offers flicker-free refresh rates at higher resolutions than the less-expensive 760SC.

Although the Matrox Millennium G200 video card supports higher refresh rates than either monitor, rates higher than the monitor can support cannot be used safely because rates in excess of the monitor's maximum refresh rate can damage the monitor!

Table 15.4 Refresh Rates Comparison

Resolution	G200 Video Card Vertical Refresh	LG 760SC (17") Monitor Vertical Refresh (Maximum)	LG 790SC (17") Monitor Vertical Refresh (Maximum)
1024x768	60–140	87Hz ¹	124Hz ¹
1,280x1024	60–100Hz ¹ 65Hz	93Hz ¹	
1,600x1200	52–85Hz ¹	Not supported	80Hz ¹

1. Rates above 72Hz will be flicker-free for many users; VESA standard for flicker-free refresh is 85Hz or above.

To determine the monitor's refresh rates for the resolutions you're planning to use, check out the monitor manufacturer's Web site to get the details for any monitor you own or are planning to purchase.

During installation, Windows 2000, Windows 98, Windows 95B (OSR 2.x), and Windows Millennium support Plug-and-Play (PnP) monitor configuration. A PnP monitor sends signals to the operating system that indicate which refresh rates it supports as well as other display information, and this data is reflected by the Display Properties sheet for that monitor.

To keep the frequency low, some video adapters use interlaced signals, alternately displaying half the lines of the total image. As discussed earlier in this chapter, interlacing produces a pronounced flicker in the display on most monitors unless the phosphor is designed with a very long persistence. For this reason, you should, if possible, avoid using interlaced video modes. Some older adapters and displays used interlacing as an inexpensive way to attain a higher resolution than what would otherwise be possible. For example, the original IBM XGA adapters and monitors used an interlaced vertical frame rate of 43.5Hz in 1,024x768 mode instead of the higher frame rate that most other adapters and displays use at that resolution.

Note

Because monitors are redrawing the screen many times per second, the change in a noninterlaced screen display is virtually invisible to the naked eye, but it is very obvious when computer screens are photographed, filmed, or videotaped. Because these cameras aren't synchronized to the monitor's refresh cycle, it's inevitable that the photo, film, or videotape will show the refresh in progress as a line across the picture.

In my experience, a 60Hz vertical scan frequency (frame rate) is the minimum anybody should use, and even at this frequency, a flicker will be noticed by most people. Especially on a larger display, this can cause eyestrain and fatigue. If you can select a frame rate (vertical scan frequency) of 72Hz or higher, most people will not be able to discern any flicker. Most modern mid-range or better displays easily handle vertical frequencies of up to 85Hz or more, which greatly reduces the flicker seen by the user. However, note that increasing the frame rate, although improving the quality of the image, can also slow down the video hardware because it now needs

to display each image more times per second. In general, I recommend that you set the lowest frame rate you find comfortable. To adjust the video card's refresh rate with Windows 9x, use the Display icon in control panel, select Settings and select the Advanced Properties button.

Click the Adapter tab and click the down arrow next to the Refresh Rate menu. You'll see the refresh rates supported by the video card. Optimal is the default setting, but this really is a "safe" setting for any monitor. Select a refresh rate of at least 72Hz or higher to reduce or eliminate flicker. Click Apply to take the new setting. If you choose a refresh rate other than Optimal, you'll see a warning about possible monitor damage.

Click OK to try the new setting. The screen changes to show the new refresh rate. If the screen display looks scrambled, wait a few moments and the screen will be restored to the previous value; you'll see a dialog box asking if you want to keep the new setting. If the display was acceptable, click Yes; otherwise, click No to restore your display. If the screen is scrambled and you can't see your mouse pointer, just press the Enter key on your keyboard because No is the default answer. With some older video drivers, this refresh rate dialog box will not be available. Get an updated video driver, or check with the video card vendor for a separate utility program that will set the refresh rate for you.

If you have a scrambled display with a high refresh rate, but you think the monitor should be able to handle the refresh rate you chose, you might not have the correct monitor selected. To check your Windows 9x monitor selection, click the Monitor tab. If your monitor is listed as Super VGA, Windows is using a generic driver that will work with a wide variety of monitors. This generic driver doesn't support refresh rates above 75Hz because some monitors could be damaged by excessive refresh rates.

Check with your monitor vendor for a driver specific for your model. After you install it, see if your monitor will safely support a higher refresh rate.

Horizontal Frequency

When you shop for a VGA monitor, make sure the monitor supports a horizontal frequency of at least 31.5KHz—the minimum that a VGA card needs to paint a 640×480 screen. The 800×600 resolution requires at least a 72Hz vertical frequency and a horizontal frequency of at least 48KHz. The sharper 1,024×768 image requires a vertical frequency of 60Hz and a horizontal frequency of 58KHz. If the vertical frequency increases to 72Hz, the horizontal frequency must be 58KHz. For a super-crisp display, look for available vertical frequencies of 75Hz or higher and horizontal frequencies of up to 90KHz or more. My favorite 17-inch NEC monitor supports vertical resolutions of up to 75Hz at 1,600×1,200 pixels, 117Hz at 1,024×768, and 160Hz at 640×480!

Virtually all the analog monitors on the market today are, to one extent or another, multiple frequency. Because literally hundreds of manufacturers produce thousands of monitor models, it is impractical to discuss the technical aspects of each monitor model in detail. Suffice it to say that before investing in a monitor, you should check the technical specifications to make sure that the monitor meets your needs. If you are looking for a place to start, check out some of the different magazines that periodically feature reviews of monitors. If you can't wait for a magazine review, investigate monitors at the Web sites run by any of the following vendors: IBM, Sony, Mitsubishi, ViewSonic, and NEC.

Each of these manufacturers creates monitors that set the standards by which other monitors can be judged. Although you typically pay a bit more for these manufacturers' monitors, they offer a known, high-level of quality and compatibility, as well as service and support.

Controls

Most of the newer monitors now use digital controls instead of analog controls. This has nothing to do with the signals that the monitor receives from the computer, but only the controls (or lack of them) on the front panel that enable you to adjust the display. Monitors with digital controls have a built-in menu system that enables you to set parameters such as brightness, contrast, screen size, vertical and horizontal shifts, and even focus. The menu is brought up on the screen by a button, and you use controls to make menu selections and vary the settings. When you complete your adjustments, the monitor saves the settings in NVRAM (nonvolatile RAM) located inside the monitor. This type of memory provides permanent storage for the settings with no battery or other power source. You can unplug the monitor without losing your settings and you can alter them at any time in the future. Digital controls provide a much higher level of control over the monitor and are highly recommended.

Digital controls make it easy to adjust monitors suffering from any of the geometry errors shown in Figure 15.4. Before making these adjustments, make sure the vertical and horizontal size and position are correct.

Tip

Get a monitor with positioning and image controls that are easy to reach, preferably on the front of the case. Look for more than just basic contrast and brightness controls; a good monitor should enable you to adjust the width and height of your screen images and the placement of the image on the screen. The monitor should also be equipped with a tilt-swivel stand so you can adjust the monitor to the best angle for your use.

Environment

One factor that you might not consider when shopping for a monitor is the size of the desk on which you intend to put it. Before you think about purchasing a monitor larger than 15 inches, be aware that a typical 17-inch monitor can be 18–24 inches deep and weigh upward of 40 pounds; 21-inch and larger monitors can be truly huge! Some of the rickety computer stands and mechanical arms used to keep monitors off the desktop might not be able to safely hold or support a large unit. Check the weight rating of the computer stand or support arm you're planning to use before you put a monitor on it. It's tragic to save a few dollars on these accessories, only to watch them crumple under the weight of a large monitor and wipe out your monitor investment.

Tip

If you are using a relatively narrow computer table, look for a monitor that uses the so-called short neck CRTs. These short neck CRTs are used in many recent 17-inch and 19-inch models and allow the monitor to take up less space front to back. Some 17-inch short neck models use no more front-to-back space than typical 14-inch models and weigh less. ViewSonic's GS773 short-depth 17" monitor is only 15.2 inches deep and weighs only 35 pounds.

Figure 15.4 Typical geometry errors in monitors; these can be corrected on most models that have digital picture controls.

Another important consideration is the lighting in the room where you will use the monitor. The appearance of a CRT display in the fluorescent lighting of an office will be markedly different from that in your home. The presence or absence of sunlight in the room also makes a big difference. Office lighting and sunlight can produce glare that becomes incredibly annoying when you are forced to stare at it for hours on end. You can reduce onscreen glare by choosing monitors equipped with flat-square or other flat CRT technologies or LCD panels and antiglare coatings. You can retrofit aftermarket filters to monitors that lack these features to help reduce glare.

Testing a Display

Unlike most of the other components of your computer, you can't really tell whether a monitor will suit you by examining its technical specifications. Price might not be a reliable indicator either. Testing monitors is a highly subjective process, and it is best to "kick the tires" of a few at a dealer showroom (with a liberal return policy) or in the privacy of your home or office.

Testing should also not be simply a matter of looking at whatever happens to be displayed on the monitor at the time. Many computer stores display movies, scenic photos, or other flashy graphics that are all but useless for a serious evaluation and comparison. If possible, you should look at the same images on each monitor you try and compare the manner in which they perform a specific series of tasks.

Before running the tests listed below, set your display to the highest resolution and refresh rate allowed by your combination of display and graphics card.

One good series of tasks is as follows:

- Draw a perfect circle with a graphics program. If the displayed result is an oval, not a circle, this monitor will not serve you well with graphics or design software.
- Using a word processor, type some words in 8- or 10-point type (1 point equals 1/72 inch). If the words are fuzzy, or if the black characters are fringed with color, select another monitor.
- Turn the brightness up and down while examining the corner of the screen's image. If the image blooms or swells, it is likely to lose focus at high brightness levels.
- Display a screen with as much white space as possible and look for areas of color variance. This can indicate a problem only with that individual unit or its location, but if you see it on more than one monitor of the same make, it might indicate a manufacturing problem; or it could indicate problems with the signal coming from the graphics card. Move the monitor to another system equipped with a different graphics card model and retry this test to see for certain whether it's the monitor or the video card.
- Load Microsoft Windows to check for uniform focus. Are the corner icons as sharp as the rest of the screen? Are the lines in the title bar curved or wavy? Monitors usually are sharply focused at the center, but seriously blurred corners indicate a poor design. Bowed lines can be the result of a poor video adapter, so don't dismiss a monitor that shows those lines without using another adapter to double-check the effect. You can also use diagnostics that come with the graphics card or third-party system diagnostics programs to perform these tests.
- A good monitor will be calibrated so that rays of red, green, and blue light hit their targets (individual phosphor dots) precisely. If they don't, you have bad convergence. This is apparent when edges of lines appear to illuminate with a specific color. If you have good convergence, the colors will be crisp, clear, and true, provided there isn't a predominant tint in the phosphor.
- If the monitor has built-in diagnostics (a recommended feature), try them as well to test the display independent of the graphics card and system to which it's attached.

Caring for Your Monitor

Since a good 17-inch or larger monitor can be used for several years on more than one computer, proper care is essential to extend its life to the fullest extent.

Use the following guidelines for proper care of your monitors:

- Although phosphor burn (where an image left onscreen eventually leaves a permanent shadow onscreen) is next-to-impossible with VGA-type displays, unlike the old TTL displays, screensavers are still useful. Windows includes several screensavers that can be enabled via the Display Control Panel. A bevy of free and inexpensive screensavers is available for download from the Internet.
- To prevent premature failure of the monitor's power supply, use the power management feature of the Display properties sheet to put the monitor into a low-power standby mode after a reasonable period of inactivity (10 to 15 minutes) and to turn it off after about 60 minutes. Using the power management feature is far better than using the on/off switch when you are away from the computer for brief periods. Turn off the monitor only at the end of your computing "day."

- Make sure the monitor has adequate ventilation along the sides, rear, and top. Since monitors use passive cooling, a lack of adequate airflow caused by piling keyboards, folders, books, or other office debris on top of the monitor will cause it to overheat and considerably shorten its life. If you're looking at a monitor with a partly melted grille on the top of the case, you're looking at a victim of poor cooling.
- The monitor screen and case should be kept clean; turn off the power and spray a cleaner such as Endust for Electronics onto a soft cloth (never directly onto the monitor!) and wipe the screen and the case gently.
- If your monitor has a degaussing button or feature, use it periodically to remove stray magnetic signals. Keep in mind that CRTs have powerful magnets around the picture tube, so keep magnetic media away from them.

Video Display Adapters

A video adapter provides the interface between your computer and your monitor and transmits the signals that appear as images on the display. Throughout the history of the PC, there have been a succession of standards for video display characteristics that represent a steady increase in screen resolution and color depth. The following list of standards can serve as an abbreviated history of PC video-display technology:

- MDA (Monochrome Display Adapter)
- HGC (Hercules Graphics Card)
- CGA (Color Graphics Adapter)
- EGA (Enhanced Graphics Adapter)
- VGA (Video Graphics Array)
- SVGA (Super VGA)
- XGA (Extended Graphics Array)

Most of these standards were pioneered by IBM but were also adopted by the manufacturers of compatible PCs as well. Today, IBM is no longer the industry leader that it once was, and many of these standards are obsolete. Those that aren't obsolete are seldom referred to by these names anymore. The sole exception to this is *VGA*, which is a term that is still used to refer to a baseline graphics display capability supported by virtually every video adapter on the market today.

When you shop for a video adapter today, you are more likely to see specific references to the screen resolutions and color depths that the device supports than a list of standards such as *VGA*, *SVGA*, and *XGA*. However, reading about these standards gives you a good idea of how video-display technology developed over the years and prepares you for any close encounters you might have with legacy equipment from the dark ages.

Today's *VGA* and later video adapters can also display most older color graphics software written for *CGA*, *EGA*, and most other obsolete graphics standards, enabling you to use older graphics software (such as game and educational programs) on your current system. Although not a concern for most users, some older programs wrote directly to hardware registers that are no longer found on current video cards.

Obsolete Display Adapters

Although many types of display systems were at one time considered to be industry standards, few of these are viable standards for today's hardware and software.

Note

If you are interested in reading more about MDA, HGC, CGA, EGA, or MCGA display adapters, see Chapter 8 of *Upgrading and Repairing PCs, Tenth Anniversary Edition*, included on the CD with this book.

VGA Adapters and Displays

When IBM introduced the PS/2 systems on April 2, 1987, it also introduced the Video Graphics Array (VGA) display. On that day, in fact, IBM also introduced the lower resolution MultiColor Graphics Array (MCGA) and higher resolution 8514 adapters. The MCGA and 8514 adapters did not become popular standards like the VGA became, and both were discontinued.

Digital Versus Analog Signals

Unlike earlier video standards, which are digital, the VGA is an analog system. Why have displays gone from digital to analog when most other electronic systems have gone digital? Compact disc players (digital) have replaced most turntables (analog), and newer VCRs and camcorders have digital picture storage for smooth slow-motion and freeze-frame capability. With a digital television set, you can watch several channels on a single screen by splitting the screen or placing a picture within another picture.

Most personal computer displays introduced before the PS/2 are digital. This type of display generates different colors by firing the RGB electron beams in on-or-off mode, which allows for the display of up to eight colors (2³). In the IBM displays and adapters, another signal doubles the number of color combinations from 8 to 16 by displaying each color at one of two intensity levels. This digital display is easy to manufacture and offers simplicity with consistent color combinations from system to system. The real drawback of the digital display system is the limited number of possible colors.

In the PS/2 systems, IBM went to an analog display circuit. Analog displays work like the digital displays that use RGB electron beams to construct various colors, but each color in the analog display system can be displayed at varying levels of intensity—64 levels, in the case of the VGA. This versatility provides 262,144 possible colors (64³), of which 256 could be simultaneously displayed. For realistic computer graphics, color depth is often more important than high resolution because the human eye perceives a picture that has more colors as being more realistic. IBM moved to analog graphics to enhance the color capabilities of its systems.

Video Graphics Array (VGA)

PS/2 systems incorporated the primary display adapter circuitry onto the motherboard, and both IBM and third-party companies introduced separate VGA cards to allow other types of systems to enjoy the advantages of VGA.

Although VGA was introduced with the IBM MicroChannel (MCA) computers, such as the PS/2 Model 50 and above, it's impossible today to find a brand-new replacement for VGA that fits in the obsolete MCA-bus systems; however, surplus and used third-party cards might be available.

The VGA BIOS (basic input/output system) is the control software residing in the system ROM for controlling VGA circuits. With the BIOS, software can initiate commands and functions without having to manipulate the VGA directly. Programs become somewhat hardware independent and can call a consistent set of commands and functions built into the system's ROM-control software.

◀◀ See "Video Adapter BIOS," p. 503.

Other implementations of the VGA differ in their hardware but respond to the same BIOS calls and functions. New features are added as a superset of the existing functions, and VGA remains compatible with the graphics and text BIOS functions built into the PC systems from the beginning. The VGA can run almost any software that was originally written for the CGA or EGA, unless it was written to directly access the hardware registers of these cards.

In a perfect world, software programmers would write to the BIOS interface rather than directly to the hardware and would promote software interchanges between different types of hardware. More frequently, however, programmers want the software to perform better, so they write the programs to control the hardware directly. As a result, these programmers achieve higher-performance applications that depend on the hardware for which they were first written.

When bypassing the BIOS, a programmer must ensure that the hardware is 100-percent compatible with the standard so that software written to a standard piece of hardware runs on the system. Just because a manufacturer claims this register level of compatibility does not mean that the product is 100-percent compatible or that all software runs as it would on a true IBM VGA. Most manufacturers have "cloned" the VGA system at the register level, which means that even applications that write directly to the video registers will function correctly. This compatibility makes the VGA a truly universal standard.

The VGA displays up to 256 colors onscreen, from a palette of 262,144 (256KB) colors. Because the VGA outputs an analog signal, you must have a monitor that accepts an analog input.

VGA displays come not only in color, but also in monochrome VGA models, which use color summing. With color summing, 64 gray shades are displayed instead of colors. The summing routine is initiated if the BIOS detects a monochrome display when the system boots. This routine uses an algorithm that takes the desired color and rewrites the formula to involve all three color guns, producing varying intensities of gray. Users who prefer a monochrome display, therefore, can execute color-based applications.

Table 15.5 lists the VGA display modes.

Table 15.5 VGA Display Modes

Resolution	Colors	Mode Type	BIOS Mode	Character Format	Character Box	Vertical (Hz)	Horizontal (KHz)
360×400	16	Text	00/01h	40×25	9×16	70	31.5
720×400	16	Text	02/03h	80×25	9×16	70	31.5

Resolution	Colors	Mode Type	BIOS Mode	Character Format	Character Box	Vertical (Hz)	Horizontal (KHz)

640×480	16	APA	12h	80×30	8×16	60	31.5
320×200	256	APA	13h	40×25	8×8	70	31.5

APA = All points addressable (graphics)

Even the least-expensive video adapters on the market today can work with modes beyond the VGA standard. VGA, at its 16-color 640×480 resolution, has come to be the baseline for PC graphical display configurations. VGA is accepted as the least common denominator for all Windows systems and must be supported by the video adapters in all systems running Windows. The installation programs of all Windows versions use these VGA settings as their default video configuration. In addition to VGA, most adapters support a range of higher screen resolutions and color depths, depending on the capabilities of the hardware. If a Windows 9x or Windows 2000 system must be started in Safe Mode because of a startup problem, the system defaults to VGA in the 640×480, 16-color mode.

IBM introduced higher-resolution versions of VGA called XGA and XGA-2 in the early 1990s, but most of the development of VGA standards has come from the third-party video card industry and its trade group, the Video Electronic Standards Association (VESA).

Note

If you are interested in reading more about the XGA and XGA-2 display adapters, see Chapter 8 of *Upgrading and Repairing PCs, Tenth Anniversary Edition*, included on the CD with this book.

Super VGA (SVGA)

When IBM's XGA and 8514/A video cards were introduced, competing manufacturers chose not to attempt to clone these incremental improvements on their VGA products. Instead, they began producing lower-cost adapters that offered even higher resolutions. These video cards fall into a category loosely known as Super VGA (SVGA).

SVGA provides capabilities that surpass those offered by the VGA adapter. Unlike the display adapters discussed so far, SVGA refers not to an adapter that meets a particular specification, but to a group of adapters that have different capabilities.

For example, one card might offer several resolutions (such as 800×600 and 1,024×768) that are greater than those achieved with a regular VGA, whereas another card might offer the same or

even greater resolutions but also provide more color choices at each resolution. These cards have different capabilities; nonetheless, both are classified as SVGA.

The SVGA cards look much like their VGA counterparts. They have the same connectors, including the feature adapter shown. Because the technical specifications from different SVGA vendors vary tremendously, it is impossible to provide a definitive technical overview in this book. The connector is shown in Figure 15.5. The pinouts are shown in Table 15.6.

Figure 15.5 SVGA connector.

Table 15.6 Standard 15-pin VGA Connector Pinout

Pin	Function	Direction	Pin	Function	Direction
1	Red Video	Out	2	Green Video	Out
3	Blue Video	Out	4	Monitor ID 2	In
5	TTL Ground (monitor self-test)	-	6	Red Analog Ground	-
7	Green Analog Ground	-	8	Blue Analog Ground	-
9	Key (Plugged Hole)	-	10	Sync Ground	-
11	Monitor ID 0	In	12	Monitor ID 1	In
13	Horizontal Sync	Out	14	Vertical Sync	Out
15	Monitor ID 3	In			

On the VGA cable connector that plugs into your video adapter, pin 9 is often pinless. Pin 5 is used only for testing purposes, and pin 15 is rarely used; these are often pinless as well. To identify the type of monitor connected to the system, some manufacturers use the presence or absence of the monitor ID pins in various combinations.

VESA SVGA Standards

The Video Electronics Standards Association (VESA) includes members from various companies associated with PC and computer video products. In October 1989, VESA, recognizing that programming applications to support the many SVGA cards on the market was virtually impossible, proposed a standard for a uniform programmer's interface for SVGA cards.

The SVGA standard is called the VESA BIOS extension (VBE). If a video card incorporates this standard, a program can easily determine the capabilities of the card and access them. The benefit of the VESA BIOS extension is that a programmer needs to worry about only one routine or

driver to support SVGA. Different cards from different manufacturers are accessible through the common VESA interface.

When first proposed, this concept met with limited acceptance. Several major SVGA manufacturers started supplying the VESA BIOS Extension as a separate memory-resident program that you could load when you booted your computer. Over the years, however, other vendors started supplying the VESA BIOS extension as an integral part of their SVGA BIOSes. Today, VBE support is a primary concern for real-mode DOS applications, especially games, and for non-Microsoft operating systems that need to access higher resolutions and color depths. VESA compliance is of virtually no consequence to Windows 9x/NT/2000 users, who use custom video drivers for their graphics cards.

Obviously, if you need VESA compliance, support for VESA in BIOS is a better solution. You do not have to worry about loading a driver or other memory-resident program whenever you want to use a program that expects the VESA extensions to be present.

The current VESA SVGA standard covers just about every video resolution and color-depth combination currently available, up to 1,280×1,024 with 16,777,216 (24-bit) colors. Beyond these resolutions, VESA has adopted a General Timing Format (GTF) that allows a resolution not supported in the BIOS to have standardized timings up to high-definition television resolutions of 1,880×1,440 pixels. Even if an SVGA video adapter claims to be VESA-compatible, however, it still might not work with a particular driver, such as the 800×600, 256-color, SVGA driver that comes with Microsoft Windows. In practice, however, manufacturers continue to provide their own driver software.

Table 15.7 lists the video modes of the Chips and Technologies 65554 SVGA graphics accelerator, a typical chipset used today.

Table 15.7 Chips and Technologies 65554 Graphics Accelerator Chipset Video Modes

BIOS Mode	Mode Type	Resolution	Character	Colors	Scan Freq (Hor./Vert.)

1. Interlaced

Note

Note that the video chipset used by a given video card controls the resolutions, color depth, and even the vertical and horizontal refresh rates supported by the card.

Video Adapter Components

All video display adapters contain certain basic components, such as the following:

- Video BIOS
- Video processor
- Video memory
- Digital-to-analog converter (DAC)
- Bus connector
- Video driver

Figure 15.6 ATI's All-in-Wonder 128 is a typical TV, video, and graphics card. Like most recent graphics cards, it uses a nonremovable flash BIOS.

Many popular adapters on the market today include additional modules intended for special purposes, such as 3D acceleration. The following sections examine these components in greater detail.

The Video BIOS

Video adapters include a BIOS (basic input/output system) that is similar in construction but completely separate from the main system BIOS. (Other devices in your system, such as SCSI adapters, might also include their own BIOS.) If you turn your monitor on first and look quickly, you might see an identification banner for your adapter's video BIOS at the very beginning of the system startup process.

Like the system BIOS, the video adapter's BIOS takes the form of a ROM (read-only memory) chip containing basic instructions that provide an interface between the video adapter hardware and the software running on your system. The software that makes calls to the video BIOS can be a stand-alone application, an operating system, or the main system BIOS. It is the programming in the BIOS chip that enables your system to display information on the monitor during the system POST and boot sequences, before any other software drivers have been loaded from disk.

◀◀ See "BIOS Basics," page 372.

The video BIOS can also be upgraded, just like a system BIOS, in one of two ways. Either the BIOS uses a rewritable chip called an EEPROM (electrically erasable programmable read-only memory) that you can upgrade with a utility that the adapter manufacturer provides, or you might be able to completely replace the chip with a new one—again, if supplied by the manufacturer and if the manufacturer did not hard solder the BIOS to the printed circuit board. A BIOS that you can upgrade using software is referred to as a flash BIOS, and most current-model video cards that offer BIOS upgrades use this method.

Video BIOS upgrades are sometimes necessary to use an existing adapter with a new operating system, or when the manufacturer encounters a significant bug in the original programming. As a general rule, the video BIOS is a component that falls into the "if it ain't broke, don't fix it" category. Try not to let yourself be tempted to upgrade just because you've discovered that a new BIOS revision is available. Check the documentation for the upgrade, and unless you are experiencing a problem that the upgrade addresses, leave it alone.

◀◀ See "Video Adapter BIOS," p. 503.

The Video Processor

The video processor, or chipset, is the heart of any video adapter and essentially defines the card's functions and performance levels. Two video adapters built using the same chipset often have many of the same capabilities and deliver comparable performance. Also, the software drivers that operating systems and applications use to address the video adapter hardware are written primarily with the chipset in mind. You can often use a driver intended for an adapter with a particular chipset on any other adapter using the same chipset. Of course, cards built using the same chipset can differ in the amount and type of memory installed, so performance can vary.

Three main types of processors are used in video adapters:

- Frame buffer controllers
- Coprocessors
- Accelerators

Table 15.8 compares these technologies.

Table 15.8 Video Processor Technologies

Processor Type	Where Video Processing Takes Place	Relative Speed	Relative Cost	How Used Today
Frame-buffer	Computer's CPU	Very slow	Very low	Obsolete; mostly ISA video cards
Graphics co-processor	Video card's own processor	Very fast	Very high	CAD and engineering workstations
Graphics accelerator	Video chip draws lines, circles, shapes; CPU sends commands to draw them	Fast	Low to moderate	All mainstream video cards

Identifying the Video and System Chipsets

Before you purchase a system or a video card, you should find out which chipset the video card or video circuit uses. This will allow you to have

- Better comparisons of card or system to others
- Access to technical specifications
- Access to reviews and opinions
- Better buying decisions
- Choice of card manufacturer or chipset manufacturer support and drivers

Because video card performance and features are critical to enjoyment and productivity, find out as much as you can before you buy the system or video card by using the chipset or video card manufacturer's Web site and third-party reviews.

The Vendor List on the CD has information on most of the popular video chipset manufacturers, including how to contact them.

The Video RAM

Most video adapters rely on their own onboard memory that they use to store video images while processing them; although some AGP video cards can use system memory for 3D textures, this feature is not universally supported. Many low-cost systems with onboard video use the Unified Memory Architecture feature to share the main system memory. In any case, the memory on the video card or borrowed from the system performs the same tasks.

The amount of memory on the adapter determines the maximum screen resolution and color depth that the device can support. You can often select how much memory you want on a

particular video adapter; for example, 4MB, 8MB, 16MB, or even 32MB are common choices today. Most cards today come with at least 8MB, and many have 16MB or more. Although adding more memory is not guaranteed to speed up your video adapter, it can increase the speed if it enables a wider bus (from 64 bits wide to 128 bits wide) or provides nondisplay memory as a cache for commonly displayed objects. It also enables the card to generate more colors and higher resolutions and, for AGP cards (see below) allows 3D textures to be stored and processed on the card, rather than in slower main memory.

Many different types of memory are used on video adapters today. These memory types are summarized in Table 15.9 and examined more fully in upcoming sections.

Table 15.9 Memory Types Used in Video Display Adapters

Memory Type	Definition	Relative Speed	Usage
FPM DRAM	Fast Page-Mode RAM	Slow	Low-end ISA cards; obsolete
VRAM ¹	Video RAM	Very fast	Expensive; rare today
WRAM ¹	Window RAM	Very fast	Expensive; rare today
EDO DRAM	Extended Data Out DRAM	Moderate	Low-end PCI-bus
SDRAM	Synchronous DRAM	Fast	Midrange PCI/AGP
MDRAM	Multibank DRAM	Fast	Little used; rare
SGRAM	Synchronous Graphics DRAM	Very fast	High-end PCI/AGP
DDR	Double-Data Rate SDRAM	Very fast	High-end AGP

1. VRAM and WRAM are dual-ported memory types that can read from one port and write data through the other port. This improves performance by reducing wait times for accessing the video RAM.

RAM Calculations

The amount of memory that a video adapter needs to display a particular resolution and color depth is based on a mathematical equation. A location must be present in the adapter's memory array to display every pixel on the screen, and the number of total pixels is determined by the resolution. For example, a screen resolution of 1,024×768 requires a total of 786,432 pixels.

If you were to display that resolution with only two colors, you would need only one bit of memory space to represent each pixel. If the bit has a value of 0, the dot is black, and if its value is 1, the dot is white. If you use 4 bits of memory space to control each pixel, you can display 16 colors because there are 16 possible combinations with a 4-digit binary number ($2^4=16$). If you multiply the number of pixels needed for the screen resolution by the number of bits required to represent each pixel, you have the amount of memory that the adapter needs to display that resolution. Here is how the calculation works:

$$\begin{aligned}
 1,024 \times 768 &= 786,432 \text{ pixels} \times 4 \text{ bits per pixel} \\
 &= 3,145,728 \text{ bits} \\
 &= 393,216 \text{ bytes} \\
 &= 384\text{KB}
 \end{aligned}$$

As you can see, displaying 16 colors at 1,024×768 resolution requires exactly 384KB of RAM on the video adapter. Because most adapters support memory amounts of only 256KB, 512KB, 1MB, 2MB, or 4MB, you would have to install 512KB to run your system using that resolution and color depth. Increasing the color depth to 8 bits per pixel results in 256 possible colors, and a memory requirement of 786,432 bytes, or 768KB. Again, because no video adapters are equipped with that exact amount, you would have to purchase an adapter with 1MB of memory.

To use the higher resolution modes and greater numbers of colors that are common today, you will need much more memory on your video adapter than the 256KB found on the original IBM VGA. Table 15.10 shows the memory requirements for some of the most commonly used screen resolutions and color depths.

Table 15.10 Video Display Adapter Minimum Memory Requirements for 2D Operations

Resolution	Color Depth	No. Colors	Onboard Video RAM	Actual Memory Required
640×480	4-bit	16	256KB	153,600 bytes
640×480	8-bit	256	512KB	307,200 bytes
640×480	16-bit	65,536	1MB	614,400 bytes
640×480	24-bit	16,777,216	1MB	921,600 bytes
800×600	4-bit	16	256KB	240,000 bytes
800×600	8-bit	256	512KB	480,000 bytes
800×600	16-bit	65,536	1MB	960,000 bytes
800×600	24-bit	16,777,216	2MB	1,440,000 bytes
1,024×768	4-bit	16	512KB	393,216 bytes
1,024×768	8-bit	256	1MB	786,432 bytes
1,024×768	16-bit	65,536	2MB	1,572,864 bytes
1,024×768	24-bit	16,777,216	4MB	2,359,296 bytes
1,280×1,024	4-bit	16	1MB	655,360 bytes
1,280×1,024	8-bit	256	2MB	1,310,720 bytes
1,280×1,024	16-bit	65,536	4MB	2,621,440 bytes
1,280×1,024	24-bit	16,777,216	4MB	3,932,160 bytes

From this table, you can see that a video adapter with 2MB can display 65,536 colors in 1,024×768 resolution mode, but for a true color (16.8 million colors) display, you would need to upgrade to 4MB.

3D video cards require more memory for a given resolution and color depth, because the video memory must be used for three different buffers: the front buffer, the back buffer, and the Z-buffer. Table 15.11 lists the memory requirements for 3D cards in popular modes.

Table 15.11 Video Display Adapter Memory Requirements for 3D Operations

Resolution	Color Depth	Onboard Video RAM	Actual Memory Required
640x480	16-bit	2MB	1.77MB
640x480	32-bit ¹	4MB	2.93MB
800x600	16-bit	4MB	2.76MB
800x600	32-bit ¹	8MB	4.58MB
1,024x768	16-bit	8MB	4.50MB
1,024x768	32-bit ¹	8MB	7.50MB
1,280x1,024	16-bit	8MB	7.50MB

1. Although 3D adapters typically operate in a 32-bit mode (see table above), this does not necessarily mean that they can produce more than the 16,277,216 colors of a 24-bit true color display. Many video processors and video memory buses are optimized to move data in 32-bit words, and they actually display 24-bit color while operating in a 32-bit mode, instead of the 4,294,967,296 colors that you would expect from a true 32-bit color depth.

If you spend a lot of time working with graphics, you might want to invest in a 24-bit (2D) or 32-bit (3D) video card with 16MB or more of RAM. Most of the cards today can easily handle 24-bit color, but you will need at least 4MB of RAM to get that capability in the higher resolution modes for 2D operation. With RAM density increasing, prices dropping, and 2D caching and 3D capability improving, 16MB or more of fast SDRAM or SGRAM will make both 2D and 3D programs perform very well.

Note

You can upgrade the RAM on some recent video adapters by installing a separate module containing the additional memory chips. The module usually takes the form of a daughter card; that is, a small circuit board that plugs into a socket on the video adapter. The design of the daughter board is usually proprietary, even if the type of memory chips on the board is not. You will usually have to purchase the module from the manufacturer of the video adapter. Some video cards use standard SODIMM memory modules instead of proprietary daughter cards.

Windows Can't Display More Than 256 Colors

If you have a video card with 1MB or more of video memory, but the Windows 9x Display Settings properties sheet won't allow you to select a color depth greater than 256 colors, Windows 9x might have misidentified the video card during installation (this is a common problem with Trident 9680-series video cards, for example).

To see which video card Windows 9x recognizes, click the Advanced Properties button, and then click the Adapter tab if needed. Your adapter type will be listed near the middle of the dialog box. It might be listed either by the video card's brand name and model or by the video card's chipset maker and chipset model.

If the card model or chipset appears to be incorrect or not specific enough, click Change and see what other drivers your system lists that appear to be compatible. Many video card and chipset makers offer a free utility that you can download from their Web sites that will identify the card model, memory size, and other important information. Use such a utility program to determine which card you have, and then manually install the driver you need.

Video Bus Width

Another issue with respect to the memory on the video adapter is the width of the bus connecting the graphics chipset and the memory on the adapter. The chipset is usually a single large chip on the card that contains virtually all the adapter's functions. It is wired directly to the memory on the adapter through a local bus on the card. Most of the high-end adapters use an internal memory bus that is 64 bits or even 128 bits wide. This jargon can be confusing because video adapters that take the form of separate expansion cards also plug into the main system bus, which has its own speed rating. When you read about a 64-bit or 128-bit video adapter, you must understand that this refers to the local video bus, and that the bus connecting the adapter to the system is actually the 32- or 64-bit PCI or AGP bus on the system's motherboard.

◀◀ See "System Bus Functions and Features," p. 309.

DRAM

Until recently, most video adapters have used regular dynamic RAM (DRAM) for this purpose. This type of RAM, although inexpensive, is rather slow. The slowness can be attributed to the need to constantly refresh the information contained within the RAM, and to the fact that DRAM cannot be read at the same time it is being written.

Modern PC graphics adapters need extremely high data transfer rates to and from the video memory. At a resolution of 1,024×768 and a standard refresh rate of 72Hz, the digital-to-analog converter (DAC) on the card needs to read the contents of the video memory frame buffer 72 times per second. In true color (24 bits per pixel) mode, this means that the DAC must be able to read from the video memory at a rate of about 170MB/sec, which is just about the maximum available from a conventional DRAM design. Because of the high bandwidth required for higher refresh rates, resolutions, and color depths, a number of competing memory technologies have emerged over the past several years to meet the needs of high-performance video memory. Today, virtually no adapters rely on ordinary DRAM.

◀◀ See "DRAM," p. 435.

EDO DRAM

One of the more-recent memory designs to be incorporated into low-cost video adapters is EDO (Extended Data Out) DRAM. EDO provides a wider effective bandwidth by offloading memory precharging to separate circuits, which means that the next access can begin before the last access has finished. As a result, EDO offers a 10-percent speed boost over DRAM, at a similar cost. EDO DRAM was introduced by Micron Technologies and was originally designed for use in a PC's main RAM array, but it has also become common for video adapter memory in low-cost PCI-bus video cards. EDO chips are constructed using the same dies as conventional DRAM chips, and they differ from DRAMs only in how they are wired in final production. This method enables manufacturers to make EDO chips on the same production lines and at the same relative costs as DRAM.

◀◀ See "EDO (Extended Data Out) RAM," p. 445.

High-Speed Video RAM Solutions—Older Types

Over the years, several methods have been used for increasing video RAM speed above the slow DRAM and the only slightly faster EDO RAM. Several, including VRAM, WRAM, and MDRAM were popular for brief periods of time but have been almost completely replaced by SDRAM and SGRAM.

VRAM

VRAM (Video RAM) is designed to be dual-ported, splitting the memory into two sections that can be accessed for reading and writing much faster than single-ported DRAM or EDO memory. This provides much greater performance than standard DRAM or even EDO, but it comes at a higher price.

WRAM

WRAM, or Windows RAM, is a modified VRAM-type, dual-ported memory technology developed by Samsung that is aimed specifically at graphics adapters. WRAM offers marginally better performance than standard VRAM at a lower cost.

MDRAM

MDRAM (Multibank DRAM) is a memory type also explicitly aimed at graphics and video applications. Developed by MoSys Inc., MDRAMs consist of a large number of small (32KB) banks.

MDRAM permits a video card with 2.5MB of RAM to be built, for example; enough to surpass the RAM requirements for 24-bit color at 1,024×768 resolution. Normally, 4MB of video RAM would be required. MDRAM was also designed to be accessed more quickly than even VRAM or WRAM. However, very few video card models ever featured this memory type.

Current High-Speed Video RAM Solutions

SGRAM, SDRAM, and DDR SDRAM have all but replaced VRAM, WRAM, and MDRAM as high-speed RAM solutions.

SGRAM

SGRAM, or Synchronous Graphics RAM, is a high-end solution for very fast video adapter designs. Like the SDRAM used in motherboard memory arrays, SGRAM can synchronize itself with the speed of the bus, up to 200MHz. This type of memory can be up to four times as fast as conventional DRAM and can operate at speeds up to 133MHz or faster; it is now being used in many of the highest quality PCI and AGP adapters. SGRAM is one of the most expensive memory technologies now used in video adapters, but it offers superior performance for graphics-intensive applications. The key difference between SGRAM and SDRAM is the inclusion of circuitry to perform block writes that can significantly increase the speed of graphics fill or 3D Z-buffer operations.

SDRAM

SDRAM, or Synchronous DRAM, is the same type of RAM used on Pentium II, Pentium III, and other systems that use DIMM (Dual Inline Memory Modules), although the SDRAMs found on video cards are normally surface-mounted or plugged into a proprietary connector. This memory is designed to work with bus speeds up to 200MHz and provides performance just slightly slower than SGRAM. SDRAM is the memory found in a number of top-line AGP and PCI video cards from some vendors, or in the midrange and low-end video cards from vendors who use SGRAM for their top-line models.

DDR SDRAM

Double Data Rate SDRAM (a.k.a. SDRAM II) is one of the newest video RAM technologies. It is designed to transfer data at speeds twice that of conventional SDRAM by transferring data on both the rising and falling parts of the processing clock cycle. It is fast enough to work with the newest 133MHz-bus motherboards from Intel and other vendors, and is designed to be easily adopted by current users of conventional SDRAM. Several video card vendors using the popular nVidia GeForce chipset have already adopted DDR SDRAM, and at high resolutions such as 1024×768 and above are seeing game performance boosts of 20 percent or more for some functions over the same chipset with standard SDRAM.

Emerging High-Speed Video RAM Solutions

The following video RAM types are designed to speed up video RAM access even further, allowing for ever more realistic 3D graphics and full-motion video on your desktop. These emerging technologies should be appearing on high-performance desktops in the near future.

Direct RAMBUS DRAM (DRDRAM)

This technology has been developed by Rambus, a company closely linked to Intel, and features a 16-bit data bus (twice that of conventional DRAMS), pipelining, and up to eight simultaneous operations.

Sync Link DRAM (SLDRAM)

This memory technology features very high speeds comparable to DRDRAM with all memory signals on the same line, compared to conventional memory's separate CAS, RAS, address, and data lines.

◀◀ See "SDRAM," p. 446.

The Digital-to-Analog Converter (RAMDAC)

The digital-to-analog converter on a video adapter (commonly called a RAMDAC) does exactly what its name describes. The RAMDAC is responsible for converting the digital images that your computer generates into analog signals that the monitor can display. The speed of the RAMDAC is measured in MHz; the faster the conversion process, the higher the adapter's vertical refresh rate. The speeds of the RAMDACs used in today's high performance video adapters can exceed 300MHz.

The benefits of increasing the RAMDAC speed include higher vertical refresh rates, which allows higher resolutions with flicker-free refresh rates (72Hz–85Hz or above).

Table 15.12 shows the effect of faster RAMDAC chips on typical video card chipsets. As RAMDAC increases, higher resolutions with higher vertical-refresh rates are supported.

Table 15.12 Typical Chipset and RAMDAC Pairings and Their Effects on Resolution and Refresh

Chipset	RAMDAC speed	Maximum Resolution	Refresh Rate
Matrox G200	250MHz	1920×1200 (2D)	70Hz (2D)
		1920×1080 (3D)	75Hz (3D)
Matrox G400MAX	360MHz	2048×1536 (2D/3D)	85Hz

Note

In some cases, the maximum resolutions and refresh rates listed for any video card might require a RAM upgrade or purchase of a video card with more RAM.

The Bus

You've learned in this chapter that certain video adapters were designed for use with certain system buses. For example, the VGA and XGA both were originally designed for use with IBM's MCA bus. The bus that you use in your computer affects the speed at which your system processes video information. For example, the ISA bus offers a 16-bit data path at speeds of 8.33MHz. The EISA or MCA buses can process 32 bits of data at a time, but they also run at speeds up to 10MHz. These three buses are no longer used for video adapters because IBM has discontinued the MCA bus and the others are too slow. The VESA Local-Bus (VL-Bus) was also 32-bit but ran at speeds up to 33MHz. Although it was much faster than the others, it has also been discontinued because it was optimized for the obsolete 486 processor family and because it was also an extension of the obsolescent ISA bus.

◀◀ See "VESA Local-Bus," p. 326.

Note

Don't confuse the system bus speed with the system processor speed, although they are both measured in megahertz (MHz). System processors run at speeds upward of 300MHz, but the system bus is much slower.

In July 1992, Intel Corporation introduced Peripheral Component Interconnect (PCI) as a blueprint for directly connecting microprocessors and support circuitry; it then extended the design to a full expansion bus with Release 2 in 1993; the current standard is Release 2.1. Popularly termed a mezzanine bus, PCI combines the speed of a local bus with microprocessor independence. PCI video adapters, like VL-Bus adapters, can dramatically increase video performance. PCI video adapters, by their design, are meant to be Plug and Play (PnP), which means that they require little configuration. The PCI standard virtually replaced the older VL-Bus standard

overnight and has dominated Pentium-class video until recently. Although the PCI bus remains the best general-purpose standard for expansion cards, the new king of high-speed video is AGP.

◀◀ See "Accelerated Graphics Port (AGP)," p. 338.

◀◀ See "The PCI Bus," p. 327.

The most recent system bus innovation is the Accelerated Graphics Port (AGP), a dedicated video bus designed by Intel that delivers a maximum bandwidth up to eight times larger than that of a comparable PCI bus. AGP is essentially an enhancement to the existing PCI bus, intended for use only with video adapters and providing them with high-speed access to the main system memory array. This enables the adapter to process certain 3D video elements, such as texture maps, directly from system memory rather than having to copy the data to the adapter memory before the processing can begin. This saves time and eliminates the need to upgrade the video adapter memory to better support 3D functions.

Although it was designed with the Pentium II in mind, AGP is not processor dependent. However, it does require support from the motherboard chipset and AGP cards require a special expansion slot, which means that you cannot upgrade an existing system to use AGP without replacing the motherboard.

Table 15.13 lists major chipsets which support AGP.

Table 15.13 AGP Support by Chipset

Manufacturer	Chipset	CPUs supported
Intel	440LX, 440EX, 440ZX-66	Celeron
	440BX, 440ZX	Pentium II, Pentium III, Celeron
	820 ¹	Pentium III, Pentium II
Ali	Aladdin Pro II	Pentium II
	Aladdin V	Socket 7
Via	Apollo VP3	Socket 7
	Apollo MVP3	Socket 7
	Apollo Pro 133A ¹	Pentium II/III/Celeron
	Apollo Pro 133	Pentium II/III/Celeron
	Apollo Pro Plus	Pentium II/III/Celeron
SiS	Apollo KX133 ¹	AMD Athlon
	SiS5591/5595	Socket 7
	SiS600/5595	Pentium II
	SiS600/5595	Pentium II

1. These chipsets support AGP version 2.0, which supports AGP 4x speed. Others listed support AGP version 1.0, which supports AGP 1x and 2x speeds.

◀◀ See "Socket 7 (and Super7)," p. 103.

Even with the proper chipset, however, you cannot take full advantage of AGP's capabilities without the proper operating system support. AGP's Direct Memory Execute (DIME) feature uses main memory instead of the video adapter's memory for certain tasks, to lessen the traffic to and from the adapter. Windows 98 and Windows 2000 both support this feature, but Windows 95 does not.

AGP Speeds

AGP support is available in three speeds: AGP 1X, AGP 2X, and AGP 4X. AGP 1x and 2x are part of the original AGP Specification 1.0; AGP 4X is part of the AGP Specification 2.0. AGP 1X is the original version of AGP, running at 66MHz clock speed and a maximum transfer rate of 266MB/second (twice the speed of 32-bit PCI video cards). It has been replaced by AGP 2X, which runs at 133MHz and offers transfer rates up to 533MB/second. The latest version of AGP supports 4X mode, which offers maximum transfer rates in excess of 1GB/second.

Which should you buy? Microsoft states that Windows 98 and Windows 2000 require that a system support AGP 2X or faster to be considered compatible with these operating systems. Because AGP 1X cards are now difficult to find except at the very bottom of the pricing barrel, this isn't a difficult choice to make.

Some vendors have sold AGP 2X cards using chipsets that are really optimized for 2D operation. For best results, buy only AGP cards equipped with true 3D chipsets (see chart below). Should you buy an AGP 4X card? Yes, if you want the very fastest rendering rate for 3D games. These cards achieve their blazing transfer speeds through the use of two data channels that can operate simultaneously. AGP 4X cards are more expensive than their 2X siblings, but they are definitely faster. AGP 4X cards require that the motherboard be AGP version 2.0 compliant, and will run at 2X on AGP 1.0-compliant motherboards.

Should you check motherboard-video card compatibility before you buy? Yes, because early AGP cards (especially those based on Intel's 740 chipset) were designed strictly for the original AGP Pentium II-based motherboards. Many AGP users have Super Socket 7 motherboards instead, and some early AGP cards don't work with these motherboards. Check with both the video card and motherboard vendors before you make your purchase.

◀◀ See "Socket 7 (and Super7)," p. 103.

The high end of the video card market has now shifted almost completely to AGP 2x or 4x; PCI video cards are being relegated to replacements for older systems. Ironically, because of the high popularity of AGP today, you might pay more for a slower PCI video card than for an AGP card with similar features.

Note

Many low-cost systems implement AGP video on the motherboard without providing an AGP expansion slot for future upgrades. This will prevent you from changing to a faster or a higher memory AGP video card in the future, although you might be able to use slower PCI video cards. For maximum flexibility, get your AGP video on a card.

VL-Bus, PCI, and AGP have some important differences, as Table 15.14 shows.

Table 15.14 Local Bus Specifications

Feature	VL-Bus	PCI	AGP
Theoretical maximum	132MB/sec	132MB/sec ¹	533MB/sec throughput (2X) 1.06GB/sec throughput (4X)
Slots ²	3 (typical)	4/5 (typical)	1
Plug and Play support	No	Yes	Yes
Cost	Inexpensive	Slightly higher	Similar to PCI
Ideal use	Low-cost 486	High-end 486, Pentium, P6	Pentium II/III/Celeron, K6, Athlon
Status	Obsolete	Current	Current

1. At the 66MHz bus speed and 32 bits. Throughput will be higher on the 100MHz system bus.
2. More slots are possible through the use of PCI bridge chips.

The Video Driver

The software driver is an essential, and often a problematic, element of a video display subsystem. The driver enables your software to communicate with the video adapter. You can have a video adapter with the fastest processor and the most efficient memory on the market, but still have poor video performance because of a badly written driver.

DOS applications address the video display hardware directly and typically include their own drivers for various types of video adapters; most recent DOS-based games can use VESA BIOS extension modes to achieve higher resolutions and color depths. All versions of Windows, however, use a driver that is installed in the operating system. Applications then can use operating system function calls to access the video hardware.

Video drivers are generally designed to support the processor on the video adapter. All video adapters come equipped with drivers supplied by the manufacturer, but often you can use a driver created by the chipset manufacturer as well. Sometimes you might find that one of the two provides better performance than the other or resolves a particular problem you are experiencing.

Most manufacturers of video adapters and chipsets maintain Web sites from which you can obtain the latest drivers. A driver from the chipset manufacturer can be a useful alternative, but you should always try the adapter manufacturer's driver first. Before purchasing a video adapter, it is a good idea to check out the manufacturer's site and see whether you can determine how many driver releases there have been for the adapter you're considering. Frequent driver revisions can be a sign that many users are experiencing problems. Although it might be a good thing to see that the company is responding to complaints, it might also indicate that the hardware is not dependable.

The video driver also provides the interface that you can use to configure the display produced by your adapter. On a Windows 9x system, the Settings page of the Display Control Panel identifies the monitor and video adapter installed on your system and enables you to select the color depth and screen resolution that you prefer. The driver controls the options that are available for these settings, so you can't choose parameters that aren't supported by the hardware. For

example, the controls would not allow you to select a 1,024×768 resolution with 24-bit color if the adapter had only 1MB of memory.

When you click the Advanced button on the Settings page, you see the Properties dialog box for your particular video display adapter. The contents of this dialog box can vary, depending on the driver and the capabilities of the hardware. Typically, on the General page of this dialog box, you can select the size of the fonts (large or small) to use with the resolution you've chosen. Windows 98 also adds a control to activate a very convenient feature. The Show Settings Icon on Task Bar check box activates a tray icon that enables you to quickly and easily change resolutions and color depths without having to open the control panel.

The Adapter page displays detailed information about your adapter and the drivers installed on the system, and it enables you to set the Refresh Rate for your display. If your adapter includes a graphics accelerator, the Performance page contains a Hardware Acceleration slider that you can use to control the degree of graphic display assistance provided by your adapter hardware.

Setting the Hardware Acceleration slider to the Full position activates all the adapter's hardware acceleration features.

Moving the slider one notch to the left addresses mouse display problems by disabling the hardware's cursor support in the display driver. This is the equivalent of adding the SWCursor=1 directive to the [Display] section of the System.ini file.

Moving the slider another notch (to the second notch from the right) prevents the adapter from performing certain bit block transfers. With some drivers, this setting also disables memory-mapped I/O. This is the equivalent of adding the Mmio=0 directive to the [Display] section of System.ini and the SafeMode=1 directive to the [Windows] section of Win.ini (and the SWCursor directive mentioned previously).

Moving the slider to the None setting (the far left) adds the SafeMode=2 directive to the [Windows] section of the Win.ini file. This disables all hardware acceleration support and forces the operating system to use only the device-independent bitmap (DIB) engine to display images, rather than bit-block transfers. Use this setting when you experience frequent screen lockups or when you receive invalid page fault error messages.

Note

If you need to disable any of the video hardware features listed earlier, this often indicates a buggy video or mouse driver. Download and install updated video and mouse drivers, and you should be able to revert to full acceleration.

Video cards with advanced 3D acceleration features will often have additional properties; these will be discussed later in this chapter.

Video Cards for Multimedia

Multimedia, including live full-motion video feeds, video conferencing, and animations has become an important element of the personal computing industry and is helping to blur the

once-solid lines between computer and broadcast media. As the demand for multimedia content increases, so do the capabilities of the hardware and software used to produce the content. Video is just one, albeit important, element of the multimedia experience, and the graphics adapters on the market today reflect the demand for these increased capabilities. Producing state-of-the-art multimedia content today often requires that the PC be capable of interfacing with other devices, such as cameras, VCRs, and television sets, and many video adapters are now equipped with this capability.

Other multimedia technologies, such as 3D animation, place an enormous burden on a system's processing and data-handling capabilities, and many manufacturers of video adapters are redesigning their products to shoulder this burden more efficiently.

The following sections examine some of the video adapter components that make these technologies possible and practical—including VFC, VAFC, VMC, and VESA VIP.

Because none of these specifications for internal video feature connectors have become true industry standards, some manufacturers of auxiliary video products, such as dedicated 3D accelerator boards and MPEG decoders, have taken an alternative route through the standard VGA connector.

Video Feature Connectors (VFC)

To extend the capabilities of the VGA standard beyond direct connections to a monitor, several auxiliary connector standards have been devised, first by individual card makers and later by the Video Electronic Standards Association, an industry trade group of monitor and video card makers.

Two early attempts to create a common connector were the Video Feature Connector (VFC) devised by IBM in 1987, and the VESA Advanced Feature Connector (VAFC) and VESA Media Channel (VMC). These connector designs were not widely used.

Note

If you are interested in reading more about VFC, VAFC, and VMC, see Chapter 8 of *Upgrading and Repairing PCs, Tenth Anniversary Edition*, included on the CD with this book.

VESA Video Interface Port (VESA VIP)

The latest attempt at a standard interface between video cards and other video devices today is the VESA Video Interface Port (VESA VIP).

The VESA VIP provides a dedicated connection designed to allow video cards to connect with one or more third-party hardware devices, such as MPEG-2 or HDTV decoders, video digitizers, video encoders, and so on. A dedicated connection prevents competition with other data movement on the PCI bus.

VIP is far more widely supported than previous standards, but it exists in two versions and is implemented in various ways by card vendors. To avoid VESA VIP compatibility problems, check the compatibility list for both the video card and the device you want to connect.

Video Output Devices

When video technology was first introduced, it was based on television. However, a difference exists between the signals used by a television and the signals used by a computer. In the United States, the National Television System Committee (NTSC) established color TV standards in 1953. Some other countries, such as Japan, followed this standard. Many countries in Europe developed more sophisticated standards, including Phase Alternate Line (PAL) and Sequential Couleur Avec Mémoire (SECAM). Table 15.15 shows the differences among these standards.

Table 15.15 Television Versus Computer Monitors

Standard	Yr. Est.	Country	Lines	Rate
Television				
NTSC	1953 (color) 1941 (b&w)	U.S., Japan	525	60fields/sec
PAL	1941	Europe ¹	625	50fields/sec
SECAM	1962	France	625	25fields/sec
Computer				
VGA	1987	U.S.	640×480 ²	72Hz

Field = 1/2 (.5 frame)

1. England, Holland, West Germany.

2. VGA is based on more lines and uses pixels (480) versus lines; genlocking is used to lock pixels into lines and synchronize computers with TV standards.

A video-output (or VGA-to-NTSC) adapter enables you to display computer screens on a TV set or record them onto videotape for easy distribution. These products fall into two categories: those with genlocking (which enables the board to synchronize signals from multiple video sources or video with PC graphics) and those without. Genlocking provides the signal stability you need to obtain adequate results when recording to tape, but it is not necessary for using a television as a video display.

VGA-to-NTSC converters are available both as internal expansion boards or external boxes that are portable enough to use with a laptop for presentations on the road. Indeed, many laptop and notebook systems these days come equipped with a built-in VGA-to-NTSC converter.

The converter does not replace your existing video adapter but instead connects to the adapter using an external cable. In addition to VGA input and output ports, a video output board has a video output interface for S-Video and composite video.

Most VGA-to-TV converters support the standard NTSC television format and might also support the European PAL format. The resolution that these devices display on a TV set or record on videotape is often limited to straight VGA at 640×480 pixels. The converter might also contain an antiflicker circuit to help stabilize the picture because VGA-to-TV products, as well as TV-to-VGA solutions, often suffer from a case of the jitters.

Still-Image Video Capture Cards

You can install a board into your PC that enables you to capture individual screen images for later editing and playback. There are also external devices that plug into a PC's parallel port. These units capture still images from NTSC video sources such as camcorders or VCRs. Although image quality is limited by the input signal, the results are still good enough for presentations and desktop publishing applications. These devices work with 8-, 16-, and 24-bit VGA cards and usually accept video input from VHS, Super VHS, and Hi-8 devices. As you might expect, however, Super VHS and Hi-8 video sources give better results, as do configurations using more than 256 colors.

Multiple Monitors

Windows 98 and Windows 2000 include a video display feature that Macintosh systems have had for years: the capability to use multiple monitors on one system. Windows 98 supports up to nine monitors (and video adapters), each of which can provide a different view of the desktop. Windows 2000 supports up to ten monitors and video adapters. When you configure a Windows 98 or Windows 2000 system to do this, the operating system creates a virtual desktop; that is, a display that exists in video memory that can be larger than the image actually displayed on a single monitor. You use the multiple monitors to display various portions of the virtual desktop, enabling you to place the windows for different applications on separate monitors and move them around at will.

Of course, each monitor that you connect to the system requires its own video adapter, so unless you have nine bus slots free, the prospects of seeing a nine-screen Windows display are slim, for now. However, even two monitors can be a boon to computing productivity.

On a multimonitor Windows 98 system, one display is always considered to be the primary display. The primary display can use any PCI or AGP VGA video adapter that uses a Windows 98 minidriver with a linear frame buffer and a packed (non-planar) format, meaning that most of the brand name adapters sold today are eligible. Additional monitors are called secondaries and are much more limited in their hardware support.

Video cards with the Permedia chipset (not the later Permedia NT and Permedia 2) cannot be used in a multiple-monitor configuration.

The following list of video card chipsets with the specified Microsoft Windows 98 drivers can be used in any combination of primary or secondary adapters. Unlisted chipsets might also work as primary adapters. This list is condensed from Microsoft's Knowledge Base article # Q182/7/08. Check it for updates to this list.

- *ATI*. Mach 64 GX and beyond, including 3D cards, Rage Pro series, Xpert series, and others using the ATIM64.driv or ATIR3.driv
- S3. 765 (Trio64V+)S3MM.driv

Note

Only certain updates work. These are 40, 42, 43, 44, 52, 53, and 54. Note that if the card is at one of these updates, Windows 98 recognizes the card as a Trio 64V+, provided the Microsoft driver is used. If the card is not

(continues)

(continued)

at one of these updates, it is recognized as a Trio 32/64. Some OEM drivers don't care which update is present; be sure to note carefully which Microsoft driver Windows 98 selects when you use this card.

Other S3 chipsets include the Trio64V2, various Diamond, STB, Hercules, Number Nine, and other cards using the Virge or newer chipsets.

- *Cirrus*. 5436, Alpine, 5446, and other cards using the CIRRUSMM.drv
- *Tseng*. Cards with the ET6000 chipset
- *Trident*. 9685/9680/9682/9385/9382/9385 chipsets

It's important that the computer correctly identifies which one of the video adapters is the primary one. This is a function of the system BIOS, and if the BIOS on your computer does not let you select which device should be the primary VGA display, it decides based on the order of the PCI slots in the machine. You should, therefore, install the primary adapter in the highest-priority PCI slot.

◀◀ See "The PCI Bus," p. 327.

After the hardware is in place, you can configure the display for each monitor from the Display control panel's Settings page. The primary display is always fixed in the upper-left corner of the virtual desktop, but you can move the secondary displays to view any area of the desktop you like. You can also set the screen resolution and color depth for each display individually.

Windows 2000 also provides multiple monitor support, but with some differences from Windows 98, as seen in Table 15.16.

Table 15.16 Comparing Windows 98 and Windows 2000 Multiple Monitor Support

Windows Version	Number of Adapters/ Monitors Supported	How Compatible Cards Listed	Finding Compatible Cards
98	10	By chipset	On Microsoft Web site
2000	9	Brand and model	HCL listing on CD-ROM

As of the initial release of Windows 2000, some of the major brands with products on the multiple-monitor approved list included the following:

- 3DFX
- 3Dlabs
- Creative Labs
- Diamond Multimedia
- ELSA
- Matrox
- Number Nine
- nVidia
- SiS 300 compatible
- STB

Windows 2000's Hardware Compatibility List is by graphics card brand and model, rather than by chipset (check the Windows 2000 CD-ROM Hardware Compatibility List for details). This list is likely to change as Windows 2000 support becomes more widespread, but unfortunately the online version of the Windows 2000 HCL doesn't provide an updated list of cards that support multiple-monitor configurations. You should check with your video card or chipset maker for the latest information on Windows 2000 and multiple-monitor support issues.

Desktop Video (DTV) Boards

You can also capture NTSC (television) signals to your computer system for display or editing. In other words, you can literally watch TV in a window on your computer. When capturing video, you should think in terms of digital versus analog. The biggest convenience of an analog TV signal is efficiency; it is a compact way to transmit video information through a low-bandwidth pipeline. The disadvantage is that although you can control how the video is displayed, you can't edit it.

Actually capturing and recording video from external sources and saving the files onto your PC requires special technology. To do this, you need a device called a video capture board, also called a TV tuner, a video digitizer, or a video grabber.

Note

In this context, the technical nomenclature again becomes confusing because the term *video* here has its usual connotation; that is, it refers to the display of full-motion photography on the PC monitor. When evaluating video hardware, be sure to distinguish between devices that capture still images from a video source and those that capture full-motion video streams.

One of the uses for analog video is with interactive Computer-Based Training (CBT) programs in which your application sends start, stop, and search commands to a laserdisc player that plays discs you have mastered. The software controls the player via an interface that also converts the laserdisc's NTSC signal into a VGA-compatible signal for display on your computer's monitor. These types of applications require NTSC-to-VGA conversion hardware.

Whereas a computer can display up to 16 million colors, the NTSC standard allows for approximately only 32,000 colors. Affordable, high-quality video is the Achilles' heel of multimedia. The images are often jerky or less than full-screen. The reason is that full-motion video, such as that which you see on TV, requires 30 images or frames per second (fps), which can be an enormous amount of data.

The typical computer screen was designed to display mainly static images. The storing and retrieving of these images requires managing huge files. Consider this: A single, full-screen color image in an uncompressed format can require as much as 2MB of disk space; a one-second video would therefore require 45MB. Likewise, any video transmission that you want to capture for use on your PC must be converted from an analog NTSC signal to a digital signal that your computer can use. On top of that, the video signal must be moved inside your computer at 10 times the speed of the conventional ISA bus structure. You need not only a superior video card and monitor but also an excellent expansion bus, such as PCI or AGP.

Considering that full-motion video can consume massive quantities of disk space, it becomes apparent that data compression is all but essential. Compression and decompression (or codec) applies to both video and audio. Not only does a compressed file take up less space, it also performs better; there is simply less data to process. When you are ready to replay the video/audio, the application decompresses the file during playback. In any case, if you are going to work with video, be sure that your hard drive is large enough and fast enough to handle the huge files that can result. There are two types of codecs: hardware-dependent codecs and software (or hardware-independent) codecs. Hardware codecs typically perform better; however, they require additional hardware; either an add-on card or a high-end video card with hardware codecs built-in. Software codes do not require hardware for compression or playback, but they typically do not deliver the same quality or compression ratio. Two of the major codec algorithms are

- *JPEG (Joint Photographic Experts Group)*. Originally developed for still images, JPEG can compress and decompress at rates acceptable for nearly full-motion video (30fps). JPEG still uses a series of still images, which makes editing easier. JPEG is typically lossy (meaning that a small amount of the data is lost during the compression process, slightly diminishing the quality of the image), but it can also be lossless. JPEG compression functions by eliminating redundant data for each individual image (intraframe). Compression efficiency is approximately 30:1 (20:1–40:1).
- *MPEG (Motion Pictures Experts Group)*. MPEG by itself compresses video at approximately a 30:1 ratio, but with precompression through oversampling, the ratio can climb to 100:1 and higher, while retaining high quality. Thus, MPEG compression results in better, faster videos that require less storage space. MPEG is an interframe compressor. Because MPEG stores only incremental changes, it is not used during editing phases. MPEG decoding can be performed in software on high-performance Pentium systems.

If you will be capturing or compressing video on your computer, you'll need software based on standards such as Microsoft's DirectShow (the successor to Video for Windows and ActiveMovie), Real Network's Real Producer series, or Apple's QuickTime Pro. Players for files produced with these technologies can be downloaded free from the vendors' Web sites.

To play or record video on your multimedia PC (MPC), you need some extra hardware and software:

- Video system software, such as Apple's QuickTime for Windows or Microsoft's Video for Windows.
- A compression/digitization video adapter that enables you to digitize and play large video files.
- An NTSC-to-VGA adapter that combines TV signals with computer video signals for output to a VCR. Video can come from a variety of sources: TV, VCR, video camera, or laserdisc player. When you record an animation file, you can save it in a variety of different file formats: AVI (Audio Video Interleave), MOV (Apple QuickTime format), or MPG (MPEG format).

When you connect video devices, use the S-Video (S-VHS) connector whenever available. This cable provides the best signal because separate signals are used for color (chroma) and brightness (luma). Otherwise, you will have to use composite video, which mixes luma and chroma. This results in a lower-quality signal. The better your signal, the better your video quality will be.

You can also purchase devices that display only NTSC signals on your computer. The way that multimedia technology is advancing, soon you will not be able to tell whether you are using a computer screen or a television. Digital video, in-screen filling, and full-motion color have arrived on desktop platforms with titles, playback boards, and encoding equipment. Soon, MPEG movie clip libraries will be the next form of clip art on CD-ROM. Hardware advances, such as the MMX instructions incorporated into the Pentium architecture, are helping to make motion video more of a useful reality rather than just a novelty.

Table 15.17 provides a breakdown of some common video cards supporting key features. This table is not inclusive and is meant to serve only as a reference example.

Table 15.17 Video Card Support for Key Multimedia Features

Device Type	Example
Built-in TV tuner	ATI All-in-Wonder 128
TV-tuner attachments	ATI-TV
Parallel-port attachments	Ricoh ZIPSHOT
USB port	Nogatech USB Live!
Dedicated PCI or ISA card	Video E-Mailer
IEEE-1394 (FireWire) from digital video	Radius MotoDV Studio 2.0

Each type of device has advantages and potential drawbacks. Table 15.18 provides a summary that will help you decide which solution might be best for you.

Table 15.18 Multimedia Device Comparison

Device Type	Pros	Cons
Graphics card with built-in TV tuner and capture	Convenience, single-slot solution	Upgrading requires card replacement
TV-tuner attachment	Allows upgrade to existing graphics cards; might be movable to newer models	Can't be used with all graphics cards
Parallel-port attachment	Universal usage on desktop or notebook computer; inexpensive	Frame rate limited by speed of port
USB-port attachment	Easy installation on late-model USB-equipped computers with Windows 98	Might not work on Windows 95B OSR 2.x with USB; requires active USB port
Dedicated ISA or PCI interface card	Fast frame rate for realistic video; doesn't require disconnecting parallel printer; works with any graphics card	High resource requirements (IRQ, and so on) on some models; ISA nearly obsolete; requires internal installation
IEEE-1394 (FireWire) connection to digital video	No conversion from analog to digital needed; all-digital image is very high quality without compression artifacts (blocky areas) in video; fast throughput	Requires IEEE-1394 interface card and IEEE-1394 digital video source; new and expensive; card requires internal installation

Troubleshooting Video Capture Devices

Table 15.19 provides some advice for troubleshooting problems with video capture devices.

Table 15.19 Troubleshooting Video Capture Devices

Device Type	Problem	Solutions
Parallel-port attachment	Can't detect device, but printers work okay	Check port settings; device might require IEEE-1284 settings (EPP and ECP); change in BIOS; make sure device is connected directly to port; avoid daisy-chaining devices unless device specifically allows it; check Windows 9x Device Manager for IRQ conflicts.
TV tuners (built-in graphics card or add-on)	No picture	Check cabling; set signal source correctly in software.
All devices	Video capture is jerky	Frame rate is too low; increasing it might require capturing video in a smaller window; use fastest parallel-port setting you can.
All devices	Video playback has pauses, dropped frames	Hard disk might be pausing for thermal recalibration; use AV-rated SCSI hard drives or new UDMA EIDE drives; install correct bus-mastering EIDE drivers for motherboard chipset to speed things up.
USB devices	Device can't be detected or doesn't work properly	Use Windows 98; late versions of Windows 95 have USB drivers, but they often don't work; if you use a USB hub, make sure it's powered.
Interface cards (all types)	Card can't be detected or doesn't work	Check for IRQ conflicts in Windows 9x Device Manager; consider setting card manually if possible.
All devices	Capture or installation problems	Use the newest drivers available; check manufacturers' Web site for updates, FAQs, and so on.

3D Graphics Accelerators

The latest trend in PC graphic-display technology is the expanded use of 3D images. Three-dimensional imagery has been used for years in the computer gaming world and has even made its way into business computing. Spreadsheet programs such as Microsoft Excel have for years used 3D charts to display spreadsheet data. Of course, the images are not truly three-dimensional because the monitor screen is a 2D medium, but software can produce 3D effects using perspective, textures, and shading.

Abstract shapes such as Excel's 3D bar graphs are not difficult to produce because they consist solely of polygons and other shapes with solid color fills of various shades. You find the truly innovative side of 3D graphics in the so-called virtual-reality environments created in games and in other applications. As with other types of multimedia, however, the techniques that originate in games and other entertainment software will eventually be assimilated into mainstream use.

A 3D image can contain an immense amount of detail, and an animated 3D sequence like those of many games requires a great many images. Obviously, the more images that are needed, the more disk space is required to store them, and the more processing and image-handling speed is needed to display them. To manage all that detail, 3D applications usually store and work with abstractions of the images rather than with the actual images themselves. In essence, the 3D images are generated—or rendered—as needed, rather than simply read from a storage medium.

To construct an animated 3D sequence, a computer can mathematically animate the sequences between keyframes. A keyframe identifies specific points. A bouncing ball, for example, can have three keyframes: up, down, and up. Using these frames as a reference point, the computer can create all the interim images between the top and the bottom. This creates the effect of a smooth-bouncing ball.

After it has created the basic sequence, the system can then refine the appearance of the images by filling them in with color. The most-primitive and least-effective fill method is called flat shading, in which a shape is simply filled with a solid color. Gouraud shading, a slightly more effective technique, involves the assignment of colors to specific points on a shape. The points are then joined using a smooth gradient between the colors.

The most-processor-intensive, and by far the most-effective type of fill, is called texture mapping. The 3D application includes patterns—or textures—in the form of small bitmaps that it tiles onto the shapes in the image, just as you can tile a small bitmap to form the wallpaper for your Windows desktop. The primary difference is that the 3D application can modify the appearance of each tile by applying perspective and shading to achieve 3D effects.

Until recently, 3D applications had to rely on support from software routines to convert these abstractions into live images. This places a heavy burden on the system processor in the PC, which has a significant impact on the performance not only of the visual display, but also of any other applications that the computer might be running. Now, a new breed of video accelerator chipsets is found on many video adapters that can take on a lot of the tasks involved in rendering 3D images, greatly lessening the load on the system processor and overall system performance.

3D accelerators are now widely available for under \$100, and both video games and 3D animation programs are taking advantage of their ability to render smooth, photo-realistic images at high speeds and in real time.

3D technology has added an entirely new vocabulary to the world of video display adapters. Before purchasing a 3D accelerator adapter, it is a good idea to familiarize yourself with some of the terms and concepts involved in the 3D image generation process.

The basic function of 3D software is to convert image abstractions into the fully realized images that are then displayed on the monitor. The image abstractions typically consist of the following elements:

- *Vertices*. Locations of objects in three dimensional space, described in terms of their X, Y, and Z coordinates on three axes representing height, width, and depth.
- *Primitives*. The simple geometric objects that the application uses to create more complex constructions, described in terms of the relative locations of their vertices. This serves not only to specify the location of the object in the 2D image, but it also provides perspective because the three axes can define any location in three-dimensional space.
- *Textures*. Two-dimensional bitmap images or surfaces that are designed to be mapped onto primitives. The software enhances the 3D effect by modifying the appearance of the textures, depending on the location and attitude of the primitive; this process is called perspective correction. Some applications use another process called MIP mapping, which uses different versions of the same texture that contain varying amounts of detail, depending

on how close the object is to the viewer in the three-dimensional space. Another technique, called depth cueing, reduces the color and intensity of an object's fill as the object moves farther away from the viewer.

Using these elements, the abstract image descriptions must then be rendered, meaning that they are converted to visible form. Rendering depends on two standardized functions that convert the abstractions into the completed image that is displayed onscreen. The standard functions performed in rendering are

- *Geometry.* The sizing, orienting, and moving of primitives in space and the calculation of the effects produced by the virtual light sources that illuminate the image.
- *Rasterization.* The converting of primitives into pixels on the video display by filling the shapes with properly illuminated shading, textures, or a combination of the two.

A modern video adapter that includes a chipset capable of 3D video acceleration will have special built-in hardware that can perform the rasterization process much faster than if it is done by software (using the system processor) alone. Most chipsets with 3D acceleration perform the following rasterization functions right on the adapter:

- *Scan conversion.* The determination of which onscreen pixels fall into the space delineated by each primitive.
- *Shading.* The process of filling pixels with smoothly flowing color using the flat or Gouraud shading technique.
- *Texturing.* The process of filling pixels with images derived from a 2D sample picture or surface image.
- *Visible surface determination.* The identification of which pixels in a scene are obscured by other objects closer to the viewer in three-dimensional space.
- *Animation.* The process of switching rapidly and cleanly to successive frames of motion sequences.

Common 3D Techniques

The following techniques are used by virtually all 3D cards. Because they are so common, data sheets for advanced cards frequently don't mention them, although these features are present.

- *Fogging.* Fogging simulates haze or fog in the background of a game screen and helps conceal the sudden appearance of newly rendered objects (buildings, enemies, and so on).
- *Gouraud Shading.* Interpolates colors to make circles and spheres look more rounded and smooth.
- *Alpha Blending.* One of the first 3D techniques, alpha blending creates translucent objects onscreen, making it a perfect choice for rendering explosions, smoke, water, and glass. Alpha blending can also be used to simulate textures, but it is less realistic than environment-based bump mapping (see "Environment-Based Bump Mapping," later in this chapter).

Advanced 3D Techniques

The following are some of the latest techniques used by leading 3D accelerator cards. Not every card will use every technique.

Stencil Buffering

Stencil buffering is a technique useful for games such as flight simulators, in which a static graphic element—such as a cockpit windshield frame, known as a HUD (Heads Up Display) used by real-life fighter pilots—is placed in front of dynamically changing graphics (such as scenery, other aircraft, sky detail, and so on). In this example, the area of the screen occupied by the cockpit windshield frame is not re-rendered. Only the area seen through the “glass” is re-rendered, saving time and improving frame rates for animation.

Z-Buffering

A closely related technique is Z-buffering, which was originally devised for CAD (Computer Aided Drafting) applications. The Z-buffer portion of video memory holds depth information about the pixels in a scene. As the scene is rendered, the Z-values (depth information) for new pixels are compared to the values stored in the Z-buffer to determine which pixels are in “front” of others and should be rendered. Pixels that are “behind” other pixels are not rendered. This method increases speed and can be used along with stencil buffering to create volumetric shadows and other complex 3D objects.

Environment-Based Bump Mapping

This technique introduces special lighting and texturing effects to simulate the rough texture of rippling water, bricks, and other complex surfaces. It combines three separate texture maps (for colors, for height and depth, and for environment—including lighting, fog, and cloud effects). This creates enhanced realism for scenery in games and could also be used to enhance terrain and planetary mapping, architecture, and landscape-design applications. This represents a significant step beyond alpha blending.

Texture Mapping Filtering Enhancements

To improve the quality of texture maps, several filtering techniques have been developed, including bilinear filtering, trilinear filtering, and anisotropic filtering.

- *Bilinear filtering.* Improves the image quality of small textures placed on large polygons. The stretching of the texture that takes place can create blockiness, but bilinear filtering applies a blur to conceal this visual defect.
- *Trilinear filtering.* Combines bilinear filtering and MIP mapping, calculating the most realistic colors needed for the pixels in each polygon by comparing the values in two MIP maps. This method is superior to either MIP mapping or bilinear filtering alone.

Note

Bilinear and trilinear filtering work well for surfaces viewed straight-on but might not work so well for oblique angles (such as a wall receding into the distance).

- *Anisotropic filtering.* Some video card makers use another method, called anisotropic filtering, for more realistically rendering oblique-angle surfaces containing text. This technique is used when a texture is mapped to a surface that changes in two of three spatial domains, such as text found on a wall down a roadway (for example, advertising banners at a raceway). The extra calculations used take time, and for that reason, this method is used only by a few video card makers on their fastest video card models.

- *T-buffer*. This technology eliminates aliasing (errors in onscreen images due to an undersampled original) in computer graphics, such as the “jaggies” seen in onscreen diagonal lines, motion stuttering, and inaccurate rendition of shadows, reflections, and object blur. The T-buffer replaces the normal frame buffer with a buffer that accumulates multiple renderings before displaying the image. Unlike some other 3D techniques, T-buffer technology doesn’t require rewriting or optimization of 3D software to use this enhancement. The goal of T-buffer technology is to provide a movie-like realism to 3D rendered animations. For more information, see the 3dfx Web site.
- *Integrated Transform and Lighting*. The 3D display process include transforming an object from one frame to the next and handling the lighting changes that result from those changes. Many 3D cards put the CPU in charge of these functions, but some graphics accelerators such as the nVidia GeForce 256 integrate separate transform and lighting engines into the accelerator chip for faster 3D rendering, regardless of CPU speed. For more information, see the nVidia Web site.
- *Virtual Texture*. This technology uses a logical address space for texture memory that is mapped to physical memory addresses on the graphics accelerator chip, on the graphics card, and in main system memory. The small 4KB logical pages allows texture data used with recent 3D games to be fetched on an as-needed basis and rendered immediately as soon as a small amount of texture data is retrieved, preventing slowdowns in graphics rendering caused by the normal practice of retrieving the entire texture before rendering begins. For more information, see the 3DLabs Web site.

Single- Versus Multiple-Pass Rendering

Different video card makers handle application of these advanced rendering techniques differently. The current trend is toward applying the filters and the basic rendering in a single pass rather than multiple passes. Video cards with single-pass rendering and filtering normally provide higher frame-rate performance in 3D-animated applications and avoid the problems of visible artifacts caused by errors in multiple floating-point calculations during the rendering process.

Hardware Acceleration Versus Software Acceleration

Compared to software-only rendering, hardware-accelerated rendering provides faster animation than with software alone. Although most software rendering would create more-accurate and better-looking images, software rendering is too slow. Using special drivers, these 3D adapters can take over the intensive calculations needed to render a 3D image that were formerly performed by software running on the system processor. This is particularly useful if you are creating your own 3D images and animation, but it is also a great enhancement to the many modern games that rely extensively on 3D effects.

To achieve greater performance, many of the latest 3D accelerators run their accelerator chips at very high speeds, and some even allow overclocking of the default RAMDAC frequencies. Just as CPUs at high speeds produce a lot of heat, so do high-speed video accelerators, and, just as CPUs now use auxiliary fans for cooling, so do many of the fastest accelerator cards today, such as the new Guillemot 3D Prophet DDR-DVI, as seen in Figure 15.7.

Figure 15.7 The Guillemot 3D Prophet DDR-DVI features a cooling fan to keep its high-speed nVidia GeForce 256 accelerator chip cool and also supports LCD panels and digital CRTs with its DVI output.

Software Optimization

It's important to realize that the presence of an advanced 3D-rendering feature on any given video card is meaningless unless game and application software designers optimize their software to take advantage of the feature. Although different 3D standards exist (OpenGL, Glide, and Direct 3D), video card makers provide drivers that make their games play with the leading standards. Because some cards do play better with certain games, you'll want to see the reviews in publications such as *Maximum PC* to see how your favorite graphics card performs with the latest games.

Some video cards allow you to perform additional optimization by adjusting settings for OpenGL, Direct 3D, RAMDAC and bus clock speeds, and other options.

Note

If you want to enjoy the features of your newest 3D card right away, make sure you purchase the individual retail-packaged version of the card from a hardware vendor. The lower cost OEM or "white box" versions of video cards are sold without bundled software, come only with driver software, and might differ in other ways from the retail advertised product. Some even use modified drivers or lack special TV-out or other features. Some 3D card makers use different names for their OEM versions to minimize confusion, but others don't. Also, some card makers sell their cards in bulk packs, which are intended for upgrading a large organization with its own support staff. These cards might lack individual documentation or driver CDs.

APIs (Application Programming Interfaces)

Application Programming Interfaces (APIs) provide hardware and software vendors a means to create drivers and programs that can work fast and reliably across a wide variety of platforms. When APIs exist, drivers can be written to interface with the API rather than directly with the operating system and its underlying hardware.

Leading game APIs include SGI's OpenGL, 3Dfx's Glide, and Microsoft's Direct 3D. Glide, an enhanced version of OpenGL, is restricted to graphics cards that use 3Dfx chipsets, whereas OpenGL and Direct 3D (part of DirectX) are available for virtually all leading graphics cards. Thus, virtually all recent video cards provide support for OpenGL and Direct 3D.

Although OpenGL support is provided by the video card maker, Direct3D support is provided by Microsoft as part of a much larger API called DirectX.

Microsoft DirectX

Microsoft DirectX was developed for Windows 95, Windows 98, and Windows NT 4.0/2000 to provide support for advanced gaming and business graphics, including 3D video, 3D sound, multiplayer support, and other benefits. Although most uses for DirectX thus far have been games, DirectX also supports business applications such as NetMeeting, ActiveMovie, and NetShow, which provide various methods for viewing content and collaborating over the World Wide Web.

Because DirectX features a HAL (Hardware Abstraction layer), software developers can create their software to work on a particular release of DirectX, rather than having to target the increasing numbers of video cards, sound cards, joysticks, and so on, all of which feature different chipsets and would therefore require different direct drivers. DirectX also features a HEL (Hardware Emulation layer), allowing the DirectX software to use software emulation of hardware features as a fallback to support hardware that lacks a specified feature. HEL is obviously slower than HAL, but the thinking is that a software-emulated feature is better than nothing.

DirectX can perform these tasks because DirectX provides drivers for the hardware it supports. Therefore, a simplified way to look at the DirectX relationship between hardware and software is

HARDWARE → DirectX → Software

DirectX's design enables hardware to be controlled and accessed by the DirectX software rather than directly by the Windows 9x/NT/2000 operating system. This means that DirectX can be updated independently of the operating system. The latest version of DirectX is version 7.0a.

DirectX contains a "foundation" layer, which provides direct access to sound, 2D and 3D graphics hardware, input devices, and setup routines. The APIs in the foundation layer with Microsoft DirectX 7.0a are shown in Table 15.20.

Table 15.20 DirectX 7.0a APIs

API Name	Function
DirectDraw	2D graphics
Direct3D	3D graphics
DirectInput	"Force feed" joysticks, steering wheels, and other input devices
DirectSound	3D and basic sound and mixer effects
DirectMusic	Provides for dynamic, interactive music
DirectPlay	Game play over networks including LANs, modems, and the Internet
DirectShow	Streaming media support for MPEG, MP3, WAV, and AVI files

Older versions of DirectX will not have all these APIs.

Various releases of DirectX are available from Microsoft as a download, as part of Internet Explorer 4, Internet Explorer 5, Windows 95 OSR 2.x, Windows 2000, Windows 98, and from hardware and software vendors whose products use DirectX.

Most products that require DirectX services check your system to see whether you have the appropriate version of DirectX installed and prompt you to install it from the installation CD or setup program if you don't. It's important to realize the following facts:

DirectX is backward compatible; DirectX 7.0a supports earlier releases of DirectX.

Older DirectX releases will not have all the APIs or the correct APIs found in the latest release. Thus, you cannot use an older version of DirectX if an application or hardware device requires DirectX 7.0, for example.

The latest release of DirectX for Windows NT 4.0 is version 3.0. Version 7.0a or later (with full 3D support and other features) is supplied with Windows 2000, and can also be downloaded from Microsoft's Web site.

If you have questions about DirectX support for your hardware, contact your video card, input device, or sound card vendor.

To determine the DirectX version on your computer, check the version number of the DDRAW.DLL file, which is one of the few files that has been part of DirectX since its first release (1.0).

Choose Start, Find, Files or Folders. Type DDRAW.DLL and click Find. After the search is complete, right-click the DDRAW.DLL file and select Properties. Click the Version tab, and scroll down to Product Version (left column). The right column (value) shows the following number, depending on the version. Table 15.21 shows the DirectX version numbers.

Check the version number of the DDRAW.DLL file, which is one of the few files that has been part of DirectX since its first release (1.0).

To check the version number of the DDRAW.DLL file, use Start, Find Files or Folders; enter DDRAW.DLL, right-click the DDRAW.DLL file, and select Properties. Click the Version tab and scroll down to Product Version (left column). The right column (value) will show the following number, depending on the version.

Table 15.21 DirectX Version Numbers

DirectX Version	DDRAW.DLL Version Number
1.0	4.02.0095
2.0	4.03.00.1096 (also 2.0a)
3.0	4.04.00.0068 ¹ (also 3.0a)
(no version 4.0)	
5.0	4.05.00.0155
6.0	4.06.00.0318
6.1	4.06.02.0436
7.0/7.0a	5.0.2180.1

1. Check the version number of the *D3DRGBXF.DLL* file to determine version 3.0 or 3.0a:

D3DRGBXF.DLL has a version number of 4.04.00.0068 in DirectX 3.0

D3DRGBXF.DLL has a version number of 4.04.00.0070 in DirectX 3.0a

Note

It's normal for some DirectX components to have a different version number than those listed earlier for *DDRAW.DLL*. This is because Microsoft retained identical files for some DirectX software components from one version to another.

Troubleshooting DirectX

If you have installed DirectX 6.1 or later, a diagnostic program called *dxdiag.exe* is installed into the `\Windows\System` folder. DirectX 6.0 has a similar program installed into the `C:\Program Files\Directx\Setup`. Use this program to check your DirectX setup, including correct files and proper operation.

The most typical cause of problems with DirectX is loading an older version over a newer version. Use the troubleshooting routines supplied with DirectX 6.1 or later to determine whether you have this type of problem, or install the latest version of DirectX available for your operating system. Note that the versions of DirectX supplied on the Windows 95 OSR 2.x and Windows 98 CD-ROMs are *not* the latest versions. Get the latest version from Microsoft's Web site.

Because DirectX problems can occasionally result in the need to reinstall your operating system, be careful about installing DirectX during a software upgrade or loading process. Some installers don't properly check to see whether you have the latest version and want to give you the "correct" version, even if it's out-of-date. If you suspect the software installer is about to slip you an out-of-date version of DirectX, skip that part of the install if you can.

3D Chipsets

As with standard 2D video adapters, there are several manufacturers of popular 3D video chipsets and many more manufacturers of video adapters that use them. Table 15.22 lists the major 3D chipset manufacturers, the various chipsets they make, and the video adapters that use them.

Note

Chipsets marked (3D only) in this table are used on boards that must be connected to and used with an existing 2D or 2D/3D graphics board in your computer. Chipsets marked (2D/3D) are used on boards that provide both features and thus can be used to replace existing boards in your computer.

In each manufacturer's section, the following symbols will be used to provide a ranking within that manufacturer's chipsets only: NEW—RECENT—OLD. Generally, NEW chipsets provide the fastest 3D performance and advanced 3D rendering features. RECENT chipsets, although lacking some of the speed or features of NEW chipsets, are also worthwhile, especially for those on a budget. OLD are generally superseded by RECENT and NEW chipsets and therefore not recommended. Be sure to use this information in conjunction with application-specific and game-specific tests to help you choose the best card/chipset solution for your needs.

Table 15.22 3D Video Chipset Manufacturers

Manufacturer	Chipset	Available Boards
3Dfx Interactive	Voodoo Graphics (3D only OLD)	A-Trend Helios 3D; Canopus Pure 3D; Deltron Flash 3D ; Diamond Monster 3D; Guillemot MAXIGamer 3Dfx; Orchid Righteous 3D; Quantum 3D Obsidian series; Skywell Magic 3D
3Dfx Interactive	Voodoo Rush (2D/3D OLD)	California Graphics Emotion 3D; Deltron Flash AT3D Rush; Hercules Stingray 128/3D; Intergraph Intense 3D; Jazz Adrenaline Rush; Viewtop Rush 3D
3Dfx Interactive	Voodoo Banshee (2D/3D OLD)	Gigabyte GA-630; A-Trend Helios 3d-Banshee Edition; Creative Labs 3D Blaster Banshee; Diamond Monster Fusion; ELSA Victory II; Guillemot Maxi Gamer Phoenix; Melco Buffalo WGP-FX; Metabyte Wicked 3D Vengeance; Pace 3D Edge; Quantum 3D Raven; Sky Well Magic Twinpower (Banshee); ASUS AGP-V3200

1. Although the Voodoo2 chipset is a 3D-only product with cards that must be connected to a 2D video card to operate, it remains a popular choice because of SLI (Scan Line Interleaving). By connecting two identical Voodoo2-chipset PCI cards from the same vendor with a special SLI ribbon cable, each card can be used to render alternate lines (card 1 renders lines 1, 3, 5, and so on and card 2 renders lines 2, 4, 6, and so on). This almost doubles fill rates and makes the combination of two Voodoo2 cards a worthy rival for newer 3D chipsets.
2. 3Dfx acquired video board maker STB in 1999 and began to sell video cards under the 3Dfx name. 3Dfx still supplies Voodoo2 and Voodoo Banshee chipsets to other video card makers.
3. Rendition is now owned by PC and memory-maker Micron Technologies, which has renamed the previous Rendition Vérité 2100/2200 chipsets the v2000 (a.k.a. v2x00). These chipsets are similar, except for the lack of video-capture features and slower speed in the 2100. A more advanced 2D/3D chipset, known as the V4400, is under development. The previously announced Redline chipset was never released, but the V4400 will be an improved version of this technology.
4. The SiS 6326 has relatively weak 3D performance but is a popular choice for built-in video on motherboards using an SiS chipset.

Upgrading or Replacing Your Video Card

With current developments in rock-bottom video card pricing, improvements in 3D display technology, and massive amounts of high-speed memory available on new video cards (up to 32MB or more!), it makes little sense today to add most upgrades to an existing video card. The component-level upgrades that can be added include

- 3D-only cards, such as the cards based on the original 3Dfx Voodoo and Voodoo2 chipsets, which connect to your existing video card with a pass-through cable.
- Memory upgrades to permit higher color depths at a specified screen resolution.
- TV tuners, permitting you to watch cable or broadcast TV on your monitor.
- Video capture devices, allowing you to capture still or moving video to a file.

3D-only cards are still available, but their major benefit (adding 3D support to 2D-only cards) has been superseded by improvements in standard video cards. All but the cheapest current-model video cards offer varying levels of 3D support, and most offer better, faster 3D, including advanced rendering features that were not available when 3D-only cards were developed.

3D-only cards must be connected to the system's existing VGA-class graphics card to work. If you already have an add-on 3D card based on the 3Dfx Voodoo2 chipset and you can purchase an

identical card (same brand and model), you can take advantage of SLI (Scan Line Interleaving) for greatly improved fill rates. SLI draws the first line of the current image with one card, and then uses the other card to draw line 2, and continues to alternate. However, many companies that once used the Voodoo2 chipset no longer make cards based on it, because 3Dfx has become a retail video card producer, so you might have problems finding a second identical card (not just another Voodoo2 chipset card).

Note

If you want to learn more about 3D add-on cards and SLI, see Chapter 15 of *Upgrading and Repairing PCs, Eleventh Edition*, available in electronic form on the CD-ROM included with this book.

As an alternative, consider multiple-accelerator chip video cards such as ATI's Rage Fury Maxx and 3Dfx's Voodoo 5 series (see Figure 15.8); these cards operate as both VGA and high-performance gaming cards and use only a single slot. ATI's Rage Fury Maxx uses a technique called Alternate Frame Rendering (AFR), which renders the first frame on one chip, the next frame on the other chip, and so forth. The Voodoo 5 series cards use a somewhat similar parallel technique.

Figure 15.8 ATI's Rage Fury Maxx gaming-optimized video card has two accelerator chips onboard, each with its own cooling fan.

Video Card Memory

Historically, most video cards have had provisions for some sort of memory upgrade, either with individual DIP (Dual Inline Pin) chips or with proprietary modules. Usually, video cards came in two versions: a low-priced variant with built-in memory and a connection for a memory upgrade, and a top-end variant with its memory fully expanded out of the box.

Starting about 1997, video card vendors began to abandon the idea of user-upgradable video card memory, probably for the following reasons:

- Most user-upgradable video cards were never upgraded, but were replaced.
- Recent memory trends have made it difficult to design memory upgrades that would work on more than one or two models.
- Increased use of surface-mount technology, high-capacity memory modules, and similar low-cost, high-reliability production techniques mean that a video card with user-upgradable memory is more expensive to make than a card loaded with 8MB or more of video memory.
- With the massive amounts of video memory available today on video cards (major-brand 32MB AGP-bus video cards retail for under \$200), along with the improvements in 2D and 3D technology, it just makes sense to replace your aging 1MB, 2MB, or 4MB video card with an up-to-date card. When you compare the price of adding 2MB or 4MB of proprietary memory (assuming you can still get it) to your existing video card to the price of a new card with 16–32MB or more of memory and better features, you'll find the new cards a much better value.

TV Tuner and Video Capture Upgrades

Most video cards don't have TV tuner and video capture upgrade features built in, and new cards with these features tend to be in the middle to high range of their manufacturers' price structures.

These features are exciting if you are already into video editing, want to add video to your Web site, or are trying to create CD-R/CD-RW archives of your home video. If you have an up-to-date video card with acceptable 2D and 3D performance and at least 8MB of video RAM, compare the price of the add-ons to the price of a new card with these features. You'll probably find the add-ons to be less expensive. If your card has 4MB of video RAM or less, I'd recommend replacing it with a new card with these features. Look at sample video captures before making your decision, as all video capture solutions require image compression with at least some loss of quality. If you have a digital camcorder with IEEE-1394 (a.k.a. FireWire and i.Link) ports, you should purchase an IEEE-1394 interface board instead to use high-quality pure digital video that needs no conversion.

Note

If you're planning to upgrade to a new video card in the next year or two, find out whether the TV or video add-on you want to buy for your present video card will work with the new model. If it's a TV tuner, you might need to consider other cards from the same vendor your current video card came from. If you're unsure of future compatibility, hold off on your purchase or consider buying a card with the desired features included.

Warranty and Support

Because a video card can go through several driver changes during its effective lifetime (about three years or two operating-system revisions), buying a video card from a major manufacturer usually assures you of better support during the card's lifetime. If you buy a card that uses widely

available chipsets (such as S3s), you might be able to try a different vendor's version of drivers or use the chipset vendor's "generic" drivers if you don't get satisfactory support from your card vendor.

Keep in mind that using generic drivers (chipset level) or a different brand of drivers can cause problems if your original card's design was tweaked from the normal. Look at the vendor's technical support forums or third-party discussions on newsgroups, computer information Web sites such as ZDNet, or magazine Web sites to get a feel for the stability, reliability, and usefulness of a vendor's support and driver services, and for alternatives in case of difficulties.

Video Card Benchmarks

Industry-standard benchmarks such as ZDBOp's Graphics Winmark attempt to measure the performance of different video cards under a controlled testing environment. Unfortunately, especially for gamers, these benchmarks are sometimes "hacked" to allow an artificially high score that doesn't reflect true performance. Also, game performance in particular is partly a function of the APIs the game requires (such as DirectX's Direct3D, Glide, or OpenGL), along with the monitor resolution, color depth, and memory on the card.

Thus, if you are a gamer, the best way to see how a particular video card will perform for you is to look at the combination of frame rates and rendering quality for popular games. Some of the game standards being used in these comparisons include Quake II (Glide and OpenGL), Forsaken (Direct3D), Hexen II, and Quake (OpenGL). You can use game and video card manufacturers' Web sites and game-review Web sites to see these comparisons. Depending on the game, command-line, keystroke, and menu options might be used to determine frame rates. The 3D Gaming Web site offers a helpful page on "Getting Framerates in Popular Games" at <http://www.3dgameing.com/games/framerates.html> with specific instructions for leading games.

Note

Two new video benchmarks are now available from MadOnion.Com, Ltd. Its Video2000 benchmark measures overall video, DVD/MPEG playback, and onscreen quality, and its 3DMark2000 measures 3D acceleration features similar to those used by major current and forthcoming 3D gaming titles. Both benchmarks were developed in cooperation with leading chipset and video card manufacturers, and can be downloaded free of charge from <http://www.madonion.com>.

Microsoft's DirectX is used with virtually all game-oriented video cards, and video card performance can vary according to the version of DirectX in use. If you see drastic differences listed for the same video card and game from different review sources, check to see which version of DirectX was used. The latest version of DirectX is usually faster than previous versions.

Make sure you determine exactly which video card was used to perform the test. Many manufacturers use the same chipset across a line of cards. See the next section to see how this can affect you.

Keep in mind that frame rates are only part of the story. Some vendors support limited color depths to render graphics faster, but because 24-bit or higher color looks more realistic, you might prefer a slightly slower frame rate and have your game look much better onscreen. Use

screen shots, live demos (when possible), reviews, as well as frame rates to choose the best 3D card for you.

Comparing Video Cards with the Same Chipset

Many manufacturers create a line of video cards with the same chipset to sell at different pricing points. Why not save some dollars and get the cheapest model? Why not say “price is no object” and get the most expensive one? When you’re faced with various cards in the “chipsetX” family, look for differences such as those shown in Table 15.23.

Table 15.23 Comparing Video Cards with the Features

Feature	Effect on You
RAMDAC speed	Less-expensive cards in a family often use a slower RAMDAC. As we saw earlier, this reduces maximum and flicker-free resolutions. If you use a 17-inch or larger monitor, this could be an eye-straining problem. Buy the card with the fastest RAMDAC, especially for use with 17-inch or larger monitors. Faster RAMDACs are often paired with SGRAM or DDR SDRAM, which are the fastest types of RAM currently found on video cards.
Amount of RAM	Although AGP video cards can use “AGP memory” (a section of main memory borrowed for texturing), it’s still faster to perform as much work as possible on the card’s own memory. PCI cards must perform all functions within their own memory. Less-expensive cards in a chipset family often have lower amounts of memory onboard, and most current-model cards aren’t expandable. Buy a card with enough memory for your games or applications—today and tomorrow; at least 8MB or more for business; 16MB or more for gaming.
Memory type	Virtually all video cards on the market today use SDRAM or its faster variants (SGRAM or DDR SDRAM). Any of these will provide you with high performance in business applications, although SGRAM and DDR SDRAM run high-resolution, high-quality 3D games faster. The once-popular EDO (Extended Data Out) RAM is obsolete for both main memory and video memory applications.
Memory and core clock speed	Many suppliers adjust the recommended speed of graphics controllers in an effort to provide users with maximum performance. Sometimes the supplier can choose to exceed the rated specification of the graphics chip. Be cautious. Current controller chips are large and they can overheat. An overclocked device in an open system with great airflow might work—or it might fail in a period of months from overstress of the circuitry. If you have questions about the rated speed of a controller, check the chip suppliers’ Web site. Many reputable companies do use overclocked parts, but the best vendors supply large heat sinks or even powered fans to avoid overheating.
Multiple accelerator chips	If you’re a hardcore gamer but don’t want to sacrifice extra slots by connecting two cards together, this can really boost performance. Make sure that your system has adequate internal cooling, enough RAM, and fast-enough storage to avoid performance bottlenecks.
TV tuner	You can save some money by having it built in, but it’s not as important as the other issues listed earlier unless you plan to do video capture. Some of the latest models have hardware-based MPEG-2 compression for higher video quality in less disk space.

Adapter and Display Troubleshooting

Solving most graphics adapter and monitor problems is fairly simple, although costly, because replacing the adapter or display is the usual procedure. However, before you take this step, make sure that you have exhausted all your other options. One embarrassingly obvious fix to monitor display problems that is often overlooked by many users is to adjust the controls on the monitor, such as the contrast and the brightness. Although most monitors today have a control panel on the front of the unit, other adjustments might be possible as well.

Some NEC monitors, for example, have a focus adjustment screw on the left side of the unit. Because the screw is deep inside the case, the only evidence of its existence is a hole in the plastic grillwork on top of it. To adjust the monitor's focus, you have to stick a long-shanked screwdriver about two inches into the hole and feel around for the screw head. This type of adjustment can save you both an expensive repair bill and the humiliation of being ridiculed by the repair technician. Always examine the monitor case, the documentation, and the manufacturer's Web site or other online services for the locations of adjustment controls.

A defective or dysfunctional adapter or display usually is replaced as a single unit rather than being repaired. Except for specialized CAD or graphics workstation-oriented adapters, virtually all today's adapters cost more to service than to replace, and the documentation required to service the hardware properly is not always available. You usually cannot get schematic diagrams, parts lists, wiring diagrams, and other documents for most adapters or monitors. Also, virtually all adapters now are constructed with surface-mount technology that requires a substantial investment in a rework station before you can remove and replace these components by hand. You cannot use a \$25 pencil-type soldering iron on these boards!

Servicing monitors is a slightly different proposition. Although a display often is replaced as a whole unit, some displays are too expensive to replace. If you decide to repair the monitor, your best bet is either to contact the company from which you purchased the display or contact one of the companies that specializes in monitor depot repair. If your monitor has a 15" diagonal measurement or less, consider replacing it with a unit that is 17" or larger, because repair costs on small monitors come close to replacement costs, and large monitors aren't much more expensive these days.

Depot repair means that you send in your display to repair specialists who either fix your particular unit or return an identical unit they have already repaired. This is normally accomplished for a flat-rate fee; in other words, the price is the same no matter what they have done to repair your actual unit.

Because you will usually get a different (but identical) unit in return, they can ship out your repaired display immediately on receiving the one you sent in, or even in advance in some cases. This way, you have the least amount of downtime and can receive the repaired display as quickly as possible. In some cases, if your particular monitor is unique or one they don't have in stock, you will have to wait while they repair your specific unit.

Troubleshooting a failed monitor is relatively simple. If your display goes out, for example, a swap with another monitor can confirm that the display is the problem. If the problem disappears when you change the display, the problem is almost certainly in the original display or the cable; if the problem remains, it is likely in the video adapter or PC itself.

Many of the better quality, late-model monitors have built-in self-diagnostic circuitry. Check your monitor's manual for details. Using this feature, if available, can help you determine whether the problem is really in the monitor, in a cable, or somewhere else in the system. If self diagnostics produce an image onscreen, look to other parts of the video subsystem for your problem.

The monitor cable can sometimes be the source of display problems. A bent pin in the DB-15 connector that plugs into the video adapter can prevent the monitor from displaying images, or it can cause color shifts. Most of the time, you can repair the connector by carefully straightening the bent pin with sharp-nosed pliers.

If the pin breaks off or if the connector is otherwise damaged, you can sometimes replace the monitor cable. Some monitor manufacturers use cables that disconnect from the monitor and the video adapter, whereas others are permanently connected. Depending on the type of connector the device uses at the monitor end, you might have to contact the manufacturer for a replacement.

If you narrow down the problem to the display, consult the documentation that came with the monitor or call the manufacturer for the location of the nearest factory repair depot. Third-party depot repair service companies are also available that can repair most displays (if they are no longer covered by a warranty); their prices often are much lower than factory service. Check the Vendor List on the CD for several companies that do depot repair of computer monitors and displays.

Caution

You should never attempt to repair a CRT monitor yourself. Touching the wrong component can be fatal. The display circuits can hold extremely high voltages for hours, days, or even weeks after the power is shut off. A qualified service person should discharge the cathode ray tube and power capacitors before proceeding.

For most displays, you are limited to making simple adjustments. For color displays, the adjustments can be quite formidable if you lack experience. Even factory service technicians often lack proper documentation and service information for newer models; they usually exchange your unit for another and repair the defective one later. Never buy a display for which no local factory repair depot is available.

If you have a problem with a display or an adapter, it pays to call the manufacturer, who might know about the problem and make repairs available. Sometimes, when manufacturers encounter numerous problems with a product, they might offer free repair, replacements, or another generous offer that you would never know about if you did not call.

Remember, also, that many of the problems you might encounter with modern video adapters and displays are related to the drivers that control these devices rather than to the hardware. Be sure you have the latest and proper drivers before you attempt to have the hardware repaired; a solution might already be available.

Troubleshooting Monitors

Problem

No picture

Solution

If the LED on the front of the monitor is yellow or flashing green, the monitor is in power-saving mode. Move the mouse or press Alt+Tab on the keyboard and wait up to one minute to wake up the system if the system is turned on.

If the LED on the front of the monitor is green, the monitor is in normal mode (receiving a signal), but the brightness and contrast are set incorrectly; adjust them.

If no lights are lit on the monitor, check the power and the power switch. Check the surge protector or power director to make sure power is going to the monitor. Replace the power cord with a known-working spare if necessary. Retest. Replace the monitor with a known-working spare to make sure the monitor is the problem.

Check data cables at the monitor and video card end.

Check TTL versus analog settings on dual-purpose monitors. TTL is used with EGA cards; analog is used with VGA and SVGA cards.

Problem

Jittery picture quality

LCD monitors. Use display-adjustment software to reduce or eliminate pixel jitter and pixel swim.

All monitors. Check cables for tightness at the video card and the monitor (if removable).

- Remove the extender cable and retest with the monitor plugged directly into the video card. If the extended cable is bad, replace it.
- Check the cables for damage; replace as needed.
- If problems are intermittent, check for interference. (Microwave ovens near monitors can cause severe picture distortion when turned on.)

CRT monitors. Check refresh-rate settings; reduce them until acceptable picture quality is achieved.

- Use onscreen picture adjustments until an acceptable picture quality is achieved.
- If problems are intermittent and can be “fixed” by waiting or by gently tapping the side of the monitor, the monitor power supply is probably bad or has loose connections internally. Service or replace the monitor.

Troubleshooting Video Cards and Drivers

Problem

Display works in DOS, not in Windows

Solution

If you have an acceptable picture quality in MS-DOS mode (system boot) but no picture in Windows, most likely you have a wrong or corrupted video driver installed in Windows. Boot Windows 9x in Safe Mode (which uses a VGA driver), boot Windows 2000 in Enable VGA mode, or install the VGA driver and restart Windows. If Safe Mode or VGA works, get the correct driver for the video card and reinstall.

Problem

Can't replace built-in video card with add-on PCI video card

Solution

Check with the video card and system vendor for a list of acceptable replacement video cards. Try another video card with a different chipset. Check the BIOS or motherboard for jumper or configuration settings to disable built-in video. Place the add-on card in a different PCI slot.

DisplayMate

DisplayMate is a unique diagnostic and testing program designed to thoroughly test your video adapter and display. It is somewhat unique in that most conventional PC hardware diagnostics programs do not emphasize video testing the way this program does.

I find it useful not only in testing whether a video adapter is functioning properly, but also in examining video displays. You can easily test the image quality of a display, which allows you to make focus, centering, brightness and contrast, color level, and other adjustments much more accurately than before. If you are purchasing a new monitor, you can use the program to evaluate the sharpness and linearity of the display and to provide a consistent way of checking each monitor that you are considering. If you use projection systems for presentations, as I do in my PC hardware seminars, you will find it invaluable for setting up and adjusting the projector.

DisplayMate can also test a video adapter thoroughly. It will set the video circuits into each possible video mode so you can test all its capabilities. It will also help you to determine the performance level of your card, both with respect to resolution and colors as well as speed. You can then use the program to benchmark the performance of the display, which enables you to compare one type of video adapter system to another.

See the Vendor List on the CD for more information on DisplayMate (formerly Sonera) Technologies, the manufacturer and distributor of DisplayMate.

Some video-card vendors supply a special version of DisplayMate for use in diagnostics testing.

CHAPTER 16

Serial, Parallel, and Other I/O Interfaces

Introduction to Input/Output Ports

This chapter covers the primary peripheral input/output ports on a modern PC system. This includes discussion of serial and parallel ports, as well as discussion of the more current Universal Serial Bus (USB), and IEEE-1394 (i.Link or FireWire) interfaces. Although SCSI and IDE are also I/O interfaces, they are important enough to warrant their own chapters for more specific and detailed coverage.

The most basic communications ports in any PC system are the serial and parallel ports.

Serial ports (also known as communication or COM ports) were originally used for devices that had to communicate bidirectionally with the system. Such devices include modems, mice, scanners, digitizers, and any other devices that “talk to” and receive information from the PC. Newer parallel port standards now allow the parallel port to perform high-speed bidirectional communications.

Several companies manufacture communications programs that perform high-speed transfers between PC systems using serial or parallel ports. Versions of these file transfer programs have been included with DOS 6.0 and higher (Interlink), and with Windows 95 and newer versions (DCC—Direct Cable Connection). There are currently several products on the market that make non-traditional use of the parallel port. For example, you can purchase network adapters, high-capacity floppy disk drives, CD-ROM drives, scanners, or tape backup units that attach to the parallel port.

Serial Ports

The asynchronous serial interface was designed as a system-to-system communications port. Asynchronous means that no synchronization or clocking signal is present, so characters can be sent with any arbitrary time spacing.

Each character that is sent over a serial connection is framed by a standard start-and-stop signal. A single 0 bit, called the start bit, precedes each character to tell the receiving system that the next eight bits constitute a byte of data. One or two stop bits follow the character to signal that the character has been sent. At the receiving end of the communication, characters are recognized by the start-and-stop signals instead of by the timing of their arrival. The asynchronous interface is character-oriented and has about a 20 percent overhead for the extra information that is needed to identify each character.

Serial refers to data that is sent over a single wire, with each bit lining up in a series as the bits are sent. This type of communication is used over the phone system because this system provides one wire for data in each direction. Add-on serial ports for the PC are available from many manufacturers. You can usually find these ports on one of the multifunction boards that is available, or on a board with at least a parallel port. Virtually all modern motherboards include a built-in Super I/O chip that adds one or two serial ports to the motherboard, which means that no

additional interface card is required. Older systems normally have the serial ports on a card. Note that card-based modems also incorporate a built-in serial port on the card as part of the modem circuitry. Figure 16.1 shows the standard 9-pin connector that is used with most modern external serial ports. Figure 16.2 shows the original standard 25-pin version.

Figure 16.1 AT-style 9-pin serial-port connector specifications.

Serial ports can connect to a variety of devices, such as modems, plotters, printers, other computers, bar code readers, scales, and device control circuits.

The official specification recommends a maximum cable length of 50 feet. The limiting factor is the total load capacitance of cable and input circuits of the interface. The maximum capacitance is specified as 2500 pF. There are special low-capacitance cables that can effectively increase the maximum cable length greatly, to as much as 500 feet or more. Also available are line drivers (amplifier/repeaters) that can extend cable length even further.

Tables 16.1, 16.2, and 16.3 show the pinouts of the 9-pin (AT-style), 25-pin, and 9-pin-to-25-pin serial connectors.

Note

Macintosh systems use a similar serial interface, defined as RS-422. Most external modems that are in use today can interface with either RS-232 or RS-422, but it is safest to make sure that the external modem you get for your PC is designed for a PC, not a Macintosh.

UARTs

The heart of any serial port is the Universal Asynchronous Receiver/Transmitter (UART) chip. This chip completely controls the process of breaking the native parallel data within the PC into serial format and later converting serial data back into the parallel format.

There have been several types of UART chips on the market. The original PC and XT used the 8250 UART, which was used for many years in low-priced serial cards. Starting with the first 16-bit systems, the 16450 UART was usually used. The only difference between these chips is their suitability for high-speed communications. The 16450 is better suited for high-speed communications than is the 8250; otherwise, both chips appear identical to most software.

The 16550 UART was the first serial chip used in the IBM PS/2 line, and other 386 and higher systems rapidly adopted it. This chip functioned as the earlier 16450 and 8250 chips, but it also included a 16-byte buffer that aided in faster communications. This is sometimes referred to as a FIFO (First In First Out) buffer. Unfortunately, the early 16550 chips had a few bugs, particularly in the buffer area. These bugs were corrected with the release of the 16550A. The most current version of the chip is the 16550D, which is produced by National Semiconductor.

Tip

The high-speed buffered 16550A (or newer) UART chip is pin-for-pin compatible with the 16450 UART. If your 16450 UART is socketed, a cheap and easy way to improve serial performance is to install a 16550 UART chip in the socket.

Because the 16550 is a faster, more reliable chip than its predecessors, it is best to ensure that your serial ports either have that chip or an equivalent. Most motherboards today that have built-in serial ports use a Super I/O chip that contains the serial port UARTs within it. If you are in doubt about which type of UART you have in your system, you can use the Microsoft MSD program (provided with Windows, MS DOS 6.x, and Windows 95) to determine the type of UART you have.

Note

Another way to tell if you have a 16550 UART in Windows 95 or 98 is to click the Start menu, and then choose Settings, Control Panel. Next, double-click Modems, and then click the Diagnostics tab. The Diagnostics tab shows a list of all COM ports in the system, even if they don't have a modem attached to them. Select the port you want to check in the list and click More Info. Windows 95 or 98 communicates with the port to determine the UART type, and that information is listed in the Port Information portion of the More Info box. If a modem was attached, additional information about the modem is displayed.

The original designer of these UARTs is National Semiconductor (NS). So many other manufacturers are producing clones of these UARTs that you probably don't have an actual NS brand part in your system. Even so, the part you have will be compatible with one of the NS parts, hopefully the 16550. In other words, check to see that whatever UART chip you have does indeed feature the 16-byte FIFO buffer, as found in the NS 16550 part.

Most motherboards now include Super I/O integrated chips that take on the functions of multiple separate chips. Most of these integrated chips function as a 16550 does; however, some that are used on older motherboards might not.

◀◀ See "Super I/O Chips," p. 300.

8250

IBM used this original chip in the PC serial port card. This chip had no transmit/receive buffer, which means that it was very slow. The chip also had several bugs, none of which were serious. The PC and XT ROM BIOSes were written to anticipate at least one of the bugs. The 8250B replaced this chip.

8250A

Do not use the second version of the 8250 in any system. This upgraded chip fixes several bugs in the 8250, including one in the interrupt enable register, but because the PC and XT ROM BIOSes expect the bug, this chip does not work properly with those systems. The 8250A works in an AT system that does not expect the bug, but it does not work adequately at 9600bps.

8250B

The last version of the 8250 fixes bugs from the previous two versions. The interrupt enable bug in the original 8250, which is expected by the PC and XT ROM BIOS software, has been put back into this chip, making the 8250B the most desirable chip for any non-AT serial port application. The 8250B chip might work in an AT under DOS, but it does not run properly at 9600bps because, like all 8250s, it has no transmit/receive buffer.

16450

IBM selected the higher-speed version of the 8250 for the AT. The higher performance mainly comes from a one-byte transmit/receive buffer that is contained within the chip. Because this chip has fixed the aforementioned interrupt enable bug, the 16450 does not operate properly in many PC or XT systems because they expect this bug to be present. OS/2 requires this chip as a minimum; otherwise, the serial ports do not function properly. It also adds a scratch-pad register as the highest register. The 16450 is used primarily in AT systems because of its increase in throughput over the 8250B.

16550A

This chip is pin-compatible with the 16450, but is much faster due to a built-in 16-character transmit/receive FIFO buffer. It also allows multiple DMA channel access. The original version of this chip did not allow the buffer to work, but all 16550A or later revisions had the bug fixed.

The last version that was produced by National Semiconductor was called the 16550D. Use a version of this UART in your serial port if you do any communications at 9600bps or higher. If your communications program makes use of the FIFO—and all of them do today—it can greatly increase communications speed and eliminate lost characters and data at the higher speeds. Virtually all Super I/O chips contain the equivalent of dual 16550A or later chips. Most 16550 UARTs have a maximum communications speed of 115Kbps (bits per second).

16650

Several companies have produced versions with larger buffers that they have called 16650 and 16750. These chips are not from National Semiconductor, and the designations only imply that they are compatible with the 16550 but have a larger buffer. The 16650 chips normally have a 32-byte buffer, and the 16750 chips have a 64-byte buffer. These larger buffered versions allow speeds of 230Kbps or 460Kbps and are recommended when you are running a high-speed external communications link such as an ISDN terminal adapter. These are discussed more in the following section.

High-Speed Serial Ports (ESP and Super ESP)

Some modem manufacturers have gone a step further in improving serial data transfer by introducing Enhanced Serial Ports (ESP) or Super High Speed Serial Ports. These ports enable a 28.8Kbps or faster modem to communicate with the computer at data rates up to 921.6Kbps. The extra speed on these ports is generated by increasing the buffer size. These ports are usually based on a 16550, 16650, or 16750 UART, and some even include more buffer memory on the card. Most allow raw port speed settings of 230Kbps or 460Kbps, which is valuable when connecting a PC to a high-speed external component that is connected to a serial port, such as an ISDN terminal adapter. You can't really get the full-speed benefit of an external ISDN modem (terminal adapter) unless your serial port can go at least 230Kbps. Lava Computer Mfg. is one company that offers a complete line of high-speed serial and parallel port cards (see the Vendor List on the accompanying CD).

As the need for additional serial devices continues to increase, users are beginning to need more than the standard two COM ports that are built into most modern motherboards. As a result, multiport serial cards were created. These cards generally have 2–32 ports on them. Often, they also provide higher baud rates than can be achieved on a standard serial port.

Most of the multiport serial cards on the market use standard 16550 UARTs with a processor (typically an 80X86 based processor) and some memory. These cards can improve performance slightly because the processor is dedicated to handling serial information. However, it's not always the best method for high-performance applications.

Some of the better multiport serial cards have broken the model of the 16550 UART in favor of a single integrated circuit. These cards have the advantage of higher sustainable throughput without loss.

Various manufacturers make versions of the 16550; National Semiconductor was the first. The current version is a 40-pin DIP (Dual In-line Pin package) chip called the NS16550D. You can contact Fry's Electronics or Jameco Electronics to obtain the NS16550D, for example.

Note that more recent systems don't use these individual UART chips; instead, there will be a component on the motherboard called a *Super I/O* chip. This normally has two serial port UARTs as well as a multimode parallel port, floppy controller, keyboard controller, and sometimes the CMOS memory, all built in to a single tiny chip. Still, this chip acts as if all these separate devices were installed: That is, from a software point of view, both the operating system and applications still act as if separate UART chips were installed on serial port adapter cards. Super I/O chips are discussed throughout this chapter and in Chapter 4, "Motherboards and Buses."

Serial Port Configuration

Each time a character is received by a serial port, it has to get the attention of the computer by raising an Interrupt Request Line (IRQ). Eight-bit ISA bus systems have eight of these lines, and systems with a 16-bit ISA bus have 16 lines. The 8259 interrupt controller chip usually handles these requests for attention. In a standard configuration, COM 1 uses IRQ4, and COM 2 uses IRQ3.

When a serial port is installed in a system, it must be configured to use specific I/O addresses (called ports), and interrupts (called IRQs for Interrupt Request). The best plan is to follow the existing standards for how these devices are to be set up. For configuring serial ports, use the addresses and interrupts indicated in Table 16.4.

Table 16.4 Standard Serial I/O Port Addresses and Interrupts

COM x	I/O Ports	IRQ
COM 1	3F8-3FFh	IRQ4
COM 2	2F8-2FFh	IRQ3
COM 3	3E8-3EFh	IRQ4 ¹
COM 4	2E8-2EFh	IRQ3 ¹

1 Note that although many serial ports can be set up to share IRQ 3 and 4 with COM 1 and COM 2, it is not recommended. The best recommendation is setting COM 3 to IRQ 10 and COM4 to IRQ 11 (if available). If ports above COM 3 are required, it is recommended that you purchase a special multiport serial board.

Make sure that if you are adding more than the standard COM 1 and COM 2 serial ports, they use unique and non-conflicting interrupts. If you purchase a serial port adapter card and intend to use it to supply ports beyond the standard COM1 and COM2, be sure that it can use interrupts other than IRQ3 and IRQ4.

Note that BIOS manufacturers never built support for COM 3 and COM 4 into the BIOS. Therefore, DOS cannot work with serial ports above COM 2 because DOS gets its I/O information from the BIOS. The BIOS finds out what is installed in your system, and where it is installed, during the POST (power on self test). The POST checks only for the first two installed ports. This is not a problem at all under Windows because both Windows 95/98 and NT have built-in support for up to 128 ports.

With support for up to 128 serial ports in Windows, it is much easier to use multiport boards in the system. Multiport boards give your system the capability to collect or share data with multiple devices while using only one slot and one interrupt.

Caution

Sharing interrupts between COM ports—or any devices—can function properly sometimes and not others. It is recommended that you never share interrupts between multiple serial ports. Trying to track down drivers, patches, and updates to allow this to work successfully—if it's even possible at all in your system—can cause you hours of frustration.

◀◀ See “Resolving Resource Conflicts,” p. 354.

Testing Serial Ports

You can perform several tests on serial and parallel ports. The two most common types of tests are those that involve software only and those that involve both hardware and software. The software-only tests are done with diagnostic programs such as Microsoft's MSD, whereas the hardware and software tests involve using a wrap plug to perform loopback testing.

▶▶ See “Testing Parallel Ports,” p. 939.

▶▶ See “Advanced Diagnostics Using Loopback Testing,” p. 931.

Microsoft Diagnostics (MSD)

MSD is a diagnostic program that is supplied with MS-DOS 6.x, Windows 3.x, and Windows 9x. Early versions of the program were also shipped with some Microsoft applications, such as Microsoft Word for DOS. Note that with Windows 95 this program can be found on the CD-ROM in the \other\msd directory. In Windows 98, you can find it on the CD-ROM in the \tools\oldmsdos directory. MSD is not automatically installed when you install the operating system. To use it, you must run it from the CD-ROM directly or copy the program from the CD-ROM to your hard disk.

For the most accurate results, many diagnostics programs, such as MSD, are best run in a DOS-only environment. Because of this, you need to restart the machine in DOS mode before using them. Then, to use MSD, switch to the directory in which it is located. This is not necessary, of course, if the directory that contains the program is in your search path, which is often the case with the DOS 6.x or Windows-provided versions of MSD. Then simply type MSD at the DOS prompt and press Enter. Soon you see the MSD screen.

Choose the Serial Ports option. Notice that you are given information about which type of serial chip you have in your system, as well as information about which ports are available. If any of the ports are in use (with a mouse, for example), that information is provided as well.

MSD is helpful in at least determining whether your serial ports are responding. If MSD cannot determine the existence of a port, it does not provide the report that indicates that the port exists. This sort of “look-and-see” test is the first action I usually take to determine why a port is not responding.

Troubleshooting I/O Ports in Windows

Windows 95/98 can tell you whether your ports are functioning. First, you need to verify that the required communications files are present to support the serial ports in your system:

1. Verify the file sizes and dates of both COMM.DRV (16-bit serial driver) and SERIAL.VXD (32-bit serial driver) in the SYSTEM directory, compared to the original versions of these files from the Windows 9x CD-ROM.
2. Confirm that the following lines are present in SYSTEM.INI:

```
[boot]
comm.drv=comm.drv
[386enh]
device=*vcd
```

The SERIAL.VXD driver is not loaded in SYSTEM.INI; instead, it is loaded through the Registry. If both drivers are present and accounted for, you can determine whether a particular serial port's I/O address and IRQ settings are properly defined by following these steps:

1. Right-click the System icon and select Properties. Click the Device Manager tab, Ports, and then select a specific port (such as COM 1).
2. Click the Properties button, and then click the Resources tab to display the current resource settings (IRQ, I/O) for that port.
3. Check the Conflicting Devices List to see if the port is using resources that conflict with other devices. If the port is in conflict with other devices, click the Change Setting button, and then select a configuration that does not cause resource conflicts. You might need to experiment with these settings until you find the right one.
4. If the resource settings cannot be changed, most likely they must be changed via the BIOS Setup. Shut down and restart the system, enter the BIOS setup, and change the port configurations there.

◀◀ See "Resolving Resource Conflicts," p. 354.

A common problem occurs when people try to use a modem on COM 3 with a serial mouse or other device on COM 1. Normally, COM 1 and COM 3 ports use the same IRQ, meaning that they cannot be used simultaneously. The COM 2 and COM 4 ports have the same problem sharing IRQs. If possible, change the COM 3 or COM 4 port to an IRQ setting that is not in conflict with COM1 or COM 2. Note also that some video adapters have an automatic address conflict with COM 4.

Advanced Diagnostics Using Loopback Testing

One of the most useful types of diagnostic test is the loopback test, which can be used to ensure the correct function of the serial port and any attached cables. Loopback tests are basically internal (digital) or external (analog). You can run internal tests by simply unplugging any cables from the port and executing the test via a diagnostics program.

The external loopback test is more effective. This test requires that a special loopback connector or wrap plug be attached to the port in question. When the test is run, the port is used to send data out to the loopback plug, which simply routes the data back into the port's receive pins so that the port is transmitting and receiving at the same time. A loopback or wrap plug is nothing more than a cable that is doubled back on itself. Most diagnostics programs that run this type of test include the loopback plug, and if not, these types of plugs can be purchased easily or even built.

Following is a list of the wiring needed to construct your own loopback or wrap plugs:

- Standard IBM type 25-Pin Serial (Female DB25S) Loopback Connector (Wrap Plug). Connect the following pins:
 - 1 to 7
 - 2 to 3
 - 4 to 5 to 8
 - 6 to 11 to 20 to 22
 - 15 to 17 to 23
 - 18 to 25
- Norton Utilities (Symantec) 25-Pin Serial (Female DB25S) Loopback Connector (Wrap Plug). Connect the following pins:
 - 2 to 3
 - 4 to 5
 - 6 to 8 to 20 to 22
- Standard IBM type 9-Pin Serial (Female DB9S) Loopback Connector (Wrap Plug). Connect the following pins:
 - 1 to 7 to 8
 - 2 to 3
 - 4 to 6 to 9
- Norton Utilities (Symantec) 9-Pin Serial (Female DB9S) Loopback Connector (Wrap Plug). Connect the following pins:
 - 2 to 3
 - 7 to 8
 - 1 to 4 to 6 to 9

◀◀ See “Serial Ports,” p. 922.

To make these loopback plugs, you need a connector shell with the required pins installed. Then wire wrap or solder wires, interconnecting the appropriate pins inside the connector shell as specified in the preceding list. In most cases, it is less expensive to purchase a set of loopback connectors that are premade than it is to make them yourself. Most companies that sell diagnostics software, such as Symantec (Norton Utilities), can also sell you a set of loopback plugs.

One advantage of using loopback connectors is that you can plug them into the ends of a cable that is included in the test. This can verify that both the cable and the port are working properly.

If you need to test serial ports further, refer to Chapter 25, “PC Diagnostics, Testing, and Maintenance,” which describes third-party testing software.

Parallel Ports

Parallel ports are normally used for connecting printers to a PC. Even though that was their sole original intention, parallel ports have become much more useful over the years as a more general-purpose, relatively high-speed interface between devices. Originally the ports were one way only; modern parallel ports can send and receive data.

Parallel ports are so named because they have eight lines for sending all the bits that comprise one byte of data simultaneously across eight wires. This interface is fast and has traditionally been used for printers. However, programs that transfer data between systems have always used the parallel port as an option for transmitting data because it can do so four bits at a time rather than one bit at a time as with a serial interface.

The following section looks at how these programs transfer data between parallel ports. The only problem with parallel ports is that their cables cannot be extended for any great length without amplifying the signal, or errors occur in the data. Table 16.5 shows the pinout for a standard PC parallel port.

Table 16.5 25-Pin PC-Compatible Parallel Port Connector

Pin	Description	I/O	Pin	Description	I/O
1	-Strobe	Out	14	-Auto Feed	Out
2	+Data Bit 0	Out	15	-Error	In

IEEE 1284 Parallel Port Standard

The IEEE 1284 standard, called “Standard Signaling Method for a Bidirectional Parallel Peripheral Interface for Personal Computers,” was approved for final release in March 1994. This standard defines the physical characteristics of the parallel port, including data transfer modes and physical and electrical specifications.

IEEE 1284 defines the electrical signaling behavior external to the PC for a multimodal parallel port that can support 4-bit modes of operation. Not all modes are required by the 1284 specification, and the standard makes some provision for additional modes.

The IEEE 1284 specification is targeted at standardizing the behavior between a PC and an attached device, specifically attached printers. However, the specification is of interest to vendors of parallel port peripherals (disks, LAN adapters, and so on).

IEEE 1284 is a hardware and line control-only standard and does not define how software is to talk to the port. An offshoot of the original 1284 standard has been created to define the software interface. The IEEE 1284.3 committee was formed to develop a standard for software that is used

with IEEE 1284-compliant hardware. This standard, designed to address the disparity among providers of parallel port chips, contains a specification for supporting EPP mode via the PC's system BIOS.

IEEE 1284 allows for much higher throughput in a connection between a computer and a printer or two computers. The result is that the printer cable is no longer the standard printer cable. The IEEE 1284 printer cable uses twisted-pair technology, which results in a much more reliable and error-free connection.

The IEEE-1284 standard also defines the parallel port connectors, including the two pre-existing types (called Type A and Type B), as well as an additional high-density Type C connector. Type A refers to the standard DB25 connector that is used on most PC systems for parallel port connections, whereas Type B refers to the standard 36-pin Centronics style connector found on most printers. Type C is a new high-density 36-pin connector that can be found on some of the newer printers on the market, such as those from HP. The three connectors are shown in Figure 16.3.

Figure 16.3 The three different types of IEEE 1284 parallel port connectors.

The IEEE 1284 parallel port standard defines five different port operating modes, emphasizing the higher speed EPP and ECP modes. Some of the modes are input only, whereas others are output only. These five modes combine to create four different types of ports, as shown in the following table:

Parallel Port Type	Input Mode	Output Mode	Comments
SPP (Standard Parallel Port)	Nibble	Compatible	4-bit input, 8-bit output
Bidirectional	Byte	Compatible	8-bit I/O
EPP (Enhanced Parallel Port)	EPP	EPP	8-bit I/O
ECP (Enhanced Capabilities Port)	ECP	ECP	8-bit I/O, uses DMA

The 1284 defined Parallel Port Modes are shown in the following table, which also shows the approximate transfer speeds:

Parallel Port Mode	Direction	Transfer Rate
Nibble (4-bit)	Input only	50KB/sec
Byte (8-bit)	Input only	150KB/sec
Compatible	Output only	150KB/sec
EPP (Enhanced Parallel Port)	Input/Output	500KB–2MB/sec
ECP (Enhanced Capabilities Port)	Input/Output	500KB–2MB/sec

Each of the port types and modes are discussed in the following sections.

Standard Parallel Ports (SPP)

Older PCs did not have different types of parallel ports available. The only available port was the parallel port that was used to send information from the computer to a device such as a printer. The unidirectional nature of the original PC parallel port is consistent with its primary use—that is, sending data to a printer. There were times, however, when it was desirable to have a bidirectional port—for example, when it was necessary to receive feedback from a printer, which was common with PostScript printers. This could not be done easily with the original unidirectional ports.

Although it was never intended to be used for input, a clever scheme was devised in which four of the signal lines can be used as a 4-bit input connection. Thus, these ports can do 8-bit (byte) output (called Compatible mode) and 4-bit input (called nibble mode). This is still very common on low-end desktop systems. Systems built after 1993 are likely to have more capable parallel ports, such as bidirectional, EPP, or ECP.

Standard parallel ports are capable of effective transfer rates of about 150KB/sec output, and about 50KB/sec input.

Bidirectional (8-bit) Parallel Ports

With the introduction of the PS/2 series of machines in 1987, IBM introduced the bidirectional parallel port. These are commonly found in PC-compatible systems today and can be designated “bidirectional,” “PS/2 type,” or “extended” parallel ports. This port design opened the way for true communication between the computer and the peripheral across the parallel port. This was done by defining a few of the previously unused pins in the parallel connector, and by defining a status bit to indicate in which direction information was traveling across the channel. This allows for a true 8-bit (called byte mode) input.

These ports can do both 8-bit input and output using the standard eight data lines, and are considerably faster than the 4-bit ports when used with external devices. Bidirectional ports are capable of approximately 150KB/sec transfer rates on both output and input.

Enhanced Parallel Port (EPP)

EPP is a newer specification, sometimes referred to as the Fast Mode parallel port. The EPP was developed by Intel, Xircom, and Zenith Data Systems, and was announced in October 1991. The

first products to offer EPP were Zenith Data Systems laptops, Xircom Pocket LAN Adapters, and the Intel 82360 SL I/O chip. Currently, almost all systems include a multimode parallel port, usually built into the Super I/O chip on the motherboard, that supports EPP mode.

EPP operates at almost ISA bus speed and offers a tenfold increase in the raw throughput capability over a conventional parallel port. EPP is especially designed for parallel port peripherals such as LAN adapters, disk drives, and tape backups. EPP has been included in the new IEEE 1284 Parallel Port standard. Transfer rates of up to 2MB/sec are possible with EPP.

Since the original Intel 82360 SL I/O chip in 1992, other major chip vendors (such as National Semiconductor, SMC, Western Digital, and VLSI) have also produced I/O chipsets that offer some form of EPP capability. One problem is that the procedure for enabling EPP across the various chips differs widely from vendor to vendor, and many vendors offer more than one I/O chip.

EPP version 1.7 (March 1992) identifies the first popular version of the hardware specification. With minor changes, this has since been abandoned and folded into the IEEE 1284 standard. Some technical reference materials have erroneously made reference to “EPP specification version 1.9,” causing confusion about the EPP standard. Note that “EPP version 1.9” technically does not exist, and any EPP specification after the original version 1.7 is more accurately referred to as a part of the IEEE 1284 specification.

Unfortunately, this has resulted in two somewhat incompatible standards for EPP parallel ports: the original EPP Standards Committee version 1.7 standard, and the IEEE 1284 Committee standard, normally called EPP version 1.9. The two standards are similar enough that new peripherals can be designed to support both standards, but older EPP 1.7 peripherals might not operate with EPP 1284 (EPP 1.9) ports. For this reason, many multimode ports allow configuration in either EPP 1.7 or 1.9 modes, normally selected via the BIOS Setup.

EPP ports are now supported in virtually all Super I/O chips that are used on modern motherboards. Because the EPP port is defined in the IEEE 1284 standard, it has also gained software and driver support, including support in Windows NT.

Enhanced Capabilities Port (ECP)

Another type of high-speed parallel port, the ECP (Enhanced Capabilities Port), was jointly developed by Microsoft and Hewlett-Packard and was formally announced in 1992. Like EPP, ECP offers improved performance for the parallel port and requires special hardware logic.

Since the original announcement, ECP is included in IEEE 1284—just like EPP. Unlike EPP, however, ECP is not tailored to support portable PCs' parallel port peripherals; its purpose is to support an inexpensive attachment to a very high-performance printer or scanner. Furthermore, ECP mode requires the use of a DMA channel, which EPP did not define and which can cause troublesome conflicts with other devices that use DMA. Most PCs with newer Super I/O chips can support either EPP or ECP mode.

Most new systems are being delivered with ECP ports that support high throughput communications. In most cases, the ECP ports can be turned into EPP or standard parallel ports via BIOS. However, it's recommended that the port be placed in ECP mode for the best throughput.

Upgrading to EPP/ECP Parallel Ports

If you are purchasing a system today, I recommend one that has a so-called Super I/O chip that supports both EPP and ECP operation. If you want to test the parallel ports in a system, especially to determine what type they are, I highly recommend a utility called Parallel. This is a handy parallel port information utility that examines your system's parallel ports and reports the Port Type, I/O address, IRQ level, BIOS name, and an assortment of informative notes and warnings in a compact and easy-to-read display. The output can be redirected to a file for tech support purposes. Parallel uses very sophisticated techniques for port and IRQ detection, and it is aware of a broad range of quirky port features. You can get it from Parallel Technologies (see the Vendor's List on the CD-ROM).

If you have an older system that does not include an EPP/ECP port and you want to upgrade, there are several companies that now offer boards with the correct Super I/O chips to implement these features. I recommend that you check with Farpoint Communications, Byterunner Technologies, or Lava Computer Mfg.; they are listed in the Vendor List on the CD accompanying this book.

High-speed parallel ports such as EPP and ECP type are often used for supporting external peripherals such as Zip drives, CD-ROM drives, scanners, tape drives, and even hard disks. Most of these devices attach to the parallel port using a pass-through connection. This means that your local printer can still work through the port, along with the device. The device will have its own drivers that mediate both the communications with the device and the printer pass-through. Using EPP or ECP modes, communications speeds that are as high as 2MB/sec can be achieved. This can allow a relatively high-speed device to function almost as if it were connected to the system bus internally.

Parallel Port Configuration

The configuration of parallel ports is not as complicated as it is for serial ports. Even the original IBM PC had BIOS support for three LPT ports. Table 16.6 shows the standard I/O address and interrupt settings for parallel port use.

Table 16.6 Parallel Interface I/O Port Addresses and Interrupts

Standard LPTx	Alternate LPTx	I/O Ports	IRQ
LPT1	-	3BC-3BFh	IRQ7
LPT1	LPT2	378-37Ah	IRQ5
LPT2	LPT3	278h-27Ah	IRQ5

Because the BIOS and DOS have always provided three definitions for parallel ports, problems with older systems are infrequent. Problems can arise, however, from the lack of available interrupt-driven ports for ISA/PCI bus systems. Normally, an interrupt-driven port is not absolutely required for printing operations; in fact, many programs do not use the interrupt-driven capability. Many programs do use the interrupt, however, such as network print programs and other types of background or spooler-type printer programs.

Also, high-speed laser-printer utility programs often use the interrupt capabilities to allow for printing. If you use these types of applications on a port that is not interrupt driven, you see the printing slow to a crawl—if it works at all. The only solution is to use an interrupt-driven port. MS-DOS and Windows 95/98/2000 now support up to 128 parallel ports.

To configure parallel ports in ISA/PCI bus systems, you normally use the BIOS setup program for ports that are built into the motherboard, or maybe set jumpers and switches for adapter card-based ports. Because each board on the market is different, you always want to consult the OEM manual for that particular card if you need to know how the card needs to be configured.

◀ See “BIOS Hardware/Software,” p. 373.

Linking Systems with Parallel Ports

The original IBM PC designers envisioned that the parallel port would be used only for communicating with a printer. Over the years, the number of devices that can be used with a parallel port has increased tremendously. You now can find everything from tape backup units to LAN adapters to CD-ROMs and scanners that connect through your parallel port.

Perhaps one of the most common uses of bidirectional parallel ports is to transfer data between your system and another, such as a laptop computer. If both systems use an EPP/ECP port, you can actually communicate at rates of up to 2MB/sec, which rivals the speed of some hard disk drives. This capability has led to an increase in software to serve this niche of the market. If you are interested in such software (and the parallel ports necessary to facilitate the software), refer to the reviews that periodically appear in sources such as *PC Magazine*.

Connecting two computers with standard unidirectional parallel ports requires a special cable known as a null modem cable. Most programs sell or provide these cables with their software. However, if you need to make one for yourself, Table 16.7 provides the wiring diagram you need.

Table 16.7 Null Modem/Lap Link Cable Wiring

25-pin	Signal Descriptions		Signal Descriptions	25-pin
pin 2	Data Bit 0	÷	-Error	pin 15
pin 3	Data Bit 1	÷	Select	pin 13
pin 4	Data Bit 2	÷	Paper End	pin 12
pin 5	Data Bit 3	÷	-Acknowledge	pin 10
pin 6	Data Bit 4	÷	Busy	pin 11
pin 15	-Error	÷	Data Bit 0	pin 2
pin 13	Select	÷	Data Bit 1	pin 3
pin 12	Paper End	÷	Data Bit 2	pin 4
pin 10	-Acknowledge	÷	Data Bit 3	pin 5
pin 11	Busy	÷	Data Bit 4	pin 6
pin 25	Ground	÷	Ground	pin 25

Tip

Even though cables are usually provided for data transfer programs, notebook users might want to look for an adapter that makes the appropriate changes to a standard parallel cable. This can make traveling lighter by preventing the need for additional cables. Most of the time, these adapters attach to the Centronics end of the cable and provide a standard DB25 connection on the other end. They're sold under a variety of names; however, null modem cable, Laplink adapter, or Laplink converter are the most common names.

Although the wiring configuration and premade interlink cables listed in Table 16.7 work for connecting two machines with ECP/EPP ports, they can't take advantage of the advanced transfer rates of these ports. Special cables are needed to communicate between ECP/EPP ports. Parallel Technologies is a company that sells ECP/EPP cables for connecting to other ECP/EPP computers, as well as a universal cable for connecting any two parallel ports in order to use the highest speed.

Windows 95 and newer versions include a special program called DCC (Direct Cable Connection), which allows two systems to be networked together via a null modem/Laplink cable. Consult the Windows documentation for information on how to establish a DCC connection. Parallel Technologies has been contracted by Microsoft to supply the special DCC cables used to connect the systems. Parallel has one special type of cable that uses active electronics to ensure a reliable high-speed interconnection.

Parallel to SCSI Converters

Parallel ports can also be used to connect peripherals such as SCSI drives, scanners, or other devices to a PC. This is done by attaching a parallel to SCSI converter to the parallel port, and then you can attach any SCSI device to the SCSI port on the converter. Adaptec is the major supplier of such converters, but they are available from other companies as well.

With a parallel to SCSI converter, you can connect any type of SCSI device such as hard disks, CD-ROM drives, tape drives, Zip drives, or scanners to your PC, all via the parallel port. To connect to a SCSI device and also continue to be able to print, most parallel-to-SCSI converters include a pass-through connection for a printer.

This means that at one end of the converter you have a connection to your parallel port, and at the other end you have both SCSI and parallel-port connections. Thus, you can plug an SCSI device (or even multiple devices via a SCSI daisy chain), and still connect your printer as well. The drivers for the parallel to SCSI converter automatically pass through any information to the printer, so the printer works normally.

Testing Parallel Ports

Testing parallel ports is, in most cases, simpler than testing serial ports. The procedures are effectively the same as those used for serial ports, except that when you use the diagnostics software, you choose the obvious choices for parallel ports rather than serial ports.

Not only are the software tests similar, but the hardware tests require the proper plugs for the loopback tests on the parallel port. Several different loopback plugs are required, depending on what software you are using. Most use the IBM style loopback, but some use the style that originated in the Norton Utilities diagnostics.

The following wiring is needed to construct your own loopback or wrap plugs to test a parallel port:

- IBM 25-Pin Parallel (Male DB25P) Loopback Connector (Wrap Plug). Connect the following pins:
 - 1 to 13
 - 2 to 15
 - 10 to 16
 - 11 to 17
- Norton Utilities 25-Pin Parallel (Male DB25P) Loopback Connector (Wrap Plug). Connect the following pins:
 - 2 to 15
 - 3 to 13
 - 4 to 12
 - 5 to 10
 - 6 to 11

USB and 1394 (i.Link) FireWire—Serial and Parallel Port Replacements

The two most recently introduced high-speed serial-bus architectures for desktop and portable PCs are Universal Serial Bus (USB) and IEEE 1394, which is also called i.Link or FireWire. These are high-speed communications ports that far outstrip the capabilities of standard serial and parallel ports. They can be used as an alternative to SCSI for high-speed peripheral connections. In addition to performance, these newer ports offer I/O device consolidation, which means that all types of external peripherals can connect to these ports.

The recent trend in high-performance peripheral bus design is to use a serial architecture, where one bit at a time is sent down a wire. Parallel architecture uses 8, 16, or more wires to send bits simultaneously. At the same clock speed, the parallel bus is faster; however, it is much easier to increase the clock speed of a serial connection than that of a parallel connection.

Parallel connections suffer from several problems, the biggest being signal skew and jitter. Skew and jitter are the reasons that high-speed parallel buses such as SCSI are limited to short distances of three meters or less. The problem is that although the 8 or 16 bits of data are fired from the transmitter at the same time, by the time they reach the receiver, propagation delays have conspired to allow some bits to arrive before the others. The longer the cable, the longer the time between the arrival of the first and last bits at the other end! This signal skew, as it is called, prevents you from running a high-speed transfer rate or a longer cable—or both. Jitter is the tendency for the signal to reach its target voltage and float above and below for a short period of time.

With a serial bus, the data is sent one bit at a time. Because there is no worry about when each bit will arrive, the clocking rate can be increased dramatically.

With a high clock rate, parallel signals tend to interfere with each other. Serial again has an advantage because, with only one or two signal wires, crosstalk and interference between the wires in the cable are negligible.

In general, parallel cabling is more expensive than serial cabling. In addition to the many additional wires needed to carry the multiple bits in parallel, the cable also needs to be specially constructed to prevent crosstalk and interference between adjacent data lines. This is one reason external SCSI cables are so expensive. Serial cabling, on the other hand, is by comparison very inexpensive. For one thing, it has significantly fewer wires. Furthermore, the shielding requirements are far simpler, even at very high speeds. Because of this, it is also easier to transmit serial data reliably over longer distances, which is why parallel interfaces have shorter recommended cable lengths than do serial interfaces.

For these reasons—in addition to the need for new Plug-and-Play external peripheral interfaces and the elimination of the physical port crowding on portable computers—these high-performance serial buses were developed. USB is a standard feature on virtually all PCs today and is used for general purpose external interfacing, and 1394 is optional for certain niche markets such as connecting video devices.

USB (Universal Serial Bus)

USB is an external peripheral bus standard designed to bring Plug and Play capability for attaching peripherals externally to the PC. USB eliminates the need to install cards into dedicated slots and reconfigure the system and saves on important system resources such as interrupts (IRQs). PCs equipped with USB will allow peripherals to be automatically recognized and configured as soon as they are physically attached, without the need to reboot or run setup. USB allows up to 127 devices to run simultaneously on a computer, with peripherals such as monitors and keyboards acting as additional plug-in sites, or hubs. USB cables, connectors, hubs and peripherals can be identified by an icon, as shown in Figure 16.4.

Figure 16.4 This icon is used to identify USB cables, connectors, hubs, and peripherals.

Intel has been the primary proponent of USB, and all its PC chipsets starting with the PIIX3 South Bridge chipset component (introduced in February 1996) have included USB support as standard. Six other companies initially worked with Intel in co-developing the USB, including Compaq, Digital, IBM, Microsoft, NEC, and Northern Telecom. Together, these companies have established the USB Implementers Forum (USB-IF) to develop, support, and promote USB architecture.

◀◀ See “Chipsets,” p. 255.

The USB-IF formally released USB 1.0 in January 1996, and USB 1.1 in September of 1998. The 1.1 revision was mostly a clarification of some issues related to hubs and other areas of the specification. Most devices and hubs should be 1.1 compliant, even if they were manufactured before the release of the 1.1 specification. More recently the USB-IF released USB 2.0 which is 40 times faster than the original USB and yet fully backward compatible.

USB 1.1 is defined to run at 12Mbit/sec (1.5MB/sec) over a simple four-wire connection. The bus supports up to 127 devices and uses a tiered-star topology, built on expansion hubs that can reside in the PC, any USB peripheral, or even standalone hub boxes. Note that although the standard allows for up to 127 devices to be attached, they all have to share the 1.5MB/sec bandwidth, meaning that for every active device you add, the bus will slow down some. In practical reality, few people will have more than eight devices attached at any one time.

For low-speed peripherals such as pointing devices and keyboards, the USB also has a slower 1.5Mbit/sec subchannel. The subchannel connection is used for slower interface devices such as keyboards and mice.

USB employs what is called NRZI (Non Return to Zero Invert) data encoding. NRZI is a method of encoding serial data in which 1s and 0s are represented by opposite and alternating high and low voltages where there is no return to a zero (or reference) voltage between the encoded bits. In NRZI encoding, a 1 is represented by no change in signal level, and a 0 is represented by a change in level. A string of 0s causes the NRZI data to toggle each bit time. A string of 1s causes long periods with no transitions in the data. This is an efficient transfer encoding scheme because it eliminates the need for additional clock pulses that would otherwise waste time and bandwidth.

USB devices are considered either *hubs* or *functions*, or both. Hubs provide additional attachment points to the USB, allowing the attachment of additional hubs or functions. Functions are the individual devices that attach to the USB, for example a keyboard, mouse, camera, printer, telephone, and so on. The initial ports in the PC system unit are called the root hub, and they are the starting point for the USB. Most motherboards have two or four USB ports, either of which can be connected to functions or additional hubs.

Hubs are essentially wiring concentrators, and through a star-type topology they allow the attachment of multiple devices. Each attachment point is referred to as a port. Most hubs have either four or eight ports, but more are possible. For more expandability, you can connect additional hubs to the ports on an existing hub. The hub controls both the connection and distribution of power to each of the connected functions. A typical hub is shown in Figure 16.5.

Besides providing additional sockets for connecting USB peripherals, a hub provides power to any attached peripherals. A hub recognizes the dynamic attachment of a peripheral and provides at least 0.5W of power per peripheral during initialization. Under control of the host PC driver software, the hub may provide more device power, up to a maximum of 2.5W, for peripheral operation.

A newly attached hub is assigned a unique address, and hubs may be cascaded up to five levels deep. A hub operates as a bidirectional repeater and repeats USB signals as required both

upstream (toward the PC) and downstream (toward the device). A hub also monitors these signals and handles transactions addressed to itself. All other transactions are repeated to attached devices. A USB 1.1 hub supports both 12Mbit/sec (full-speed) and 1.5Mbit/sec (low-speed) peripherals.

Figure 16.5 A typical USB hub with eight ports.

Maximum cable length between two full-speed (12Mbit/sec) devices or a device and a hub (see Figure 16.6) is five meters using twisted pair shielded cable with 20 gauge wire. Maximum cable length for low speed (1.5Mbit/sec) devices using non-twisted pair wire is three meters. These distance limits are shorter if smaller-gauge wire is used (see Table 16.8).

Table 16.8 Maximum Cable Lengths Versus Wire Gauge

Gauge	Resistance (in Ohms/meter Ω/m)	Length (Max.)
28	0.232 Ω/m	0.81m
26	0.145 Ω/m	1.31m
24	0.091 Ω/m	2.08m
22	0.057 Ω/m	3.33m
20	0.036 Ω/m	5.00m

Although USB 1.1 is not as fast at data transfer as FireWire or SCSI, it is still more than adequate for the types of peripherals for which it is designed. USB 2.0 operates a surprising 40 times faster than USB 1.1 and allows transfer speeds of 480Mbit/sec or 60MB/sec.

Two different connectors are specified for USB, called Series A and Series B. The Series A connector is designed for devices where the cable remains permanently attached, such as hubs, keyboards, and mice. The USB ports on most motherboards are also normally a Series A connector. Series B connectors are designed for devices that require detachable cables, such as printers, scanners, modems, telephones, and speakers. The physical USB plugs are small and, unlike a typical serial or parallel cable, the plug is not attached by screws or thumbscrews. The USB plugs (shown in Figure 16.7) snap into place on the USB connector. Table 16.9 shows the pinout for the USB four-wire connector and cable.

Figure 16.6 A typical PC with USB devices can use multiple USB hubs to support a variety of different peripherals, connected to whichever hub is most convenient.

Figure 16.7 USB Series A and Series B plugs and receptacles.

Table 16.9 USB Connector Pinout

Pin	Signal Name	Wire Color	Comment
1	VCC	Red	Cable power
2	- Data	White	Data transfer

Pin	Signal Name	Wire Color	Comment
3	+ Data	Green	Data transfer
4	Ground	Black	Cable ground
Shell	Shield	-	Drain wire

USB conforms to Intel's Plug-and-Play (PnP) specification, including hot plugging, which means that devices can be plugged in dynamically without powering down or rebooting the system. Simply plug in the device, and the USB controller in the PC detects the device and automatically determines and allocates the required resources and drivers. Microsoft has developed USB drivers and included them automatically in Windows 95C, 98, and Windows 2000.

Note that the Windows 95B release or later is required for USB support; the necessary drivers are not present in the original Windows 95 or 95A. Windows 98 includes full USB support, as does Windows 2000. With Windows 95B, the USB drivers are not automatically included; they are provided separately, although a late release of Windows 95—Windows 95C—includes USB support. USB support is also required in the BIOS. This is included in newer systems with USB ports built in. After-market boards are also available for adding USB to systems that don't include it as standard on the motherboard. USB peripherals include modems, scanners, telephones, joysticks, keyboards, and pointing devices such as mice and trackballs.

One interesting feature of USB is that all attached devices are powered by the USB bus. The PnP aspects of USB allow the system to query the attached peripherals as to their power requirements and issue a warning if available power levels are being exceeded. This is important for USB when it is used in portable systems because the battery power that is allocated to run the external peripherals might be limited.

Another of the benefits of the USB specification is the self-identifying peripheral, a feature that greatly eases installation because you don't have to set unique IDs or identifiers for each peripheral—the USB handles that automatically. Also, USB devices can be "hot" plugged or unplugged, meaning that you do not have to turn off your computer or reboot every time you want to connect or disconnect a peripheral.

Virtually all motherboards built in the last few years have support for USB built in. One thing to keep in mind before purchasing USB peripherals is that your operating system must offer USB support. Whereas the original Windows 95 upgrade and Windows NT 4.0 do not support USB, the later OSR-2 (OEM Service Release 2) release of Windows 95 (also called 95B) does. Windows 95B will require that you add or install the USB drivers, while Windows 95C has them included on the Windows CD-ROM. Windows 98 and Windows 2000 have full support for USB. The USB standard has become an important bus technology.

One of the biggest advantages of an interface such as USB is that it only requires a single interrupt from the PC. This means that you can connect up to 127 devices and they will not use separate interrupts as they might if each were connected over a separate interface. This is a major benefit of the USB interface.

There are some unique USB devices available, including USB-to-serial, USB-to-parallel, USB-to-Ethernet, USB-to-SCSI, USB-to-PS/2 (standard keyboard and mouse port), and even direct-connect

USB bridges, which allow two systems to be connected together via USB. USB-to-serial or USB-to-parallel converters allow an easy way to connect legacy RS232 or Centronics parallel interface peripherals such as modems and printers to a USB port. USB-to-Ethernet adapters provide a LAN connection through a USB port. Drivers that are supplied with these devices allow them to fully emulate standard devices.

USB 2.0

USB 2.0 is a backward-compatible extension of the USB 1.1 specification that uses the same cables, connectors, and software interfaces, but that runs 40 times faster than the original 1.0 and 1.1 versions. The higher speed allows higher-performance peripherals such as video-conferencing cameras, scanners, printers, and storage devices to be connected externally with the same easy plug-and-play installation of current USB peripherals. From the end-user point of view, USB 2.0 works exactly the same as 1.1, only faster and with more interesting, higher-performance devices available. All existing USB 1.1 devices work in a USB 2.0 bus since USB 2.0 supports all the slower-speed connections. USB data rates are shown in Table 16.10.

Table 16.10 USB Data Rates

Interface	Megabits per Second	Megabytes per Second
USB 1.1 low speed	1.5Mbit/sec	0.1875MB/sec
USB 1.1 high speed	12Mbit/sec	1.5MB/sec
USB 2.0	480Mbit/sec	60MB/sec

The support of higher-speed USB 2.0 peripherals requires using a USB 2.0 hub. You can still use older USB 1.1 hubs on a 2.0 bus, but any peripherals or additional hubs connected downstream from a 1.1 hub will operate at the slower 1.5MB/sec USB 1.1 maximum speed. Devices connected to USB 2.0 hubs will operate at the maximum speed of the device, up to the full USB 2.0 speed of 60MB/sec. The higher transmission speeds through a 2.0 hub are negotiated on a device-by-device basis and if the higher speed is not supported by a peripheral, the link operates at a lower USB 1.1 speed.

As such, a USB 2.0 hub accepts high-speed transactions at the faster USB 2.0 frame rate and must deliver them to high-speed USB 2.0 peripherals as well as USB 1.1 peripherals. This data rate matching responsibility will require increased complexity and buffering of the incoming high-speed data. When communicating with an attached USB 2.0 peripheral, the 2.0 hub simply repeats the high-speed signals; however, when communicating with USB 1.1 peripherals, a USB 2.0 hub will buffer and manage the transition from the high speed of the USB 2.0 host controller (in the PC) to the lower speed of a USB 1.1 device. This feature of USB 2.0 hubs means that USB 1.1 devices can operate along with USB 2.0 devices and not consume any additional bandwidth.

USB Adapters

If you still have a variety of older peripherals and yet you want to take advantage of the USB connector on your motherboard, there are a number of signal converters or adapters available. Companies like Belkin and others currently have adapters in the following types:

- USB-to-parallel (printer)
- USB-to-serial
- USB-to-SCSI
- USB-to-Ethernet
- USB-to-keyboard/mouse
- USB-to-TV/video

These adapters normally look just like a cable, with a USB connector at one end (which you plug into your USB port), and various other interface connectors at the other end. There is more to these devices than just a cable: There are active electronics hidden in a module along the cable or sometimes packed into one of the cable ends. The electronics is powered by the USB bus and converts the signals to the appropriate other interface.

There are some drawbacks to these adapters. One is cost—they normally cost from \$50 to \$100 or more. It can be tough to spend \$70 on a USB-to-parallel adapter to drive a printer that barely cost twice that amount. There are also other limitations that might apply. For example, USB-to-parallel converters work only with printers and not other parallel-connected devices like scanners, cameras, external drives, and so on. Before purchasing one of these adapters, make sure it will work with the device or devices you had in mind.

Another type of adapter available is a direct-connect cable, which allows you to connect two USB-equipped PCs directly together using USB as a network. These are popular for people playing two-player games, with each player on his own system. Another use is for transferring files, as this connection usually works as good or better than the direct parallel connection that otherwise might be used. Also available are USB switchboxes that allow one peripheral to be shared among two or more USB buses. Note that both the direct connect cables and USB switchboxes are technically not allowed as a part of the USB specification, although they do exist.

Legacy-Free PCs

USB adapters may find more use in the future as more and more legacy-free PCs are shipped. A *legacy-free PC* is one that lacks any components that were connected to or a part of the traditional ISA bus. This especially includes the otherwise standard Super I/O chip, which integrated serial, parallel, keyboard, mouse, floppy, and other connections. A legacy-free motherboard will therefore not have the standard serial, parallel, and keyboard/mouse connectors on the back and will also lack an integrated floppy controller. The devices that were previously connected to those ports must instead be connected via USB, ATA, PCI, and other interfaces.

Legacy-free systems will primarily be found on the low-end, consumer-oriented systems. For those systems USB will likely be one of the only external connections provided. To compensate for the loss of the other external interfaces, most legacy-free motherboards will feature four or more integrated USB connectors on one or two buses.

IEEE-1394 (Also Called i.Link or FireWire)

IEEE-1394 (or just 1394 for short) is a relatively new bus technology; it is the result of the large data-moving demands of today's audio and video multimedia devices. It is extremely fast, with

data transfer rates up to an incredible 400Mbit/sec, and even faster speeds are being developed. The IEEE-1394 (as it is officially known) specification was published by the IEEE Standards Board in late 1995. IEEE is shorthand for *The Institute of Electrical and Electronic Engineers*, the group that wrote the standard. The number comes from the fact that this happened to be the 1394th standard that they published.

1394 also goes under two other common names: i.Link and FireWire. *i.Link* is a recently unveiled IEEE-1394 designation initiated by Sony in an effort to put a more user-friendly name on IEEE-1394 technology. Most companies that produce 1394 products for PCs have endorsed this new name initiative. The term *FireWire* is an Apple-specific trademark. Companies that want to include the FireWire name in a 1394 product must first sign a licensing agreement with Apple, something not all companies that are producing PC products have done.

The IEEE-1394 standard currently exists with three different signaling rates—100-, 200-, and 400Mbit/sec (12.5-, 25-, 50MB/sec)—and there are gigabit-per-second versions in the works! Most PC adapter cards support the 200Mbit/sec rate, even though current devices generally only operate at 100Mbit/sec. A maximum of 63 devices can be connected to a single IEEE-1394 adapter card by way of daisy chaining or branching. Cables for IEEE-1394 devices use Nintendo GameBoy–derived connectors and consist of six conductors: Four wires transmit data and two wires conduct power. Connection with the motherboard is made either by a dedicated IEEE-1394 interface or by a PCI adapter card. Figure 16.8 shows the 1394 cable, socket, and connector.

Figure 16.8 IEEE-1394 cable, socket, and connector plug.

The 1394 bus derived from the FireWire bus that was originally developed by Apple and Texas Instruments, and it is also a part of the new Serial SCSI standard that is discussed later in this chapter.

1394 uses a simple six-wire cable with two differential pairs of clock and data lines, plus two power lines. Just as with USB, 1394 is fully PnP, including the capability for hot plugging (insertion and removal of components without powering down). Unlike the much more complicated parallel SCSI bus, 1394 does not require complicated termination, and devices that are connected to the bus can draw up to 1.5 amps of electrical power. 1394 offers equal or greater performance compared to ultra-wide SCSI, with a much less expensive and less complicated connection.

1394 is built on a daisy-chained and branched topology, and it allows up to 63 nodes, with a chain of up to 16 devices on each node. If this is not enough, the standard also calls for up to 1,023 bridged buses, which can interconnect more than 64,000 nodes! Additionally, as with SCSI, 1394 can support devices with different data rates on the same bus. Most 1394 adapters have three nodes, each of which can support 16 devices in a daisy-chain arrangement.

The types of devices that can be connected to the PC via 1394 include all forms of disk drives, including hard disk, optical, floppy, CD-ROM, and DVD-ROM drives. Also, digital cameras, tape drives, and many other high-speed peripherals that feature 1394 have interfaces built in. Expect the 1394 bus to be implemented in both desktop and portable computers as a replacement for other external high-speed buses such as SCSI.

Chipsets and PCI adapters for the 1394 bus are available from several manufacturers. Microsoft has developed drivers to support 1394 in Windows 95/98/2000 and Windows NT. The most popular devices that conform to the IEEE-1394 standard are primarily camcorders and VCRs with digital video (DV) capability. Sony was among the first to release such devices, under the i.Link name. In typical Sony fashion, however, its products have a unique four-wire connector that requires an adapter cord to be used with IEEE-1394 PC cards, and Sony doesn't even call it IEEE-1394 or FireWire, but created its own designation (i.Link) instead. DV products using 1394 are also available from Panasonic, Sharp, Matsushita, and others. IEEE-1394 applications include DV conferencing devices, satellite audio and video data streams, audio synthesizers, DVD, and other high-speed disc drives.

Because of the current DV emphasis for IEEE-1394 peripherals, most PC cards that are currently offered by Adaptec, FAST Multimedia, Matrox, and others involve DV capturing and editing. With a DV camera or recording equipment, these items provide substantial video editing and dubbing capabilities on your PC. Of course, you need IEEE-1394 I/O connectivity, which is still a rarity on current motherboards. Fortunately, Adaptec and Texas Instruments both offer PCI adapter cards that support IEEE-1394.

Because of the similarity in both the form and function of USB and 1394, there has been some confusion about the two. Table 16.11 summarizes the differences between the two technologies.

Table 16.11 IEEE-1394 and USB Comparison

	IEEE-1394 (a.k.a. i.Link; FireWire)	USB 1.1	USB 2.0
PC-host required	No	Yes	Yes
Max. no. of devices	63	127	127
Hot-swappable?	Yes	Yes	Yes
Max. cable length between devices	4.5 meters	5 meters	5 meters
Transfer rate	200Mbps (25MB/sec)	12Mbps (1.5MB/sec)	480Mbps (60MB/sec)
Proposed future transfer rates	400Mbps (50MB/sec) 800Mbps (100MB/sec) 1Gbps+ (125MB/sec+)	None	None
Typical devices	-DV camcorders -high-res digital cameras -HDTV -set-top boxes -high-speed drives -high-res scanners -electronic musical instruments	-keyboards -mice -joysticks -low-res digital cameras -low-speed drives -modems -printers -low-res scanners	All USB 1.1 devices plus: -DV camcorders -high-res digital cameras -HDTV -set-top boxes -high-speed drives -high-res scanners

The main differences are popularity, PC- or non-PC-centricity, and speed. USB is by far the most popular external interface, eclipsing all others by comparison.

In the future, practically all PCs will include USB 2.0 as standard, but are unlikely to have 1394 as an integral interface. This is largely controlled by Intel, which has integrated USB into all its motherboard chipsets since 1996 and will likely not integrate 1394 and 1394 interfaces. All this means is that to use 1394, bus adapter cards will be required.

Even with the overwhelming popularity of USB, there is still a market for 1394. Perhaps the main reason 1394 will survive in the shadow of the popular high-speed USB 2.0 interface is that USB is PC-centric whereas 1394 is not. USB requires a PC as the host, but an important benefit of 1394 is that a PC host connection is not required. As such, 1394 can be used to directly connect a digital video (DV) camcorder to a DV-VCR for dubbing tapes or editing. This is one reason it will remain popular in the digital video environment, even with the advent of USB 2.0.

As for speed, that is a constantly changing parameter. 1394 offers a data transfer rate that is more than 16 times faster than that of USB 1.1, but that is less than half as fast as USB 2.0. This speed differential will change again in the future as higher-speed versions of 1394 debut. USB 1.1 is clearly designed for low-speed peripherals such as keyboards, mice, modems, and printers, whereas USB 2.0 can be used to connect most high-speed external devices. 1394 will be used to connect mostly high-performance digital video electronics products.

In general, IEEE-1394 offers unprecedented multimedia capabilities to current and future PC users. Current peripherals—particularly DV devices—are still fairly expensive, but as with any emerging technology, prices should come down in the future, opening the door wide for new PC uses in both the home and office. A great number of people would gain the capability to do advanced audio and video editing. If you anticipate having multimedia needs on your PC in the future, IEEE-1394 will likely be the interface of choice.

CHAPTER 17

Input Devices

Keyboards

One of the most-basic system components is the keyboard, which is the primary input device. It is used for entering commands and data into the system. This section looks at the keyboards available for PC-compatible systems, examining the different types of keyboards, how the keyboard functions, the keyboard-to-system interface, and keyboard troubleshooting and repair.

In the years since the introduction of the original IBM PC, IBM has created three different keyboard designs for PC systems; Microsoft has augmented one of them. These designs have become de facto standards in the industry and are shared by virtually all PC manufacturers. With the introduction of Windows 95, a modified version of the standard 101-key design (created by Microsoft) appeared, called the 104-key Windows keyboard.

The primary keyboard types are as follows:

- 101-key Enhanced keyboard
- 104-key Windows keyboard
- 83-key PC and XT keyboard (obsolete)
- 84-key AT keyboard (obsolete)

This section discusses the 101-key Enhanced keyboard and the 104-key Windows keyboard, showing the layout and physical appearance of both. Although you can still find old systems that use the 83-key and 84-key designs, these are rare today. Because all new systems today use the 101- and 104-key keyboard designs, these versions are covered here.

Note

If you need to learn more about the 83-key PC and XT keyboard or the 84-key AT keyboard, see Chapter 7 of *Upgrading and Repairing PCs, Tenth Anniversary Edition*, on the CD included with this book.

Enhanced 101-Key (or 102-Key) Keyboard

In 1986, IBM introduced the “corporate” Enhanced 101-key keyboard for the newer XT and AT models (see Figure 17.1). I use the word corporate because this unit first appeared in IBM’s RT PC, which was a RISC (Reduced Instruction Set Computer) system designed for scientific and engineering applications. Keyboards with this design were soon supplied with virtually every type of system and terminal that IBM sold. Other companies quickly copied this design, which has been the standard on Intel-based PC systems ever since.

The layout of this universal keyboard was improved over that of the 84-key unit, with perhaps the exception of the Enter key, which reverted to a smaller size. The 101-key Enhanced keyboard was designed to conform to international regulations and specifications for keyboards. In fact, other companies, such as Digital Equipment Corporation (DEC) and Texas Instruments (TI), had already been using designs similar to the IBM 101-key unit. The IBM 101-key units originally came in versions with and without the status indicator LEDs, depending on whether the unit was sold with an XT or AT system. Now there are many other variations to choose from, including some with integrated pointing devices.

Figure 17.1 101-key Enhanced keyboard layout.

The Enhanced keyboard is available in several different variations, but all are basically the same electrically and all can be interchanged. IBM and its Lexmark keyboard and printer spinoff have produced a number of keyboards, including versions with built-in pointing devices and new ergonomic layouts. Some of the Enhanced keyboards still attach to the system via the five-pin DIN (an acronym for Deutsche Industrie Norm) connector, but most today come with cables for the six-pin mini-DIN connector introduced on the IBM PS/2s. Although the connectors might be physically different, the keyboards are not, and you can either interchange the cables or use a cable adapter to plug one type into the other.

The 101-key keyboard layout can be divided into the following four sections:

- Typing area
- Numeric keypad
- Cursor and screen controls
- Function keys

The 101-key arrangement is similar to the Selectric keyboard layout, with the exception of the Enter key. The Tab, Caps Lock, Shift, and Backspace keys have a larger striking area and are located in the familiar Selectric locations. Ctrl and Alt keys are on each side of the spacebar. The typing area and numeric keypad have home-row identifiers for touch typing.

The cursor- and screen-control keys have been separated from the numeric keypad, which is reserved for numeric input. (As with other PC keyboards, you can use the numeric keypad for cursor and screen control when the keyboard is not in Num Lock mode.) A division-sign key (/) and an additional Enter key have been added to the numeric keypad.

The cursor-control keys are arranged in the inverted T format that is now expected on all computer keyboards. The Insert, Delete, Home, End, Page Up, and Page Down keys, located above the dedicated cursor-control keys, are separate from the numeric keypad. The function keys, spaced in groups of four, are located across the top of the keyboard. The keyboard also has two additional function keys: F11 and F12. The Esc key is isolated in the upper-left corner of the keyboard. Dedicated Print Screen/Sys Req, Scroll Lock, and Pause/Break keys are provided for commonly used functions.

Foreign-language versions of the Enhanced keyboard include 102 keys and a slightly different layout from the 101-key U.S. versions.

One of the many useful features of the IBM/Lexmark enhanced keyboard is removable keycaps. This permits the replacement of broken keys and provides access for easier cleaning. Also, with clear keycaps and paper inserts, you can customize the keyboard. Keyboard templates are also available to provide specific operator instructions.

104-Key (Windows 95/98 Keyboard)

If you are a touch typist as I am, you probably really hate to take your hands off the keyboard to use a mouse. Windows 95 and 98 make this even more of a problem because they use both mouse buttons (the right button is used to open shortcut menus). Many new keyboards, especially those in portable computers, include a variation of the IBM TrackPoint or the Alps Glidepoint pointing devices (discussed later in this chapter), which allow touch typists to keep their hands on the keyboard even while moving the pointer. However, there is still another alternative that can help. Microsoft has come up with a specification that calls for three new Windows-specific keys to be added to the keyboard. These new keys help with functions that would otherwise require multiple keystrokes or mouse clicks.

The Microsoft Windows keyboard specification outlines a set of new keys and key combinations. The familiar 101-key layout has now grown to 104 keys, with the addition of left and right Windows keys and an Application key. These keys are used for operating-system and application-level keyboard combinations, similar to today's Ctrl and Alt combinations. You don't need the new keys to use Windows 95/98 or NT or Windows 2000, but software vendors are starting to add specific functions to their Windows products that use the new Application key (which provides the same functionality as clicking with the right mouse button). Figure 17.2 shows the standard Windows keyboard layout, including the three new keys.

Figure 17.2 104-key Windows keyboard layout.

The recommended Windows keyboard layout calls for the Left and Right Windows keys (called WIN keys) to flank the Alt keys on each side of the spacebar, as well as an Application key on the right of the Right Windows key. Note that the exact placement of these keys is up to the keyboard designer, so you will see variations from keyboard to keyboard.

The WIN keys open the Windows Start menu, which you can then navigate with the cursor keys. The Application key simulates the right mouse button; in most applications, it brings up a context-sensitive pop-up menu. Several WIN key combinations offer preset macro commands as well. For example, you press WIN+E to launch the Windows Explorer application. The following table shows a list of all the Windows 9x key combinations.

Key Combination	Resulting Action
WIN+R	Run dialog box
WIN+M	Minimize All
Shift+WIN+M	Undo Minimize All
WIN+D	Minimize All or Undo Minimize All
WIN+F1	Help
WIN+E	Start Windows Explorer
WIN+F	Find Files or Folders
Ctrl+WIN+F	Find Computer
WIN+Tab	Cycle through taskbar buttons
WIN+Break	System Properties dialog box
Application key	Displays a context menu for the selected item

When a 104-key Windows keyboard is used with Microsoft IntelliType Software installed, the following additional key combinations can be used:

Key Combination	Resulting Action
WIN+L	Log off Windows
WIN+P	Opens Print Manager
WIN+C	Opens the control panel
WIN+V	Opens Clipboard
WIN+K	Opens Keyboard Properties dialog box
WIN+I	Opens Mouse Properties dialog box
WIN+A	Opens Accessibility Options (if installed)
WIN+spacebar	Displays the list of IntelliType hotkeys
WIN+S	Toggles the Caps Lock key on and off

The Windows keyboard specification requires that keyboard makers increase the number of trilograms in their keyboard designs. A *trilogram* is a combination of three rapidly pressed keys that perform a special function, such as Ctrl+Alt+Delete. Designing a keyboard so that the switch matrix will correctly register the additional trilograms plus the additional Windows keys add somewhat to the cost of these keyboards compared to standard 101-key models.

Many keyboard manufacturers are now producing keyboards with these Windows-specific keys.

The new Windows keys are not mandatory when running Windows. In fact there are preexisting standard key combinations that perform the same functions as these new keys. I have also noticed that few people who have these extra keys on their keyboards actually use them. Because of these factors and the fact that adding these keys increases the cost of the keyboard, the new keys have not been universally accepted by all PC manufacturers. Some manufacturers have added browser control or other keys that, although are not standard, can make them easier to use for viewing Web pages.

Portable Keyboards

One of the biggest influences on keyboard design in recent years has been the proliferation of laptop and notebook systems. Because of size limitations, it is obviously impossible to use the standard keyboard layout for a portable computer. Manufacturers have come up with many different solutions. Unfortunately, none of these solutions has become an industry standard, as is the 101-key layout. Because of the variations in design, and because a portable system keyboard is not as easily replaceable as that of a desktop system, the keyboard arrangement should be an important part of your purchasing decision.

Early laptop systems often used smaller than normal keys to minimize the size of the keyboard, which resulted in many complaints from users. Today, the keytops on portable systems are usually comparable in size to that of a desktop keyboard, although some systems include half-sized keytops for the function keys and other lesser-used keyboard elements. In addition, consumer demand has caused most manufacturers to retain the inverted-T design for the cursor keys after a few abortive attempts at changing their arrangement.

Of course, the most obvious difference in a portable system keyboard is the sacrifice of the numeric keypad. Most systems now embed the keypad into the standard alphabetical part of the keyboard, as shown in Figure 17.3. To switch the keys from their standard values to their keypad values, you typically must press a key combination involving a proprietary function key, often labeled Fn.

Figure 17.3 Most portable systems today embed the numeric keypad into an oddly shaped block of keys on the alphabetical part of the keyboard.

This is an extremely inconvenient solution, and many users abandon their use of the keypad entirely on portable systems. Unfortunately, some activities, such as the entry of ASCII codes

using the Alt key, require the use of the keypad numbers, which can be quite frustrating on systems using this arrangement.

To alleviate this problem, many portable system manufacturers sell external numeric keypads that plug into either the external keyboard port or, on some systems, a serial port. This is a great feature for somebody doing a lot of numeric data entry.

In addition to keypad control, the Fn key is often used to trigger other proprietary features in portable systems, such as toggling between an internal and external display and controlling screen brightness and sound volume.

Some portable system manufacturers have gone to great lengths to provide users with adequate keyboards. For a short time, IBM marketed systems with a keyboard that used a “butterfly” design. The keyboard was split into two halves that rested on top of one another when the system was closed. When you opened the lid, the two halves separated to rest side by side, forming a keyboard that was actually larger than the computer case.

Ironically, the trend toward larger-sized displays in portable systems has made this sort of arrangement unnecessary. Many manufacturers have increased the footprint of their notebook computers to accommodate 12- and even 14-inch display panels, leaving more than adequate room for a full-sized keyboard.

▶▶ See “Keyboards,” p. 1313.

Num Lock

On IBM systems that support the Enhanced keyboard, when the system detects the keyboard on power-up, it enables the Num Lock feature and the light goes on. If the system detects an older 84-key AT-type keyboard, it does not enable the Num Lock function because these keyboards do not have cursor keys separate from the numeric keypad. When the Enhanced keyboards first appeared in 1986, many users (including me) were irritated to find that the numeric keypad was automatically enabled every time the system booted. Most system manufacturers subsequently began integrating a function into the BIOS setup that enabled you to specify the Num Lock status imposed during the boot process.

Some users thought that the automatic enabling of Num Lock was a function of the Enhanced keyboard because none of the earlier keyboards seemed to operate in this way. Remember that this function is not really a keyboard function but instead a function of the motherboard ROM BIOS, which identifies an Enhanced 101-key unit and turns on the Num Lock as a “favor.” In systems with a BIOS that cannot control the status of the numeric keypad, you can use the DOS 6.0 or higher version `NUMLOCK=` parameter in `CONFIG.SYS` to turn Num Lock on or off, as desired. If you are running a version of DOS earlier than 6.0, you can use one of the many public domain programs available for controlling the Num Lock function. Running the program from the `AUTOEXEC.BAT` file can set the numeric keypad status whenever the system reboots.

Keyboard Technology

The technology that makes up a typical PC keyboard is very interesting. This section focuses on all the aspects of keyboard technology and design, including the keyswitches, the interface between the keyboard and the system, the scan codes, and the keyboard connectors.

Keyswitch Design

Today's keyboards use any one of several switch types to create the action for each key. Most keyboards use a variation of the mechanical keyswitch. A mechanical keyswitch relies on a mechanical momentary contact type switch to make the electrical contact that forms a circuit. Some high-end keyboards use a totally different nonmechanical design that relies on capacitive switches. This section discusses these switches and the highlights of each design.

The most common type of keyswitch is the mechanical type, available in the following variations:

- Pure mechanical
- Foam element
- Rubber dome
- Membrane

Pure Mechanical Switches

The pure mechanical type is just that—a simple mechanical switch that features metal contacts in a momentary contact arrangement. The switch often includes a tactile feedback mechanism, consisting of a clip and spring arrangement designed to give a “clicky” feel to the keyboard and offer some resistance to the keypress. Several companies, including Alps Electric, Lite-On, and NMB Technologies, manufacture this type of keyboard using switches obtained primarily from Alps Electric. Mechanical switches are very durable, usually have self-cleaning contacts, and are normally rated for 20 million keystrokes, which is second only to the capacitive switch in longevity. They also offer excellent tactile feedback.

Foam Element Switches

Foam element mechanical switches were a very popular design in some older keyboards. Most of the older PC keyboards, including those made by Keytronics and many others, use this technology. These switches are characterized by a foam element with an electrical contact on the bottom. This foam element is mounted on the bottom of a plunger that is attached to the key (see Figure 17.4).

When the switch is pressed, a foil conductor on the bottom of the foam element closes a circuit on the printed circuit board below. A return spring pushes the key back up when the pressure is released. The foam dampens the contact, helping to prevent bounce, but unfortunately gives these keyboards a “mushy” feel. The big problem with this type of keyswitch design is that there is often little tactile feedback. These types of keyboards send a clicking sound to the system speaker to signify that contact has been made. Compaq has used keyboards of this type (made by Keytronics) in many of its systems. Preferences in keyboard feel are somewhat subjective; I personally do not favor the foam element switch design.

Another problem with this type of design is that it is more subject to corrosion on the foil conductor and the circuit board traces below. When this happens, the key strikes might become intermittent, which can be frustrating. Fortunately, these keyboards are among the easiest to

clean. By disassembling the keyboard completely, you can usually remove the circuit board portion—without removing each foam pad separately—and expose the bottoms of all the pads. Then you can easily wipe the corrosion and dirt off the bottom of the foam pads and the circuit board, thus restoring the keyboard to a “like-new” condition. Unfortunately, over time, the corrosion problem will occur again. I recommend using some Stabilant 22a from D.W. Electrochemicals to improve the switch contact action and prevent future corrosion. Because of such problems, the foam element design is not used much anymore and has been superseded in popularity by the rubber dome design.

Figure 17.4 Typical foam element mechanical keyswitch.

Rubber Dome Switches

Rubber dome switches are mechanical switches that are similar to the foam element type but are improved in many ways. Instead of a spring, these switches use a rubber dome that has a carbon button contact on the underside. As you press a key, the key plunger presses on the rubber dome, causing it to resist and then collapse all at once, much like the top of an oil can. As the rubber dome collapses, the user feels the tactile feedback, and the carbon button makes contact between the circuit board traces below. When the key is released, the rubber dome re-forms and pushes the key back up.

The rubber eliminates the need for a spring and provides a reasonable amount of tactile feedback without any special clips or other parts. Rubber dome switches use a carbon button because it resists corrosion and because it has a self-cleaning action on the metal contacts below. The rubber domes themselves are formed into a sheet that completely protects the contacts below from dirt, dust, and even minor spills. This type of switch design is the simplest, and it uses the fewest parts. This makes the rubber dome keyswitch very reliable and helps make the keyboards that use it the most popular in service today.

If the rubber dome keyboard has any drawback, it is that the tactile feedback is not as good as many users would like. Although many people find its touch acceptable, some users prefer more tactile feedback than rubber dome keyboards normally provide.

Membrane Switches

The membrane keyboard is a variation on the rubber dome type. The keys themselves are no longer separate, but instead are formed together in a sheet that sits on the rubber dome sheet. This arrangement severely limits key travel. For this reason, membrane keyboards are not considered usable for normal touch typing. However, they are ideal for use in extremely harsh environments. Because the sheets can be bonded together and sealed from the elements, membrane keyboards can be used in situations in which no other type could survive. Many industrial applications use membrane keyboards for terminals that do not require extensive data entry but are used instead to operate equipment, such as cash registers.

Capacitive switches are the only nonmechanical types of keyswitch in use today (see Figure 17.5). The capacitive switch is the Cadillac of keyswitches. It is much more expensive than the more common mechanical rubber dome, but it is more resistant to dirt and corrosion and offers the highest-quality tactile feedback of any type of switch.

Figure 17.5 A capacitive keyswitch.

A capacitive switch does not work by making contact between conductors. Instead, two plates usually made of plastic are connected in a switch matrix designed to detect changes in the capacitance of the circuit.

When the key is pressed, the plunger moves the top plate in relation to the fixed bottom plate. Usually a mechanism provides for a distinct over-center tactile feedback with a resounding “click.” As the top plate moves, the capacitance between the two plates changes. The comparator circuitry in the keyboard detects this change.

Because this type of switch does not rely on metal contacts, it is nearly immune to corrosion and dirt. These switches are very resistant to the key bounce problems that result in multiple characters appearing from a single strike. They are also the most durable in the industry—rated for 25 million or more keystrokes, as opposed to 10 to 20 million for other designs. The tactile feedback is unsurpassed because the switch provides a relatively loud click and a strong over-center feel. The only drawback to the design is the cost. Capacitive switch keyboards are among the most expensive designs. The quality of the feel and their durability make them worth the price, however.

Traditionally, the only vendors of capacitive keyswitch keyboards have been IBM and the inheritors of its keyboard technology, Lexmark and Unicomp.

The Keyboard Interface

A keyboard consists of a set of switches mounted in a grid or array called the *key matrix*. When a switch is pressed, a processor in the keyboard identifies which key is pressed by determining which grid location in the matrix shows continuity. The keyboard processor, which also interprets how long the key is pressed, can even handle multiple keypresses at the same time. A 16-byte hardware buffer in the keyboard can handle rapid or multiple keypresses, passing each one to the system in succession.

When you press a key, the contact bounces slightly in most cases, meaning that there are several rapid on/off cycles just as the switch makes contact. This is called *bounce*. The processor in the keyboard is designed to filter this, or debounce the keystroke. The keyboard processor must distinguish bounce from a double key strike that the keyboard operator intends to make. This is fairly easy because the bouncing is much more rapid than a person could simulate by striking a key quickly several times.

The keyboard in a PC is actually a computer itself. It communicates with the main system through a special serial data link. This link transmits and receives data in 11-bit packets of information, consisting of eight data bits, plus framing and control bits. Although it is indeed a serial link (in that the data flows on one wire), the keyboard interface is incompatible with the standard RS-232 serial port commonly used to connect modems.

The processor in the original PC keyboard was an Intel 8048 microcontroller chip. Newer keyboards often use an 8049 version that has built-in ROM or other microcontroller chips compatible with the 8048 or 8049. For example, in its Enhanced keyboards, IBM has always used a custom version of the Motorola 6805 processor, which is compatible with the Intel chips. The keyboard's built-in processor reads the key matrix, debounces the keypress signals, converts the keypress to the appropriate scan code, and transmits the code to the motherboard. The processors built into the keyboard contain their own RAM, possibly some ROM, and a built-in serial interface.

In the original PC/XT design, the keyboard serial interface is connected to an 8255 Programmable Peripheral Interface (PPI) chip on the motherboard of the PC/XT. This chip is connected to the interrupt controller IRQ1 line, which is used to signal to the system that keyboard data is available. The data is sent from the 8255 to the processor via I/O port address 60h. The IRQ1 signal causes the main system processor to run a subroutine (INT 9h) that interprets the keyboard scan code data and decides what to do.

In an AT-type keyboard design, the keyboard serial interface is connected to a special keyboard controller on the motherboard. This controller is an Intel 8042 Universal Peripheral Interface (UPI) slave microcontroller chip in the original AT design. This microcontroller is essentially another processor that has its own 2KB of ROM and 128 bytes of RAM. An 8742 version that uses EPROM (Erasable Programmable Read Only Memory) can be erased and reprogrammed. In the past, when you purchased a motherboard ROM upgrade from a motherboard manufacturer for an older system, the upgrade included a new keyboard controller chip as well because it had

somewhat dependent and updated ROM code in it. Some systems might use the 8041 or 8741 chips, which differ only in the amount of built-in ROM or RAM, whereas other systems now have the keyboard controller built into the main system chipset.

In an AT system, the (8048-type) microcontroller in the keyboard sends data to the (8042-type) keyboard controller on the motherboard. The motherboard-based controller can also send data back to the keyboard. When the keyboard controller on the motherboard receives data from the keyboard, it signals the motherboard with an IRQ1 and sends the data to the main motherboard processor via I/O port address 60h, just as in the PC/XT. Acting as an agent between the keyboard and the main system processor, the 8042-type keyboard controller can translate scan codes and perform several other functions as well. The system can also send data to the 8042 keyboard controller via port 60h, which then passes it on to the keyboard. Additionally, when the system needs to send commands to or read the status of the keyboard controller on the motherboard, it reads or writes through I/O port 64h. These commands are usually followed by data sent back and forth via port 60h.

In older systems, the 8042 keyboard controller is also used by the system to control the A20 memory address line, which provides access to system memory greater than 1MB. More modern motherboards usually incorporate this functionality directly into the motherboard chipset.

Typematic Functions

If a key on the keyboard is held down, it becomes *typematic*, which means the keyboard repeatedly sends the keypress code to the motherboard. In the AT-style keyboards, the typematic rate is adjusted by sending the appropriate commands to the keyboard processor. This is impossible for the earlier PC/XT keyboard types because the keyboard interface for these types is not bidirectional.

AT-style keyboards have programmable typematic repeat rate and delay parameters. Most operating systems include functions that enable you to adjust these parameters to your own specifications. In Windows you use the Keyboard control panel. In DOS, you use the `MODE` command.

Adjusting Keyboard Parameters in Windows

You can modify the default values for the typematic repeat rate and delay parameters in any version of Windows using the Keyboard control panel. The Repeat Delay slider controls the number of times a key must be pressed before the character begins to repeat, and the Repeat Rate slider controls how fast the character repeats after the delay has elapsed.

Note

The increments on the Repeat Delay and Repeat Rate sliders in the Keyboard control panel correspond to the timings given for the `MODE` command's `RATE` and `DELAY` values, as listed in Tables 17.1 and 17.2 later in this chapter. In those tables you can see that each mark in the Repeat Delay slider adds about 0.25 seconds to the delay, and the marks in the Repeat Rate slider are worth about one character per second each.

The dialog box also contains a text box you can use to test the settings you have chosen before committing them to your system. When you click in the box and press a key, the keyboard reacts using the settings currently specified by the sliders, even if you have not yet applied the changes to the Windows environment.

Adjusting Keyboard Parameters in DOS

In DOS versions 4.0 and later, the `MODE` command enables you to set the keyboard typematic (repeat) rate, as well as the delay, before typematic action begins. The default value for the `RATE` parameter (`r`) is 20 for most PC systems and 21 for IBM PS/2 systems. The default value for the `DELAY` parameter (`d`) is 2. Therefore, for most systems, the standard keyboard typematic speed is 10cps (characters per second), and the delay before typematic action occurs is 0.5 seconds.

To use the DOS `MODE` command to reset the keyboard typematic rate and delay, use the following command:

```
MODE CON[:] [RATE=r DELAY=d]
```

The acceptable values for the rate `r` and the resulting typematic rate in cps are shown in Table 17.1.

Table 17.1 DOS 4.0+ MODE Command Keyboard Typematic Rate Parameters

Rate No.	Rate \pm 20%	Rate No.	Rate \pm 20%	Rate No.	Rate \pm 20%
32	30.0cps	21	10.9cps	10	4.3cps
31	26.7cps	20	10.0cps	9	4.0cps
30	24.0cps	19	9.2cps	8	3.7cps
29	21.8cps	18	8.6cps	7	3.3cps
28	20.0cps	17	8.0cps	6	3.0cps
27	18.5cps	16	7.5cps	5	2.7cps
26	17.1cps	15	6.7cps	4	2.5cps
25	16.0cps	14	6.0cps	3	2.3cps
24	15.0cps	13	5.5cps	2	2.1cps
23	13.3cps	12	5.0cps	1	2.0cps
22	12.0cps	11	4.6cps		

Table 17.2 shows the values for `DELAY` and the resulting delay time in seconds.

Table 17.2 DOS MODE Command Keyboard Typematic Delay Parameters

DELAY No.	Delay Time
1	0.25sec
2	0.50sec
3	0.75sec
4	1.00sec

For example, when running DOS, I always place the following command in my AUTOEXEC.BAT file:

```
MODE CON: RATE=32 DELAY=1
```

This command sets the typematic rate to the maximum speed possible, or 30cps. It also trims the delay to the minimum of 0.25 seconds before repeating begins. This command “turbocharges” the keyboard and makes operations requiring repeated keystrokes work much faster, such as moving within a file by using arrow keys. The quick typematic action and short delay can be disconcerting to some keyboard operators. Slower typists might want to leave their keyboard speed at the default until they become more proficient.

Note

Note that if you are working on a very old system or keyboard, you might get the following message:

```
Function not supported on this computer
```

This indicates that your system, keyboard, or both do not support the bidirectional interface or the commands required to change the typematic rate and delay. Upgrading the BIOS or the keyboard might enable this function, but it is probably not cost effective to do it on an older system.

Note

Some BIOS versions feature keyboard speed selection capability; however, not all of them allow for full control over the speed and delay.

Keyboard Key Numbers and Scan Codes

When you press a key on the keyboard, the processor built into the keyboard (8048- or 6805-type) reads the keyswitch location in the keyboard matrix. The processor then sends to the motherboard a serial packet of data containing the scan code for the key that was pressed.

This is called the *Make code*. When the key is released, a corresponding *Break code* is sent, indicating to the motherboard that the key has been released. The Break code is equivalent to the Make scan code plus 80h. For example, if the Make scan code for the “A” key is 1Eh, the Break code would be 9Eh. By using both Make and Break scan codes, the system can determine if a particular key has been held down and determine whether multiple keys are being pressed.

In AT-type motherboards that use an 8042-type keyboard controller, the 8042 chip translates the actual keyboard scan codes into one of up to three different sets of system scan codes, which are sent to the main processor. It can be useful in some cases to know what these scan codes are, especially when troubleshooting keyboard problems or when reading the keyboard or system scan codes directly in software.

When a keyswitch on the keyboard sticks or otherwise fails, the Make scan code of the failed keyswitch is usually reported by diagnostics software, including the POST (power on self test), as well as conventional disk-based diagnostics. That means you have to identify the malfunctioning key by its scan code. See the Technical Reference section of the CD included with this book for a comprehensive listing of keyboard key numbers and scan codes for both the 101/102-key

(enhanced keyboard) and 104-key Windows keyboard. By looking up the reported scan code on these charts, you can determine which keyswitch is defective or needs to be cleaned.

Note

The 101-key Enhanced keyboards are capable of three different scan code sets. Set 1 is the default. Some systems, including some of the IBM PS/2 machines, use one of the other scan code sets during the POST. For example, my IBM P75 uses Scan Code Set 2 during the POST, but switches to Set 1 during normal operation. This is rare, and it really threw me off in diagnosing a stuck key problem one time. It is useful to know whether you are having difficulty interpreting the scan code number, however.

IBM also assigns each key a unique key number to distinguish it from the others. This is important when you are trying to identify keys on foreign keyboards, which might use different symbols or characters than the U.S. models do. In the Enhanced keyboard, most foreign models are missing one of the keys (key 29) found on the U.S. version and have two additional keys (keys 42 and 45). This accounts for the 102-key total instead of the 101 keys found on the U.S. version.

Note

The following figures and tables show the keyboard numbering and character locations for modern keyboards. If you need this information for the original 83-key PC keyboard or the 84-key AT keyboard, see Chapter 7 of *Upgrading and Repairing PCs, Tenth Anniversary Edition*, included on the CD with this book.

Figure 17.6 shows the keyboard numbering and character locations for the 101-key Enhanced keyboard. Figure 17.7 shows the layout of a typical non-U.S. 102-key version of the Enhanced keyboard—in this case, a U.K. version.

Figure 17.6 101-key Enhanced keyboard key number and character locations (U.S. version).

Note

See the Technical Reference section of the CD included with this book for a comprehensive listing of keyboard key numbers and scan codes for both the 101/102-key (enhanced keyboard) and 104-key Windows keyboard.

Knowing these key number figures and scan codes can be useful when you are troubleshooting stuck or failed keys on a keyboard. Diagnostics can report the defective keyswitch by the scan code, which varies from keyboard to keyboard on the character it represents and its location.

Figure 17.7 102-key Enhanced keyboard key number and character locations (U.K. English version).

International Keyboard Layouts

After the keyboard controller in the system receives the scan codes generated by the keyboard and passes them to the main processor, the operating system converts the codes into the appropriate alphanumeric characters. In the United States, these characters are the letters, numbers, and symbols found on the standard American keyboard.

However, no matter what characters you see on the keytops, it is a relatively simple matter to adjust the scan code conversion process to map different characters to the keys. Windows 9x and Windows NT take advantage of this capability by enabling you to install multiple keyboard layouts to support different languages.

Open the Keyboard control panel and select the Language page. The Language box should display the keyboard layout you selected when you installed the operating system. By clicking the Add button, you can select any one of several additional keyboard layouts supporting other languages.

These keyboard layouts map different characters to certain keys on the standard keyboard. The standard French layout provides easy access to the accented characters commonly used in that language. For example, pressing the 2 key produces the é character. To type the numeral 2, you press the Shift+2 key combination. Other French-speaking countries have different keyboard conventions for the same characters, so Windows includes support for several keyboard layout variations for some languages, based on nationality.

Note

It is important to understand that this feature is not the same as installing the operating system in a different language. These keyboard layouts do not modify the text already displayed on the screen; they only alter the characters generated when you press certain keys.

The alternative keyboard layouts also do not provide support for non-Roman alphabets, such as Russian and Chinese. The accented characters and other symbols used in languages such as French and German are part of the standard ASCII character set. They are always accessible to

English-language users through the Windows Character Map utility or through the use of Alt+keypad combinations. An alternative keyboard layout simply gives you an easier way to access the characters used in certain languages.

If you work on documents using more than one language, you can install as many keyboard layouts as necessary and switch between them at will. When you click the Enable Indicator on Taskbar check box on the Language page of the Keyboard control panel, a selector appears in the taskbar's tray area that enables you to switch languages easily. On the same page, you can enable a key combination that switches between the installed keyboard layouts.

Keyboard/Mouse Interface Connectors

Keyboards have a cable with one of two primary types of connectors at the system end. On most aftermarket keyboards, the cable is connected inside the keyboard case on the keyboard end, requiring you to open up the keyboard case to disconnect or test it. Enhanced keyboards manufactured by IBM use a unique cable assembly that plugs into both the keyboard and the system unit. This makes cable interchange or replacement an easy plug-in affair. A special connector called an *SDL (Shielded Data Link)* is used at the keyboard end, and the appropriate DIN connector is used at the PC end. Any IBM keyboard or cable can be ordered separately as a spare part. The newer Enhanced keyboards come with an externally detachable keyboard cable that plugs into the keyboard port with a special connector, much like a telephone connector. The other end of the cable is one of the following two types:

- *5-pin DIN connector.* Used on most PC systems with Baby-AT form factor motherboards.
- *6-pin mini-DIN connector.* Used on PS/2 systems and most PCs with LPX, ATX, and NLX motherboards.

Figure 17.8 and Table 17.3 show the physical layout and pinouts of all the respective keyboard connector plugs and sockets.

Figure 17.8 Keyboard and mouse connectors.

Table 17.3 Keyboard Connector Signals

Signal Name	5-Pin DIN	6-Pin Mini-DIN	6-Pin SDL
Keyboard Data	2	1	B
Ground	4	3	C
+5v	5	4	E
Keyboard Clock	1	5	D
Not Connected	—	2	A
Not Connected	—	6	F
Not Connected	3	—	—

DIN = Deutsche Industrie Norm, a committee that sets German dimensional standards.

SDL = Shielded Data Link, a type of shielded connector created by AMP and used by IBM and others for keyboard cables.

Motherboard mouse connectors also use the 6-pin mini-DIN connector and have the same pinout and signal descriptions as the keyboard connector; however, the data packets are incompatible. That means you can easily plug a motherboard mouse (PS/2 style) into a mini-DIN keyboard connector or plug the mini-DIN keyboard connector into a motherboard mouse port; however, neither one will work properly in this situation.

Caution

I have also seen PCs with external power supplies that used the same standard DIN connectors to attach the keyboard and the power supply. Although cross-connecting the mini-DIN connectors of a mouse and a keyboard is a harmless annoyance, connecting a power supply to a keyboard socket can be disastrous.

USB Keyboards and Mice

The latest innovation in keyboard (and pointing device) interfacing is connecting them to the PC via a USB (Universal Serial Bus) connection instead of the standard keyboard and mouse ports. Because USB is a universal bus, a single USB port in a system can replace the standard serial and parallel ports as well as the keyboard and mouse ports. Current systems still include both USB and the standard ports, but future systems might forgo the others in lieu of a single USB port.

Several keyboard manufacturers have been marketing USB keyboards and pointing devices, including Microsoft with the Natural Keyboard Elite. This is a newer version of its Natural keyboard, which can work in the standard keyboard port as well as via the USB port in newer systems. The Natural Keyboard Elite looks like a standard Natural keyboard as it has a standard 6-pin mini-DIN connector that plugs into the keyboard port on all modern motherboards, but it also includes a special USB adapter that allows it to plug in directly via a USB port.

Note

Note that the internal electronics of this keyboard are different, and the USB adapter included with the Natural keyboard Elite will not work on other standard keyboards, such as the original Microsoft Natural keyboard version 1.0.

Not all systems accept USB keyboards, even those with USB ports, because the standard PC BIOS has a keyboard driver that expects a standard keyboard port interface keyboard to be present. When a USB keyboard is installed, the system can't use it because there is no driver in the BIOS to make it work. In fact, some systems see the lack of a standard keyboard as an error and halt the boot process until one is installed.

To use a keyboard connected via the USB port, you must meet three requirements:

- Have a USB port in the system
- Run Microsoft Windows 98, Windows Millennium, or Windows 2000 (which include USB keyboard drivers)
- Have what is referred to as USB Legacy support in your BIOS

USB Legacy support means your motherboard ROM BIOS includes drivers to recognize a USB keyboard. Without this BIOS support, you can't use a USB keyboard when in MS-DOS or when installing Windows on the system for the first time. Also, should the Windows installation fail and require manipulation outside of Windows, the USB keyboard will not function unless it is supported in the BIOS. Virtually all 1998 and newer systems with USB ports include a BIOS with USB Legacy (meaning USB Keyboard) support.

For more information on USB, see Chapter 16, "Serial, Parallel, and Other I/O Interfaces."

Keyboards with Special Features

A number of keyboards on the market have special features not found in standard designs. These additional features range from simple things, such as built-in calculators, clocks, and volume control, to more complicated features, such as integrated pointing devices, special character layouts, shapes, and even programmable keys.

Note

In the mid-1930s, a simplified character layout called the Dvorak keyboard was designed to replace the common QWERTY layout used on nearly all keyboards available today. The Dvorak keyboard was approved as an ANSI standard in 1982 but has seen limited use. For a comparison between the Dvorak keyboard and the common QWERTY keyboard you most likely use, see "The Dvorak Keyboard" in the Technical Reference section of the CD accompanying this book.

Ergonomic Keyboards

A recent trend is to change the shape of the keyboard instead of altering the character layout. This trend has resulted in a number of different so-called ergonomic designs. The goal is to shape the keyboard to better fit the human hand. The most common of these designs splits the keyboard in the center, bending the sides outward. Some designs allow the angle between the sides to be adjusted, such as the Lexmark Select-Ease design. Others, such as the Microsoft Natural keyboard, are fixed. These split or bent designs more easily conform to the hands' natural angle while typing than the standard keyboard. They can improve productivity and typing speed and help prevent repetitive strain injuries, such as carpal tunnel syndrome (tendon inflammation).

Virtually every keyboard company now has some form of similar ergonomic keyboard, and the same criteria for quality and feel apply as with standard keyboard designs. One of the most popular ergonomic keyboards, the Microsoft Natural Keyboard, is manufactured for Microsoft by Keytronics. It uses the inexpensive soft-touch foam pad or rubber dome keyswitches Keytronics is known for. For those who prefer a more-rugged keyboard with higher-quality switches, I recommend the Lexmark Select-Ease, Alps, NMB Technologies, or Lite-On keyboards. These keyboards are available with very high-quality mechanical switches that have a positive tactile feel to them. The Lexmark design, in particular, enables you to adjust the angle between the two sides of the keyboard from fully closed, like a standard keyboard, to split at practically any angle. You can even separate the two halves completely. It also features built-in palm rests, an oversized spacebar, and cursor keys on both sides of the keyboard.

Because of their novelty and their trendy appeal, some ergonomic keyboards can be considerably more expensive than traditional designs, but for users with medical problems caused or exacerbated by improper positioning of the wrists at the keyboard, they can be an important remedy to a serious problem. General users, however, are highly resistant to change, and these designs have yet to significantly displace the standard keyboard layout.

Cordless Keyboards

A number of manufacturers now offer keyboards that use cordless technology. The keyboard and motherboard are the same, only the cord (or lack thereof) is different. Cordless keyboards use a transceiver combination to replace the cable. A transceiver is plugged into the keyboard port on the motherboard, and the keyboard itself contains a compatible transceiver as well. These transceivers can be based on either infrared or RF (radio frequency) technology. Infrared is cheaper, but it works over a shorter distance and only line of sight. This means that the infrared emitter on the keyboard must be aimed at the infrared receiver on the system for it to work. RF allows for longer distances and the keyboard doesn't have to be aimed directly at the system. Of course the superior RF versions are more expensive.

Cordless keyboards and mice are popular with PCs that are a part of a home entertainment system or that use a big-screen television as a display. These enable you to sit at a couch and operate the system without lengthy and cumbersome cables.

Keyboard Troubleshooting and Repair

Keyboard errors are usually caused by two simple problems. Other more difficult, intermittent problems can arise, but they are much less common. The most frequent problems are as follows:

- Defective cables
- Stuck keys

Defective cables are easy to spot if the failure is not intermittent. If the keyboard stops working altogether or every keystroke results in an error or incorrect character, the cable is likely the culprit. Troubleshooting is simple, especially if you have a spare cable on hand. Simply replace the suspected cable with one from a known, working keyboard to verify whether the problem still exists. If it does, the problem must be elsewhere. You can also test the cable for continuity when it is removed from the keyboard by using a Digital Multi-Meter (DMM). DMMs that have an

audible continuity tester built in make this procedure much easier to perform. Wiggle the ends of the cable as you check each wire to make sure there are no intermittent connections. If you discover a problem with the continuity in one of the wires, replace the cable or the entire keyboard, whichever is cheaper. Because replacement keyboards are so inexpensive, sometimes it can be cheaper to replace the entire unit than to get a new cable.

Many times you first discover a problem with a keyboard because the system has an error during the POST. Most systems use error codes in a 3xx numeric format to distinguish the keyboard. If you have any such errors during the POST, write them down. Some BIOS versions do not use cryptic numeric error codes; they simply state something like the following:

```
Keyboard stuck key failure
```

This message is normally displayed by a system with a Phoenix BIOS if a key is stuck. Unfortunately, the message does not identify which key it is!

If your system displays a 3xx (keyboard) error preceded by a two-digit hexadecimal number, the number is the scan code of a failing or stuck keyswitch. Look up the scan code in the tables provided in this section to determine which keyswitch is the culprit. By removing the keycap of the offending key and cleaning the switch, you can often solve the problem.

For a simple test of the motherboard keyboard connector, you can check voltages on some of the pins. Using Figure 17.8 as a guide, measure the voltages on various pins of the keyboard connector. To prevent possible damage to the system or keyboard, turn off the power before disconnecting the keyboard. Then unplug the keyboard and turn the power back on. Make measurements between the ground pin and the other pins according to Table 17.4. If the voltages are within these specifications, the motherboard keyboard circuitry is probably okay.

Table 17.4 Keyboard Connector Specifications

DIN Connector Pin	Mini-DIN Connector Pin	Signal	Voltage
1	5	Keyboard Clock	+2.0v to +5.5v
2	1	Keyboard Data	+4.8v to +5.5v
3	-	Reserved	—
4	3	Ground	—
5	4	+5v Power	+2.0v to +5.5v

If your measurements do not match these voltages, the motherboard might be defective. Otherwise, the keyboard cable or keyboard might be defective. If you suspect that the cable is the problem, the easiest thing to do is replace the keyboard cable with a known good one. If the system still does not work normally, you might have to replace the entire keyboard or the motherboard.

In many newer systems, the motherboard's keyboard and mouse connectors are protected by a fuse that can be replaced. Look for any type of fuse on the motherboard in the vicinity of the keyboard or mouse connectors. Other systems might have a socketed keyboard controller chip (8042-type). In that case, it might be possible to repair the motherboard keyboard circuit by

replacing this chip. Because these chips have ROM code in them, it is best to get the replacement from the motherboard or BIOS manufacturer.

Following is a list of standard POST (power on self test) and diagnostics keyboard error codes:

Error Code	Description
3xx	Keyboard errors
301	Keyboard reset or stuck-key failure (XX 301; XX = scan code in hex)
302	System unit keylock switch is locked
302	User-indicated keyboard test error
303	Keyboard or system-board error; keyboard controller failure
304	Keyboard or system-board error; keyboard clock high
305	Keyboard +5v error; PS/2 keyboard fuse (on motherboard) blown
341	Keyboard error
342	Keyboard cable error
343	Keyboard LED card or cable failure
365	Keyboard LED card or cable failure
366	Keyboard interface cable failure
367	Keyboard LED card or cable failure

Keyboard Disassembly

Although it is possible to disassemble a keyboard, it's not likely that you'll need or want to do that given the reasonable prices of keyboards. If you do want to disassemble your keyboard, see "Keyboard Disassembly" in the Technical Reference section of the CD accompanying this book.

Cleaning a Keyboard

One of the best ways to keep a keyboard in top condition is periodic cleaning. As preventive maintenance, you should vacuum the keyboard weekly, or at least monthly. When vacuuming, it is best to use a soft brush attachment; this will help dislodge the dust. Also note that many keyboards have key caps that can come off easily; be careful or you'll have to dig them out of the vacuum cleaner.

You can also use canned compressed air to blow the dust and dirt out instead of using a vacuum. Before you dust a keyboard with the compressed air, turn the keyboard upside down so that the particles of dirt and dust collected inside can fall out.

On all keyboards, each keycap is removable, which can be handy if a key sticks or acts erratically. For example, a common problem is a key that does not work every time you press it. This problem usually results from dirt collecting under the key. An excellent tool for removing keycaps on almost any keyboard is the U-shaped chip-puller included in many computer tool kits. Simply slip the hooked ends of the tool under the keycap, squeeze the ends together to grip the underside of the keycap, and lift up. IBM sells a tool designed specifically for removing keycaps from its keyboards, but the chip puller works even better. After removing the cap, spray some compressed air into the space under the cap to dislodge the dirt. Then replace the cap and check the action of the key.

Caution

When you remove the keycaps, be careful not to remove the spacebar on the original 83-key PC and the 84-key AT-type keyboards. This bar is difficult to reinstall. The newer 101-key units use a different wire support that can be removed and replaced much more easily.

Spills can be a problem, too. If you tip a soft drink or cup of coffee into a keyboard, you do not necessarily have a disaster. However, you should immediately (or as soon as possible) flush out the keyboard with distilled water. Partially disassemble the keyboard and use the water to wash the components. (See “Keyboard Disassembly” in the Technical Reference section of the CD accompanying this book for disassembly instructions.) If the spilled liquid has dried, soak the keyboard in some of the water for a while. When you are sure the keyboard is clean, pour another gallon or so of distilled water over it and through the keyswitches to wash away any residual dirt. After the unit dries completely, it should be perfectly functional. You might be surprised to know that drenching your keyboard with water does not harm the components. Just make sure you use distilled water, which is free from residue or mineral content. Also make sure the keyboard is fully dry before you try to use it, or some of the components might short out.

Tip

If spills or excessive dust or dirt are expected due to the environment or conditions the PC is used in, several companies make thin membrane skins that mold over the top of the keyboard, protecting it from liquids, dust, and other contaminants. These skins are generally thin enough so that they don't interfere too much with the typing or action of the keys.

Keyboard Recommendation

In most cases, it is cheaper or more cost effective to replace a keyboard rather than repair it. This is especially true if the keyboard has an internal malfunction or if one of the keyswitches is defective. Replacement parts for keyboards are almost impossible to procure, and installing any repair part is usually difficult. In addition, many of the keyboards supplied with lower-cost PCs leave much to be desired. They often have a mushy feel, with little or no tactile feedback. A poor keyboard can make using a system a frustrating experience, especially if you are a touch typist. For all these reasons, it is often a good idea to replace an existing keyboard with something better.

Perhaps the highest quality keyboards in the entire computer industry are those made by IBM, or, more accurately, Unicomp. Several years ago, IBM spun off its keyboard and printer divisions as a separate company called Lexmark. Lexmark used to manufacture most IBM-brand keyboards and printers and sold them not only to IBM, but also to other PC vendors and end users. In 1996, Lexmark sold its keyboard technology to a company called Unicomp, which now maintains an extensive selection of over 1,400 keyboards.

Table 17.5 shows the part numbers of all IBM-labeled keyboards and cables. These numbers can serve as a reference when you are seeking a replacement IBM keyboard from IBM directly or from third-party companies. Many third-party companies sell IBM label keyboards for much less than IBM, in both new and refurbished form. Remember that you can also purchase these same keyboards through Unicomp, although they do not come with an IBM label.

Table 17.5 IBM Keyboard and Cable Part Numbers

Description	Part Number
83-key U.S. PC keyboard assembly with cable	8529297
Cable assembly for 83-key PC keyboard	8529168
84-key U.S. AT keyboard assembly with cable	8286165
Cable assembly for 84-key keyboard	8286146
101-key U.S. keyboard without LED panel	1390290
101-key U.S. keyboard with LED panel	6447033
101-key U.S. keyboard with LED panel (PS/2 logo)	1392090
6-foot cable for Enhanced keyboard (DIN plug)	6447051
6-foot cable for Enhanced keyboard (mini-DIN plug)	61X8898
6-foot cable for Enhanced keyboard (shielded mini-DIN plug)	27F4984
10-foot cable for Enhanced keyboard (mini-DIN plug)	72X8537

Notice that the original 83/84-key IBM keyboards are sold with a cable that has the larger, five-pin DIN connector already attached. IBM Enhanced keyboards are always sold (at least by IBM) without a cable. You must order the proper cable as a separate item. Cables are available to connect the keyboards to either the older system units that use the larger DIN connector or to PS/2 systems (and many compatibles) that use the smaller mini-DIN connector.

Recently, IBM has started selling complete keyboard assemblies under a program called IBM Options. This program is designed to sell these components in the retail channel to end users of both IBM and compatible systems from other vendors. Items under the IBM Options program are sold through normal retail channels, such as CompUSA and Computer Discount Warehouse (CDW). These items are also priced much cheaper than items purchased as spare parts. They include a full warranty and are sold as complete packages, including cables. Table 17.6 lists some of the IBM Options keyboards and part numbers.

Table 17.6 IBM Options Keyboards (Sold Retail)

Description	Part Number
IBM Enhanced keyboard (cable w/ DIN plug)	92G7454
IBM Enhanced keyboard (cable w/ mini-DIN plug)	92G7453
IBM Enhanced keyboard, built-in Trackball (cable w/ DIN plug)	92G7456
IBM Enhanced keyboard, built-in Trackball (cable w/ mini-DIN plug)	92G7455
IBM Enhanced keyboard, integrated TrackPoint II (cables w/ mini-DIN plugs)	92G7461
IBM TrackPoint IV keyboard, Black	01K1260
IBM TrackPoint IV keyboard, White	01K1259

The extremely positive tactile feedback of the IBM/Lexmark/Unicomp design is also a benchmark for the rest of the industry. Although keyboard feel is an issue of personal preference, I have never used a keyboard that feels better than the IBM/Lexmark/Unicomp designs. I now equip every system I use with a Unicomp keyboard, including the many non-IBM systems I use. You

can purchase these keyboards directly from Unicomp at very reasonable prices. Also, you can sometimes find IBM-labeled models selling for under \$100 available from advertisers in computer magazines.

Unicomp sells other keyboards for reasonable prices, too. Many different models are available, including some with a built-in trackball or even the revolutionary TrackPoint pointing device. (TrackPoint refers to a small stick mounted between the G, H, and B keys.) This device was first featured on the IBM ThinkPad laptop systems, although the keyboards are now sold for use on other manufacturers' PCs. The technology is being licensed to many other manufacturers, including Toshiba. Other manufacturers of high-quality keyboards that are similar in feel to the IBM/Lexmark/Unicomp units are Alps, Lite-On, and NMB Technologies. These keyboards have excellent tactile feedback, with a positive click sound. They are my second choice, after a Unicomp unit. Maxi-Switch also makes a high-quality aftermarket keyboard, which is used by a number of PC manufacturers, including Gateway 2000. They have a good feel, too, and are recommended. Many of these companies can make their keyboards with your own company logo on them (such as the Maxi-Switch models used by Gateway 2000), which is ideal for clone manufacturers looking for name-brand recognition.

Pointing Devices

The mouse was invented in 1964 by Douglas Englebart, who at the time was working at the Stanford Research Institute (SRI), a think tank sponsored by Stanford University. The mouse was officially called an X-Y Position Indicator for a Display System. Xerox later applied the mouse to its revolutionary Alto computer system in 1973. At the time, unfortunately, these systems were experimental and used purely for research.

In 1979, several people from Apple, including Steve Jobs, were invited to see the Alto and the software that ran the system. Steve Jobs was blown away by what he saw as the future of computing, which included the use of the mouse as a pointing device and the GUI (graphical user interface) it operated. Apple promptly incorporated these features into what was to become the Lisa computer and lured away 15 to 20 Xerox scientists to work on the Apple system.

Although Xerox released the Star 8010 computer that used this technology in 1981, it was expensive, poorly marketed, and perhaps way ahead of its time. Apple released the Lisa computer, its first system that used the mouse, in 1983. It was not a runaway success, largely because of its \$10,000 list price, but by then Jobs already had Apple working on the low-cost successor to the Lisa, the Macintosh. The Apple Macintosh was introduced in 1984. Although it was not an immediate hit, the Macintosh has grown in popularity since that time.

Many credit the Macintosh with inventing the mouse and GUI, but as you can see, this technology was actually borrowed from others, including SRI and Xerox. Certainly the Macintosh, and now Microsoft Windows and OS/2, have gone on to popularize this interface and bring it to the legion of Intel-based PC systems.

Although the mouse did not catch on quickly in the PC marketplace, today the GUIs for PC systems such as Windows and OS/2 practically demand the use of a mouse. Therefore, it is common for a mouse to be sold with nearly every new system on the market.

Mice come in many shapes and sizes from many different manufacturers. Some have taken the standard mouse design and turned it upside down, creating the trackball. In the trackball devices, you move the ball with your hand directly rather than the unit itself. IBM even produced a very cool mouse/trackball convertible device called the TrackPoint (p/n 1397040). The TrackPoint could be used as either a mouse (ball side down) or as a trackball (ball side up). In most cases, the dedicated trackballs have a much larger ball than would be found on a standard mouse. Other than the orientation and perhaps the size of the ball, a trackball is identical to a mouse in design, basic function, and electrical interface.

The largest manufacturers of mice are Microsoft and Logitech. Even though mice can come in different varieties, their actual use and care differ very little. The standard mouse consists of several components:

- A housing that you hold in your hand and move around on your desktop
- A roller ball that signals movement to the system
- Buttons (usually two) for making selections
- A cable for connecting the mouse to the system
- An interface connector to attach the mouse to the system

The housing, which is made of plastic, consists of very few moving parts. On top of the housing, where your fingers normally rest, are buttons. There might be any number of buttons, but in the PC world, there are typically only two. If additional buttons are on your mouse, specialized software is required for them to operate. On the bottom of the housing is a small rubber ball that rolls as you move the mouse across the tabletop. The movements of this rubber ball are translated into electrical signals transmitted to the computer across the cable. Some mice use a special optical sensor that detects movement over a grid. These optical mice have fallen into disfavor because they work only if you use a special grid pad underneath them.

The cable can be any length, but it is typically between four and six feet long. Some mice are available in a cordless design, which uses either infrared or RF transceivers to replace the cable. A receiver is plugged into the mouse port, while the mouse contains a compatible transmitter.

Tip

If you have a choice on the length of cable to buy, go for a longer one. This allows easier placement of the mouse in relation to your computer.

After the mouse is connected to your computer, it communicates with your system through the use of a device driver, which can be loaded explicitly or built into the operating system software. For example, no separate drivers are needed to use a mouse with Windows or OS/2, but using the mouse with most DOS-based programs requires a separate driver to be loaded from the CONFIG.SYS or AUTOEXEC.BAT file. Regardless of whether it is built in or not, the driver translates the electrical signals sent from the mouse into positional information and indicates the status of the buttons.

Internally, a mouse is very simple, too. The ball usually rests against two rollers, one for translating the X-axis movement and the other for translating the Y-axis movement. These rollers are

usually connected to small disks with shutters that alternately block and allow the passage of light. Small optical sensors detect movement of the wheels by watching an internal infrared light blink on and off as the shutter wheel rotates and “chops” the light. These blinks are translated into movement along the axes. This type of setup, called an *opto-mechanical mechanism*, is by far the most popular in use today (see Figure 17.9). Figure 17.10 shows a typical mouse connector.

Figure 17.9 Typical opto-mechanical mouse mechanism.

Figure 17.10 Typical mouse connector.

Pointing Device Interface Types

The connector used to attach your mouse to the system depends on the type of interface you are using. Three basic interfaces are used for mouse connections, with a fourth combination device possible as well. Mice are most commonly connected to your computer through the following three interfaces:

- Serial interface
- Dedicated motherboard mouse port
- Bus-card interface

Serial

A popular method of connecting a mouse to older PCs is through the standard serial interface. As with other serial devices, the connector on the end of the mouse cable is either a 9-pin or 25-pin male connector. Only a couple of pins in the DB-9 or DB-25 connectors are used for communications between the mouse and the device driver, but the mouse connector typically has all 9 or 25 pins present.

Because most PCs come with two serial ports, a serial mouse can be plugged into either COM1 or COM2. The device driver, when initializing, searches the ports to determine which one the mouse is connected to.

Because a serial mouse does not connect to the system directly, it does not use system resources by itself. Instead, the resources used are those used by the serial port to which it is connected. For example, if you have a mouse connected to COM2, it most likely uses IRQ3 and I/O port addresses 2F8h–2FFh.

◀◀ See “Serial Ports,” p. 922.

Motherboard Mouse Port (PS/2)

Most newer computers now come with a dedicated mouse port built into the motherboard. This practice was introduced by IBM with the PS/2 systems in 1987, so this interface is often referred to as a *PS/2 mouse interface*. This term does not imply that such a mouse can work only with a PS/2; instead, it means the mouse can connect to any system that has a dedicated mouse port on the motherboard. Refer to Figure 17.8.

From a hardware perspective, a motherboard mouse connector is usually exactly the same as the mini-DIN connector used for newer keyboards. In fact, the motherboard mouse port is connected to the 8042-type keyboard controller found on the motherboard. All the PS/2 computers include mini-DIN keyboard and mouse port connectors on the back. Most compatible Slimline computers also have these same connectors for space reasons. Other motherboards have a pin-header type connector for the mouse port because most standard cases do not have a provision for the mini-DIN mouse connector. If that is the case, an adapter cable is usually supplied with the system. This cable adapts the pin-header connector on the motherboard to the standard mini-DIN type connector used for the motherboard mouse.

Caution

As mentioned in the “Keyboard/Mouse Interface Connectors” section earlier in this chapter, the mini-DIN sockets used for both keyboard and mouse connections on many systems are physically and electrically interchangeable, but the data packets they carry are not. Be sure to plug each device into the correct socket or neither will function correctly.

Connecting a mouse to the built-in mouse port is the best method of connection because you do not sacrifice any of the system’s interface slots or any serial ports, and the performance is not limited by the serial port circuitry. The standard resource usage for a motherboard (or PS/2) mouse port is IRQ12, as well as I/O port addresses 60h and 64h. Because the motherboard mouse port uses the 8042-type keyboard controller chip, the port addresses are those of this chip. IRQ12 is an interrupt that is usually free on most systems and it, of course, must remain free on any ISA bus systems that have a motherboard mouse port because interrupt sharing is not allowed with the ISA bus.

Serial and Motherboard Mouse Port (PS/2)

A hybrid type of mouse can plug into a serial port or a motherboard mouse port connection. This combination serial-PS/2 mouse is more flexible than the single design types. Circuitry in this mouse automatically detects the type of port to which it is connected and configures the mouse automatically. These mice usually come with a mini-DIN connector on the end of their cable and an adapter that converts the mini-DIN to a 9- or 25-pin serial port connector.

Sometimes people use adapters to try to connect a serial mouse to a motherboard mouse port or a motherboard mouse to a serial port. That this does not work is not the fault of the adapter. If the mouse does not explicitly state that it is both a serial and a PS/2-type mouse, it works only on the single interface for which it was designed. Most of the time, you find the designation for what type of mouse you have printed on its underside.

Bus

A bus mouse is typically used in systems that do not have a motherboard mouse port or any available serial ports. The name *bus mouse* is derived from the fact that the mouse requires a special bus interface board, which occupies a slot in your computer and communicates with the device driver across the main motherboard bus. Although the user can’t detect whether it’s a bus mouse (there is no operational difference between a bus mouse and other types of mice), many people view a bus mouse as less desirable than other types because it occupies a slot that could be used for something else.

Another drawback to the bus mouse is that it is electrically incompatible with the other types of mice. Because they are not very popular, bus mice can be hard to find in a pinch. Likewise, the bus adapters are typically available only for ISA slots; because they are always 8-bit cards, you are limited in the choice of nonconflicting hardware interrupts. A bus mouse can also be dangerous because it uses a mini-DIN connector—similar to the motherboard (PS/2)-type mouse—except with nine pins instead of only five.

Bus mouse adapter cards usually have a selectable interrupt and I/O port address setting, but the IRQ selection is limited to 8-bit interrupts. This usually means you must choose IRQ5 in most systems that already have two serial ports because all the other 8-bit interrupts are in use. If you are already using another 8-bit-only card that needs an interrupt, like some sound cards, you can't run both devices in the same system without conflicts. All in all, I think bus mice should be avoided.

Note

Microsoft sometimes calls a bus mouse an *inport mouse*, which is its proprietary name for a bus mouse connection.

USB

The newest interface for PC keyboards, and virtually every other type of peripheral you can name, is the Universal Serial Bus (USB). USB keyboards connect to a PC through the universal four-wire connector used by all USB devices. Because you can plug up to 127 devices into a single USB port on your PC, these keyboards frequently include additional USB sockets built into the housing, enabling them to function as hubs for other USB devices.

Alternatively, the USB plug that connects to your PC might have a *pass-through* connector. This is a standard USB plug with an integrated USB socket, so you can connect another device using the same port on the computer. Some USB keyboards also include a standard PS/2 mouse port, so you can connect your existing mouse directly to the keyboard instead of to the computer. If your system has a conventional mouse port, I recommend you use it over a USB mouse, as there is no advantage to a USB mouse, and they generally cost more.

Mouse Troubleshooting

If you are experiencing problems with your mouse, you need to look in only two general places—hardware or software. Because mice are basically simple devices, looking at the hardware takes very little time. Detecting and correcting software problems can take a bit longer, however.

Cleaning Your Mouse

If you notice that the mouse pointer moves across the screen in a jerky fashion, it might be time to clean your mouse. This jerkiness is caused when dirt and dust get trapped around the mouse's ball-and-roller assembly, thereby restricting its free movement.

From a hardware perspective, the mouse is a simple device, so cleaning it is easy. The first step is to turn the mouse housing over so that you can see the ball on the bottom. Notice that surrounding the ball is an access panel that you can open. Sometimes instructions indicate how the panel is to be opened. (Some off-brand mice might require you to remove some screws to get at the roller ball.) Remove the panel to see more of the roller ball and the socket in which it rests.

If you turn the mouse back over, the rubber roller ball should fall into your hand. Take a look at the ball. It might be gray or black, but it should have no visible dirt or other contamination. If it does, wash it in soapy water or a mild solvent, such as contact lens cleaner solution or alcohol, and dry it off.

Now take a look at the socket in which the roller ball normally rests. You will see two or three small wheels or bars against which the ball normally rolls. If you see dust or dirt on or around these wheels or bars, you need to clean them. The best way is to use a compressed air duster, which can blow out any dust or dirt. You also can use some electrical contact cleaner to clean the rollers. Remember: Any remaining dirt or dust impedes the movement of the roller ball and results in the mouse not working as it should.

Put the mouse back together by inserting the roller ball into the socket and then securely attaching the cover panel. The mouse should look just as it did before you removed the panel, except that it will be noticeably cleaner.

Interrupt Conflicts

Interrupts are internal signals used by your computer to indicate when something needs to happen. With a mouse, an interrupt is used whenever the mouse has information to send to the mouse driver. If a conflict occurs and the same interrupt used by the mouse is used by a different device, the mouse will not work properly—if at all.

Interrupt conflicts do not normally occur if your system uses a mouse port, but they can occur with the other types of mouse interfaces. Mouse ports built into modern motherboards are almost always set to IRQ12. If your system has a motherboard mouse port, be sure you don't set any other adapter cards to IRQ12, or a conflict will result.

When you are using a serial mouse, interrupt conflicts typically occur if you add a third and fourth serial port, using either an expansion card or an internal serial device, such as a modem. This happens because in ISA bus systems, the odd-numbered serial ports (1 and 3) are usually configured to use the same interrupts, as are the even-numbered ports (2 and 4). Therefore, if your mouse is connected to COM2 and an internal modem uses COM4, they both might use the same interrupt, and you cannot use them at the same time.

Because the mouse generates interrupts only when it is moved, you might find that the modem functions properly until you touch the mouse, at which point the modem is disconnected. You might be able to use the mouse and modem at the same time by moving one of them to a different serial port. For instance, if your mouse uses COM1 and the modem still uses COM4, you can use them both at once because odd and even ports use different interrupts.

The best way around these interrupt conflicts is to make sure no two devices use the same interrupt. Serial port adapters are available for adding COM3 and COM4 serial ports that do not share the interrupts used by COM1 and COM2. These boards enable the new COM ports to use other normally available interrupts, such as IRQs 10, 11, 12, 15, or 5. I never recommend configuring a system with shared interrupts; it is a sure way to run into problems later.

If you suspect an interrupt problem with a bus-type mouse, you can use the Device Manager built into Windows 9x (which is accessible from the System control panel) or even a program such as Microsoft Diagnostics (MSD) to help you identify what interrupt is being used by the mouse. You get MSD free with Windows 3.0 or later, as well as with MS-DOS 6.0 or later.

▶▶ See "Operating System Diagnostics," p. 1383.

Be aware that programs, such as MSD, that attempt to identify IRQ usage are not always 100-percent accurate—in fact, they are inaccurate in many cases—and they usually require that the device driver for the particular device be loaded to work.

The Device Manager in Windows 9x is part of the Plug-and-Play (PnP) software for the system, and it is usually 100-percent accurate on PnP hardware. Although some of these interrupt-reporting programs can have problems, most can easily identify the mouse IRQ if the mouse driver has been loaded. After the IRQ is identified, you might need to change the IRQ setting of the bus mouse adapter or one or more other devices in your system so that everything works together properly.

If your driver refuses to recognize the mouse at all, regardless of its type, try using a different mouse that you know works. Replacing a defective mouse with a known good one might be the only way to know whether the problem is indeed caused by a bad mouse.

I have had problems in which a bad mouse caused the system to lock right as the driver loaded or even when diagnostics such as MSD tried to access the mouse. You can easily ferret out this type of problem by loading MSD with the `/I` option, which causes MSD to bypass its initial hardware detection. Then run each test separately, including the mouse test, to see whether the system locks. If the system locks during the mouse test, you have found a problem with the mouse or the mouse port. Try replacing the mouse to see whether that helps. If it does not, you might need to replace the serial port or bus mouse adapter. If a motherboard-based mouse port goes bad, you can replace the entire motherboard—which is usually expensive—or you can just disable the motherboard mouse port via jumpers or the system BIOS setup program and install a serial or bus mouse instead. This method enables you to continue using the system without having to replace the motherboard.

Driver Software

To function properly, the mouse requires the installation of a device driver. In DOS, you have to load the driver manually through your `CONFIG.SYS` or `AUTOEXEC.BAT` file, but the driver is automatically loaded in all versions of Windows. I normally recommend using the default drivers built into the Windows or OS/2 operating systems. In those environments, no additional external driver is necessary. The only reason for loading an external driver (via `CONFIG.SYS`) is if you want the mouse to work with DOS applications in Windows 3.1. Windows 9x drivers support the use of the mouse in DOS applications by default.

If you need the mouse to work in standard DOS—in other words, outside Windows or OS/2—you must load a device driver through your `CONFIG.SYS` file or your `AUTOEXEC.BAT` file. This driver, if loaded in the `CONFIG.SYS` file, is typically called `MOUSE.SYS`. The version that loads in the `AUTOEXEC.BAT` file is called `MOUSE.COM`. (It is possible that your mouse drivers have different names, depending on who manufactured your mouse.) Again, remember that if you use a mouse only in Windows or OS/2, no external drivers are required because the mouse driver is built in.

The first step to installing a DOS mouse driver is to make sure the proper command to load the driver is in your `CONFIG.SYS` or `AUTOEXEC.BAT` file. If it isn't, add the proper line, according to the information supplied with your mouse. For instance, the proper command to load the mouse driver through the `CONFIG.SYS` file for a Microsoft mouse is as follows:

```
DEVICEHIGH=\DOS\MOUSE.SYS
```

The actual syntax of the command could vary, depending on whether you are loading the device into upper memory and where the device driver is located on your disk.

One of the biggest problems with the separate mouse driver is getting it loaded into an Upper Memory Block (UMB). The older Microsoft mouse drivers—versions 9.0 and earlier—require a large block of 40–56KB UMB to load; upon loading, they shrink down to less than 20KB. Even though they take only 20KB or less after loading, you still need a very large area to get them “in the door.”

The best tip I can give you for these separate drivers is to use the newest drivers available from Microsoft. These drivers are included with the newer Microsoft mice and are sold separately as an upgrade. The Microsoft driver works with any type of Microsoft-compatible mouse, which basically means just about any mouse at all. Microsoft requires that you pay about \$50 for an upgrade to the newer versions of the mouse driver. You can also get the new driver with a new mouse for \$35 or less, which makes the driver-only purchase not very cost effective. Microsoft still includes only the older driver with MS-DOS 6.22 or earlier. IBM included the new driver with PC DOS 6.3 but switched back to the 8.2 driver in PC DOS 17.0.

If you use version 9.01 or later, the driver requires less memory than previous versions and automatically loads into high memory. One of the best features is that the driver first loads into low memory, shrinks down to about 24KB, and then moves into upper memory automatically. In addition, the driver seeks out the smallest UMB that can hold it instead of trying only the largest, as would happen if you used the `DEVICEHIGH`, `LOADHIGH`, or `LH` commands to load the driver. Previous versions of the driver could not fit into an upper memory block unless that block was at least 40–56KB or larger, and they would certainly not move into upper memory automatically. The enhanced self-loading capability of the Microsoft DOS mouse driver 9.01 and higher can save much memory space. It is well worth having.

After placing the proper driver load command in your `CONFIG.SYS` or `AUTOEXEC.BAT` file, reboot the system with the mouse connected and make sure the driver loads properly. If the proper command is in place and the driver is not loading, watch your video screen as your system boots. At some point, you should see a message from the mouse driver indicating that it is loaded. If you see a message indicating that the driver failed to load, you must determine why. For example, the driver might not be able to load because not enough memory is available. After you determine why the driver is not loading, you need to rectify the situation and make sure the driver loads.

DOS Application Software

If your mouse does not work with a specific piece of DOS application software, check the setup information or configuration section of the program. Make sure you indicated to the program (if necessary) that you are using a mouse. If it still does not work and the mouse works with other software you are using, contact the technical support department of the application software company.

Microsoft IntelliMouse/IBM Scrollpoint

Late in 1996, Microsoft introduced a new variation of its popular mouse, called the IntelliMouse. This device looks exactly like the standard Microsoft mouse except for a miniature gray wheel rising up between the two buttons. This wheel represents the only major change in external mouse design in many years.

The wheel has two main functions. The primary function is to act as a scrolling device, enabling you to scroll through documents or Web pages by manipulating the wheel with your index finger. The wheel also functions as a third mouse button when you press it.

Although three-button mice have been available for years, the scrolling function is a real breakthrough. No longer do you have to move the mouse pointer to click the scrollbar on the right side of your screen or take your hand off the mouse to use the arrow keys on the keyboard. You just push or pull on the wheel. This is a major convenience, especially when browsing Web pages or working with word processing documents or spreadsheets. Also, unlike three-button mice from other vendors, the IntelliMouse's wheel-button doesn't seem to get in the way and you are less likely to click it by mistake.

The major drawback to the IntelliMouse is that the wheel functions only in software that is written to support it. At the time the IntelliMouse debuted, Microsoft Internet Explorer had already been modified to use the new wheel, and all the applications in Office 97 support it as well. For example, most Office 97 applications allow you to hold down the Ctrl key while turning the wheel to zoom in and out. Manipulating the wheel while holding down the Shift key expands and collapses outlines. As new and updated versions of other software come out, you can expect that they will also support the new wheel functions.

The IntelliMouse 2.0 driver combines features from earlier versions of Microsoft's mouse driver with some interesting new functions. A feature called ClickLock allows you to drag items without holding down the primary mouse button. You can customize this feature by specifying how long you have to hold the button down to activate ClickLock. You can also configure the wheel to scroll a specified number of lines or scroll a screen with each click of the wheel.

You can also set the driver software so that the wheel-button ignores all application-specific functions and instead performs one of four preset functions in all Windows applications. The four choices are as follows:

- Double left-click
- Open an application's Help file
- Switch to Windows Explorer
- Bring up the Windows Start menu

Other driver features retained from earlier versions include a Snap To feature, which moves the pointer to the default button of a dialog box, and functions that add trails when the pointer moves and make the pointer disappear when you start typing.

IBM has released an improved version of the IntelliMouse called the Scrollpoint mouse, which uses a button strain gauge (similar to the TrackPoint pointing device covered in the next section)

instead of the wheel. The scrollpointer in the center of the mouse allows you to smoothly scroll through documents without having to lift your finger to roll the wheel, as you do on the Microsoft version, which makes it much easier and more convenient to use. Because there are no moving parts, the Scrollpoint is also more reliable.

More recently Microsoft has released an optical version of the IntelliMouse called the IntelliMouse Explorer. This mouse uses optical technology to detect movement and itself has no moving parts (except for the scroll wheel on top). Optical mice have been around for many years, but usually they required a special mouse pad with an optical grid to function. The Explorer mouse can work on any surface without the use of a special pad. This is done by upgrading the optical sensor from the simple type used in older optical mice to a more advanced CCD (charge coupled device). This is essentially a crude version of a video camera sensor which detects movement by seeing the surface move under the mouse. An LED is used to provide light for the sensor.

With this advanced optical design, the IntelliMouse Explorer should be one of the most durable and trouble-free mice on the market. This technology is more expensive than the simple ball and roller design of standard mechanical mice, but unlike the mechanical types it won't pick up dirt and debris, the mechanism doesn't require cleaning, and it works on just about any surface. If you are hard on your conventional mice and replace them frequently, the IntelliMouse Explorer might be worth the extra cost.

TrackPoint II/III

On October 20, 1992, IBM introduced a revolutionary new pointing device called TrackPoint II as an integrated feature of its new ThinkPad 700 and 700C computers. Often referred to as a *pointing stick device*, it consists primarily of a small rubber cap that appears on the keyboard right above the B key, between the G and H keys. This was the first significant new pointing device since the mouse had been invented nearly 30 years earlier!

This device occupies no space on a desk, does not have to be adjusted for left-handed or right-handed use, has no moving parts to fail or become dirty, and—most importantly—does not require you to move your hands from the home row to use it. This is an absolute boon for touch typists.

I was fortunate enough to meet the actual creator and designer of this device in early 1992 at the spring Comdex/Windows World in Chicago. He was in a small corner of the IBM booth showing off his custom-made keyboards with a small silicone rubber nub in the middle. In fact, the devices he had were hand-built prototypes installed in standard desktop keyboards, and he was there trying to get public reaction and feedback on his invention.

I was invited to play with one of the keyboards, which was connected to a demonstration system. By pressing on the stick with my index finger, I could move the mouse pointer on the screen. The stick itself did not move, so it was not a joystick. Instead, it had a silicone rubber cap that was connected to pressure transducers that measured the amount of force my finger was applying and the direction of the force and moved the mouse pointer accordingly. The harder I pressed, the faster the pointer moved. I could move the pointer in any direction smoothly by slightly changing the direction of push or pull. The silicone rubber gripped my finger even though I had

been sweating from dashing about the show. After playing around with it for just a few minutes, the movements became automatic—almost as though I could just think about where I wanted the pointer to go.

After reflecting on this for a minute, it really hit me: This had to be the most revolutionary pointing device since the mouse itself! Not only would it be a natural replacement for a mouse, but it would also be a boon for touch typists like me who don't like to take their hands off the keyboard.

The gentleman at the booth turned out to be Ted Selker, the primary inventor of the device. He and Joseph Rutledge created this integrated pointing device at the IBM T.J. Watson Research Center. When I asked him when such keyboards would become available, he could not answer. At the time, there were apparently no plans for production, and he was only trying to test user reaction to the device.

Just over six months later, IBM announced the ThinkPad 700, which included this revolutionary device, then called the TrackPoint II Integrated Pointing Device. Since the original version came out, an enhanced version with greater control and sensitivity called the TrackPoint III has become available.

Note

The reason the device was called TrackPoint II is that IBM had previously been selling a convertible mouse/trackball device called the TrackPoint. No relationship exists between the original TrackPoint mouse/trackball, which has since been discontinued, and the TrackPoint II integrated device. Since the original TrackPoint II came out, an improved version called TrackPoint III has been available. It is basically an improved version of the same design. In the interest of simplicity, I will refer to all the TrackPoint II, III, and successive devices as just *TrackPoint*.

In its final production form, the TrackPoint consists of a small red silicone rubber knob nestled between the G, H, and B keys on the keyboard. The primary and secondary mouse buttons are placed below the spacebar where you can easily reach them with your thumbs without taking your hands off the keyboard.

IBM studies conducted by Selker found that the act of removing your hand from the keyboard to reach for a mouse and replacing the hand on the keyboard takes approximately 1.75 seconds. If you type 60wpm, that can equal nearly two lost words per minute, not including the time lost while you regain your train of thought. Almost all this time can be saved each time you use TrackPoint to move the pointer or make a selection (click or double-click). The combination of the buttons and the positioning knob also enable you to perform drag-and-drop functions easily.

IBM's research also found that people can get up to 20 percent more work accomplished using the TrackPoint instead of a mouse, especially when the application involves a mix of typing and pointing activities, such as with word processing, spreadsheets, and other typical office applications. In usability tests with the TrackPoint III, IBM gave a group of desktop computer users a TrackPoint and a traditional mouse. After two weeks, 80 percent of the users had unplugged their mice and switched solely to the TrackPoint device. Selker is convinced (as am I) that the TrackPoint is the best pointing solution for both laptop and desktop systems.

Another feature of the TrackPoint is that a standard mouse can be connected to the system at the same time to allow for dual-pointer use. In this case, a single mouse pointer would still be on the screen, but both the TrackPoint and the connected mouse could move the pointer. This setup not only enables a single person to use both devices, but also enables two people to use the TrackPoint and the mouse simultaneously to move the pointer on the screen. The first pointing device that moves (thus issuing a system interrupt) takes precedence and retains control over the mouse pointer on the screen until it completes its movement action. The second pointing device is automatically locked out until the primary device is stationary. This enables the use of both devices and prevents each one from interfering with the other.

Recognizing the significance of the TrackPoint, especially for portable systems, several other manufacturers of laptop and notebook portable computers, such as Toshiba and Texas Instruments, have licensed the TrackPoint pointing device from IBM. They often give the device a different name, but the technology and operation are the same. For example, Toshiba calls its pointing stick the Accupoint.

I have compared the TrackPoint device to other pointing devices for notebooks, such as the trackballs and even the capacitive touch pads, but nothing compares in terms of accuracy and control—and, of course, you don't have to take your hands off the keyboard!

Unfortunately, many of the lower-end portable system manufacturers have chosen not to license the IBM TrackPoint technology, but instead have attempted to copy it using inferior transducers and control software. The major drawback to these unlicensed TrackPoint-type devices is that they simply do not perform as well as the official versions licensed from IBM. They are usually slow to respond, sluggish in operation, and lack the sensitivity and accuracy found in the IBM-designed versions.

One way of telling whether the TrackPoint device is licensed from IBM and uses the IBM technology is if it accepts IBM TrackPoint II or III rubber caps. They have a square hole in them and will properly lock on to any of the licensed versions, such as those found in Toshiba systems.

IBM has upgraded its pointing stick and now calls it TrackPoint III. There are two main differences in the III system, but the most obvious one is in the rubber cap. IBM always uses red caps in its TrackPoint device, but other companies use different colors (Toshiba uses green or gray, for example). However, the main difference in the new TrackPoint III caps is in the rubber composition, not the color.

The IBM TrackPoint II and Toshiba Accupoint caps are made from silicone rubber, which is grippy and works well in most situations. However, if the user has greasy fingers, the textured surface of the rubber can absorb some of the grease and become slippery. Cleaning the cap (and the user's hands) solves the problem, but it can be annoying at times. The new TrackPoint III caps are made from a different type of rubber, which Selker calls "plastic sandpaper." This type of cap is much more grippy and does not require cleaning except for cosmetic purposes. I have used both types of caps and can say for certain that the TrackPoint III cap is superior!

Note

Because the Accupoint device used in the Toshiba notebooks is licensed from IBM, it uses the same hardware (a pressure transducer called a *strain gauge*) and takes the same physical caps. I ordered a set of the new TrackPoint III caps and installed them on my Toshiba portable systems, which dramatically improved the grip. You can get these caps by ordering them from IBM Parts directly or from others who sell IBM parts, such as DakTech, under IBM part number 84G6536. The cost is approximately \$5 for a set of two “plastic sandpaper” red caps.

Replacing the cap is easy—grab the existing cap with your fingers and pull straight up; it pops right off. Then push on the new red IBM TrackPoint III cap in its place. You will thank me when you feel how you can grip the new IBM cap much more easily than you can grip the designs used by others.

The other difference between the TrackPoint II and III from IBM is in the control software. IBM added routines that implement a subtle technique Selker calls “negative inertia,” which is marketed under the label *QuickStop response*. This software not only takes into account how far you push the pointer in any direction, but also how quickly you push or release it. Selker found that this improved software (and the sandpaper cap) allows people to make selections up to 8 percent faster.

There is now a TrackPoint IV that includes an extra scroll button, as well as the ability to press the TrackPoint nub to select as if using the left mouse button. These new features make the TrackPoint even better to use.

The TrackPoint is obviously an ideal pointing device for a portable system in which lugging around an external mouse or trackball can be inconvenient. The trackballs and mini-trackballs built into some laptop keyboards are difficult to use and usually require removing your hands from the home row. Mouse and trackball devices are notorious for becoming sticky because the ball picks up dirt that affects the internal roller motion. This problem is especially noticeable with the smaller mini-trackball devices.

Many newer notebook systems include a touch pad, and although this seemed like a good idea at first, it pales in comparison with the TrackPoint. The touch pads are based on a capacitive effect, and pointer operation can become erratic if your skin is too dry or too moist. Their biggest drawback is that they are positioned on the keyboard below the spacebar, which means you have to remove your hand from the home row to place your index finger on the pad, or try to use the pad with your thumb, which has too wide a contact area for precise movement and control.

The bottom line is that anyone who touch types should strongly consider only portable systems that include an IBM-licensed TrackPoint device (such as Toshiba). TrackPoints are far superior to other pointing devices, such as the touch pads, because the TrackPoint is faster to use (you don’t have to take your hands off the keyboard’s home row), easier to adapt to (especially for speedy touch typists), and far more precise.

The benefits of the TrackPoint are not limited to portable systems, however. Because I use a notebook so often and have found the TrackPoint so fast and easy to use, I wanted to use it on my desktop systems, too. For desktop systems, I use a Lexmark keyboard with the IBM-licensed

TrackPoint device built in. This makes for a more consistent interface between desktop and notebook use because I can use the same pointing device in both environments. One drawback for some older systems is that the TrackPoint device in these keyboards works only with systems that used a PS/2- or motherboard-type mouse connector—no serial version is available. I list the part number for the IBM keyboards with the integrated TrackPoint II and TrackPoint IV in the section “Replacement Keyboards” in the Technical Reference section of the CD accompanying this book. You can also buy these keyboards directly from Unicomp, which has purchased Lexmark’s keyboard technology.

Glidepoint/Track Pads

In response to the TrackPoint, other companies have adopted new pointing device technologies. For example, Alps Electric has introduced a touch pad (also called a *track pad*) pointing device called the Glidepoint. The Glidepoint uses a flat, square pad that senses finger position through body capacitance. This is similar to the capacitance-sensitive elevator button controls you sometimes encounter in office buildings or hotels. Instead of sitting between the keys, the Glidepoint is mounted below the spacebar, and it detects pressure applied by your thumbs or fingers. Transducers under the pad convert finger movement into pointer movement. Several laptop and notebook manufacturers have licensed this technology from Alps and are incorporating it into their portable systems. Apple was one of the first to adopt it in its portable systems.

Although it seems to have gained wide acceptance, this technology has a number of drawbacks. Operation of the device can be erratic, depending on skin resistance and moisture content. The biggest drawback is that to operate the touch pad, users have to remove their hands from the home row on the keyboard, which dramatically slows their progress. In addition, the operation of the touch pad can be imprecise, depending on how pointy your finger or thumb is!

On the other hand, if you’re not a touch typist, removing your hands from the keyboard to operate the touch pad might be easier than using a TrackPoint. Even with their drawbacks, touch pad pointing devices are still vastly preferable to using a trackball or a cumbersome external mouse with portable systems.

Running Windows Without a Mouse

Many people do not know that it is possible to dramatically enhance the use of Windows by using the keyboard as an adjunct to the mouse for system control. Many keyboard shortcuts and other key commands can greatly increase the speed and efficiency with which you operate Windows, especially if you are creating a document, spreadsheet, email message, and so forth, and even more so if you are an accomplished touch typist. Because I use my PC mainly for writing, I find that taking my hand off the keyboard to use a mouse noticeably slows me down. By augmenting Windows operations with the keyboard, you can control them more efficiently and accurately than with a mouse alone.

In some cases, it is not only desirable, but necessary, to use the keyboard instead of a mouse, such as when your mouse is not functioning properly or is missing altogether. Because technicians often find themselves operating or testing equipment that is not fully functional, it is even more important for them to know how to operate Windows with the keyboard.

The following are the general keyboard-only commands for Windows 95/98:

Key Combination	Resulting Action
F1	Starts Windows Help.
F10	Activates menu bar options.
Shift+F10	Opens a context menu (shortcut menu) for the selected item.
Ctrl+Esc	Opens the Start menu. Use the arrow keys to select an item.
Ctrl+Esc, Esc	Selects the Start button. Press Tab to select the taskbar, or press Shift+F10 for a context menu.
Alt+Tab	Switch to another running application. Hold down the Alt key and then press the Tab key to view the task-switching window.
Shift	Press down and hold the Shift key while you insert a CD-ROM to bypass the AutoPlay feature.
Alt+spacebar	Displays the main window's System menu. From the System menu, you can restore, move, resize, minimize, maximize, or close the window.
Alt+< (Alt+hyphen)	Displays the Multiple Document Interface (MDI) child window's System menu. From the MDI child window's System menu, you can restore, move, resize, minimize, maximize, or close the child window.
Ctrl+Tab	Switches to the next child window of a MDI application.
Alt+<underlined letter in menu>	Opens the corresponding menu.
Alt+F4	Closes the current window.
Ctrl+F4	Closes the current MDI window.
Alt+F6	Switches between multiple windows in the same program. For example, when Notepad's Find dialog box is displayed, Alt+F6 switches between the Find dialog box and the main Notepad window.

Here are the Windows dialog box keyboard commands:

Key Combination	Resulting Action
Tab	Move to the next control in the dialog box.
Shift+Tab	Move to the previous control in the dialog box.
Spacebar	If the current control is a button, this keyboard command clicks the button. If the current control is a check box, it toggles the check box. If the current control is an option button, it selects the option button.
Enter	Equivalent to clicking the selected button (the button with the outline).
Esc	Equivalent to clicking the Cancel button.
Alt+<underlined letter in dialog box item>	Move to the corresponding item.
Ctrl+Tab/ Ctrl+Shift+Tab	Move through the property tabs.

These are the keyboard combinations for Windows Explorer tree controls:

Key Combination	Resulting Action
Numeric Keypad *	Expands everything under the current selection.
Numeric Keypad +	Expands the current selection.
Numeric Keypad -	Collapses the current selection.
Right arrow	Expands the current selection if it is not expanded; otherwise, goes to the first child.
Left arrow	Collapses the current selection if it is expanded; otherwise, goes to the parent.

Here are the general Windows folder/shortcut controls:

Key Combination	Resulting Action
F4	Selects the Go To a Different Folder box and moves down the entries in the box (if the toolbar is active in Windows Explorer).
F5	Refreshes the current window.
F6	Moves among panes in Windows Explorer.
Ctrl+G	Opens the Go To Folder tool (in Windows 95 Windows Explorer only).
Ctrl+Z	Undoes the last command.
Ctrl+A	Selects all the items in the current window.
Backspace	Switches to the parent folder.
Shift+click	Selects the close button. (For folders, closes the current folder plus all parent folders.)

These are general folder and Windows Explorer shortcuts for a selected object:

Key Combination	Resulting Action
F2	Renames object.
F3	Finds all files.
Ctrl+X	Cuts.
Ctrl+C	Copies.
Ctrl+V	Pastes.
Shift+Del	Deletes selection immediately, without moving the item to the Recycle Bin.
Alt+Enter	Opens the property sheet for the selected object.
Press down and hold the Ctrl key while you drag the file to another folder	To copy a file.
Press down and hold Ctrl+Shift while you drag a file to the desktop or a folder	To create a shortcut.

CHAPTER 18

Internet Connectivity

Relating Internet and LAN Connectivity

Communications between computers is a major part of the PC computing industry. Thanks to the World Wide Web (WWW), no computer user is an island. Whether by using a modem or a faster technology, virtually all PCs can be connected to other computers, enabling them to share files, send and receive email, and access the Internet. This chapter explores the various technologies you can use to expand the reach of your PC around the block and around the world.

It might surprise you to see discussions of protocols and networking setup in both this chapter and the LAN chapter of this book, but a modem connection is really just another form of networking. In fact, the Windows 9x, Windows NT, and Windows 2000 operating systems have all but blended the two services into a single entity.

The reason for this combination is that the typical target for a modem connection has changed over the years. For a long time, PC users dialed in to *bulletin board systems* (or BBSes)—proprietary services that provided terminal access to other computers. Online services such as America Online and CompuServe have also been around for many years, but they traditionally used proprietary clients and protocols, quite different from those found on local area networks (LANs). Today, BBSes are practically extinct, and America Online, Prodigy, and CompuServe have been reborn as gateways to the Internet.

With the explosive growth of the Internet, modem and network technologies were joined, because both could use the same client software and protocols. Today, the most popular suite of networking protocols—TCP/IP—is used on both LANs and the Internet. When you dial in to an Internet service provider (ISP), you are actually connecting to a network using a modem instead of a network interface card.

Asynchronous Modems

For PCs that are not connected to a network by some other means, a modem has become virtually a standard piece of equipment. For many home users, connecting to the Internet is their primary reason for owning a computer. Whether for business, entertainment, or just keeping in touch with friends and family, a modem connection takes an isolated system and makes it a part of a worldwide network.

The word *modem* (from modulator/demodulator) basically describes a device that converts the digital data used by computers into analog signals suitable for transmission over a telephone line and converts the analog signals back to digital data at the destination. The typical PC modem is an asynchronous device, meaning that it transmits data in an intermittent stream of small packets. The receiving system takes the data in the packets and reassembles it into a form the computer can use.

Asynchronous modems transmit each byte of data individually as a separate packet. One byte equals eight bits, which, using the standard ASCII codes, is enough data to transmit a single alphanumeric character. For a modem to transmit asynchronously, it must identify the beginning and end of each byte to the receiving modem. It does this by adding a start bit before and after every byte of data, thus using 10 bits to transmit each byte (see Figure 18.1). For this reason, asynchronous communications have sometimes been referred to as start-stop communications.

This is in contrast to synchronous communications, in which a continuous stream of data is transmitted at a steady rate.

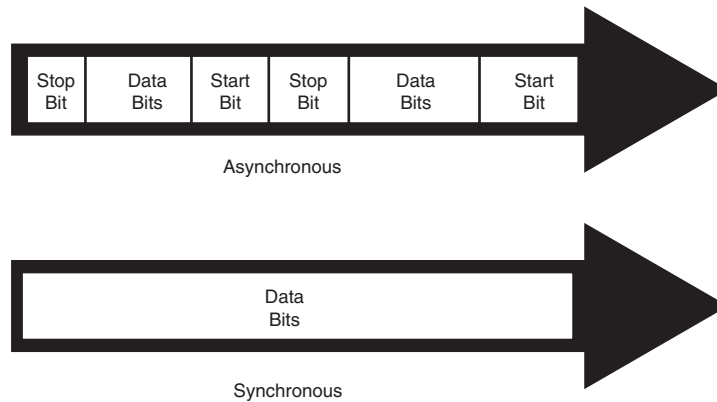

Figure 18.1 Asynchronous modems frame each byte of data with a start bit and a stop bit, whereas synchronous communications use an uninterrupted stream of data.

Synchronous modems are generally used in leased-line environments and in conjunction with multiplexers to communicate between terminals to UNIX-based servers and mainframe computers. Thus, this type of modem is outside the scope of this book.

Whenever modems are referred to in this book, I will be discussing the asynchronous variety. (Synchronous modems are *not* found in typical computer stores and aren't included in normal computer configurations, so you might not ever see one unless you go into the data center of a corporation that uses them).

Note

During high-speed modem communications, the start and stop bits are usually not transmitted over the telephone line. Instead, they are eliminated by the data compression algorithm implemented by the modem. However, these bits are part of the data packets generated by the communications software in the computer, and they exist until they reach the modem hardware.

The use of a single start bit is required in all forms of asynchronous communication, but some protocols use more than one stop bit. To accommodate systems with different protocols, communications software products usually enable you to modify the format of the frame used to transmit each byte. The standard format used to describe an asynchronous communications format is parity/data bits/stop bits. Almost all asynchronous connections today are therefore abbreviated as N-8-1 (No parity/8 data bits/1 stop bit). The meanings for each of these parameters and their possible variations are as follows:

- **Parity.** Before error-correction protocols became standard modem features, a simple parity mechanism was used to provide basic error checking at the software level. Today, this is almost never used, and the value for this parameter is nearly always set to none. Other possible parity values that you might see in a communications software package are odd, even, mark, and space.

- **Data Bits.** This parameter indicates how many bits are actually carried in the data portion of the packet (exclusive of the start and stop bits). PCs typically use eight data bits, but some types of computers use a 7-bit byte, and others might call for other data lengths. Communications programs provide this option to prevent a system from confusing a stop bit with a data bit.
- **Stop Bits.** This parameter specifies how many stop bits are appended to each byte. PCs typically use one stop bit, but other types of protocols might call for the use of 1.5 or 2 stop bits.

In most situations, you will never have to modify these parameters manually, but the controls are almost always provided. In Windows 9x, for example, if you open the Modems control panel and look at the Connection page of your modem's Properties dialog box, you will see Data Bits, Parity, and Stop Bits selectors.

Unless you use the Windows 9x HyperTerminal program to establish a direct connection to another computer via phone lines, you might never need to modify these parameters. However, if you need to call a mainframe computer to perform *terminal emulation* for e-banking, checking a library's catalog, or working from home, you might need to adjust these parameters. (Terminal emulation means using software to make your PC keyboard and screen act like a terminal such as a DEC VT-100, and so on.) Many mainframe computers use even parity and a 7-bit word length. If your PC is set wrong, you'll see garbage text on your monitor instead of the other system's login or welcome screen.

Note

Because it has become such a familiar term, even to inexperienced computers users, the word *modem* is frequently used to describe devices that are, strictly speaking, not modems at all. Later in this chapter, you will learn about ISDN, and the latest Internet-access standards, such as cable modems, DirecPC, and xDSL, none of which convert digital information to analog signals. However, because these devices look something like a standard modem and are used to connect PCs to the Internet or to other networks, they are called modems.

Modem Standards

For two modems to communicate, they must share the same *protocol*. A protocol is a specification that determines how two entities will communicate. Just as humans must share a common language and vocabulary to speak with each other, two computers or two modems must share a common protocol. In the case of modems, the protocol determines the nature of the analog signal that the device creates from the computer's digital data.

Through the years, there have been many standards for modem communications, most of them developed by bipartisan committees and accepted by nearly all modem manufacturers. As the hardware technology has improved, modem communications have become faster and more efficient, and new standards are constantly being developed to take advantage of the hardware's capabilities.

Note

The term *protocol* is also used to describe software standards that must be established between different computers to allow them to communicate, such as TCP/IP.

Bell Labs and the CCITT are two of the bodies that have set standards for modem protocols. CCITT is an acronym for Comité Consultatif International Téléphonique et Télégraphique, a French term that translates into English as the Consultative Committee on International Telephone and Telegraph. The organization was renamed the International Telecommunication Union (ITU) in the early 1990s, but the protocols developed under the old name are often referred to as such. Newly developed protocols are referred to as ITU-T standards, which refers to the Telecommunication Standardization Sector of the ITU. Bell Labs no longer sets new standards for modems, although several of its older standards are still used. Most modems built in recent years conform to the standards developed by the CCITT.

The ITU, headquartered in Geneva, Switzerland, is an international body of technical experts responsible for developing data communications standards for the world. The group falls under the organizational umbrella of the United Nations, and its members include representatives from major modem manufacturers, common carriers (such as AT&T), and governmental bodies. The ITU establishes communications standards and protocols in many areas, so one modem often adheres to many different standards, depending on its various features and capabilities. Modem standards can be grouped into the following three areas:

■ **Modulation**

Bell 103

Bell 212A

CCITT V.21

ITU V.22bis

ITU V.29

ITU V.32

ITU V.32bis

ITU V.34

ITU V.90

■ **Error Correction**

ITU V.42

■ **Data Compression**

ITU V.42bis

▶▶ See "Modulation Standards," p. 1000.

Other standards have been developed by different companies (not Bell Labs or the ITU). These are sometimes called proprietary standards, even though most of these companies publish the full specifications of their protocols so that other manufacturers can develop modems to work with them. The following list shows some of the proprietary standards that have been popular over the years:

■ **Modulation**

HST

K56flex

x2

■ **Error Correction**

MNP 1-4

Hayes V-series

■ **Data Compression**

MNP 5 CSP

Note

K56flex and x2 were competing, proprietary methods for reaching a maximum download speed of up to 56Kbps. K56flex was developed by modem chipset makers Rockwell and Lucent, whereas x2 was developed by U.S. Robotics (now part of 3Com). These two quasi-standards have now been replaced by the ITU V.90 standard for 56Kbps downloads, but K56flex is still supported by many ISPs, and some still also support x2.

In the interests of backward compatibility, modem manufacturers typically add support for new standards as they are developed, leaving the support for the old standards in place. As a result, when you evaluate modems, you are likely to see long lists of the standards they support, like those just shown. In most cases, you will want to know whether a modem supports the most recent standards, so support for an archaic and seldom-used protocol should not govern your purchasing decision.

Modem manufacturers used to claim to be Hayes-compatible, a phrase that became as meaningless as IBM-compatible when referring to PCs. Today modem manufacturers instead say that they support standard AT command sets, which is what being Hayes-compatible meant. AT commands are text strings sent to the modem by software to activate the modem's features. For example, the ATDT command, followed by a telephone number, causes the modem to dial that number using tone dialing mode. Applications that use modems typically generate AT commands for you, but you can control a modem directly using a communications program with a terminal mode, or even the DOS ECHO command. For this reason, the term Hayes-compatible is seldom used anymore.

Assuming that you have a modem connected to your PC's COM 2 port, you can demonstrate this capability by issuing the following command from the DOS command line:

```
ECHO ATH1 > COM2
```

This command sends the ATH1 command string out through your computer's COM 2 port to the modem, causing it to go "off hook." If your modem has a speaker, you should hear a dial tone. To hang up, issue the following command:

```
ECHO ATH0 > COM2
```

Because almost every modem uses the Hayes command set, this compatibility is a given and should not really affect your purchasing decisions about modems. The basic modem commands might vary slightly from manufacturer to manufacturer, depending on a modem's special features, but the basic AT command set is all but universal. Some modems, most notably U.S. Robotics (now part of 3Com), allow you to query the command set by sending the string AT\$ to the modem. To query the modem's command set, launch a terminal program, such as Windows 9x HyperTerminal, set up a new connection, and type AT\$ in the terminal window. The results of querying a U.S. Robotics (3Com) x2 56K PnP internal modem are shown in Figure 18.2.

Note

A list of the basic AT commands can be found in the "Technical Reference" on the CD included with this book. However, the best source for the commands used by your modem is the manual that came with the device.

It's very important you keep the manual that came with your modem so you have this information. Although most Windows 9x/NT communications programs use the standard .INF file setup for the modem, some MS-DOS-based programs and some specialized Windows programs might require you to enter or edit an *initialization string*, which is a series of commands sent to the modem before dialing. If these commands are not correct, the modem will not work with these programs!

Figure 18.2 The commands and command options that will work with a U.S. Robotics/3Com 56Kbps x2 modem are shown here.

Baud Versus Bits per Second (bps)

When discussing modem transmission speeds, the terms *baud rate* and *bit rate* are often confused. Baud rate (named after a Frenchman named Emile Baudot, the inventor of the asynchronous telegraph printer) is the rate at which a signal between two devices changes in one second. If a signal between two modems can change frequency or phase at a rate of 300 times per second, for example, that device is said to communicate at 300 baud.

Thus, baud is a signaling rate, not a data-transmission rate. The number of bits transmitted by each baud is used to determine the actual data-transmission rate (properly expressed as *bps* or *Kbps*).

Sometimes a single modulation change is used to carry a single bit. In that case, 300 baud also equals 300 bps.

If the modem could signal two bit values for each signal change, the bps rate would be twice the baud rate, or 600bps at 300 baud. Most modems transmit several bits per baud, so that the actual baud rate is much slower than the bps rate. In fact, people often use the term *baud* incorrectly. We normally are not interested in the raw baud rate, but in the bps rate, which is the true gauge of communications speed. As the following chart shows, more recent modems can signal multiple bit values with each signal change:

Baud rate	# of bits/baud	Actual modem bps
600	4	2,400
2400	4	9,600
2400	6	14,400
3200	9	28,800

(continues)

(continued)

As before, the baud rate is multiplied by the number of bits/ baud to determine the actual bps speed of the modem.

It can be difficult to reach rates above 2,400 baud on normal telephone lines, which explains why a 28.8Kbps (28,800bps) modem might not work above 19,200bps when telephone line quality is poor. As we'll see later, the so-called 56Kbps modems don't use baud as explained earlier, but work in a completely different manner.

Modulation Standards

Modems start with modulation, which is the electronic signaling method used by the modem (from modulator to demodulator). Modulation is a variance in some aspect of the transmitted signal. By modulating the signal using a predetermined pattern, the modem encodes the computer data and sends it to another modem that demodulates (or decodes) the signal. Modems must use the same modulation method to understand each other. Each data rate uses a different modulation method, and sometimes more than one method exists for a particular rate.

Regardless of the modulation method, all modems must perform the same task: Change the digital data used inside the computer (ON-OFF, 1-0) into the analog (variable tone and volume) data used by the telephone company's circuits, which were built over a period of years and never intended for computer use. That's the "Mo(dulate)" in modem. When the analog signal is received by the other computer, the signal is changed back from the analog waveform into digital data (see Figure 18.3). That's the "Dem(odulate)" in modem.

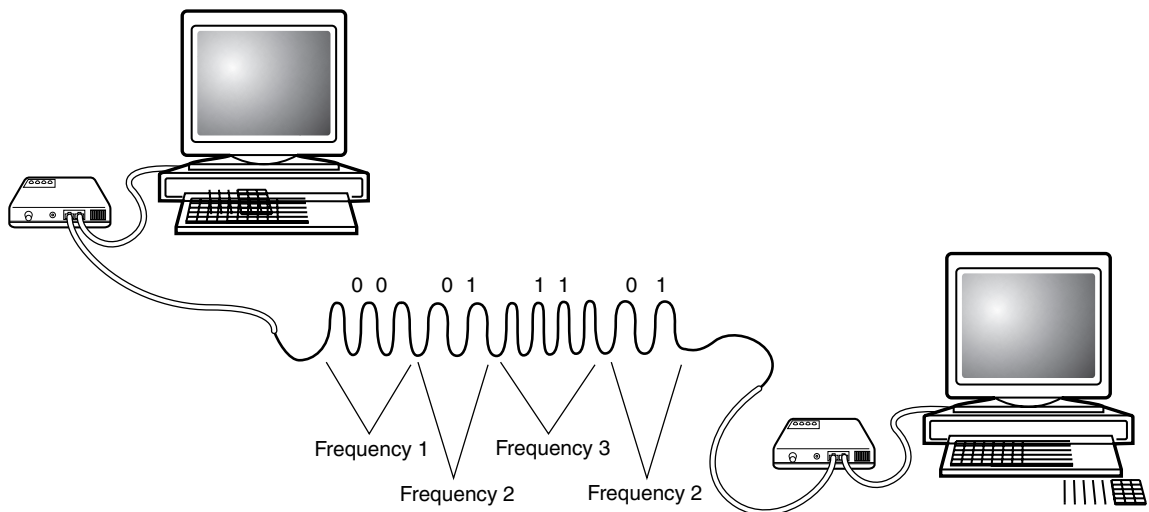

Figure 18.3 The modem at each computer changes digital (computer) signals to analog (telephone) signals when transmitting data or analog back to digital when receiving data.

The three most popular modulation methods are

- *Frequency-shift keying (FSK)*. A form of frequency modulation, otherwise known as FM. By causing and monitoring frequency changes in a signal sent over the phone line, two modems can send information.
- *Phase-shift keying (PSK)*. A form of phase modulation in which the timing of the carrier signal wave is altered and the frequency stays the same.
- *Quadrature amplitude modulation (QAM)*. A modulation technique that combines phase changes with signal-amplitude variations, resulting in a signal that can carry more information than the other methods.

Table 18.1 lists the protocols that define the modulation standards used by asynchronous modems, along with their maximum transmission rates and duplex modes. A full duplex protocol is one in which communications can travel in both directions at the same time and at the same speed. A telephone call, for example, is full duplex, because both parties can speak at the same time. In half duplex mode, communications can travel in both directions, but only one side can transmit at a time. A radio call in which only one party can speak at a time is an example of half duplex communications.

These protocols are automatically negotiated between your modem and the modem at the other end of the connection. Basically, the modems start with the fastest protocol common to both and work their way down to a speed/protocol combination that will work under the line conditions existing at the time of the call. The ITU V.90, V.34, and V.32 family are the industry-standard protocols most commonly used today.

Table 18.1 Modem Modulation Standards and Transmission Rates

Protocol	Maximum Transmission Rate (bits per second)	Duplex Mode
Bell 103	300bps	Full
CCITT V.21	300bps	Full
Bell 212A	1200bps	Full
ITU V.22	1200bps	Half
ITU V.22bis	2400bps	Full
ITU V.23	1200/75bps	Pseudo-Full
ITU V.29	9600bps	Half
ITU V.32	9600bps	Full
ITU V.32bis	14400bps (14.4Kbps)	Full
ITU V.32fast	28800bps (28.8Kbps)	Full
ITU V.34	28800bps (28.8Kbps)	Full
ITU V.90	56000bps (56Kbps)*	Full

Although the ITU V.90 (successor to the proprietary 56Kflex and x2 standards) allows for this speed of transmission, the U.S. FCC (Federal Communications Commission) allows only 53000 bps (53Kbps) at this time.

The antiquated protocols are included in Table 18.2, whereas protocols still in common use today are explained in more detail in the following sections.

Note

For more information about older modem standards (modems with speeds of 9600bps or below), see the *Upgrading and Repairing PCs, Eleventh Edition*, included in electronic form on the CD-ROM included with this book

Table 18.2 Antiquated Modem Protocols

Modem Protocol	Speed and Notes
Bell 103	300bps standard used in U.S. and Canada.
V.21	International 300bps standard; used primarily outside of U.S.
Bell 212A	1200bps standard used in U.S. and Canada.
V.22	International 1200bps standard; primarily used outside of U.S.
V.22bis ¹	International 2400bps standard used both inside and outside of U.S. (see the following note).
V.23	International standard for 1,200bps in one direction and 75bps in the reverse direction. Used primarily in Europe, the modem is only pseudo full-duplex. ²
V.29	International standard for 9600bps used by Group III fax machines; modem version of this standard not fully defined and rarely used.
V.32	International standard for 9600bps modems; includes error-correction.
V.32bis ¹	Improved version of V.32 for 14,400bps modems, with error-correction and fallback to V.32 if necessary.
V.32Fast	(A.K.A. V.FC) A nonstandard 28,800bps standard that is not interchangeable with the V.34 28,800bps standard.
V.34	International standard for 28,800bps; some units using DSPs ³ can be upgraded with software to 33,600bps version (see the following note).
V.34 annex	Improvement to original V.34 to support 31,200bps and 33,600bps; fastest purely analog telephone connection possible.

1 Bis is derived from the Latin meaning second, indicating that this data transmission is an improvement to, or follows the original version of the standard

2 Pseudo full-duplex can transmit data in both directions simultaneously, but not at the maximum data rate

3 DSP: Digital Signal Processor

Note

The 56Kbps standards that represent the highest current increment in modem communication speed require a digital connection at one end and are therefore not purely analog. Other high-speed communication technologies such as ISDN and cable network connections eschew analog communications entirely, so they should not be called modems, strictly speaking.

V.90

V.90 is the ITU-T designation for a 56Kbps communication standard that reconciles the conflict between the U.S. Robotics (3Com) x2 and Rockwell K56flex modem specifications.

▶▶ See “56Kbps Modems,” p. 1008.

Error-Correction Protocols

Error correction refers to the capability of some modems to identify errors during a transmission, and to automatically resend data that appears to have been damaged in transit. Although it is also possible to implement error correction using software, this places an additional burden on the computer's expansion bus and processor. By performing error correction using dedicated hardware in the modem, errors are detected and corrected before any data is passed to the computer's CPU.

As with modulation, both modems must adhere to the same standard for error correction to work. Fortunately, most modem manufacturers use the same error correction protocols.

MNP 1–4

This is a proprietary standard that was developed by Microcom to provide basic error correction. The Microcom Networking Protocol (MNP) levels are examined in greater detail in the “Proprietary Standards” section, later in this chapter.

MNP10, MNP10EC

MNP10 was developed to provide a better way to cope with changing line conditions. MNP10EC is an enhanced version developed to allow modems to use constantly changing cellular telephone connections.

V.42

V.42 is an error-correction protocol, with fallback to MNP 4; version 4 is an error-correction protocol as well. Because the V.42 standard includes MNP compatibility through Class 4, all MNP 4-compatible modems can establish error-controlled connections with V.42 modems.

This standard uses a protocol called LAPM (Link Access Procedure for Modems). LAPM, like MNP, copes with phone line impairments by automatically retransmitting data corrupted during transmission, assuring that only error-free data passes between the modems. V.42 is considered to be better than MNP 4 because it offers approximately a 20% higher transfer rate due to its more intelligent algorithms.

Data-Compression Standards

Data compression refers to a built-in capability in some modems to compress the data they're sending, thus saving time and money for modem users. Depending on the type of files the modem is sending, data can be compressed to nearly one-fourth its original size, effectively

quadrupling the speed of the modem. For example, a 14,400bps modem with compression can yield transmission rates of up to 57,600bps, a 28,800bps can yield up to 115,200bps, and a 56,000bps modem up to 224,000bps (download only)—at least in theory. This assumes that the modem has V.42bis data compression built-in (true since about 1990) *and* that the data hasn't already been compressed by software. Thus, in reality, the higher throughput caused by data compression applies only to HTML and plain-text files on the Web. Graphics and ZIP or EXE archives have already been compressed, as have most PDF (Adobe Acrobat Reader) files.

Can Non-56Kbps Modems Achieve Throughput Speeds Above 115,200bps?

Yes. To achieve speeds above 115,200bps, a better UART chip than the standard 16550-series chip found in modern PC serial ports and internal modems is required. 16650 UARTs have a 32-byte buffer, as opposed to the 16-byte buffer found in the standard 16550 UART. The 16650 is seldom used in PCs' built-in serial ports or as part of an internal modem, but it can be added by installing a high-speed serial port interface card (which might require you to disable your current COM ports).

Thus, to achieve the highest possible speeds, you need the following: an external modem capable of running at 230.4Kbps throughput, a 16650 UART chip in the serial (COM) port connected to the modem, and appropriate software drivers for the modem. Note that a 56Kbps-compatible modem isn't required! 230.4Kbps connections are available with anything from V.34bis to ISDN modems *if* the device is designed for that speed and you have the correct UART chip and drivers. But, as with the lower speed throughput rates mentioned earlier, these speeds apply only to data that has not been compressed already.

As with error correction, data compression can also be performed with software. Data can only be compressed once, so if you are transmitting files that are already in a compressed form, such as ZIP archives, GIF or JPEG images, or Adobe Acrobat PDF files, there will be no palpable increase in speed from the modem's hardware compression. The transmission of plain-text files (such as HTML pages) and uncompressed bitmaps, however, is accelerated greatly by modem compression.

MNP 5

Microcom continued the development of its MNP protocols to include a compression protocol called MNP 5. This protocol is examined more fully in the section "Proprietary Standards," later in this chapter.

V.42bis

V.42bis is a CCITT data-compression standard similar to MNP Class 5, but provides about 35% better compression. V.42bis is not actually compatible with MNP Class 5, but nearly all V.42bis modems include the MNP 5 data-compression capability as well.

This protocol can sometimes quadruple throughput, depending on the compression technique. This fact has led to some deceptive advertising; for example, a 2,400bps V.42bis modem might advertise "9,600bps throughput" by including V.42bis as well, but this would be possible in only extremely optimistic cases, such as when sending text files that are very loosely packed. V.42bis is superior to MNP 5 because it analyzes the data first and then determines whether compression would be useful. V.42bis only compresses data that needs compression. MNP 5 always attempts to compress the data, which slows down throughput on previously compressed files.

To negotiate a standard connection using V.42bis, V.42 also must be present. Therefore, a modem with V.42bis data compression is assumed to include V.42 error correction. When combined, these two protocols result in an error-free connection that has the maximum data compression possible.

Proprietary Standards

In addition to the industry-standard protocols for modulation, error correction, and data compression that are generally defined and approved by the ITU-T, several protocols in these areas were invented by various companies and included in their products without any official endorsement by any standards body. Some of these protocols have been quite popular at times and became pseudo-standards of their own.

The most successful proprietary protocols are the MNP (Microcom Networking Protocol) standards developed by Microcom. These error-correction and data-compression protocols are supported widely by other modem manufacturers as well.

Another company that has been successful in establishing proprietary protocols as limited standards is U.S. Robotics (now part of 3Com), with its HST (high-speed technology) modulation protocols. Because of an aggressive marketing campaign with BBS operators, HST modems captured a large portion of the market in the 1980s.

Note that many proprietary protocols are limited to the modems made by one particular manufacturer. In those cases, both the sender and receiver would need to have modems of the same brand equipped with the same proprietary protocol to make use of that protocol's features. The use of proprietary protocols is declining because the modems that feature them can't work at their maximum performance when communicating with modems that lack those protocols.

The following sections examine these and other proprietary modem protocols.

HST

HST is a 14,400bps and 9,600bps modified half-duplex proprietary modulation protocol developed by U.S. Robotics. Although commonly used by BBSes in the 1980s, the HST was made all but extinct by the introduction of V.32 modems at very competitive prices. HST modems run at 9,600bps or 14,400bps in one direction and 300bps or 450bps in the other direction. U.S. Robotics also marketed modems that used the ITU-T standard protocols and the U.S. Robotics proprietary standard. These dual-standard modems incorporated both V.32bis and HST protocols, giving you the best of the standard and proprietary worlds and enabling you to connect to virtually any other system at the maximum communications rate available at the time.

DIS

DIS is a 9,600bps proprietary modulation protocol by CompuCom, which uses Dynamic Impedance Stabilization (DIS), with claimed superiority in noise rejection over V.32. Because of the lower costs of V.32 and V.32bis, this proprietary standard quickly disappeared.

MNP

MNP offers end-to-end error correction, meaning that the modems are capable of detecting transmission errors and requesting retransmission of corrupted data. Some levels of MNP also provide data compression.

As MNP evolved, different classes of the standard were defined, describing the extent to which a given MNP implementation supports the protocol. Most current implementations support Classes 1–5; some new PCI modems and most PC Card (PCMCIA) modems might also support Class 10 and Class 10EC. Other classes usually are unique to modems manufactured by Microcom, Inc. because they are proprietary.

MNP generally is used for its error-correction capabilities, but MNP Classes 4 and 5 also provide performance increases, with Class 5 offering real-time data compression. The lower classes of MNP are not important to today's modem user, but they are included in the following table for the sake of completeness. Efficiency ratings in Table 18.3 are compared to a non-MNP modem, with 100% equaling the performance of a non-MNP modem.

Table 18.3 MNP Classes

MNP Class	Notes
MNP Class 1 (block mode)	70% efficiency and error correction only; rarely used today
MNP Class 2 (stream mode)	84% efficiency and error correction only; rarely used today
MNP Class 3	108% efficiency and incorporates Class 2
MNP Class 4	105% overall efficiency; can rise as high as 125%–150% on some types of calls and connections
MNP Class 5	Data compression; can increase throughput to 150% of normal with text files but is actually slower with compressed files; often disabled on systems transmitting .ZIP and other compressed files
MNP Class 10	Error correction for impaired lines: starts with lowest data rate and goes up to fastest reliable data rate (opposite of other speed-negotiation methods); can adjust data rate up and down as line conditions change
MNP Class 10EC	Enhanced Cellular version of MNP Class 10; handles cellular hand-offs, drop-offs, echoes and other line problems better and faster than regular MNP Class 10; works best when both ends have MNP Class 10EC support

V-Series

The Hayes V-series is a proprietary error-correction protocol from Hayes that was used in some of its modems. However, the advent of lower cost V.32 and V.32bis modems (even from Hayes) made the V-series all but extinct.

CSP

The CSP (CompuCom Speed Protocol) is an error-correction and data-compression protocol available on CompuCom DIS modems.

Fax Modem Standards

Facsimile technology is a science unto itself, although it has many similarities to data communications. These similarities have led to the combination of data and fax capabilities into the same modem. Virtually all the modems on the market today support fax and data communications, although in the late 1980s, when PC fax capabilities were first developed, separate fax and modem devices were required.

Over the years, the ITU has set international standards for fax transmission. This has led to the grouping of faxes into one of four groups. Each group (I through IV) uses different technology and standards for transmitting and receiving faxes. Groups I and II are relatively slow and provide results that are unacceptable by today's standards and are therefore not discussed in detail here. Group III is the universal standard in use today by virtually all fax machines, including those combined with modems.

The Group III Fax Protocol

The Group III protocol specifies a maximum fax transmission rate of 9600 baud and two levels of image resolution: standard (203×98 pixels) and fine (303×196 pixels). The protocol also calls for the use of a data-compression protocol defined by the CCITT (called T.4) and V.29 modulation.

There are two general subdivisions within the Group III fax standard: Class 1 and Class 2. The difference between the two is that in Class 1 faxing, the fax software generates the images and handles the session protocol and timing with the receiving system. In Class 2, the software generates an image for each page and passes it to the fax modem, which handles the session protocol and timing. Thus, with Class 1, compatibility with other fax devices is more the responsibility of the software, whereas with Class 2, compatibility is more the responsibility of the modem. Although both classes call for additional fax-related AT commands to be recognized and acted on by the modem, the Class 2 command set is much larger, consisting of over 40 new instructions.

The Class 1 specification was readily accepted and ratified by the CCITT in 1988, but the Class 2 document was rejected repeatedly. However, some manufacturers have designed Class 2 modems using the draft (that is, unratified) version of the standard. Today, nearly all fax modems support the Group III, Class 1 standard, and this should be the minimum acceptable requirement for any fax modem you intend to purchase. Class 2 support is an additional benefit, but by itself does not provide the almost universal compatibility of Class 1.

The Group IV Fax Protocol

Whereas Groups I through III are analog in nature (like modems) and are designed to use standard analog telephone lines, the Group IV specification calls for the digital transmission of fax images and requires an ISDN or other digital connection to the destination system. Group IV supports fax resolutions of up to 400dpi and uses a newer CCITT data compression protocol called T.6.

For a digital solution such as Group IV faxing to function, the connection between the source and the destination system must be fully digital. This means that even though your office might

use a PBX-based telephone system that is digital and your telephone carrier might use digital connections, it is very likely that there is at least some analog communication involved in the circuit, such as between the PBX and the local telephone service. Until the telephone system has been converted to a fully digital network (a monumental task), Group IV fax systems will not be capable of replacing Group III systems.

56Kbps Modems

In the ever-continuing quest for speed, modem manufacturers have overcome what was considered to be an unbreakable ceiling for asynchronous data transfer rates over standard telephone lines, and have released modems that support speeds of up to 56,000bps (or 56Kbps). To understand how this additional speed was achieved, you must consider the basic principle of modem technology—that is, the digital-to-analog conversion.

As you've learned, a traditional modem converts data from digital to analog form so it can travel over the Public Switched Telephone Network (PSTN). At the destination system, another modem converts the analog data back to its digital form. This conversion from digital to analog and back causes some speed loss. Even though the phone line is physically capable of carrying data at 56Kbps or more, the effective maximum speed because of the conversions is about 33.6Kbps. A man by the name of Shannon came up with a law (Shannon's Law) stating that the maximum possible error-free data communications rate over the PSTN is approximately 35Kbps, depending on the noise present.

However, Shannon's Law assumes a fully analog connection between the two modems. That is not the case in most of the United States today. In urban areas, most circuits are digital until they reach the telephone company's central office (CO) to which your phone line is connected. The CO converts the digital signal into an analog signal before sending it to your home.

Considering the fact that the phone system is largely digital, you can—in some cases—omit the initial digital-to-analog conversion and send a purely digital signal over the PSTN to the recipient's CO (see Figure 18.4). Thus, there is only one digital-to-analog conversion needed, instead of two or more. The result is that you can theoretically increase the speed of the data transmission, in one direction only, beyond the 35Kbps specified by Shannon's Law, to nearly the 56Kbps speed supported by the telephone network. The transmission in the other direction is still limited to the V.34 annex maximum of 33.6Kbps.

56Kbps Limitations

Thus, 56Kbps modems can increase data transfer speeds beyond the limits of V.34 modems, but they are subject to certain limitations. Unlike standard modem technologies, you cannot buy two 56Kbps modems, install them on two computers, and achieve 56Kbps speeds. One side of the connection must use a special digital modem that connects directly to the PSTN without a digital-to-analog conversion.

56Kbps modems, therefore, can be used at maximum speeds only to connect to ISPs or other hosting services that have invested in the necessary infrastructure to support the connection. Because the ISP has the digital connection to the PSTN, its downstream transmissions to your

computer are accelerated, whereas your communications back to the ISP are not. On a practical level, this means you can surf the Web and download files more quickly, but if you host a Web server on your PC, your users will realize no speed gain, because the upstream traffic is not accelerated. If you connect to another regular modem, your connection is made at standard v.34 annex rates (33.6Kbps or less).

Figure 18.4 56Kbps connections allow you to send data at standard analog modem rates (36,000bps maximum) but allow you to receive data nearly twice as fast.

Also, there can only be one digital-to-analog conversion in the downstream connection from the ISP to your computer. This is dictated by the nature of the physical connection to your local telephone carrier. If additional conversions are involved in your connection, 56Kbps technology will not work for you; 33.6Kbps will be your maximum possible speed. The leading Web site for line testing is the one created by 3Com's U.S. Robotics division, located at http://www.3com.com/56k/need4_56k/linetest.html.

This site provides a toll-free number and a simple procedure for you to use in testing your line with your existing modem. Although 33.6Kbps and slower modems have disappeared from the market, it's still useful to know whether buying a 56Kbps modem will give you faster speed at your current location.

Note

Although most advertising for 56Kbps modems refers to them as simply “56K” modems, this is inaccurate. “K” is most often used in the computer business to refer to kilobytes. If that were true, a “real” 56K modem would be downloading at 56,000 bytes per second (or 448,000 bits per second)!

Because the line test is specific to your location, test the line you’ll actually be using for the modem. With the way that the telephone system has had to grow to accommodate new exchanges and devices, even neighbors down the street from each other might have different results.

Caution

56Kbps modem communications are also highly susceptible to slowdowns caused by line noise. Your telephone line might be perfectly adequate for voice communications and even lower-speed modem communications, but inaudible noise can easily degrade a 56Kbps connection to the point at which there is only a marginal increase over a 33.6Kbps modem, or even no increase at all. If you do have a problem with line noise, it would help if you got a surge suppressor with noise filtration.

If you plan to use a PCMCIA/PC Card modem in a notebook computer, be aware that your hotel room will soon host the world’s slowest 56Kbps modem—yours! The connection quality of the separate analog phone jacks or the “data port” in the side of the typical hotel guest telephone is usually poor, and you’ll be lucky to see even a 24Kbps transmission rate. The analog-digital conversions that happen between your room’s telephone and the hotel’s digital PBX system eliminate the possibility of using any of the 56Kbps standards the modem supports, because they depend on a direct digital connection to the central switch (CS).

If you travel frequently on business and want to access the Internet more quickly without tying up your telephone line, ask the hotel staff whether they have rooms that support LAN connections, a developing option at more and more business hotels. These connections usually support 10BASE-T Ethernet, so a 10BASE-T or dual-speed 10/100 Ethernet card and cable would be a useful accessory to carry with you on the road.

56Kbps Standards

To achieve a high-speed connection, both modems and your ISP (or other hosting service to which you connect), must support the same 56Kbps technology. Here rises the biggest issue surrounding “56K” compatibility. In late 1996, modem manufacturers were anxious to bring the latest technology to market, so two companies released products using competing 56K standards. U.S. Robotics (now part of 3Com) introduced a line of 56Kbps modems using Texas Instruments chipsets that it called x2, whereas Rockwell, a manufacturer of modem chipsets, released another 56Kbps standard that it called K56flex. Naturally, these two standards were not compatible, and the rest of the modem industry rapidly polarized, supporting one standard or the other. The result was a latter-day version of the Beta/VHS conflict of the 1970s.

Note

To complicate matters further, it was discovered only days before U.S. Robotics shipped its first x2 modems that an old FCC regulation known as Part 68 specifies the maximum amount of power that you can run through a PSTN phone line. Because faster communications require more power, this regulation effectively limits modem communications to a maximum speed of approximately 53Kbps. The regulation was created because increasing the power transmitted over a line beyond a certain point causes increased interference, called *crosstalk*, on neighboring lines.

The FCC implemented this regulation long ago, not intending it to apply specifically to modems and is currently reevaluating its position. This reevaluation process began in the fall of 1998 and is still ongoing.

As a result of having two standards, users were forced to wait and see which technology their ISPs would adopt or commit to one of the two standards and then find an ISP that supported it. During this time, it was not uncommon for people to wind up with the “wrong” modem, because many ISPs initially supported only one of the rival standards. As the sales and popularity of both x2 and K56flex increased, many ISPs were forced to create separate dial-up phone numbers for each standard, increasing their costs but making their users happier.

V.90

After over a year of confusion and frustration for high-speed modem users, a single standard was finally created to solve the “war” between K56flex and x2. On February 5, 1998, the ITU-T approved a “determination” for a 56Kbps modem standard called V.90. The standard was ratified on September 15, 1998. Now that an official standard exists, all modem manufacturers have upgraded their current products to support V.90, and interoperability between devices supporting the two earlier standards should be possible.

Because the x2 and K56flex implementations are fundamentally similar in the hardware requirements described earlier, many existing modems of either type can be modified to support V.90 by upgrading their firmware using a flash update or a simple chip replacement. If you purchased your modem before the V.90 standard became official, see your modem vendor’s Web site for information about upgrading to V.90.

Depending on your modem model, one of three outcomes is likely:

- Some users will be able to download software to “flash” their BIOS firmware to the new V.90 standard.
- Others will need to do a physical modem swap at a reduced price.
- Some will need to replace their modems outright.

Note

Hayes is back! The pioneering modem brand is now sold and manufactured by Zoom Telephonics as of June 1999.

Zoom is also providing users of Hayes, Practical Peripherals, and Cardinal modems sold by the now-defunct Hayes Corporation the option to try firmware upgrades or replace their modems at a reduced cost through Zoom’s hardware upgrade program. See Zoom Telephonics’s Web site at <http://www.zoomtel.com> for details.

Note

Before you upgrade a K56flex modem to V.90, see the tips later in this chapter to determine whether it’s really necessary; x2 owners should upgrade, because x2 dialup access is rapidly fading away. If your ISP has stopped supporting your proprietary 56Kbps standard, the best download speed you can hope for is 33.6Kbps.

Since the adoption of V.90, users with x2 modems who have updated their firmware to V.90 standards have generally had good luck in connecting, often obtaining higher speeds. However, there

have been a number of reports of K56flex users having problems in a V.90 world, even after updating their modems to the V.90 standard. If you have problems connecting reliably or speedily after doing a V.90 update from K56flex, try these tips:

Troubleshooting the V.90 (ex-K56flex) Modems

1. Make sure you have the latest firmware release. Even if you have just purchased your modem, your vendor might have put a firmware update on its Web site. To get there for the update, if you're having problems making the connection, dial in with your modem on a 33.6Kbps line, or pretend that your modem is an older model by installing it as a 33.6Kbps model from the same vendor.
2. See whether you can continue to use the modem as a K56flex. According to Lucent Technologies' 56K site (<http://www.k56flex.com>), many V.90-compliant sites can still support dialing in with a K56flex modem to get similar speed results compared to a user with a V.90 modem. "If it ain't broke, don't fix it!"
3. Check whether you can use both K56flex and V.90 firmware at the same time. Some modems' firmware ROM (read-only memory) chips have enough room for both K56flex and V.90 code, whereas others have space for just one or the other (Zoom Telephonics, for example, calls its modems with provision for both standards "Dualmode"). Typically, modems with a 1MB ROM chip can only handle one type of firmware, whereas modems with a 2MB ROM chip have room for both. If you can't have both code types in your modem at the same time, download both K56flex and V.90 firmware to your system, try each one, and see which works better for you. As long as your ISP has a K56flex-specific modem pool or has V.90 modems which also support K56flex, you don't really need to change to V.90.
4. If your vendor has several versions of firmware available for download, try some of the earlier versions, as well as the latest version. An earlier version might actually work better for you.
5. If you are using your modem in a country other than the United States or Canada, you might need an international update. Zoom Telephonics's Web site, for example, lists separate K56flex-to-V.90 updates for Australia, Belgium, Denmark, Finland, France, Germany, Holland (the Netherlands), Italy, Portugal, Sweden, Switzerland, and the United Kingdom (Great Britain and Northern Ireland).
6. Don't forget that your operating system drivers for your modem might also need to be updated.

Note

The problems some users have with moving from K56flex to V.90 do not apply to users who have updated their V.34 modems directly to the V.90 standard, whether by a downloadable firmware update or by a physical modem or chip swap. Even if your V.34 modem was made by a company that later made K56flex modems, you don't need to worry about this unless you updated to K56flex. Then the troubleshooting advice given earlier applies to you as well.

Modem Recommendations

A modem for a PC can take the form either of an external device with its own power supply that plugs into a PC's serial port or USB port, or an internal expansion card that you insert into a bus

slot inside the computer. Most manufacturers of modems have both internal and external (RS-232 serial and/or USB) versions of the same models.

External versions are slightly more expensive because they include a separate case and power supply. Both are equally functional, however, and the decision as to which type you use should typically depend on whether you have a free bus slot or serial port, whether you have USB ports and Windows 98, how much room you have on your desk, the capabilities of your system's internal power supply, and how comfortable you are with opening up your computer.

I often prefer external modems because of the visual feedback they provide through indicator lights. These lights make it easy to see if the modem is still connected and transmitting or receiving data. However, some communication programs today include onscreen simulations of the lights, providing the same information.

There are other situations, too, where an internal modem is preferable. In case your computer's serial ports do not have buffered UART chips such as the 16550, many internal modems include an onboard 16550 UART. This onboard UART with the modem saves you the trouble of upgrading the UART serial port. Also, external 56Kbps modems can be hampered from achieving their full speed by the limitations of the computer's serial port. An internal model might be preferable instead. Use Table 18.4 to see how internal and external units compare.

Table 18.4 External Versus Internal Modems

Features	External	Internal
Built-in 16550 UART or higher	No (uses computer's serial port UART or might use USB).	Yes (if 14.4Kbps or faster).
Price comparison	Higher.	Lower.
Extras to buy	RS-232 Modem Interface cable or USB cable.	Nothing.
Ease of moving to another computer	Easy—unplug the cables and go! (USB modems require a functioning USB port on the computer and Windows 98 or above.) ¹	Difficult—must open case and remove card, open other PC's case and insert card.
Power supply	Plugs into wall ("brick" type).	None—powered by host PC.
Reset if modem hangs	Turn modem off, and then on again.	Restart computer.
Monitoring operation	Easy—External signal lights.	Difficult—unless your communication software simulates the signal lights.
Interface type	Almost always via the RS-232 port, although USB modems are now on the market. Parallel-port modems were made a few years ago, but never proved popular.	Traditionally ISA, but many models now available in PCI, which should work better in new machines, allow mapping of COM 3 and 4 away from COM 1 and 2 to avoid IRQ sharing, and be usable in machines of the future which will lack ISA slots.

¹ Although late versions of Windows 95 OSR 2.x have USB support, many USB devices actually require Windows 98 or better. Use Windows 98 to achieve more reliable support for USB devices.

Not all modems that function at the same speed have the same functionality. Many modem manufacturers produce modems running at the same speed, but with different feature sets at different price points. The more expensive modems usually support advanced features such as distinctive ring support, caller ID, voice and data, video teleconferencing, and call-waiting support. When purchasing a modem, be sure that it supports all the features you need. It's also a good idea to make sure the software you plan to use, including the operating system, has been certified for use with the modem you select.

If you live in a rural area, or in an older city neighborhood, your telephone line quality might influence your decision. Look at comparison test results carefully and pay particular attention to how well different modems perform with noisy lines. If your phone line sounds crackly during a rainstorm, that poor-quality line makes reliable modem communications difficult too, and can limit your ability to connect at speeds above 33.6Kbps.

Most of the brand-name modems on the market today support a wide range of modulation, error-correction, and data-connection standards. This is because most modems are *auto-negotiating*—that is, when they connect to another modem they implement the most efficient set of protocols they have in common. Even if the two modems do not agree on the most advanced protocol of a particular type, they are likely to have at least one protocol in common.

Another feature to consider is the modem's resistance to electrical damage. Some brands feature built-in power protection to shield against damage from digital telephone lines (higher powered and not compatible with modems) or power surges. However, every modem should be used with a surge protector that allows you to route the RJ-11 telephone cable through the unit for protection against high-voltage surges.

Virtually all modems on the market today support V.90, and even if your particular location can't support those speeds, your modem might still offer advanced features such as voicemail or simultaneous voice and data. Keep in mind that V.90 connections seem to work better for many users if their modem also supports x2. If you prefer a modem made by a vendor which also supports K56flex, try to buy a modem that contains both types of standards in its firmware (referred to by some vendors as "Dualmode" modems).

Choosing to Upgrade

If you bought your modem in 1997 or early 1998, chances are good that it came with 56Kbps support or that you've upgraded it to some form of 56Kbps support. However, even though today's modems still can't download data any faster, there have been other changes in modem design that might make a modem upgrade desirable for you. And if you are still using a 33.6Kbps modem or even slower model, you should get a 56Kbps modem if your line quality can support it.

Table 18.5 summarizes the major changes in modem design and features currently available, along with advice on who should consider these features.

Modems introduced in 1999 and beyond still run at the 53Kbps FCC maximum with the potential to run at up to 56Kbps if the FCC regulations change, but they might offer one or more of the following features:

- Call-waiting support
- PCI expansion slot for internal modems
- USB connection for external modems
- Faster performance for gaming
- MNP10 and MNP10EC

Table 18.5 New Modem Features and Types

Modem Feature	Benefit	Who Should Buy	Cautions
MNP10EC support	Improves performance on poor-quality phone lines by quickly adjusting line speed up and down with changing conditions.	Anyone with poor-quality lines, especially if modem at other end also has MNP10EC support; users who want to use modem with cellular phones.	Don't buy MNP10 support by mistake; MNP10EC is much better and includes MNP10. Check with ISP to see whether cellular connections are supported; speed of such connections can be 14.4Kbps or slower.
PCI bus	Works in PCI slots which dominate current systems and are replacing ISA slots; can be set to can share IRQs with other devices.	Anyone without ISA slots or who is planning to move the modem to another computer in the future and prefers internal modems.	Verify one or more PCI slots are available; look for other features listed here to make change as useful as possible; see also "Software Modem inModems)" later in this chapter.
USB connection	Works with USB connectors on most current and all future computers; high-speed connection and ability to connect many devices via a hub.	Anyone who wants portability and has USB connectors along with Windows 98 or above.	Although Windows 95 OSR2.5 (Win95"C") has USB support, many devices require Win98; make sure USB has been activated in BIOS.
Gaming-optimized modem	Faster PING and response for gaming, which is more important than data throughput.	Anyone who plays a lot of online games, or wants to get started.	Game optimizations are not useful for ordinary Web surfing. These modems are more expensive than others, especially if you don't use game features.
Call-waiting support	Allows you to answer the phone and not lose modem connection instead of disabling call waiting as currently.	Anyone who uses call waiting and doesn't like voice callers to get busy signals; check with manufacturer to see if your existing modem can be upgraded with a driver.	Seven seconds maximum talk time; make sure you have phone at computer for fast "hello, I'll call you later" answers to avoid exceeding time limit.
Voice support	Allows digitizing of received calls; computerized answering machine and faxback; inbound and outbound phone calls via computer.	Anyone who wants to use PC as a tele-communications center.	Check quality of voice recording; can use up a lot of disk space.
V.90 Plus	Allow uploads faster than 33.6Kbps current limit as well as faster handshaking.	Coming in late 2000; standard must be approved by ITU, but some models might ship sooner.	Avoid models that ship before ITU approves standard; these "early-bird" modems might not be upgradeable.

Software Modems (WinModems)

Software modems, a.k.a. “WinModems” after the popular U.S. Robotics/3Com version, are controversial devices.

For users looking for an inexpensive internal modem, a software modem using Windows instead of a UART-equipped internal or external modem looks like a great deal, often under \$40.00. But, there is no free lunch for modem users. What can you lose with a “soft modem”?

First, you need to realize that there are actually two types of software modems: those that rely on Windows and the CPU for all operations, and those that use a programmable DSP (Digital Signal Processor) chip to replace the UART. Although both are “software modems,” there’s an enormous difference in what you’re getting.

A Windows-based modem must run under Windows because Windows provides the brains of the modem, a cost-cutting move similar to that used by some low-cost host-based printers. You’ll want to avoid this if you’re planning to try Linux or use an old MS-DOS based communications program. Having no drivers means no luck using the software modem.

Software modems that lack a DSP have a second major strike against them: making your CPU do all the work. Many of these modems require a Pentium 133 or faster and might also need MMX technology to make the modem work properly. The CPU utilization rate can skyrocket with these “dumb” modems in use, and if you like to multitask with Windows while you’re on the Web, you’ll watch your other software slow down even as your connection slows down.

However, both types of software modems use less power than traditional modems, allowing a longer battery life for notebook computers using this type of modem.

Most of the modems bundled with computer systems are software modems, and the major chipsets used include Lucent LT, Conexant (formerly Rockwell) HCF, U.S. Robotics/3Com WinModem, ESS, Ambient (spinoff of Cirrus Logic), and PCTel.

Except for U.S. Robotics, the other companies produce chipsets which can be found in the modems made by many different brands.

For best results,

- Make sure your software modem uses a DSP; typically, these modems don’t require a particular CPU or a particular speed of CPU
- Consider modems built around the Lucent LT chipset; these modems have a DSP and Lucent’s firmware is frequently revised to achieve the best results in a rapidly changing telephony environment
- Use the modem manufacturer’s own drivers first, but software modems can often use any manufacturer’s drivers for the same chipset with excellent results
- Don’t delete the old software driver when you download and install new modem software; as with UART-equipped modems, the latest firmware isn’t always the best
- If you have a software modem that requires a fast CPU, try to use the fastest CPU you can; if your CPU is barely faster than the minimum, avoid multitasking to improve performance, or upgrade your CPU
- Look carefully at the CPU, RAM, and operating system requirements before you buy your modem

Tip

Many manufacturer sell both hardware-based and software modems. If you have an older system, or want the option to use MS-DOS or Linux-based communications programs, the hardware modem with a traditional UART might cost more but be your better choice.

Support for “Brand-X” Modems

Many computer users today didn’t install their modems, or even purchase them as a separate unit. Their modems came bundled inside the computer, and often have a bare-bones manual that makes no mention of the modem’s origin or where to get help. Getting V.90 firmware, drivers, or even jumper settings for OEM modems like this can be difficult.

One of the best Web sites for getting help when you don’t know where to start is <http://www.windrivers.com>, which features a modem identification page with the following features:

- FCC ID: Enter the FCC ID number attached to the modem to determine who made it
- Lookup by chipset manufacturer
- Modem throughput tests
- Links to major modem manufacturers

Squeezing Performance from Your 56Kbps Modem

Although many users of 56Kbps modems have seen significant improvements in their connect speed and throughput over their previous V.34-type modems, many have not or see only sporadic improvements. According to the research of Richard Gambert, available online at his “56k=v.Unreliable” Web site (<http://www.808hi.com/56k/>), a combination of five different factors comes into play to affect your ability to get reliable connections in the range of 45Kbps–53Kbps (the current FCC maximum):

- The modem
- The modem firmware/driver
- Your line conditions
- The ISP’s modems
- The ISP’s modem firmware

It’s up to you to make sure that you match your modem 56Kbps type to the 56Kbps standards your ISP supports, and that you use the best (not always the latest!) modem firmware and drivers, as discussed in the previous section.

Other modem adjustments recommended at the “56k=v.Unreliable” site include:

- Modifying existing modem .INF files used by Windows 9x to accurately reflect connection speed
- Disabling 56Kbps connections (!) when playing games to minimize lag times

Note

This last suggestion might seem odd, but “fast” modems are designed to push a large amount of data through for downloads, and game play over modems actually deals with small amounts of data instead. The lag time caused by 56Kbps data handling can make a regular “fast” modem seem slow. If you want a fast modem for both downloading and game playing, see “Choosing to Upgrade,” earlier in this chapter.

The site also hosts a forum area for discussing modem configuration, reliability, and performance issues.

Telco “Upgrades” and Your Modem

In addition to the well-known analog-to-digital conversion issue that prevents some phone lines from handling 56Kbps modems at anything beyond 33.6Kbps, other local telephone company (telco) practices can either prevent 56Kbps from ever working or take it away from you after you’ve enjoyed it for a while.

If you were getting 45Kbps or faster connections with your 56Kbps modem but can no longer get past 33.6Kbps, what happened? Some local telephone companies have been performing network “upgrades” that prevent 56Kbps modems from running faster than 28Kbps but don’t affect voice calls. The cause seems to be the telephone companies’ change from a signaling type called RBS (Robbed Bit Signaling) to SS7 (Signaling System 7), which changes how data used by the modem for high-speed access is detected.

What can you do? If you have a modem using Lucent Technologies firmware, check with your modem supplier or with Lucent (see “Software Modems (WinModems),” earlier in this chapter) for updates, because Lucent has developed workarounds for this problem. You can also check with your local telephone company to see whether it can update its firmware to solve the problem. Even if your modem has different firmware, checking on an upgrade might still be useful, as this problem is likely to become widespread as telephone numbers, exchanges, and area codes continue to multiply like weeds and telephone network upgrades must keep pace.

Integrated Services Digital Network (ISDN)

To get past the speed limitations of asynchronous modems, you have to go completely digital, and ISDN is the next step in telecommunications. ISDN makes the break from the old technology of analog data transfer to the newer digital data transfer. With ISDN, you can connect to the Internet at speeds of up to 128Kbps.

ISDN has been available for over 10 years but has only recently become a practical solution for private users. This was mostly due to the difficulties involved in arranging for the installation of the service with the telephone company. Just a few years ago, it was difficult to find someone at most regional phone companies who had even heard of ISDN, but now quite a few businesses provide turnkey solutions, including ISP services, ISDN hardware, and negotiations with the phone company.

Although it can be used for voice communications, ISDN is not like a normal telephone connection, even though it uses your existing telephone wiring. To achieve high speeds, both ends of

the connection must be digital, so you would typically set up an ISDN line specifically for connecting to an ISP that also uses ISDN. Businesses also use higher bandwidth ISDN connections for Internet access or to connect LANs in remote offices.

ISDN is also not like a leased telephone line, however, which permanently connects two specific locations. Your software still dials the number of your intended destination (although it is a special ISDN number) and breaks the connection (that is, hangs up) when the session is finished. Thus, you can change to a different ISP that supports ISDN, if necessary, without dealing with the phone company again.

What Does ISDN Really Mean for Computer Users?

Because ISDN carries three channels, it allows integrated services that can include combinations such as voice+data, data+data, voice+fax, fax+data, and so on.

The “Digital” in ISDN represents the end of the need for your venerable telecom pal, the modem. ISDN connections are digital from the origination straight to your PC—no digital-analog conversions needed. Thus, the so-called ISDN modem used to hook your PC to an ISDN line is more properly called a *terminal adapter*.

The “Network” in ISDN refers to its capability to interconnect with other ISDN devices around the world. Unlike the earlier high-speed access method for business, the leased line, ISDN isn’t limited to making fast connections to a single computer. In fact, if your ISDN equipment includes support for analog services, your ISDN connection can “reach out and touch” regular telephones, fax machines, and other plain old telephone service (POTS) devices (see Figure 18.5).

Figure 18.5 This typical ISDN configuration shows how ISDN can link your advanced telecommunications devices with both the ISDN and analog worlds.

How Standard ISDN Works

On a standard ISDN connection, bandwidth is divided into bearer channels (B channels) that run at 64Kbps and a delta channel (D channel) that runs at either 16Kbps or 64Kbps, depending on the type of service. The B channels carry voice transmissions or user data, and the D channel carries control traffic. In other words, you talk, surf, or fax through the B-channel lines. The typical BRI service would allow you to use one B channel to talk at 64Kbps and one B channel to run your computer for Web surfing at 64Kbps. Hang up the phone, and both B channels become available. If your ISDN service is configured appropriately, your Web browsing becomes super-charged, because you're now running at 128Kbps.

There are two types of ISDN service: Basic Rate Interface (BRI) and Primary Rate Interface (PRI). The BRI service is intended for private and home users and consists of two B channels and one 16Kbps D channel, for a total of 144Kbps. The PRI service is oriented more toward business use, such as for PBX connections to the telephone company's central office (CO). In North America and Japan, the PRI service consists of 23 B channels and one 64Kbps D channel for a total of 1536Kbps, running over a standard T-1 interface. In Europe, the PRI service is 30 B channels and one 64Kbps D channel, totaling 1984Kbps, corresponding to the E1 telecommunications standard. For businesses that require more bandwidth than one PRI connection provides, it's possible to use one D channel to support multiple PRI channels using Non-Facility Associated Signaling (NFAS).

The BRI limit of two B channels might seem limiting to anyone other than a small office or home office user, but this is misleading. The BRI line can actually accommodate up to eight different ISDN devices, each with a unique ISDN number. The D channel provides call routing and "on-hold" services, also called "multiple call signaling", allowing all the devices to share the two B channels (see Figure 18.6).

Figure 18.6 BRI permits use of up to eight ISDN devices, each with its own ISDN number.

Compare this to how a normal analog modem connection works (see Figure 18.7).

Figure 18.7 An analog modem connection connects only your PC to the Internet or other online services, whereas ISDN can connect your computer, fax, and many other devices via a single ISDN terminal adapter.

Note

When speaking of ISDN connections, one kilobyte equals 1,000 bytes, not 1,024 bytes as in standard computer applications.

As we saw earlier, this is also true of speed calculations for modems. Calculations that use 1,000 as a base are often referred to as “decimal kilobytes,” whereas the ones based on 1,024 are called “binary kilobytes.”

If you need a more powerful and more flexible version of ISDN, use the PRI version along with a switching device such as a PBX or server. Although PRI allows only one device per B channel, it can dynamically allocate unused channels to support high-bandwidth uses such as videoconferencing when a switching device is in use along with PRI.

Benefits of ISDN for Internet Access

It is possible to aggregate the bandwidth of multiple B channels using a protocol such as Multilink PPP or BONDING (developed by the Bandwidth on Demand Interoperability Group), so you can use the BRI service to establish a single 128Kbps connection to the Internet. You can also connect multiple devices (up to eight for BRI) to a single ISDN connection and transmit multiple signals to different destinations at the same time, thus replacing several standard telephone lines. For example, you can have your computer, digital phone, fax machine, and up to five more devices, each assigned its own telephone number. This way incoming calls will go directly to the appropriate device.

To have an ISDN connection installed, you must be within 18,000 feet (about 3.4 miles or 5.5km) of the CO (telco central office or central switch) for the BRI service. For greater distances, expensive repeater devices are needed, and some telephone companies might not offer the service at all. Most of the existing telephone wiring in the United States is capable of supporting ISDN communications, so you usually need not pay for the installation of new telephone cable.

Prices for ISDN service vary widely depending on your location. In the United States, the initial installation fee can be in the area of from \$100 to \$150, depending on whether you are converting an existing line or installing a new one. The monthly charges are typically from \$30 to \$50, and often there is a connect-time charge as well, ranging from 1 to 6 cents per minute or more, depending on the state. Keep in mind that you also must purchase an ISDN terminal adapter for your PC and possibly other hardware as well, and these charges are only for the telephone company's ISDN service. You must also pay your ISP for access to the Internet at ISDN speeds.

Because ISDN pricing plans offer many different options depending on the channels you want and how you want to use them, make sure you plan out carefully how you want to use ISDN. Check the telco's Web site for pricing and package information to get a jump on the decision-making process. Even with the large multi-state telcos such as Ameritech or other Baby Bells, your state and location will make an enormous difference in both the pricing and availability of ISDN services.

Always on with Dynamic ISDN

Earlier, I compared ISDN with leased-line services and pointed out that for many users ISDN would be a superior solution. However, conventional ISDN isn't the answer when you want to keep a continuous connection available at minimal cost.

A *nailed-up* connection is continuously kept up for uninterrupted remote access to a LAN. This uses up the resources of at least one B channel, even though the full capacity of the channel is seldom in use at one time. Because traffic varies greatly over an "always on" connection, Dynamic ISDN was developed to use the power of ISDN more flexibly. Dynamic ISDN is also referred to as *Always On/Dynamic ISDN (AO/DI)*.

Dynamic ISDN combines the circuit-switching of a traditional phone system connection with the packet-switching of LANs and the World Wide Web.

The D channel is used to make each connection using the X.31 protocol that runs over the normal telco packet-switched network. Normally used for signaling, the D channel has sufficient bandwidth to carry such low-demand traffic as email notification (or even email itself), channel subscription, and PointCast+ "push" information to users.

The high-speed B channels are activated only when needed for high-bandwidth uses such as file transfer. The D channel can automatically switch this type of traffic to either one or both B channels (one provides 64Kbps transfer rates; both would provide 128Kbps transfer rates). The B channels are automatically released when the heavy traffic uses are finished and are free to handle voice or fax traffic until high-volume computer traffic requires their use.

Thus, Dynamic ISDN makes the potential of ISDN a reality by allowing intelligent allocation of resources.

This is the best type of ISDN to get if you want to use ISDN for more than just high-speed Internet access. Check with your ISDN vendor for price and availability in your area. You might need to contact an ISP that specializes in ISDN access, rather than a local telephone company, to find this service in your area. Although Dynamic ISDN has been in the works since 1997, it is still not as widely available in the U.S. as other forms of ISDN. However, use of this technology in Europe and Asia is growing rapidly.

ISDN Hardware

To connect a PC to an ISDN connection, you must have a hardware component called a *terminal adapter (TA)*. The terminal adapter takes the form of an expansion board or an external device connected to a serial port, much like a modem. In fact, terminal adapters are often mistakenly referred to as ISDN modems. Actually, they are not modems at all, because they do not perform analog/digital conversions.

There are two different interfaces to the ISDN service. The U interface consists of a single pair of wires leading to the telephone company's CO. The Subscriber/Termination (S/T) interface consists of two pairs of wires that typically run from a wall jack to your terminal adapter. The device that converts the U interface signal to the S/T interface is called a *network termination device*, or NT-1.

Some terminal adapters include an NT-1 integrated into the hardware, enabling you to connect the U interface directly to the computer. This is an excellent solution as long as the computer is the only device that you plan to connect to the ISDN line. If you want to connect multiple devices, or if your terminal adapter does not include an NT-1, you must purchase an NT-1 separately. Another alternative is to get a network-ready terminal adapter that you can connect to your current NIC. This is an especially good alternative if you have several PCs, as you can share one TA among them.

Caution

When purchasing an ISDN terminal adapter, you will almost always want to invest in an internal version. A terminal adapter with compression can easily exceed a serial port's capability to reliably send and receive data. Consider that even a moderate 2:1 compression ratio exceeds the maximum rated speed of 232Kbps, which most high-speed COM ports support.

Leased Lines

For users with high bandwidth requirements (and deep pockets), dedicated leased lines provide digital service between two locations at speeds that can far exceed ISDN. A *leased line* is a permanent 24-hour connection to a particular location that can be changed only by the telephone company. Businesses use leased lines to connect LANs in remote locations or to connect to the Internet through a service provider. Leased lines are available at various speeds, as described in the following sections.

T-1 and T-3 Connections

To connect networks in distant locations, networks that must support a large number of Internet users, or especially organizations that will be hosting their own Internet services, a T-1 connection

might be the wise investment. A *T-1* is a digital connection running at 1.55Mbps. This is more than 10 times faster than an ISDN link. A T-1 can be split (or fractioned), depending on how it is to be used. It can be split into 24 individual 64Kbps lines or left as a single high-capacity pipeline. Some ISPs allow you to lease any portion of a T-1 connection that you want (in 64Kbps increments). Ameritech, for example, offers a flexible T-1 service it calls DS1, available at full bandwidth or in various fractional sizes. Figure 18.8 shows how a T-1 line is fractioned.

Figure 18.8 Full T-1 service uses all 24 lines (each one is 64Kbps) as a single pipeline; a fractional T-1 service of 256Kbps could use slots 1–4 only, for example.

An individual user of the Internet interacts with a T-1 line only indirectly. If you're accessing the Internet via a dial-up (modem) or ISDN connection, your ISP will normally have a connection to one or more T-1 or T-3 lines, which represent the backbone of the Internet. This connection to the backbone is sometimes referred to as a *point of presence*. When you make your dial-up connection to the Internet, your ISP shares a small chunk of that T-1 pipe with you. Depending on how many other users are accessing the Internet at your ISP or elsewhere, you might experience very fast to slow throughput, even if your modem connection speed remains constant. It's a bit like splitting up a pizza into smaller and smaller slices to accommodate more people at a party: the more users of a high-speed connection, the slower each individual part of it will be. To keep user connections fast while growing, ISPs will add full or fractional T-1 lines to their point of presence. Or they might switch from a T-1 connection to the even faster T-3 if available.

Note

Equivalent in throughput to approximately 28 T-1 lines, a T-3 connection runs at 45Mbps and is suitable for use by very large networks and university campuses. Pricing information falls into the "if you have to ask, you can't afford it" category.

If your Internet connection is on a corporate LAN or your office is located in a downtown building, your relationship to a T-1 line might be much closer. If your building or office is connected directly to a T-1, you're sharing the capacity of that line with just a relative few other users rather than with the hundreds or thousands of dial-up users that a normal ISP is hosting at one time. Full or fractional T-1 lines are being added to more and more apartments and office buildings in major cities to allow residents and workers faster Internet access. In these cases, a LAN connection to the T-1 is usually provided, so that your Internet access device is a network card, rather than a modem or ISDN Terminal Adapter.

With the rise of the Internet and the demand for high-speed data access for networks, the price of T-1 links in the United States has fallen drastically. T-1 service can be acquired from either your local telco or third-party firms. A typical example of a third-party T-1 service provider, Shore.net,

offers full T-1 service including fast-response service and router management for \$1,000 per month, plus a one-time fee of \$795, plus the cost of a router. Other plans are even less. For a large organization that requires a lot of bandwidth, the lower cost of T-1 services today make it more economical than ever to install a higher-capacity service and grow into it, rather than constantly upgrade the link.

Comparing Conventional High-Speed Services

Some telcos who formerly posted pricing for ISDN, T-1, or other high-end telecommunications services now have a “call us” button on their Web sites, because pricing is complicated by many factors including

- Location (state and locality, because telephone companies are regulated public utilities)
- Fixed and variable costs
- Installation costs
- Your needs

Be sure to consider hardware and usage costs when you price services and, for items such as ISDN terminal adapters and network cards, compare the official offerings with products available elsewhere. If you decide to provide some of the equipment yourself, find out whose responsibility repairs become. Some companies provide lower-cost “value” pricing for services in which you agree to configure the hardware yourself and maintain it. If you have knowledgeable staffers who can handle routers and other network configuration, you can save money every month, but if not, go with the “full-service” option.

The huge gap in performance (and price) between relatively slow (but inexpensive) 56Kbps modems on the one hand and fast (but pricey) services such as ISDN and T-1 lines on the other hand has helped promote a new breed of high-speed but relatively low-priced Internet access options for small-office/home-office (SOHO) users:

- Cable TV (CATV) networks
- DirecPC/DirecDuo
- DSL

High Speed = Less Freedom

Although ISDN, T-1, and the newer high-speed services all represent major improvements in speed over existing dial-up analog or 56Kbps connections, one big drawback you should consider is the loss of freedom in choosing an ISP.

With an analog or 56Kbps modem, you can choose from a wide variety of services, including

- Local ISPs (personalized service)
- National ISPs with dial-up access across the country (great for travelers)
- Online services with customized content plus Web access (AOL and CompuServe)
- Family friendly filtered Internet access (Mayberry USA and Integrity Online)
- Business-oriented Web hosting plus Internet access plans from many vendors

The price you pay at present for faster speed is using the ISP provided with your high-speed service. Whether it's your local telephone company, a third-party vendor, or your friendly cable TV operator, their ISP is your ISP.

CATV Networks

Although ISDN represents a significant increase in speed over standard modem technologies, the installation difficulties and the expense (especially when there are connect-time charges) might not be justified. The next step up in speed is a cable TV (CATV) network connection. This service, when available, is usually less expensive than ISDN and is becoming widely available across the country as CATV providers gear up to battle for markets against both satellite dish and telephone companies.

Connecting to the Internet with a “Cable Modem”

As with ISDN, the device used to connect a PC to a CATV network is somewhat inaccurately called a modem. In fact, the so-called “cable modem” (a name I will continue to use, for the sake of convenience) is actually a great deal more. The device does indeed modulate and demodulate, but it also functions as a tuner, a network bridge, an encryptor, an SNMP agent, and a hub.

To connect your PC to a CATV network, you do not use a serial port as with standard modem technologies. Instead, the most typical connection used today requires that you install a standard Ethernet network interface adapter into a bus slot. The Ethernet adapter connects to the cable modem with the same type of twisted-pair cable used on LANs. In fact, your PC and the cable modem actually form a two-node LAN, with the modem functioning as a hub. PCI-based internal and USB-based external cable modems are now under development.

The Cable Modem and the CATV Network

The cable modem connects to the CATV network using the same coaxial cable connection as your cable TV service (see Figure 18.9). Thus, the cable modem functions as a bridge between the tiny twisted-pair network in your home and the hybrid fiber/coax (HFC) network that connects all the cable customers in your neighborhood.

A few cable modem CATV systems have been built using the older one-way (download-only) coax cable, but this type of cable is much slower for cable modem use and is obsolete for both CATV and data communications. The industry has largely replaced coax with HFC. Before you sign up for CATV Internet service, find out which type of service is being offered. Only the two-way HFC-based systems allow you to use the Internet independently of the telephone system.

Originally, cable modems were not sold to users of CATV Internet access, but were leased by the CATV companies offering Internet access. This is because each cable modem on a particular CATV network had to match the proprietary technology used by the network. In late 1998, DOCSIS-compliant cable modems began to be used by some CATV companies. DOCSIS refers to devices that meet the Data Over Cable Service Interface Specification standards. Many vendors of traditional modems and other types of communications products such as Zoom Telephonics, 3Com, GVC, General Instruments, Philips, Motorola, Cabletron, and others now make DOCSIS-compliant cable modems, but some CATV Internet providers still require you to lease their own cable modems.

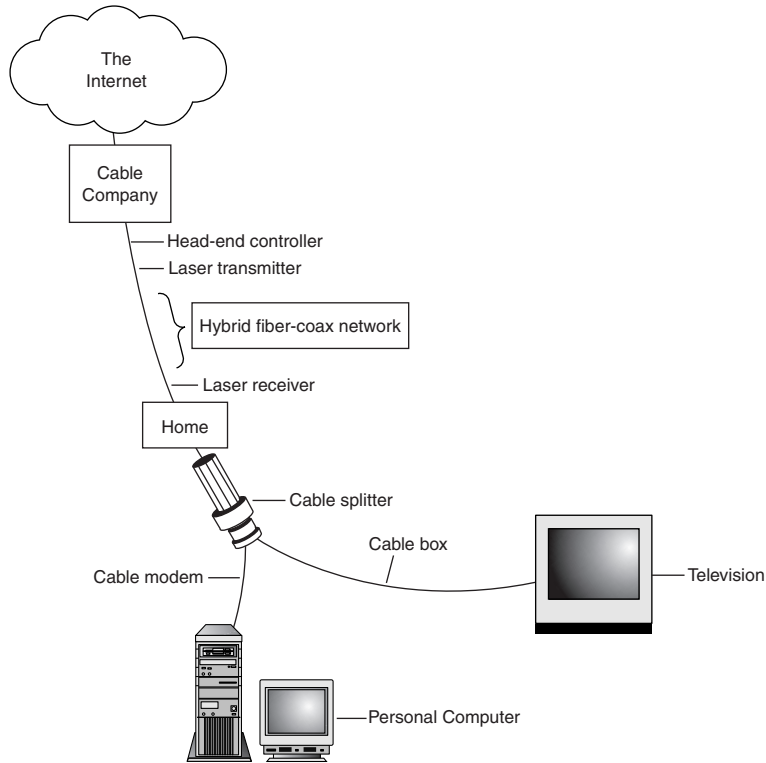

Figure 18.9 A basic cable modem connection to the Internet.

Types of Cable Modems

Cable modems come in several forms:

- *External cable modem “box”;* requires an Ethernet NIC. Some vendors provide “bundles” that combine the external cable modem with the NIC at a lower price. This type of cable modem is designed for fast uploads as well as fast downloads, and works only on newer “two-way” CATV Internet connections.
- *Internal cable modem with a 56Kbps analog modem built-in.* This type of cable modem provides fast downloads, but uploads at analog speeds only; this type might use either an ISA or PCI slot.
- *Internal cable modem for use with a separate 56Kbps analog modem.* This type might use either an ISA or PCI slot. As with the previous model, uploads are at analog speeds only.

Cable modem models which must be used with (or include) an analog modem are designed for older “one-way” CATV Internet connections; these will tie up your phone line to transmit page requests as well as to send uploads.

Before you purchase a cable modem, check with your CATV Internet provider; although DOCSIS-compatible cable modems are becoming widely available, some CATV Internet providers prefer to provide their own equipment, including the charge in their monthly rate, whereas others allow you to either lease the cable modem or purchase it.

CATV Bandwidth

Cable TV uses what is known as a *broadband network*, meaning that the bandwidth of the connection is split to carry many signals at the same time. These various signals correspond to the various channels you see on your TV. A typical HFC network provides approximately 750MHz of bandwidth, and each channel requires 6MHz. Therefore, because the television channels start at about 50MHz, you would find channel 2 in the 50MHz–56MHz range, channel 3 at 57MHz–63MHz, and continuing on up the frequency spectrum. At this rate, an HFC network can support about 110 channels.

For data networking purposes, cable systems typically allocate one channel's worth of bandwidth in the 50MHz–750MHz range for downstream traffic—that is, traffic coming into the cable modem from the CATV network. In this way, the cable modem functions as a tuner, just like your cable TV box, ensuring that your PC receives signals from the correct frequency.

Upstream traffic (data sent from your PC to the network) uses a different channel. Cable TV systems commonly reserve the bandwidth from 5MHz to 42MHz for upstream signals of various types (such as those generated by cable TV boxes that enable you to order pay-per-view programming). Depending on the bandwidth available, you might find that your CATV provider does not furnish the same high speed upstream as it does downstream. This is called an *asymmetrical network*.

Note

Because the upstream speed often does not match the downstream speed (and to minimize noise, which tends to accumulate because of the tree-and-branch nature of the network), cable TV connections are usually not practical for hosting Web servers and other Internet services. This is largely deliberate, as most CATV providers are currently targeting their traditional home user market. As the technology matures, however, this type of Internet connection is likely to spread to the business world as well. There are now specialized domain name services that can be used to “point” Web surfers to your cable modem or xDSL connection.

The amount of data throughput that the single 6MHz downstream channel can support depends on the type of modulation used at the head end (that is, the system to which your PC connects over the network). Using a technology called 64 QAM (quadrature amplitude modulation), the channel might be capable of carrying up to 27Mbps of downstream data. A variant called 256 QAM can boost this to 36Mbps.

You must realize, however, that you will not achieve anything even approaching this throughput on your PC. First of all, the Ethernet adapter used to connect to the cable modem is limited to 10Mbps, but even this is well beyond the real-life results you will achieve. As with any LAN, you are sharing the available bandwidth with other users. All your neighbors who also subscribe to the service make use of the same 6MHz channel. As more users are added, more systems are contending for the same bandwidth, and throughput goes down.

In November 1999 ZDTV tested five different brands of cable modems in typical operations and found that the overhead of CATV proved to be a major slowdown factor. The cable modems were first connected directly to the server to provide a baseline for comparisons. Some of these tests showed speeds as high as 4Mbps. However, when the CATV cable was connected and the same tests were run, the best performer dropped to just 1.1Mbps, with others running even slower.

Widespread reports from cable-modem users across the country indicate that there are rush hour-type conditions at certain times of the day on some systems, with big slowdowns. This rush hour is due to increasing use of cable modem systems in the late afternoon and early evening, as daytime workers get home and pull up the day's news, weather, stocks, and sports on their Internet connections. Because cable modems are shared access, this type of slowdown is inevitable, and becomes exceptionally severe if the CATV Internet provider doesn't use a fast enough connection to the rest of the Internet.

CATV Security

Because your PC is sharing a network with other users in your neighborhood, and because the traffic is bidirectional on systems using two-way cable modems, the security of your PC and the network becomes an issue. In most cases, some form of encryption is involved to prevent unauthorized access to the network. As with your cable TV box, the cable modem might contain encryption circuitry that is needed to access the network. Your CATV provider might also supply encryption software that uses a special protocol to log you on to the network. This protects the CATV provider from non-paying users, but it doesn't protect you. The security features vary according to which cable modem is used by your CATV provider.

If you use an operating system such as Windows 9x that has built-in peer networking capabilities, you might be able to see your neighbors' computers on the network. The operating system has settings that enable you to specify whether other network users can access your drives. If these settings are configured improperly, your neighbors might be able to view, access, and even delete the files on your hard drives. Be sure that the technician from the cable company installing the service addresses this problem. If you want to use a cable modem along with sharing access on your computer (for printing, file storage, and so on), I'd recommend that you use passwords for any shared drives, but you're even safer if you disable file and printer sharing on the system you connect to the cable modem.

For more information about keeping your system secure, see "CATV Internet Connection Security," later in this chapter.

CATV Performance

The fact that you are sharing the CATV network with other users doesn't mean that the performance of a cable modem isn't usually spectacular. Although the CATV network takes a big cut out of the maximum speeds, you'll still realize a throughput that hovers around 512Kbps, almost 10 times that of the fastest modem connection and four times that of ISDN. You will find the Web to be an entirely new experience at this speed. Those huge audio and video clips you avoided in the past now download in seconds, and you will soon fill your hard drives with all the free software available.

Add to this the fact that the service is typically quite reasonably priced. Remember that the CATV provider is replacing both the telephone company and your ISP in your Internet access solution. The price can be about \$40–50 per month, twice that of a normal dial-up ISP account, but it is far less than ISDN, does not require a telephone line (if your provider has two-way service), and provides you with 24-hour access to the Internet. The only drawback is that the service might not yet be available in your area. In my opinion, this technology exceeds all the other Internet access

solutions available today in speed, economy, convenience, and widespread availability. Its nearest rival is DSL, which is still far from being widely available.

CATV Internet Connection Security

Because any Internet connection must use TCP/IP, which uses service ports from 0 to 65,535 for different types of activity, any user of the Internet can be vulnerable to various types of Internet attacks, even if precautions such as turning off drive and folder sharing have been followed. Steve Gibson of Gibson Research Corporation (makers of the classic SpinRite disk maintenance program) has established a free Web-based service called Shields Up that you should try with *any* Internet-connected PC to see how safe or vulnerable you are.

Shields Up (<http://www.grc.com>) probes your system's Internet Connection security and Internet service ports, as shown in Figure 18.10.

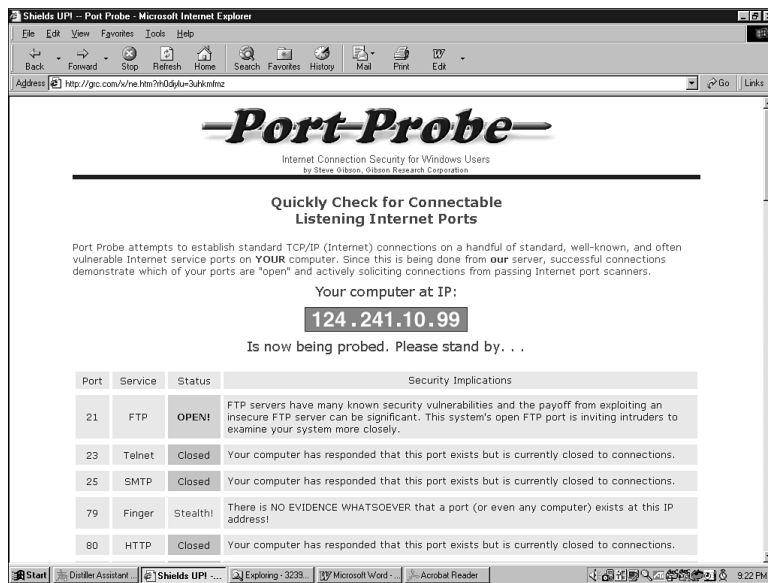

Figure 18.10 Steve Gibson's Port Probe test looks for open, closed, and stealth Internet service ports on your system. The site also provides recommendations for firewall software to secure your system.

After testing your system, Shields Up provides reviews and recommendations for proxy server and firewall software (such as BlackIce Defender) you can use to help secure your system.

With the increasing importance of the Internet and the multiple vulnerabilities we saw in 1999 to Internet-borne viruses, Trojan horses, and denial-of-service attacks, Shields Up provides a valuable service for *any* Internet user.

Note

Proxy servers and firewalls are subjects that go far beyond the scope of this book. If you want to learn more, I suggest you pick up a copy of *Upgrading and Repairing Networks, Second Edition*, also published by Que.

DirecPC—Internet Connectivity via Satellite

If you're in an area where cable TV doesn't exist, or you already have a DirecTV satellite dish, take a look at the southern sky from your home, condo, or apartment building. If you have a good, clear 45-degree window view to the southern sky and you want fast downloads of big files, DirecPC might be the high-speed choice for you.

Tip

If you want both high-speed Internet access and satellite TV, look into DirecPC's sibling, DirecDuo. In the discussion that follows, "DirecPC" refers to both products for computer use.

How DirecPC/DirecDuo Works

DirecPC is a *hybrid* system, meaning that incoming and outgoing data streams and other operations are actually routed two ways. DirecPC's much-vaunted 400Kbps satellite connection is for downloads, and downloads only. You'll not only upload by using a conventional modem, but you'll also request pages (Web surfing) with that creaky modem as well. This makes DirecPC a great choice for download junkies, but not the best choice for researchers, Web surfers with an impatient mouse-clicker finger, or users looking to free up the phone line for voice calls. Although ISDN offers up to 128Kbps in both directions, DirecPC downloads are typically as much as three times faster. DirecPC works as shown in Figure 18.11.

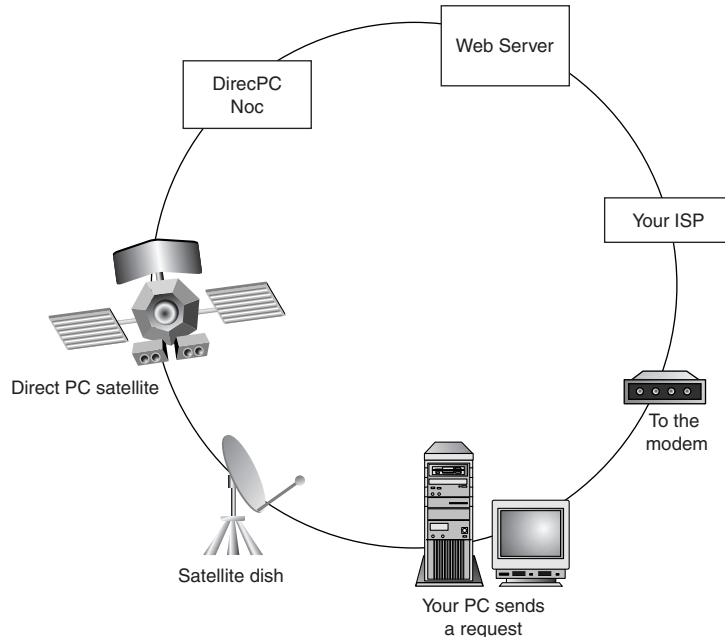

Figure 18.11 DirecPC routes your request for Web pages, graphics, and files using a modem. The speed advantage comes when you receive your data, with a download speed of 400Kbps, thanks to a satellite link.

DirecPC Requirements

DirecPC requires a small satellite dish, similar but not compatible to those used for DirecTV and USSB satellite services (DirecDuo combines DirecPC and DirecTV into a single service, using the same type of dish as DirecPC). The dish is connected to a so-called satellite modem, which is a PCI card or USB device used for data receiving. You use a conventional modem for sending out page requests or for uploading data. Although all services beyond 33.6Kbps are *asymmetrical*—faster for downloading than uploading—except ISDN, the only other fast-download Internet service with a similarly poky speed for uploads is the 56Kbps V.90 modem and its proprietary predecessors (x2 and K56flex).

Installing DirecPC

A DirecPC installation combines the dangers of satellite-TV installation with the usual issues involved in connecting a network-style device to your computer. You'll need an unobstructed 45-degree clear line of sight to the south and room for the 21" satellite dish. Windows 95, 98, and NT/2000 users make the PC connection to the DirecPC dish with a PCI card. Windows 98 users with USB ports should use the USB-based solution. Because the DirecPC satellite link uses a single satellite in the southern sky, dish positioning and aiming is much more important than with USSB-type TV dishes, which can be directed at any one of several satellites.

The DirecPC "Getting Started" guide (available online from <http://www.direcpc.com> as a PDF file) strongly suggests that DirecPC installers have experience with normal satellite dishes or TV antennas, because issues such as running coaxial cable, proper electrical grounding to code, and other challenges await. Detailed installation instructions for the antenna and other DirecPC components are found on the CD-ROM that comes with the self-installation kit for DirecPC but are not available on the Web site. Consider professional installation for a carefree, reliable, and safe setup at a reasonable price.

When you install DirecPC on a system that already has a PCI-based Ethernet card, you can choose to have both DirecPC and your existing network use the card, or use the card just with DirecPC. This choice affects the TCP/IP bindings configuration.

Make sure you have your IP addresses handy; you'll need them to complete the installation.

DirecPC's minimum configurations have specified Pentium-class processors, but if you're considering putting that old P-100 to work as a Web-surfer, think again. The latest DirecPC data-sheet now recommends a Pentium 200-class processor with at least 32MB of RAM for Windows 95 and 64MB of RAM for Windows 98 or NT/2000.

Purchasing DirecPC

After the complex price structure based on transfer rate of the original version of DirecPC (1.0), DirecPC 2.0 and above offer pricing plans from \$30 to \$130 for anywhere from 25 to 200 hours per month. Some plans also allow up to four network users to share the connection and include ISP charges. Generally, lower rates are available for users who already have an ISP. All plans include an email account and some offer four separate email accounts.

The typical cost of DirecPC is under \$200, which includes hardware and software, but not installation.

DirecPC's FAP—Brakes on High-Speed Downloading?

A big concern for those wanting to exploit the high-speed download feature is DirecPC's Fair Access Policy (FAP), which was introduced long after the service was started. FAP uses unpublished guidelines to determine who is "abusing" the service with large downloads. Abusers have their download bandwidth reduced by about 50% until their behavior changes. A class-action lawsuit was filed in July 1998 by DirecPC users who objected to this policy. Users said that Hughes Network Systems, Inc., the developer of DirecPC, was simultaneously selling the system on the basis of very fast download times, and then punishing those who wanted to use it in the way DirecPC had sold to the public.

DirecPC recommends that to avoid being "FAPPED", users should take advantage of the Turbo Newsgroups and Turbo Webcasts feature, which "pushes" newsgroup and selected Web site content to subscribers' systems without the traffic being counted for FAP calculation purposes.

Note

I'm concerned about FAP limitations when it's time to download the increasingly bulky service packs for operating systems, Web browsers, and office suites. Some users have reported their service speed dropping by 50% or more after downloading 40MB of files. In a time when a single service pack can be about 40MB by itself, this isn't good news. Although DirecPC refuses to release details of its FAP-calculating algorithm, it seems to make sense to avoid downloading a lot of large files in sequence if you want to avoid being "FAPPED."

Real-World Performance

Benchmark addicts will find that DirecPC will perform poorly on ping tests because the complex pathway your data must travel (ground to space and back again) means that pings will take at least 400ms to 600ms. Interactive benchmarks are also disappointing. The hybrid architecture makes DirecPC a very poor choice for Internet gaming, teleconferencing, or Internet telephony, because these applications require fast connections in both directions. However, real-world speeds in excess of 225Kbps can be reached when downloading big files.

DirecPC has been a controversial choice for fast Internet access because of the confusing pricing of the original version, concerns about FAP, and its unusual hybrid architecture. However, it performs well for downloads up to 50–70MB at a time. (Many users report that FAP limitations often drastically cut speeds on downloads larger than this.) If you can't get cable-modem or xDSL Internet access, consider DirecPC or the TV/PC combo called DirecDuo. Just remember that DirecPC still requires you to use your phone line for page requests and uploading. If you want to get more user-oriented information about DirecPC, join the DirecPC newsgroup at `alt.satellite.direcpc`.

DSL (Digital Subscriber Line)

The newest solution to the high-speed Internet-access problem is Digital Subscriber Line, also called xDSL. The *x* stands for the various versions of DSL that are being proposed and, in a small but growing number of cases, actually being offered by a few local telephone companies.

DSL appeals to the telephone companies, who can use the existing plain old telephone service (POTS) analog wiring to provide high-speed Internet access. Not every type of DSL is suitable for existing wiring; however, all but the fastest, most expensive types can be used with the existing POTS plant. DSL is also appealing to businesses which don't have access to cable modems, but are looking for an alternative to the expensive ISDN services that top out at 128Kbps.

One advantage of DSL compared to its most popular rival, cable modems, is that cable modems are sharing common bandwidth, which means that a lot of simultaneous use by your neighbors can slow your connection down. DSL users don't have this concern; whatever bandwidth speed you paid for is yours—period.

Who Can Use DSL—and Who Can't

DSL services are slowly rolling out across the country, first to major cities and then to smaller cities and towns. As with 56Kbps modems, rural and small-town users are probably out of luck and should consider satellite-based DirecPC or cable modems if available for a faster-than-56Kbps experience.

Just as we saw that distance to a telephone company's central switch (CS) was an important consideration for people purchasing an ISDN connection, distance also affects who can use DSL in the markets offering it. Micron Internet Services' DSL FAQ states that you must be within about 18,000 feet (about three miles) *wire distance* (not a straight line!) to a telco offering DSL. Repeaters or a local loop that's been extended by the telco with fiber-optic line might provide longer distances. The speed of your DSL connection will vary with distance: The closer you are to the telco, the faster your DSL access will be. Many telcos that offer some type of DSL service provide Web sites that help you determine if, and what type of, DSL is available to you.

If you want to locate DSL service providers in your area, compare rates, and see reviews from users of the hundreds of ISPs now providing DSL service, set your browser to <http://www.dslreports.com>. The site provides a verdict on many of the ISPs reviewed, summarizing users' experiences and ranking each ISP in six categories. An excellent FAQ can be found at <http://www.dsl.com>, which covers the many different flavors of xDSL and many links to other DSL sites. Both sites offer user forums.

Note

If you want to connect a DSL to your SOHO or office LAN, check first to see what the provider's attitude is. Some users report good cooperation, whereas others indicate they were told "we can't help you" or were told that DSL "couldn't be connected to a LAN." Again, check around for the best policies. For "field-tested" ADSL information (written originally for Pacific Bell ADSL users but useful for everyone), check out <http://users.deltanet.com/~ochen/adsl/index.html>.

Major Types of DSL

- **ADSL (Asymmetrical DSL).** The type of DSL used most often. Asymmetrical means that "downstream" (download) speeds are much faster than "upstream" (upload) speeds. For most users, this is no problem, because downloads of Web pages, graphics, and files are the major uses of Internet connections. Maximum downstream speeds are up to 1.6Mbps, with

up to 640Kbps upstream. Most vendors who offer ADSL provide varying levels of service at lower speeds and prices as well. Voice calls are routed over the same wire using a small amount of bandwidth, making it possible to have a single-line service that does voice and data. ADSL is more expensive to set up than some other forms of DSL because a splitter must be installed at the customer site, meaning that you must pay for a service call (a.k.a. truck roll) as part of the initial setup charge.

- *CDSL (Consumer DSL)*. A slower (1Mbps upstream) form of DSL that was developed by modem chipset maker Rockwell. It doesn't require a service call because there's no splitter required at the customer site.
- *G.Lite (Universal DSL, and also called DSL Lite or splitterless DSL)*. Another version that splits the line at the telco end rather than at the consumer end. Downstream speeds range from 1.544 to 6.0 Mbps, and upstream speeds can be from 128 to 384Kbps. This might become the most popular form of DSL. Note that the service might be "capped" by the DSL vendor at rates lower than those listed earlier in the chapter; check the vendor for details.

Table 18.6 summarizes the various types of DSL.

Table 18.6 DSL Type Comparison

DSL Type	Description	Data Rate Downstream; Upstream	Distance Limit	Application
DSL	Digital Subscriber Line	160Kbps	18,000 feet on 24-gauge wire	Used for basic rate interface
IDSL	ISDN Digital Subscriber Line	128Kbps	18,000 feet on 24-gauge wire	Similar to the ISDN BRI service but data only (no voice on the same line)
CDSL	Consumer DSL from Rockwell	1Mbps downstream; less upstream	18,000 feet on 24-gauge wire	Splitterless home and small business service; similar to DSL Lite
DSL Lite (same as G.Lite)	Splitterless DSL without the "truck roll"	From 1.544 Mbps to 6Mbps downstream, depending on the subscribed service	18,000 feet on 24-gauge wire	The standard ADSL; sacrifices speed for not having to install a splitter at the user's home or business
G.Lite (same as DSL Lite)	Splitterless DSL without the "truck roll"	From 1.544 Mbps to 6Mbps, depending on the subscribed service	18,000 feet on 24-gauge wire	The standard ADSL; sacrifices speed for not having to install a splitter at the user's home or business
HDSL	High bit-rate Digital Subscriber Line	1.544Mbps duplex on two twisted-pair lines; 2.048Mbps duplex on three twisted-pair lines	12,000 feet on 24-gauge wire	T-1/E1 service between server and phone company or within a company; WAN, LAN, server access
SDSL	Symmetric DSL (a.k.a. X-speed)	1.544Mbps duplex (U.S. and Canada); 2.048Mbps (Europe) on a single-duplex line downstream and upstream	12,000 feet on 24-gauge wire	Same as for HDSL but requiring only one line of twisted pair

(continues)

Table 18.6 Continued

DSL Type	Description	Data Rate Downstream; Upstream	Distance Limit	Application
ADSL	Asymmetric Digital Subscriber Line	1.544 to 8.4Mbps downstream; 16 to 640Kbps upstream	1.544Mbps at 18,000 feet; 2.048Mbps at 16,000 feet; 6.312Mbps at 12,000 feet; 8.448Mbps at 9,000 feet	Used for Internet and Web access, motion video, video on demand, remote LAN access
RADSL	Rate-Adaptive DSL from Westell	Adapted to the line, 640Kbps to 2.2Mbps downstream; 272Kbps to 1.088Mbps upstream	Not provided	Similar to ADSL
UDSL	Unidirectional DSL proposed by a company in Europe	Not known	Not known	Similar to HDSL
VDSL	Very high Digital Subscriber Line	12.9 to 52.8Mbps downstream; 1.5 to 2.3Mbps upstream; 1.6Mbps to 2.3Mbps downstream	4,500 feet at 12.96Mbps; 3,000 feet at 25.82Mbps; 1,000 feet at 51.84Mbps	ATM networks; Fiber to the Neighborhood

DSL Pricing

DSL pricing varies widely, with different telephone companies offering different speeds of DSL and different rates. One thing that's true about the most commonly used flavors of DSL is that it is usually another asymmetrical service—with download speeds faster than upload speeds.

For unlimited use, typical DSL pricing ranges anywhere from \$25 to \$500 a month depending on the download speed, ranging from 256Kbps to 1.5Mbps.

The wide variance is partly due to the upload speeds permitted. The lower-cost plans typically use a lower upload speed (some variation on ADSL or G.Lite), but not always. Check carefully with your vendor, because your traditional telephone company might not be the only xDSL game in town. Some major cities might have as many as a half-dozen vendors selling various flavors of xDSL.

Time Versus Access

So-called *Personal DSL* plans give you an interesting puzzle: time online versus data transfers.

Before the advent of unlimited Internet access, the time you spent online and the speed of your modem were the two variables used to calculate the cost per hour of services such as the original CompuServe. I remember looking for files on CIS at 2400bps because surfing the site was cheaper

that way, noting the files needed, and then hanging up and downloading them at the “blazing” speed of 9600bps (a speed that cost you extra to use some years ago).

Some Personal DSL plans have gone back to a consumption-based pricing scheme. But with Personal DSL plans, the speed of your connection or the time you spend are unimportant: It’s the amount of data transfer you do.

For many people, this won’t be a major issue. Micron Internet Service’s Personal DSL plan allows up to 500MB of data transfer per month before a surcharge (\$10.00 per additional 500MB) is incurred, for example.

Unless you’re routinely downloading massive software service packs or working beyond the fringes of legality by downloading entire CDs, this limitation is more apparent than real. Even though every Web page and graphic you view on the Web counts as a file transfer, the sizes of GIF, JPG, and HTML pages are usually miniscule. Still, find out what the file-transfer limitations are before you sign up for any type of metered DSL.

Technical Problems with DSL

Telecommunications has always had its share of problems, starting with the incredibly slow 300bps modems used on early PCs, but as speed increases, so do problems. DSL connections are often very tricky because DSL, as you’ve seen, combines the problems of adding high-speed data access to the telephone line with network configuration using TCP/IP (the most powerful and most complex network protocol in widespread use; see Chapter 19, “Local Area Networking,” for details).

A review of comments from DSL users in various forums shows that the most common problems include

- *Poor coordination between the DSL sales department of the telco or third-party provider and the installers.* This can lead to broken or very late appointments; if possible, contact the installer company to verify the appointment.
- *Installers who install the hardware and software and then leave without verifying it works properly.* Ask whether the installer carries a notebook computer that can test the line; don’t let the installer leave until the line is working.
- *Poor technical support before and after installation.* Record the IP address and other information used during the installation; read reviews and tips from sources listed earlier in the chapter to help you find better DSL providers and solutions you can apply yourself or ask your telco or provider to perform.
- *Lower speeds than anticipated.* This can be due to a poor-quality connection to the telco from your home or business or problems at the central switch; ask the installer to test the line for you during initial installation and tell you the top DSL speed the line can reach. On a healthy line, the problem is often traceable to a very low value for the Windows 9x Registry key called “RWIN” (receive window), which should be adjusted from its default of 8192 (8KB) to a value as high as 32768 (32KB) or even 65535 (64KB). If your system was previously used with a dial-up modem, the value for RWIN can be as low as 2144; low values will force your DSL connection to receive data at rates hardly faster than those for a dial-up analog modem connection. For a step-by-step procedure for adjusting the value of RWIN, go to <http://www.ds1reports.com> and follow the “Win speed” link under the “Got DSL?” section of the home page.

Comparing High-Speed Internet Access

One way of making sense out of the confusing morass of plans available from cable modem, xDSL, and DirecPC vendors is to calculate the average cost per Mbps of data downloaded.

According to *PC Magazine* (April 20, 1999), the cost per Mbps for DirecPC was \$229 per Mbps, based on an average FTP download speed of 223.2Kbps. xDSLs provided a wide variance in cost, from as little as \$115 per Mbps to as high as \$1,091 per Mbps. Cable modems provided the best cost factors, coming in at a range of \$67 to \$184 per Mbps. How did a V.90 modem fare? A whopping \$977 per Mbps, based on an average throughput of only 20.9Kbps!

As the study shows, cable modems offer the best performance of the Internet connections tested. Some DSL services were comparable to the medium-priced cable modems, but some were outlandishly expensive for their performance level, providing a higher cost per-Mbps than the V.90 modem.

DirecPC is a good choice for those who lack a reasonably priced cable modem or DSL provider in their area.

Generally, the services stack up like this, from slowest to fastest:

- 33.6Kbps
- 56Kbps
- ISDN 128Kbps
- ADSL 384Kbps¹
- DirectPC 400Kbps
- ADSL 512Kbps¹
- Cable
- ADSL 1GB¹

1 xDSL bandwidth depends on the package you select; higher bandwidth packages carry higher monthly fees.

If you're looking for a close to real-time benchmark of large-file download times, check out Bill Faust's "Comparison of Cable Modem Download Speeds" Web site at <http://pobox.com/~faust/soapbox/speed/speed.html>.

This site provides instructions for how to download a large (11MB) file and send the results of the download time, equipment used, Internet provider, and so on back for inclusion in the growing database of results, which can be viewed in either ASCII or as a table.

Because the connection and location are listed, stop by the site and see whether your current or possible future "fast" ISP is listed to see how well (or how badly) it's doing. Another way to compare Internet connection types is by feature, as in Table 18.7.

Table 18.7 Comparing High-Speed Internet Access by Feature

Service	Always On?	Shared with Other Users?	Ties Up Phone Line?	Reliability Affected By?
Cable modem (two-way)	Yes	Yes	No	Cable outages
Cable modem (one way)	No	Yes	Yes	Cable outages; phone line outages
DirecPC	No	No	Yes	Satellite outages; phone line outages
DSL	Yes	No	No	Phone line outages; telco network changes

Having a Backup Plan in Case of Service Interruptions

Because no high-speed connection is immune to service interruptions, you should consider having some sort of backup plan in place in case of a significant service outage.

If your high-speed Internet access uses an ISP that can also accept 56Kbps connections, you might still be able to use your regular modem for emergencies. You could also consider using a free trial subscription to an ISP that uses a conventional modem. If you temporarily switch to a different ISP, especially one that uses its own client such as AOL, be sure to back up your current Internet configuration information before you install the client software. Your best bet is to use an Internet-only ISP whose dial-up connection can be configured manually with the Dial-Up Networking connection wizard. Then, you can construct a new connection without destroying your existing configuration.

Note

Each type of Internet connection uses a particular combination of TCP/IP settings. TCP/IP is the protocol (software rules) used by all computers on the Internet. TCP/IP is covered in Chapter 19, but for now keep in mind that different TCP/IP settings are required for modem access and access through a NIC or USB port device (cable modem, xDSL, and DirecPC). Modems usually have an IP address provided dynamically by the ISP when the modem connects with the ISP. The other types of Internet access devices normally have a static IP address that doesn't change. IP addresses are just one of the network settings that, if changed, will prevent you from getting on the Internet.

Sharing Your Modem Connection

Whether you have a 56Kbps dial-up modem or a fast xDSL or cable modem, one connection is often not enough for a home or small-office setting. A proxy server or gateway program plus a small network allows you to share a single Internet connection among two or more computers.

Gateways Versus Proxy Servers

To the typical user, it won't matter whether a gateway or proxy server is used to provide shared Internet access. Traditional gateway programs use a method of shared access called NAT (Network Address Translation), which allows sharing by converting network addresses into

Internet-compatible addresses during the file request and download process. This process requires little client PC configuration, but doesn't permit page caching, content filtration, firewalls or other useful services that can be provided by a proxy server. Proxy servers traditionally required tricky configuration, sometimes at an individual application level, but many of the newer products on the market, such as WinProxy, SyGate, and WinGate, combine the ease of configuration of a gateway with the extra features of a proxy server.

Proxy server programs are often provided with SOHO-oriented Ethernet and phone line-based networks for Internet sharing, and Microsoft's ICS (Internet Connection Sharing) is a gateway program using NAT.

Windows 98 SE, Windows 2000, and ICS

Windows 98 Second Edition and Windows 2000 feature a built-in gateway program called ICS (Internet Connection Sharing), which allows users to share a single dial-up, ISDN, cable modem, or xDSL connection. Windows 98 SE and Windows 2000 can be purchased as an upgrade to older versions of Windows, and users of the original version of Windows 98 can purchase a CD-ROM from Microsoft which will upgrade the original version to the Second Edition.

Because ICS is a gateway and clients use TCP/IP networking to use the gateway, only the gateway computer needs to use Windows 98 SE or Windows 2000. Any computer using TCP/IP with the option to set up a gateway can be used as a client, including computers using older versions of Windows 9x and other operating systems.

Requirements for ICS

ICS requires a NIC (network interface card) to be installed in the host computer and a network connection to each guest computer to share the host's Internet connection.

If the Internet connection is made through a NIC (as is the case with xDSL or two-way cable modem connections), two NICs are required: one for the Internet connection, and one for sharing the connection.

ICS will not work with one-way cable modems or with DirecPC, because these devices use a separate connection for downloading and uploading.

Overview of the Configuration Process

The configuration process has two parts:

- Installing ICS on the gateway computer
- Configuring the clients to use the ICS gateway to reach the Internet

Configuring ICS on the Gateway Computer

If ICS was not installed when Windows was installed, install it by choosing Start, Settings, Add/Remove Programs, Windows Setup. Select ICS from the Internet Tools category.

Next, specify whether you are using a dial-up connection (modem or ISDN) or a high-speed connection (LAN, including cable modem or DSL).

If you select dial-up, choose the dial-up connection (which must be set up already) you'll be sharing, followed by the NIC (network interface card) that connects you with the client PCs that will share the connection. Windows creates a client configuration floppy and prompts you to reboot the computer.

When you view the Network Configuration in the Control Panel after rebooting, you should see the following:

- Three adapters (your actual NIC, the dial-up adapter, and a new one called Internet Connection Sharing)
- Three Internet Connection Sharing protocol entries, listing the adapters mentioned earlier in the chapter
- Three TCP/IP protocol entries, listing the adapters mentioned earlier in the chapter

The TCP/IP protocol entry for Home must point to the NIC that connects the clients to the host PC; the TCP/IP protocol entry called Shared must point to Dial-Up Networking; the remaining TCP/IP protocol entry must point to Internet Connection Sharing.

Also, check the TCP/IP configuration for Home (the NIC) and verify the IP address; it should be 192.168.0.1. This IP address must be provided to the computers that will share the Internet connection. If the settings aren't correct, remove ICS and start over. Start an Internet connection on the gateway (host) computer before continuing.

Configuring ICS on the Client Computers

Although the ICS configuration process on the gateway (host) computer created a disk that can be used for setting up the ICS connection on client computers, most non-Microsoft sources advocate using manual configuration instead. The following steps are required:

- Install the TCP/IP protocol on each client.
- Set the Gateway option in the TCP/IP properties for each client's NIC to the IP address of the gateway (ICS) computer: 192.168.0.1 is the usual value; click Add to insert this value after you enter it.
- Use a Web browser on each guest to verify the connection is working; Internet Explorer should not have any dial-up settings configured for it, and should have no LAN settings enabled; the ICS client diskette incorrectly selects Use a Proxy Server here, which is not correct. Netscape Navigator/Communicator should be set to Direct Connection to the Internet.
- Some versions of Netscape Navigator might not work unless you create a Dial-Up Networking adapter on the guest and set its gateway as explained earlier in the chapter.

If you are using Windows 9x, reboot before you test the connection.

Note

Useful Web sites that cover this process in more detail include:

<http://www.timhiggins.com/ppd/icsinstall.htm>

<http://www.duxcw.com/digest/Howto/network/win98se/>

(continues)

(continued)

The following Microsoft Web page answers common questions about Windows 98 SE:

<http://support.microsoft.com/support/windows/faq/win98se/w98seics.asp>

If you want the additional benefits of a proxy server, check out products such as WinProxy (<http://www.winproxy.com>), WinGate (<http://www.wingate.deerfield.com>), and Sybergen SyGate (<http://www.sybergen.com>). Many home-oriented networks and modems are bundled with these or similar products, so if you're in the market for a new modem or are building a small network, ask whether a proxy server program for Internet sharing is included.

Modem Troubleshooting

Modem Fails to Dial

1. Check line and phone jacks on modem. Use the line jack to attach the modem to the telephone line. The phone jack takes the same RJ-11 silver cord cable, but it's designed to let you daisy-chain a telephone to your modem, so you need only a single line for modem and telephone use. If you've reversed these cables, you'll get no dial tone.
2. If the cables are attached properly, check the cable for cuts or breaks. The shielding used on RJ-11 telephone cables is minimal. If the cable looks bad, replace it.
3. If the modem is external, make sure the RS-232 modem cable is running from the modem to a working serial port on your computer and that it is switched on. Signal lights on the front of the modem can be used to determine if the modem is on and if it is responding to dialing commands.
4. If the modem is a PCMCIA/PC Card, make sure it is fully plugged into the PCMCIA/PC slot. With Windows 9x, you should see a small PCMCIA/PC Card icon on the toolbar. Double-click it to view the cards that are currently connected (see Figure 18.12). If your modem is properly attached, it should be visible. Otherwise, remove it, reinsert it into the PCMCIA/PC Card slot, and see whether the computer detects it.

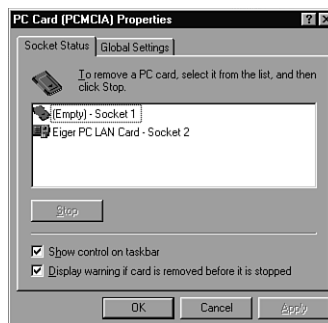

Figure 18.12 This notebook computer has a network card properly installed in its PCMCIA slots but not a modem. If the modem isn't pushed into the slot firmly, it will appear to be missing.

Connecting a PCMCIA Modem Card via a Dongle

Most PCMCIA modem cards don't use a standard RJ-11 cable because the card is too thin. Instead, they use a connection called a *dongle*, which runs from the PCMCIA Card to the telephone. If this proprietary cable is damaged, your modem is useless. It's a good idea to purchase a spare from the modem vendor and carry it with you. And if you find the dongle is too short to reach the data jacks in a hotel room, buy a coupler from your local Radio Shack or telephone-parts department and attach a standard RJ-11 cable to your dongle via the coupler.

5. Make sure your modem has been properly configured by your OS. With Windows 9x, use the Modems control panel to view and test your modem configuration. Select your modem and click the Diagnostics tab. This displays the COM (serial) ports in your computer. Select the COM port used by the modem, and click the More Info tab. This sends test signals to your modem. A properly working modem responds with information about the port and the modem (see Figure 18.13).

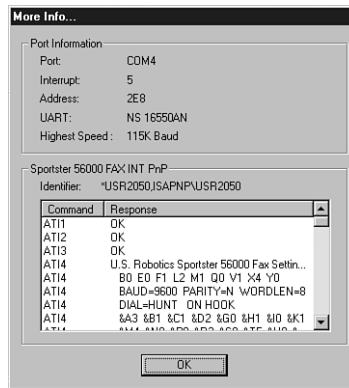

Figure 18.13 The U.S. Robotics 56000 PnP modem was configured to a nonstandard IRQ of 5 when it was installed. It contains an up-to-date 16550 UART chip.

6. If you get a *Couldn't Open Port* error message, your modem isn't connected properly. It might be in use already, or there might be an IRQ or I/O port address conflict with another card in your computer. Whether you have a modem installed or not, every COM port that's working will display its IRQ, I/O port address, and UART (Universal Asynchronous Receive-Transmit) chip type when you run Diagnostic. The UART type should be 16550 or above for use with any modern modem.

Note

You can also test your modem response by setting up a HyperTerminal session (discussed earlier) to send the modem commands. If the modem fails to respond, this is another indication of a problem with the modem-PC connection.

Computer Locks Up After Installing Internal Modem

Most likely, you've stumbled across the curse of the shared IRQ. COM 3 shares IRQ 4 with COM 1, and COM 4 shares IRQ 3 with COM 2 by default. The problem is that IRQ sharing for ISA

devices (like your COM ports) works when only one device at a time is using the IRQ. The most likely cause for your problem is that your mouse is connected to COM 1, your internal modem is using COM 3, and both COM ports are using the default IRQ of 4. There's no problem as long as the mouse has IRQ 4 all to itself, but the moment you try to use the modem, the computer can't handle two devices trying to use IRQ 4 and locks up. The only solution is to get the internal modem and mouse working on a *separate*, non-conflicting IRQ. You have two options: Move the mouse to another port or disable COM 2 in your computer to make room for an internal modem on COM 2.

Move the Mouse to Another Port

Any mouse that can work on COM 1 can also work on COM 2, usually without any software changes. If both COM 1 and COM 2 are the typical AT-style 9-pin ports, turn off the computer, unplug the mouse from COM 1, plug it back into COM 2, and restart the computer. You should be able to use your mouse and modem at the same time.

If your modem is using COM 4 and your mouse is using COM 2, move the mouse to COM 1 instead. With Windows 9x, use the System Properties Device Manager tab to determine which devices are using what IRQs.

On a few computers, the COM 2 port might be a 25-pin connector. If your mouse didn't ship with an adapter, any computer store will have one. (The 9-pin and 25-pin COM ports are both RS-232, and the adapter will make a device wired for one type of port work with the other.)

If your computer has a PS/2 (6-pin round) mouse port, use it for your mouse instead of tying up a serial port. The PS/2 port uses IRQ 12. If your Pentium-class PC doesn't have a visible PS/2 port, check your system/motherboard instruction manual to see if the motherboard has provision for a PS/2 mouse port header cable. Most Pentium-class baby-AT motherboards have the connector, but some companies don't provide the header cable unless you think to request it (and pay extra!). Check with your system vendor.

Disable COM 2

COM 2, the second serial port, is found on the motherboard of most Pentium-class PCs. To disable it, go into your computer's BIOS setup program, look for the screen that controls built-in ports (such as Onboard Peripherals), and disable the port. Save the changes, exit the setup program, and the system reboots. To see whether COM 2 is disabled, use the Windows 9x System Properties sheet Device Manager. Then set your modem for COM 2, IRQ 3, and install it.

Computer Can't Detect External Modem

1. Make sure the modem has been connected to the computer with the correct type of cable.

For most external modems, you need an RS-232 modem cable, which will have a 9-pin connector on one end and a 25-pin connector on the other end. Because RS-232 is a very flexible standard encompassing many different pinouts, make sure the cable is constructed according to the following diagram:

PC (with 9-pin COM port - male)		Modem (25-pin port - female)
3	TX data	2
2	RX data	3
7	RTS	4
8	CTS	5
6	DSR	6
5	SIG GND	7
1	CXR	8
4	DTR	20
9	RI	22

If you purchase an RS-232 modem cable prebuilt at a store, you'll have a cable that works with your PC and your modem. However, you can use the preceding chart to build your own cable or, by using a cable tester, determine whether an existing RS-232 cable in your office is actually made for modems or some other device.

2. Make sure the COM (serial) port the modem is connected to is working.

The Windows 9x diagnostics test listed earlier can be useful in this regard, but third-party testing programs such as Touchstone Software's CheckIt, AMIDIAG, and many others have more thorough methods for testing the system's COM ports. These programs can use loopback plugs to test the serial ports. The loopback plug loops signals that would be sent to the modem or other serial device back to the serial port. These programs normally work best when run from the MS-DOS prompt.

Touchstone Software's CheckIt PRO software uses a loopback plug to test serial ports. You can build the loopback plug yourself or buy it from the vendor. Loopback plugs will vary in design depending on the vendor.

3. Check the power cord and power switch.
4. Check the USB connector or hub (for USB-based models).

Using Your Modem Sound to Diagnose Your V.90 Modem

If you listen to your modem when it makes a connection, you might have realized that different types of modems make a distinctive connection sound, and that different connection speeds also make distinctive sounds.

The three different types of 56Kbps modems (K56flex, x2, and V.90) have distinctly different handshakes of tones, buzzes, and warbles as they negotiate speeds with the ISP's modem. Learning what your modem sounds like when it makes a 56Kbps connection and when it settles for a V.34-speed connection can help you determine when you should hang up and try to connect at a faster speed.

The "56k=v.Unreliable" Web site's troubleshooting section has a number of sound samples of different modems you can play back with RealAudio:

<http://www.808hi.com/56k/trouble3.htm>

Compare these sound samples to your own modem; make sure you adjust the speaker volume for your modem so you can hear it during the call.

Diagnosing Problems with High-Speed Internet Access

Because all these solutions involve the use of an Ethernet network card, see Chapter 19 for network troubleshooting. You'll need to verify that your in-house connection is working properly before you call the provider for help.

Diagnosing Problems with a Shared Internet Connection

Although each Internet-sharing product has individual configuration issues, the following tips provide general guidelines useful for solving problems with all of them.

Check Your Host Configuration

If your host isn't set up correctly, it can't share its connection with clients. Check the bindings for TCP/IP or other protocols used to create the shared connection.

Check Your Client Configuration

Make sure your clients have correct TCP/IP, DHCP, and other protocol settings for the host. Setting up a gateway product such as Windows 98 SE/Windows 2000 ICS as if it were a proxy server won't work.

Verify that the host has a working Internet connection that's active before you try to share it. Check the sharing program's documentation to see how guests can dial the host's modem to start a connection if necessary.

Speed Will Drop with Multiple Users

It's normal for the speed of an Internet connection to drop with multiple users, but if you're concerned about the degree of decline, check with the sharing-software provider for Registry tweaks and other options to improve performance.

CHAPTER 19

Local Area Networking

What Is a Network?

A network is a group of two or more computers that are intelligently sharing hardware or software devices with each other. A network can be as small and simple as two computers that share the printer and CD-ROM drive attached to one of them, or as large as the world's largest network: the Internet.

Intelligently sharing means that each computer that shares resources with another computer or computers maintains control of that resource. Thus, a switchbox for sharing a single printer between two computers doesn't qualify as a network device; because the switchbox, not the computers, handles the print jobs, neither computer knows when the other one needs to print, and print jobs can interfere with each other.

A shared printer, on the other hand, can be controlled remotely, and can store print jobs from different computers on the print server's hard disk. Users can change the sequence of print jobs, hold them, or cancel them. And, sharing of the device can be controlled through passwords, further differentiating it from a switchbox.

Shared Hardware Components

Virtually any storage or output device can be shared over a network, but the most-common devices to be used over a network include

- Printers
- Disk drives
- CD-ROM and optical drives
- Modems
- Fax
- Tape backup units

Entire drives, selected folders, or individual files can be shared with other users via the network.

Benefits of Sharing Information via Networks

In addition to reducing hardware costs by sharing expensive printers and other peripherals among multiple users, networks provide additional benefits to users:

- Software and data files can be shared for access by multiple users
- Electronic mail (email) can be sent and received
- Collaboration features allow contributions by multiple users to a single document
- Remote-control programs can be used to troubleshoot problems or show new users how to perform a task

Focus of This Chapter

This chapter concentrates on how to build and use a peer-to-peer network, the lowest-cost network that is still highly useful to small business and home-office users. This type of network can

be created by adding network hardware to any recent version of Windows, from Windows 95 and NT through Windows 98 and 2000. As you'll see, most peer-to-peer networks can be "grown" into client/server networks at a later point by adding a dedicated server and the appropriate software to the server and to client PCs.

Thus, this chapter provides the hands-on and practical information you need to create a small office, workgroup, or home-office network. If you are managing a corporate network using Linux, UNIX, Windows NT Server, Windows 2000 Server, or Novell NetWare, you will also be concerned with matters such as security, user profiles, SIDs, and other factors beyond the scope of this book.

Note

Networking is an enormous topic. For more information about client/server networking, wide-area networking, the Internet, and corporate networking, I recommend *Upgrading and Repairing Networks, Second Edition*, from Que.

Types of Networks

Several types of networks exist, from small two-station arrangements to networks which interconnect offices in many cities.

- **Local Area Networks.** The smallest office network is referred to as a LAN (Local Area Network). A LAN is formed from computers and components in a single office or single building. A LAN can also be built at home from the same components used in office networking, but, as you'll see later, special home-networking components now exist to allow the creation of what can be called a Home Area Network or HAN.
- **Wide Area Networks.** LANs in different locations can be connected together by high-speed fiber-optic, satellite, or leased phone lines to form a Wide Area Network, or WAN.
- **The Internet.** The World Wide Web is the most visible part of the world's largest network, the Internet. Although many users of the Internet use modems over a dial-up connection rather than a LAN or WAN connection, any user of the Internet is a network user. The Internet is really a network of networks, all of which are connected to each other through the TCP/IP protocol. Programs such as Web browsers, File Transfer Protocol (FTP) clients, and newsreaders are some of the most common ways that users work with the Internet.
- **Intranets.** Intranets use the same Web browsers and other software, and the same TCP/IP protocol as the public Internet, but Intranets exist as a portion of a company's private network. Typically, intranets comprise one or more LANs that are connected to other company networks, but, unlike the Internet, the content is restricted to authorized company users only. Essentially, an intranet is a private Internet.
- **Extranets.** Intranets that share a portion of their content with customers, suppliers, or other businesses, but not with the general public, are called extranets. As with intranets, the same Web browsers and other software are used to access the content.

Note

Both intranets and extranets rely on firewalls and other security tools and procedures to keep their private contents private. If you want to learn more about firewalls and security, I recommend picking up copies of

- *Practical Firewalls*, ISBN 0-7897-2416-2
 - *Upgrading and Repairing Networks, Second Edition*, ISBN 0-7897-2034-5
-

Client/Server Versus Peer Networks

Although every computer on a LAN is connected to every other, they do not necessarily all communicate with each other. There are two basic types of LANs, based on the communication patterns between the machines, called client/server networks and peer-to-peer networks.

Client/Server Networks

On a client/server network, every computer has a distinct role, that of either a client or a server. A server is designed to share its resources among the client computers on the network. Typically, servers are located in secured areas, such as locked closets and data centers, because they hold the organization's most valuable data and do not have to be accessed by operators on a continuous basis. The rest of the computers on the network function as clients (see Figure 19.1).

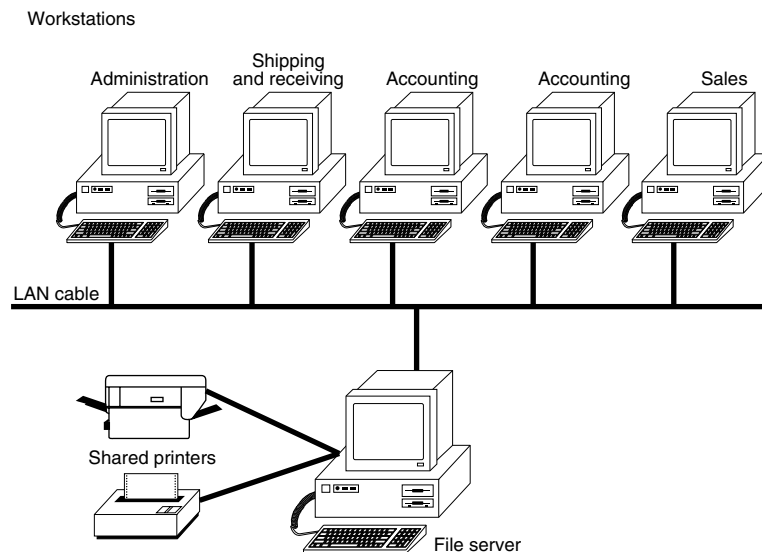

Figure 19.1 The components of a client/server LAN.

Servers

A dedicated server computer typically has a faster processor, more memory, and more storage space than a client, as it might have to service dozens or even hundreds of users at the same time. The server runs a special network operating system—such as Windows NT Server, Windows 2000, or Novell NetWare—that is designed solely to facilitate the sharing of its resources. These resources can reside on a single server or on a group of servers. When more than one server is used, each server can “specialize” in a particular task (file server, print server, fax server, email server, and so on) or provide redundancy (duplicate servers) in case of server failure. For very demanding computing tasks, several servers can act as a single unit by parallel processing.

Clients

A client computer communicates only with servers, not with other clients. A client system is a standard PC that is running an operating system such as DOS or Windows. The only difference is the addition of a client software package that enables the computer to access the resources shared by servers.

Peer-to-Peer Network

By contrast, on a peer-to-peer network, every computer is equal and can communicate with any other computer on the network to which it has been granted access rights (see Figure 19.2). Essentially, every computer on a peer-to-peer network functions as both a server and a client. This is why you might hear about client and server activities, even when the discussion is about a peer-to-peer network. Peer-to-peer networks can be as small as two computers or as large as hundreds of units. Although there is no theoretical limit to the size of a peer-to-peer network, performance drops significantly and security becomes a major headache on peer-based networks with more than 10 computers. Also, Microsoft imposes a 10-station limit on computers running Windows 2000 Professional who are sharing resources with other systems. For these reasons, I recommend that you switch to a client/server network when your network climbs above about 10 stations.

Figure 19.2 The logical architecture of a typical peer-to-peer network.

Peer-to-peer networks are more common in small offices or within a single department of a larger organization. The advantage of a peer-to-peer network is that you don't have to dedicate a computer to function as a file server. Instead, every computer can share its resources with any other. The potential disadvantages to a peer-to-peer network are that there is typically less security and less control because users normally administer their own systems, whereas client/server networks have the advantage of centralized administration.

Comparing Client/Server and Peer-to-Peer Networks

Client/server LANs offer enhanced security for shared resources, greater performance, increased backup efficiency for network-based data, and the potential for use of redundant power supplies and RAID drive arrays. Client/server LANs also have a much greater cost to purchase and maintain. Table 19.1 compares client/server and peer-to-peer server networking.

Table 19.1 Comparing Client/Server and Peer-to-Peer Networking

Item	Client/Server	Peer-to-Peer
Access control	Via user/group lists of permissions; single password provides user access to only the resources on his list; users can be given several different levels of access	Via password lists by resource; each resource requires a separate password; all-or-nothing access; no centralized user list
Security	High because access is controlled by user or by group identity	Low because knowing the password gives anybody access to a shared resource
Performance	High because server doesn't waste time or resources handling workstation tasks	Low because servers often act as workstations
Hardware Cost	High, due to specialized design of server, high-performance nature of hardware, redundancy features	Low because any workstation can become a server by sharing resources
Software Cost	License fees per workstation user are part of the cost of the Network Operating System server software (Windows NT and Windows 2000 Server, Novell NetWare)	Free; all client software is included with any release of Windows 9x and Windows NT Workstation and Windows 2000 Professional
Backup	Centralized when data is stored on server; enables use of high-speed, high-capacity tape backups with advanced cataloging	Left to user decision; usually mixture of backup devices and practices at each workstation
Redundancy	Duplicate power supplies, hot-swappable drive arrays, and even redundant servers are common; network OS normally capable of using redundant devices automatically	No true redundancy among either peer "servers" or clients; failures require manual intervention to correct with high possibility of data loss

Windows 9x, Windows Millennium, Windows NT, and Windows 2000 have peer-to-peer networking capabilities built into them. Because of Plug-and-Play technology used by Windows 9x, Windows Millennium, and Windows NT/2000, it is a relatively easy matter to install network interface cards in a collection of Windows 9x, Millennium, and Windows 2000 systems; connect them with the right kind of cable; and build your own peer-to-peer network.

Requirements for a Network

Unless the computers that are connected know they are connected and agree on a common means of communication and what resources are to be shared, they cannot work together. Networking software is just as important as networking hardware because it establishes the logical connections that make the physical connections work.

At a minimum, each network requires the following:

- Physical (cable) or wireless (infrared [IRDA] or radio-frequency) connections between computers.
- A common set of communications rules, known as a network protocol.
- Software that enables resources to be shared with other PCs, known as a network operating system.
- Resources that can be shared, such as printers, disk drives, and CD-ROMs.
- Software that enables computers to access the computers with shared resources, provides some level of access control, and provides some means of distinguishing which computers are active on the network—a network client allows a workstation to access the shared resources on the network.

These rules apply to the simplest, the most powerful, and all networks in between, regardless of their nature. The details of the hardware and software you need will be discussed in detail later in this chapter.

Ethernet Versus Token-Ring

The protocol that you choose to run is the single most important decision you make when setting up a local area network. This protocol defines the speed of the network, the medium access control mechanism it uses, the types of cables you can use, the network interface adapters that you must buy, and the adapter drivers that you install in the network client software.

The Institute of Electrical and Electronic Engineers (IEEE) has defined and documented a set of standards for the physical characteristics of both collision-detection and token-passing networks. These standards are known as IEEE 802.3 (Ethernet) and IEEE 802.5 (Token-Ring).

Note

Be aware, however, that the colloquial names Ethernet and Token-Ring actually refer to earlier versions of these protocols, on which the IEEE standards were based. There are minor differences between the frame definitions for true Ethernet and true IEEE 802.3. In terms of the standards, IBM's 16Mbps Token-Ring products are an extension of the IEEE 802.5 standard. There is also an older data link protocol called ARCnet that is now rarely used.

The two major choices today are Ethernet and Token-Ring, but other network data link protocols you might also encounter are summarized in the following table.

Table 19.2 summarizes the major types of network protocols. The abbreviations used for the cable types are explained in the following sections.

Table 19.2 LAN Protocol Summary

Network Type	Speed of Stations	Maximum Number	Cable Types	Notes
ARCnet	2.5Mbps	255 stations	RG-62 coax UTP/Type 1 STP	Obsolete for new installations; was used to replace IBM 3270 terminals (which used the same coax cable)
Ethernet	10Mbps	Per segment: 10BaseF-2 10Base2-30 10Base5-100 10BaseFL-2	UTP Cat 3 (10BaseT), Thicknet (coax; 10Base5), Thinnet (RG-58 coax; 10Base2), fiber-optic (10BaseF)	Being replaced by Fast Ethernet; can be interconnected with Fast Ethernet by use of dual-speed hubs and switches; use switches and routers to overcome "5-4-3" rule in building very large networks
Fast Ethernet	100Mbps	Per segment: 2	Cat 5 UTP	Fast Ethernet can be interconnected with standard Ethernet through use of dual-speed hubs, switches, and routers
Gigabit Ethernet	1000Mbps	Per segment: 2	Cat 5 UTP	Gigabit Ethernet can be interconnected with Fast or standard Ethernet through use of dual-speed hubs, switches, and routers
Token-Ring	4Mbps or 16Mbps	72 on UTP, 250-260 on type 1 STP	UTP, Type 1 STP, and Fiber Optic	High price for NICs and MAUs to interconnect clients; primarily used with IBM mid-size and mainframe systems

A few years ago, the choice between Token-Ring or Ethernet wasn't easy. Ethernet has become the leading data link layer protocol in the world, but the original versions of standard Ethernet (10Base5 "Thick Ethernet" and 10Base2 "Thin Ethernet") used hard-to-install coaxial cable and were expensive to build beyond a certain point because of the technical limitations expressed by the "5-4-3" rule (see below).

Token-Ring's 16Mbps version was substantially faster than 10Base versions of Ethernet, and had larger limits on the numbers of workstations permitted per segment. However, as the twenty-first century begins, the popularity and low cost of Fast Ethernet; the use of easy-to-install twisted-pair cabling for standard, 100Mbps Fast, and even 1000Mbps Gigabit Ethernet; and the use of hubs and switches to overcome classic Ethernet station limitations have made Fast Ethernet the preferred choice for workgroup-sized networks and a competitor to Token-Ring for larger networks. A properly designed Fast Ethernet network can be upgraded to Gigabit Ethernet in the future.

Ethernet

With tens of millions computers connected by Ethernet cards and cables, Ethernet is the most widely used data link layer protocol in the world. Ethernet-based LANs enable you to interconnect a wide variety of equipment, including UNIX and Linux workstations, Apple computers,

printers, and PCs. You can buy Ethernet adapters from dozens of competing manufacturers, supporting all three of the cable types defined in the standard: Thinnet, Thicknet, and UTP (Unshielded Twisted Pair). Traditional Ethernet operates at a speed of 10Mbps, but the more recent Fast Ethernet standards push this speed to 100Mbps. The latest version of Ethernet, Gigabit Ethernet, reaches speeds of 1000Mbps, or 100 times the speed of original Ethernet.

Fast Ethernet

Fast Ethernet requires adapters, hubs, and UTP or fiber-optic cables designed to support the higher speed, but you can buy combination devices that run at both 10Mbps and 100Mbps, enabling you to gradually upgrade your network by installing new NICs and hubs over an extended period of time.

Both the most-popular form of Fast Ethernet (100BaseTX) and 10BaseT standard Ethernet use two of the four wire pairs found in UTP Category 5 cable.

Gigabit Ethernet

Gigabit Ethernet also requires special adapters, hubs, and cables. Most users of Gigabit Ethernet use fiber-optic cables, but it is possible to run Gigabit Ethernet over the same Category 5 UTP cabling used by Fast Ethernet and newer installations of standard Ethernet.

Unlike Fast Ethernet and standard Ethernet over UTP, Gigabit Ethernet uses all four wire pairs.

Neither Fast Ethernet nor Gigabit Ethernet support the use of thin or thick coaxial cable originally used with traditional Ethernet.

Note

For more information about Ethernet, Fast Ethernet, Token-Ring, and other network data link standards, see *Upgrading & Repairing PCs, Eleventh Edition*, available in electronic form on the CD-ROM provided with this book. Also see *Upgrading and Repairing Networks, Second Edition*, published by Que.

Hardware Elements of Your Network

Your network requires hardware and software components. After you have selected a data link protocol, you can select appropriate hardware, including network interface cards, cables, and hubs or switches.

Network Interface Cards (NICs)

On most computers, the network interface adapter takes the form of a network interface card, or NIC, that fits into a PCI, ISA, or EISA slot in each computer. Some systems incorporate the network interface adapter onto the motherboard, but this practice is more commonly found in workstations and rarely in servers because most network administrators prefer to select their own NIC.

Ethernet and Token-Ring adapters have unique hardware addresses coded into their firmware. The data link layer protocol uses these addresses to identify the other systems on the network. A packet gets to the right destination because its data link layer protocol header contains the hardware addresses of both the sending and receiving systems.

Network adapters range in price from well under \$100 to as much as \$300. Network adapters are built in all the popular interface-card types, and are also optimized for either workstation or server use. For first-time network users, so-called network in a box kits are available that contain two Ethernet or Fast Ethernet NICs, a small hub, and prebuilt UTP cables for around \$100. When combined with the built-in networking software in Windows, these kits make networking very inexpensive.

Recommended Features for Client Workstation NICs

For client workstations (including peer servers on peer-to-peer networks), here are my recommendations on the features you need:

Speed

Your NIC should run at the maximum speed you want your network to support. For a Fast Ethernet network, for example, you should purchase Ethernet cards that support 100BaseTX's 100Mbps speed. Most Fast Ethernet cards also support standard Ethernet's 10Mbps speed, allowing the same card to be used on both older and newer portions of the network.

Your NIC should support both half-duplex and full-duplex operation.

- *Half-duplex* means that the network card can send or receive in a single operation.
- *Full-duplex* means that the network card can receive and send simultaneously. Full-duplex options boost network speed if switches are used in place of hubs.

Switches, which provide a dedicated path between two computers, provide faster performance than hubs, but their extra expense is usually not justified on a workgroup peer-to-peer LAN.

Bus Type

If you are networking desktop computers built from 1995 to the present, you should consider only PCI-based NICs (these computers typically have three or more PCI slots). Although almost all computers still have one or more ISA expansion slots, the superior data bus width and data transfer rate of PCI make it the only logical choice for networks of all types.

Table 19.3 summarizes difference between these expansion slot types.

Table 19.3 Bus Choices for Client PC NICs

Slot Type	Speed	Bus Width
PCI	33MHz ¹	32-bit ²
ISA	8.33MHz ³	16-bit ⁴

¹ PCI speed of 33MHz assumes a motherboard (frontside bus) speed of 66MHz or 100MHz; other motherboard speeds would cause this to vary.

² Some PCI host adapters made for network servers are 64-bit or can operate in either 64-bit or 32-bit PCI slots.

³ ISA speed of 8.33MHz assumes default of PCI clock speed/4; variations in motherboard speed or PCI clock divisor could cause this to vary.

⁴ Some ISA slots are only 8-bit design.

Although ISA-based NICs are still on the market, their slow speed and narrow bus width severely restrict their performance. ISA-based Ethernet cards can't support speeds above 10Mbps, and thus don't support Fast Ethernet or Gigabit Ethernet.

Network Adapter Connectors

Ethernet adapters typically have a connector that looks like a large telephone jack called an RJ45 (for 10BaseT and Fast Ethernet twisted-pair cables), a single BNC connector (for Thinnet coaxial cables), or a D-shaped 15-pin connector called a DB15 (for Thicknet coaxial cables). Some adapters have a combination of two or all three of these connector types; adapters with two or more connectors are referred to as “combo” adapters. Token-Ring adapters can have a 9-pin connector called a DB9 or sometimes an RJ45 jack. Figure 19.3 shows all three of the Ethernet connectors.

Figure 19.3 Three Ethernet connectors on two NICs: RJ-45 connector (left), DB-15 connector (top right), and BNC connector (bottom right).

Figures 19.4 and 19.5 provide profile views of the most common types of NIC connections. Figure 19.4 shows a 10Base2 NIC configured to be at the end of a network; the T-adapter connected to the BNC connector has a Thinnet (RG-58) cable attached to one side and a 50-ohm terminator at the other end.

Figure 19.4 An Ethernet 10Base2 NIC configured as the last station in a Thin Ethernet network.

Figure 19.5 shows a 10BaseT NIC with its UTP cable attached.

Figure 19.6 shows the two cables side-by-side.

Figure 19.5 An Ethernet 10BaseT NIC with a UTP cable attached.

Figure 19.6 An RJ-45 UTP cable (left) and a Thin Ethernet cable with BNC T-adaptor and terminator (right).

Most standard and Fast Ethernet NICs made for client-PC use on the market today are designed to support twisted-pair cable exclusively. If you are adding a client PC to an existing network that uses some form of coaxial cable, you have two options:

- Purchase a combo NIC that supports coaxial cable as well as RJ-45 twisted-pair cabling.
- Purchase a media converter that can be attached to the coaxial cable to allow the newer UTP-based NICs to connect to the existing network.

Network Cables

For maximum economy, NICs and network cables must match, although media converters can be used to interconnect networks based on the same standard, but using different cable.

Thick and Thin Ethernet Coaxial Cable

Older Ethernet networks were based on coaxial cable. The original form of Ethernet, 10Base5, used a thick coaxial cable (called Thicknet) that was not directly attached to the NIC. A device called an AUI (Attachment Unit Interface) ran from a DB15 connector on the rear of the NIC to the cable. The cable had a hole drilled into it to allow the “vampire tap” to be connected to the cable. NICs designed for use with thick Ethernet cable are almost impossible to find as new hardware today.

10Base2 Ethernet cards use a BNC (Bayonet-Neill-Concilman) connector on the rear of the NIC. Although the thin coaxial cable (called “Thinnet” or RG-58) used with 10Base2 Ethernet has a bayonet connector that can physically attach to the BNC connector on the card, this configuration is incorrect and won’t work. Instead, a BNC T-connector is attached to the rear of the card, allowing a thin Ethernet cable to be connected to both ends of the T (for a computer in the middle of the network), or to one end only (for a computer at the end of the network). A 50 ohm terminator is connected to the other arm of the T to indicate the end of the network and prevent erroneous signals from being sent to other clients on the network. Combo cards with both BNC and RJ-45 connectors are still available, but can run at only standard Ethernet speeds.

Figure 19.7 shows an Ethernet BNC coaxial T-connector, and Figure 19.8 illustrates the design of coaxial cable.

Figure 19.7 An Ethernet coaxial cable T-connector.

Figure 19.8 Coaxial cable.

Twisted-Pair Cable

Twisted-pair cable is just what its name implies: insulated wires within a protective casing with a specified number of twists per foot. Twisting the wires reduces the effect of electromagnetic interference (that can be generated by nearby cables, electric motors, and fluorescent lighting) on the signals being transmitted. Shielded twisted pair (STP) refers to the amount of insulation around the cluster of wires and therefore its immunity to noise. You are probably familiar with unshielded twisted-pair (UTP) cable; it is often used for telephone wiring. Figure 19.9 shows unshielded twisted-pair cable; Figure 19.10 illustrates shielded twisted-pair cable.

Figure 19.9 An unshielded twisted-pair (UTP) cable.

Figure 19.10 A shielded twisted-pair (STP) cable.

Shielded Versus Unshielded Twisted Pair

When cabling was being developed for use with computers, it was first thought that shielding the cable from external interference was the best way to reduce interference and provide for greater transmission speeds. However, it was discovered that twisting the pairs of wires is a more-effective way to prevent interference from disrupting transmissions. As a result, earlier cabling scenarios relied on shielded cables rather than the unshielded cables more commonly in use today.

Shielded cables also have some special grounding concerns because one, and only one, end of a shielded cable should be connected to an earth ground; issues arose where people inadvertently caused grounding loops to occur by connecting both ends or caused the shield to act as an antenna because it wasn't grounded.

Grounding loops are situations where two different grounds are tied together. This is a bad situation because each ground can have a slightly different potential, resulting in a circuit that has very low voltage but infinite amperage. This causes undue stress on electrical components and can be a fire hazard.

Most Ethernet and Fast Ethernet installations that use twisted-pair cabling use UTP because the physical flexibility and small size of the cable and connectors makes routing it very easy. However, its lack of electrical insulation can make interference from fluorescent lighting, elevators, and alarm systems (among other devices) a major problem. If you use UTP in installations where interference can be a problem, you need to route the cable away from the interference, use an external shield, or substitute STP for UTP near interference sources.

Network Topologies

Each computer on the network is connected to the other computers with cable (or some other medium).

These different topologies are often mixed, forming what is called a hybrid network. For example, you can link the hubs of several star networks together with a bus, forming a star-bus network. Rings can be connected in the same way.

Table 19.4 summarizes the relationship between network types and topologies.

Table 19.4 Network Cable Types and Topologies

Network Type	Standard	Cable Type	Topology
Ethernet	10Base2	Thick coaxial	Bus
	10Base5	Thin (RG-58) coaxial	Bus
	10BaseT	Cat 3 or Cat 5 UTP	Star
Fast Ethernet	100BaseTX	Cat 5 UTP	Star
Gigabit Ethernet	1000BaseTX	Cat 5 UTP	Star
Token-Ring	(all)	STP or coaxial	Logical Ring

The bus, star, and ring topologies are discussed in the following sections.

Bus Topology

Sometimes a single piece of cable winds from station to station, visiting all the network's computers along the way. This cabling arrangement is called a *bus topology*, as shown in Figure 19.11. (A topology is a description of the way the workstations and servers are physically connected.) The potential disadvantage to this type of wiring is that if one computer or cable connection malfunctions, it can cause all the stations beyond it on the bus to lose their network connections. Thin and thick Ethernet coaxial cables are typically installed using a bus topology.

Star Topology

The most popular type of topology in use today has separate cables to connect each computer to a central wiring nexus, often called a hub or a concentrator. Figure 19.12 shows this arrangement, which is called a *star topology*. Because each computer uses a separate cable, the failure of a network connection affects only the single machine involved. The other computers can continue to function normally. Bus cabling schemes use less cable than the star but are harder to diagnose or bypass when problems occur. At this time, Ethernet using 10BaseT (Category 3 or 5) cable or Fast Ethernet in a star topology is the most commonly implemented type of LAN; this is the type of network you build with most preconfigured network kits.

Figure 19.11 The linear bus topology, attaching all network devices to a common cable.

Figure 19.12 The star topology, linking the LAN's computers and devices to one or more central hubs, or access units.

Ring Topology

The other topology often listed in discussions of this type is a *ring*, in which each workstation is connected to the next, and the last workstation is connected to the first again (essentially a bus topology with the two ends connected). Data travels around a Token-Ring network in this fashion, for example. However, the ring is not physically evident in the cabling layout for the network. In fact, the ring exists only within the hub (called a multistation access unit or MSAU on a Token-Ring network). See Figure 19.13.

Signals generated from one computer travel to the hub, are sent out to the next computer, and then go back to the hub again. The data is then passed to each system in turn until it arrives back at the computer that originated it, where it is removed from the network. Therefore, although the physical wiring topology is a star, the data path is theoretically a ring. This is called a *logical ring*.

Figure 19.13 All computers and printers are connected to the same circuit, creating a loop.

The logical ring is preferable to a physical ring topology because it affords a greater degree of fault tolerance. As on a bus network, a cable break anywhere in a physical ring would affect the entire network. On a Token-Ring network, the MSAU can effectively remove a malfunctioning computer from the logical ring, enabling the rest of the network to function normally.

Hubs for Ethernet Networks

As you have seen, modern Ethernet workgroup networks are based on UTP cable with workstations arranged in a star topology. The center of the star is a hub.

All Ethernet hubs have the following features:

- Multiple RJ-45 UTP connectors
- Diagnostic and activity lights
- A power supply

There are two different types of Ethernet hubs: managed and unmanaged. Workgroup and home-office networks use unmanaged hubs, whereas corporate networks often use managed hubs, which are controlled with software.

Note

The now-obsolete ARCnet network used its own types of hubs: Passive hubs were unpowered, whereas active hubs used a power supply. Neither type of hub is compatible with Ethernet.

The connection between each workstation and the hub is the UTP cable running from the RJ-45 jack on the rear of the NIC to the RJ-45 jack on the rear of the hub.

Signal lights on the front of the hub indicate which connections are in use by computers. Your hub needs to have at least one RJ-45 UTP connector for each computer you want to connect to it. Figure 19.14 shows a typical five-port hub suitable for small networks at home or a small business.

Figure 19.14 A typical 10BaseT five-port workgroup hub. Connectors 1 and 4 are connected to computers (as shown by the lights at the front of the hub (bottom of the picture)). The light at right indicates the hub is receiving power from a AC/DC transformer “brick.”

In Figure 19.14, the left-hand cable goes to the power supply. The middle cable is a prebuilt cable that has an anti-snag design for easier threading through walls. The right-hand cable was built from bulk cable and connectors and was assembled in the field.

How Hubs Work

A computer on an Ethernet network broadcasts (sends) a request for network information or programs from a specific computer through the cable to the hub, which broadcasts the request to all computers connected to it. When the destination computer receives the message, it sends the requested information back to the hub, which broadcasts it again to all computers, although only the requesting computer will act on the information. Thus, a hub acts something like a radio transmitter and receiver that sends a signal to all radios, but only the radios set for the correct station can send or receive the information.

Additional Hub Features You May Need

The least-expensive hubs are those which run at only a single speed and have only a few RJ-45 connectors. Depending on your needs, you might find the following options useful:

- **Dual-speed hubs.** If you are adding Fast Ethernet (100BaseTX) clients to an existing 10BaseT network, you need a dual-speed hub to connect the different types of Ethernet together. Even if you are building a brand-new Fast Ethernet network, a dual-speed hub is useful for occasionally hosting a “guest” notebook PC which has only a standard 10BaseT Ethernet NIC on-board. Many dual-speed hubs for smaller networks are only a bit more expensive than Fast Ethernet-only hubs, but the extra versatility can be worthwhile.
- **“Extra” Ports Beyond Your Current Requirements.** If you are connecting four computers together into a small network, you need a four-port hub (the smallest available). But, if you buy a hub with only four ports and you want to add an additional client PC to the network, you’ll need to replace the hub. Instead, plan for the future by buying a hub which can handle your projected network growth over the next year. If you plan to add two workstations, buy at least a six-port hub (the cost per connection drops as you buy hubs with more connections). To prepare for even more growth, buy a hub that’s stackable.
- **Stackable Hub with an Uplink Port.** A “stackable” hub is one that can be connected to another hub, allowing you to add computers to your network without replacing your hub every time it runs out of connections. Most hubs on the market today are stackable, but very small hubs and some older models might lack this feature.

To determine whether a hub is stackable, look for an uplink port. This port looks like an ordinary RJ-45 UTP port, but it is wired differently, allowing you to use a standard-pinout RJ-45 UTP cable to connect it to another hub. Without the uplink port, you’d need to use a specially wired crossover cable.

Many small hubs with an uplink port allow you to use the port along with all but one of the normal ports on the hub (see Figure 19.15). My office uses a five-port hub made by Linksys with an uplink port. I use the uplink port to connect my network with a larger LAN for Internet access. I can use all five ports if my hub is used in isolation, but if I use the uplink port, only four ports are usable.

The uplink port connects
this hub to another hub

Up to five devices (computers and
printers) can be connected to this hub

Figure 19.15 The connectors on a typical 5-port workgroup hub with an uplink port (at left) for connecting this hub to another hub (“stacking” the hubs). Either port #5 or the uplink port can be used, not both.

Hub Placement

Although large networks will have a wiring closet near the server, the workgroup-sized LANs you'll be building don't need a wiring closet. But the location of the hub is important.

Ethernet hubs require electrical power, whether they are small units that use a power "brick" or larger units that have an internal power supply and a standard three-prong AC cord.

In addition to electrical power, consider placing the hub where its signal lights will be easy to view for diagnostic purposes, and where its RJ-45 connectors can be reached easily when it's time to add another user or two.

Except for the 328' (100 meter) limit for 100BaseTX Fast Ethernet, distances between each computer on the network and the hub aren't critical, so put the hub wherever you can supply power and gain easy access. In my office, the hub sits on the tower case of my PC, allowing me to see network problems just by looking down at the hub. The corner of an out-of-the-way desk can also work for small hubs.

Tip

Decide where you plan to put your hub before you buy prebuilt UTP wiring or make your own; if you move the hub, some of your wiring will no longer be the correct length. Although excess lengths of UTP cable can be coiled and secured with cable ties, cables that are too short should be replaced. You can buy RJ-45 connectors, but you need to make sure they are Category 5 if you are running Fast Ethernet. You're really better off to replace the too-short cable with the correct length.

Network Cable Installations

If you have to run cables (of any type) through existing walls and ceilings, the cable installation can be the most-expensive part of setting up a LAN. At every branching point, special fittings connect the intersecting wires. Sometimes, you also need various additional components along the way, such as hubs, repeaters, or MSAUs.

Note

A few companies, such as Motorola, market LAN technologies that do not require cables at all. Wireless LAN uses infrared, lasers, or radio waves to carry network signals from computer to computer. These technologies are uniquely suited to certain specialized environments but have not yet achieved the speed, reliability, and distance needed for general use.

With the development of easy-to-build (or prebuilt) Category 5 twisted-pair cabling, high-speed and low-cost NICs and hubs, and built-in basic networking in current versions of Windows, it's far easier to install and set up a network today than ever before. For small cubicle/office networking in which no wire must be routed through walls and in which Windows 9x peer networking software will be used, you should be able to set up the network yourself if you're comfortable with the technical information in this book.

If your wiring must go through walls, be run through dropped ceilings, be piggybacked on air ducts, or be run between floors, you might want to have the cable installed professionally by network-cable specialists. A good company will know the following:

- When UTP (unshielded twisted pair) cabling is adequate
- Where STP (shielded twisted pair) cabling might be necessary to avoid excessive cable runs to avoid interference
- How to route cable between rooms, floors, and nonadjacent offices
- How to use wall panels to make cable attachments look better and more professional
- When you must use fireproof Plenum cable
- How to deal with sources of electrical interference such as elevator motors, transmitters, alarm systems, and even florescent office lighting by using fiber-optic or shielded cable

Building Your Own Twisted-Pair Cables

You should build your own Twisted Pair cables if you

- Plan to perform a lot of networking
- Need longer cable lengths than the 25-foot maximum cable length you can buy preassembled at typical computer departments
- Want to create both standard and crossover cables
- Want to choose your own cable color
- Want maximum control over cable length
- Want to save money

Selecting the Proper Cable

A network is only as fast as its slowest component; to achieve the maximum speeds of the network, all its components, including cables, must meet the standards. There are two standard types of twisted pair cabling:

- *Category 3 Cable.* The original type of UTP cable used for Ethernet networks was also the same as that used for business telephone wiring. This is known as Category 3, or voice-grade UTP cable, measured according to a scale that quantifies the cable's data-transmission capabilities. The cable itself is 24 AWG (American Wire Gauge, a standard for measuring the diameter of a wire), copper tinned with solid conductors, 100–105 ohm characteristic impedance, and a minimum of two twists per foot. Category 3 cable is adequate for networks running at up to 16Mbps. This cable usually looks like “silver” telephone cable, but with the larger RJ-45 connector.
- *Category 5 Cable.* Newer, faster network types require greater performance levels, however. Fast Ethernet (100BaseTX) uses the same two wire pairs as 10BaseT, but Fast Ethernet needs a greater resistance to signal crosstalk and attenuation. Therefore, the use of Category 5 UTP cabling is essential with 100BaseTX Fast Ethernet. Although the 100BaseT4 version of Fast Ethernet can use all four wire pairs of Category 3 cable, this flavor of Fast Ethernet is not widely supported. Thus, for practical purposes, if you mix Category 3 and Category 5 cables, you should use only 10BaseT (10Mbps) Ethernet hubs; if you try to run Fast Ethernet 100BaseTX over Category 3 cable, you will have a slow and unreliable network.

You should use existing Category 3 cable for your LAN only if you are content with the 10Mbps speeds of 10BaseT and if the cable is in good condition. The silver exterior on Category 3 cabling can become brittle and deteriorate, leading to frequent network failures. If you are installing brand-new wiring for a new network, or replacing deteriorated Category 3 cable, Category 5 cabling should be used. It's widely available in either prebuilt assemblies or in bulk.

Caution

A chain is only as strong as its weakest link, and the same rule holds true for a network cable installation. If you choose to install Category 5 UTP cable, make sure that all the connectors, wall plates, and other hardware components involved are also Category 5.

If you are trying to connect prebuilt Category 5 cabling together on a Fast Ethernet network, use Category 5-grade connectors, or you'll create a substandard section that might fail in your network.

Choosing the correct type of Category 5 cable is also important. Use solid PVC cable for network cables that represent a permanent installation, but the slightly more expensive stranded cables are a better choice for a notebook computer or for temporary wiring of no more than 10-foot lengths (from a computer to a wall socket, for example), because it is more flexible and is thus able to withstand frequent movement.

If you plan to use air ducts or suspended ceilings for cable runs, you should use Plenum cable, which doesn't emit harmful fumes in a fire. It is much more expensive, but the safety issue is a worthwhile reason to use it (and it is required by some localities).

EIA/TIA 568B TP Standard

If you want to create twisted pair (TP) cables yourself, make sure your cable pairs match the color-coding of any existing cable or the color-coding of any prebuilt cabling you want to add to your new network. Because there are eight wires in TP cables, many incorrect combinations are possible. There are several standards for UTP cabling.

Tip

The key is to be consistent and use the same scheme for all your cables and to be sure that anyone else working on your network understands the scheme used in your network.

One common standard is the AT&T 258A configuration. Table 19.5 lists the wire pairing and placement within the standard RJ-45 connector.

Table 19.5 RJ-45 Connector Wire Pairing and Placement AT&T 258A Standard

Wire Pairing	Wire Connected to Pin #	Pair Used For
White/blue and blue	White/blue - #5 Blue - #4	Not used ¹
white/orange and orange	White/orange - #1 Orange - #2	Transmit

(continues)

Table 19.5 Continued

Wire Pairing	Wire Connected to Pin #	Pair Used For
white/green and green	white/green - #3 Green - #6	Receive
white/brown - brown	White/brown - #7 Brown - #8	Not used ¹

¹ This pair is not used with 10BaseT or Fast Ethernet 100BaseTX, but all four pairs are used with Fast Ethernet 100BaseT4 and with Gigabit Ethernet 1000BaseTX standards.

Another common standard is the EIA 568B standard as shown in Figure 19.16.

Note

You might also encounter the similar EIA 568A standard. It reverses the position of the orange and green pairs listed above.

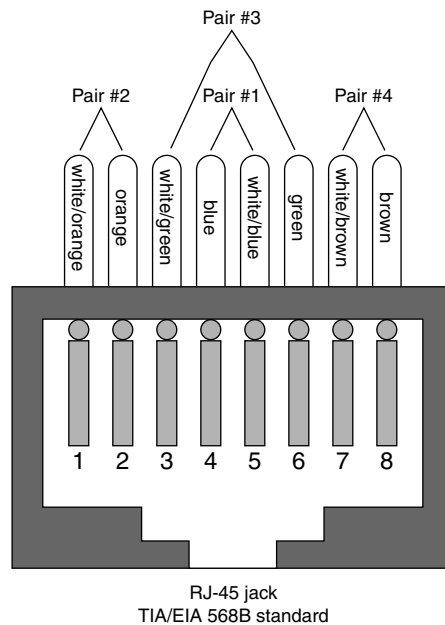

Figure 19.16 EIA 568B standard.

Crossover UTP Cables

Crossover cables are used in two situations:

- Connecting two, and only two, computers together when no hub is available
- Connecting a hub that lacks an uplink (stacking) port to another hub

The pinout for a crossover cable is shown in Table 19.6. This pinout is for one end of the cable only; the other end of the cable should correspond to the standard TIA 568B pinout as shown in Figure 19.16.

Table 19.6 RJ-45 Connector Wire Pairing and Placement for Crossover Variation on EIA 568B Standard

Wire	Pin #
White/blue	5
Blue	4
White/green	1
Green	2
White/orange	3
Orange	6
White/brown	7
Brown	8

Note

It should be noted that other wiring schemes exist, such as IEEE and USOC. All told, there are at least eight agreed-on standards for connecting UTP cables and RJ-45 connectors. The ones I list in this chapter are the most common.

Making Your Own UTP Cables

You will need the following tools and supplies to build your own Ethernet cables (see Figure 19.17):

- UTP cable (Category 5 or better)
- RJ-45 connectors
- Wire stripper
- RJ-45 crimping tool

You can buy all of the above for a single price from many different network-products vendors. If you are working with a network with a wiring closet, you will also want to add a punchdown tool to your kit.

Before you make a “real” cable of any length, follow the procedures below and practice on a short length of cable. RJ-45 connectors and bulk cable are cheap; network failures are not.

Figure 19.17 You'll need wire strippers, crimping tool, UTP cable, and RJ-45 connectors to make your own 10BaseT (100BaseT) cables.

Follow these steps for creating your own twisted-pair cables:

1. Determine how long your UTP cable should be. You'll want to allow adequate slack for moving the computer and for avoiding strong interference sources. Keep the maximum distances for UTP cables listed later in this chapter in mind.
2. Roll out the appropriate length of cable.
3. Cut the cable cleanly from the box of wire.
4. Use the wire stripper to strip the insulation jacket off the cable to expose the TP wires (see Figure 19.18); you'll need to rotate the wire about 1-1/4 turns to strip away all the jacket. If you turn it too far, you'll damage the wires inside the cable.

Caution

Don't strip the UTP wires themselves, just the jacket!

5. Check the outer jacket and inner TP wires for nicks; adjust the stripper tool and repeat steps 3 and 4 if you see damage.
6. Arrange the wires according to the EIA 568B standard listed earlier in "EIA/TIA 568B TP Standard" (see Figure 19.19).

Figure 19.18 Carefully strip the cable jacket away to expose the four wire pairs.

Figure 19.19 Arrange the wire pairs for insertion into the RJ-45 connector according to your chosen scheme (EIA for instance).

7. Trim the wire edges so the eight wires are even with one another and are slightly less than 1/2 inch past the end of the jacket. If the wires are too long, crosstalk (wire-to-wire interference) can result; if the wires are too short, they can't make a good connection with the RJ-45 plug (see Figure 19.20).

Figure 19.20 An even trim and proper stripping of the UTP cable is essential to a good RJ-45 cable.

8. With the clip side of the RJ-45 plug facing away from you, push the cable into place (see Figure 19.21). Verify that the wires are arranged according to the EIA/TIA 568B standard *before* you crimp the plug onto the wires (see Figure 19.16, earlier in this chapter). Adjust the connection as needed.
9. Use the crimping tool to squeeze the RJ-45 plug onto the cable (see Figure 19.22). The end of the cable should be tight enough to resist being removed by hand.
10. Repeat steps 4–9 for the other end of the cable. Recut the end of the cable if needed before stripping it.
11. Label each cable with the following information:
 - Wiring standard
 - Length
 - End with crossover (if any)
 - _____ (blank) for computer ID

Figure 19.21 Push the RJ-45 connector into place, ensuring the cable pairs are ordered properly.

Figure 19.22 Firmly squeeze the crimping tool to attach the connector to the cable.

Note

The cables should be labeled at both ends to make matching the cable with the correct computer easy and to facilitate troubleshooting at the hub. Check with your cable supplier for suitable labeling stock or tags you can attach to each cable.

An excellent online source for this process is
<http://www.duxcw.com/digest/Howto/network/cable/>.

Cable Distance Limitations

The people who design computer systems love to find ways to circumvent limitations. Manufacturers of Ethernet products have made it possible to build networks in star, branch, and tree designs that overcome the basic limitations already mentioned. You can have thousands of computers on a complex Ethernet network.

LANs are local because the network adapters and other hardware components typically cannot send LAN messages more than a few hundred feet. Table 19.7 lists the distance limitations of different kinds of LAN cable. In addition to the limitations shown in the table, keep the following points in mind:

- You cannot connect more than 30 computers on a single Thinnet Ethernet segment.
- You cannot connect more than 100 computers on a Thicknet Ethernet segment.
- You cannot connect more than 72 computers on a UTP Token-Ring cable.
- You cannot connect more than 260 computers on an STP Token-Ring cable.

Table 19.7 Network Distance Limitations

Network Adapter	Cable Type	Maximum	Minimum
Ethernet	Thin ¹	607 ft.	20 in.
	Thick (drop cable) ¹	164 ft.	8 ft.
	Thick (backbone) ¹	1,640 ft.	8 ft.
100BaseTX	UTP	328 ft.	8 ft.
10BaseT	UTP	994 ft.	8 ft.
Token-Ring	STP	328 ft.	8 ft.
	UTP	148 ft.	8 ft.
ARCnet ¹ (passive hub)		393 ft.	Depends on cable
ARCnet ¹ (active hub)		1,988 ft.	Depends on cable

¹ indicates obsolete for new installations; may be found in existing installations

Note that 10BaseT (Ethernet on UTP) can have a maximum cable length three times longer than 100BaseTX. If you plan to change a 10BaseT-wired Ethernet network to Fast Ethernet 100BaseTX, you should check the wiring distances in use. If you have a station wired with Category 5 cable that is over 328 ft (100 meters) from a hub, you'll need to use a repeater if you want it to use Fast Ethernet, as well as replace all the NICs and hubs with Fast Ethernet-compatible hardware.

Even if you are putting in a 10BaseT-only network today, use Category 5 cables and keep each client PC within 328 ft of the hub if you want to upgrade to 100BaseTX Fast Ethernet in the future.

Wireless Ethernet

Various forms of wireless networks using either radio or IR (infrared) have been developed over the years, but until recently, the benefits of a wireless network (no wires to pull or holes to drill) were outweighed by the lack of standards and relatively slow speed. In conventional Ethernet

networks, you can use different brands of NICs, hubs, and switches without any problems, as long as each device corresponds to the same Ethernet standard.

The IEEE 802.11b Wireless Ethernet Standard

A new IEEE standard called 802.11b has been introduced that is supported by a trade group called the Wireless Ethernet Compatibility Alliance (WECA). IEEE 802.11b-compliant wireless networks run at a maximum speed of 11Mbps, about the same as 10BaseT Ethernet (the original version of IEEE 802.11 supported data rates up to 2Mbps only). IEEE 802.11b networks can be used to connect with conventional Ethernet networks or can be run as independent networks, like other wireless networks. The major advantage of IEEE 802.11b networks is their interoperability; just as you can mix and match conventional Ethernet hardware, you can mix and match IEEE 802.11b-compliant hardware on the same network.

Wireless Ethernet Technologies

Wireless networks running IEEE 802.11b hardware use the same 2.4GHz spectrum that is used by many portable phones, wireless speakers, and security devices. Although the increasing use of these non-computer products is a potential source of interference, the short range of wireless networks (only up to 300 feet) minimizes the practical risks, at least for the present.

IEEE 802.11b networks use two different types of devices to connect via the 2.4GHz band:

- *Access Points.* An access point is a bookend-sized device that uses an RJ-45 port to attach to a 10BaseT Ethernet network (if desired) and contains a radio transceiver, encryption, and communications software. It translates conventional Ethernet signals into wireless Ethernet signals it broadcasts to wireless NICs on the network, and performs the same role in reverse to transfer signals from wireless NICs to the conventional Ethernet network.

For coverage of a large area, purchase two or more access points and connect them to an Ethernet switch or hub. This will allow users to “roam” inside of a building without losing contact with the network.

- *NICs equipped with radio transceivers.* NICs equipped for wireless Ethernet communications have a fixed or detachable radio antenna in place of the usual coaxial or RJ-45 port or dongle. Because a major market for wireless Ethernet use is notebook computer users, some vendors sell only PC Cards in their wireless Ethernet product lines, but PCI cards for desktop computers are supported by most vendors. A few vendors even sell cards for the venerable ISA bus. Since you can mix and match products, you can incorporate any mix of desktop and notebook computers into your wireless network.

Client systems “lock on” to the strongest signal from access points and automatically “roam” (switch) to another access point when the signal strength is stronger and the error level is lower than the current connection.

Security and Other Features

Because wireless networks could, in theory, be accessed by anyone with a compatible NIC, most models of NICs and access points provide for encryption options. Some devices with this feature allow you to set a security code known as an ESSID on the wireless devices on your network. This seven-digit code prevents unauthorized users from “sneaking” onto your network and acts as an additional layer of security along with your normal network authentication methods such as user

passwords. Others use a list of authorized MAC numbers (each NIC has a unique MAC) to limit access to authorized devices only. Most products support only 40-bit data encryption at this time, but you can expect to see widespread support for 128-bit encryption before the end of 2000. You should match the encryption level used on both the access points and the NICs for best security.

Some products' access points can be managed via a Web browser and provide diagnostic and monitoring tools to help you optimize the positioning of access points.

Many products feature support for DHCP (Dynamic Host Configuration Protocol), allowing a user to move from one subnet to another without difficulties.

Figure 19.23 illustrates a typical IEEE 802.11b wireless network.

Figure 19.23 A typical wireless network with multiple access points. As users with wireless NICs move from one office to another, the "roaming" feature of the NIC automatically switches from one access point to another, permitting seamless network connectivity without wires or logging off the network and reconnecting.

Users per Access Point

Although performance of an access point reaches its optimal level at about four users, according to tests performed by *PC Magazine* in Spring 2000, IEEE 802.11b wireless networks can handle many more users, varying by brand and model: 3Com's AirConnect product is designed to handle as many as 63 simultaneous connections per access point, for example. Cisco's Aironet 340

series offers a low-cost access point that supports only 10 users, and more expensive models that support up to 2,048 users.

Cost per User

Although workgroup “network in a box” solutions can connect two PCs for around \$100 (\$50 per user), and additional network cards are available for under \$25, wireless Ethernet networking is far more expensive because of the high cost of access points and wireless NICs. 3Com’s AirConnect “starter kit,” which provides three wireless PC Card NICs and a single access point, has a retail price of \$1795, for an initial cost per user of about \$600, for example. Additional NICs from 3Com or other companies range in price from \$200 to \$349 each. Access points sell separately for about \$900 to \$1200 each. Thus, the ability to roam with a notebook and to avoid wiring problems must be very critical to make up for the much higher cost of wireless Ethernet networking when compared to basic (and obsolescent) 10BaseT Ethernet networks.

Since IEEE 802.11b is a true standard, you can mix and match access point and wireless NIC hardware to meet your desired price, performance, and feature requirements for your wireless network, just as you can for conventional Ethernet networks.

Alternatives to the IEEE 802.11b Standard

The RadioLAN Wireless MobilLINK uses the same access point plus wireless NIC design used by the IEEE 802.11b networks discussed earlier. RadioLAN uses the 5.8GHz radio frequency, providing faster speed than IEEE 802.11b-based networks, but preventing interconnection with them (since they use the 2.4GHz radio band). However, RadioLAN products can be interconnected with conventional 10BaseT LANs through the use of its BackboneLINK bridge, and RadioLAN also offers wireless bridges between 10BaseT Ethernet networks up to one mile apart.

Other solutions can be regarded as industry standards, because they are supported by multiple companies. These include

- *Bluetooth*. This low-speed (up to 400Kbps), low-power standard is designed to interconnect notebook computers, PDAs, cell phones, and pagers for data synchronization and user authentication in public areas such as airports, hotels, rental car pickups, and sporting events.

Bluetooth-compliant devices should become available in the second half of 2000, but their frequencies and transmission methods may interfere with IEEE 802.11b wireless networks in the same area.

- *HomeRF*. The HomeRF Consortium, headed by Proxim, is developing wireless products designed for home networking, using the SWAP (Shared Wireless Access Protocol).

Current products run at a leisurely 1.6Mbps, but the HomeRF standard is designed to support speeds up to 10Mbps. HomeRF products can be interconnected with conventional Ethernet networks through the use of a cordless Ethernet bridge.

Proxim’s line of HomeRF products, called Symphony, includes a Cordless Ethernet bridge product to allow Symphony wireless clients to connect with the Ethernet. Although the 1.6Mbps performance of Symphony is far lower than that of IEEE 802.11b-based products, the cost for one or two users is much smaller, since HomeRF-based products connect directly with each other. Wireless NICs for PCI, ISA, and PC Card slots are under \$150 each,

and the cordless Ethernet bridge retails for under \$400. Both Bluetooth and HomeRF products use the same 2.4GHz frequency used by IEEE 802.11b wireless products, which may cause interference between devices. Industry discussions are under way to resolve this potential problem.

Wireless Network Logical Topologies

Wireless networks use two logical topologies:

- *Star.* The star topology, used by IEEE 802.11b-based products and Radiolan, resembles the topology used by 10BaseT and faster versions of Ethernet that use a hub. The access point takes the place of the hub because stations connect via the access point, rather than directly with each other. This method is much more expensive per unit, but permits performance near 10BaseT Ethernet speeds and easier management.
- *Point-to-Point.* The point-to-point topology is used by HomeRF products and will be used by the forthcoming Bluetooth-enabled products. These devices connect directly with each other, and require no access point or other hub-like device to communicate with each other. This method is much less expensive per unit, but is suited to very small, simple networks only, and is currently much slower than 10BaseT networks.

Comparing Wireless Standards

Table 19.8 compares the major wireless network standards in current use.

Table 19.8 Comparison of Current Wireless Networks

Network	Rated Speed	Logical Topology	Connects with 10BaseT Ethernet via	Maximum Number of PCs per access point	Average Cost per user ⁵
IEEE 802.11b	11Mbps	Logical Star (requires access point)	Access point	Varies by brand and model; up to 2048	\$525 ^{1,2}
Radiolan	10Mbps ³	Logical Star (requires access point)	Wireless BackboneLINK (access point)	128	\$600 ²
HomeRF ⁴	1.6Mbps	Point-to-Point	Symphony Cordless Ethernet Bridge	10	\$139

¹ Average price of products from Cisco, Lucent, and 3Com as of 1Q2000

² Price includes access point (required)

³ Actual throughput of Radiolan compared to average of IEEE 802.11b products is about 25 percent faster due to higher radio frequency used

⁴ Figures for Proxim Symphony, first HomeRF product available

⁵ Average cost per user based on a 4-station network with two PCI desktop and two notebook PCs and one access point if needed

Network Protocols

The second-most important choice you must make when you create your network is which network protocol you will use. The network protocol, another part of the OSI Reference mode, affects which types of computers your network can connect with.

The three major network protocols are TCP/IP, IPX/SPX, and NetBEUI. Unlike data-link protocols, though, network protocols are not tied to particular hardware (NIC or cable) choices. Network protocols are software and can be installed or removed to any computer on the network at any time as needed.

Table 19.9 summarizes the differences between these protocols.

Table 19.9 Overview of Network Protocols and Suites

Protocol	Included in Protocol Suite	Best Used for	Notes
IP	TCP/IP	Internet and large networks	Also used for dial-up Internet access; native protocol suite of Windows 2000 and Novell NetWare 5.x
IPX	IPX/SPX	Networks with Novell 4.x and earlier servers	Used by NetWare 5.x for certain special features only
NetBEUI	N/A	Windows 9x, 2000, or Windows for Workgroups peer networks	Can't be routed between networks; simplest network protocol; also used with Direct Cable Connection NIC-less "networking"

All the computers on any given network must use the same network protocol or protocol suite to communicate with each other.

IP and TCP/IP

IP stands for Internet Protocol; it is the network layer of the collection of protocols (or "protocol suite") developed for use on the Internet and commonly known as TCP/IP (Transmission Control Protocol/Internet Protocol).

Later, the TCP/IP protocols were adopted by the UNIX operating systems, and they have now become the most commonly used protocol suite on PC LANs. Virtually every operating system with networking capabilities supports TCP/IP, and it is well on its way to displacing all the other competing protocols. Novell NetWare 5 and Windows 2000 both use TCP/IP as their native protocol for most services.

TCP/IP—LAN and Dial-Up Networks

TCP/IP, unlike the other network protocols listed in the previous section, is also a protocol used by people who have never seen a NIC. People who access the Internet via modems (with what Windows 9x calls "Dial-Up Networking") use TCP/IP just as those whose Web access is done with their existing LAN. Although the same protocol is used in both cases, the settings vary a great deal.

Table 19.10 summarizes the differences you're likely to encounter. If you access the Internet with both modems and a LAN, you will need to make sure that the TCP/IP properties for modems and LANs are set correctly. You might also need to adjust your browser settings to indicate which connection type you are using. Table 19.10 provides general guidelines; your ISP or network administrator will give you the specific details.

Table 19.10 TCP/IP Properties by Connection Type—Overview

TCP/IP Property Tab	Setting	Modem Access (Dial-Up Adapter)	LAN Access (Network Card)
IP Address	IP Address	Automatically assigned by ISP	Specified (get value from network administrator)
WINS Configuration	Enable/Disable WINS Resolution	Disabled	Indicate server or enable DHCP to allow NetBIOS over TCP/IP
Gateway	Add Gateway/List of Gateways	None (PPP is used to connect modem to Internet)	IP Address of Gateway used to connect LAN to Internet
DNS Configuration	Enable/Disable Host Domain	Usually disabled, unless Proxy server used by ISP	Enabled, with Host and Domain specified (get value from network administrator)

As you can see from the preceding table, correct settings for LAN access to the Internet and Dial-up Networking (modem) settings are almost always completely different. In general, the best way to get your Dial-up Networking connection working correctly is to use your ISP's automatic setup software. This is usually supplied as part of your ISP's signup software kit. After the setup is working, view the properties and record them for future troubleshooting use.

Note

In Windows 98 and Millennium Edition, Microsoft suggests that TCP/IP properties be viewed through the DialUp Networking icon for the connection, rather than through the Network icon in the control panel.

IPX

The IPX protocol suite (often referred to as IPX/SPX) is the collective term for the proprietary protocols created by Novell for their NetWare operating system. Although based loosely on some of the TCP/IP protocols, the IPX protocol standards are privately held by Novell. However, this has not prevented Microsoft from creating its own IPX-compatible protocol for the Windows operating systems.

IPX (Internetwork Packet Exchange) itself is a connectionless, unreliable, network layer protocol that is equivalent in function to IP. The suite's equivalent to TCP is the Sequenced Packet Exchange (SPX) protocol, which provides connection-oriented, reliable service at the transport layer.

The IPX protocols are typically used today only on networks with NetWare servers and are often installed along with another protocol suite such as TCP/IP. Even NetWare, however, is phasing out its use of IPX and making the move over to TCP/IP, along with the rest of the networking

industry. NetWare 5 uses IPX/SPX only for specialized operations. Most of the product uses TCP/IP.

NetBEUI

NetBEUI (NetBIOS Extended User Interface) is a protocol used primarily on small Windows NT networks, as well as on peer networks based on Windows for Workgroups and Windows 9x. It was the default protocol in Windows NT 3.1, the first version of that operating system. Later versions, however, use the TCP/IP protocols as their default.

NetBEUI is a simple protocol that lacks many of the features which enable protocol suites such as TCP/IP to support networks of almost any size. NetBEUI is not routable, so it cannot be used on large internetworks. It is suitable for small peer-to-peer networks, but any serious Windows NT network installation should use TCP/IP.

NetBEUI is still useful for creating “instant networks” with the Direct Cable Connection (see below), and it is the minimum protocol required for use in a Windows 9x peer-to-peer network.

Choosing What You Need

In this section, you’ll receive a detailed checklist of the hardware and software you need to build your network.

First, start with the number of computers you plan to network together. You need the items discussed in the following section to set up your network.

NIC

You’ll need a NIC for every computer on the network. To simplify technical support, buy the same model of NIC for each computer in your network. If you are creating a Windows NT/2000 or Novell NetWare network with a dedicated server, you will want to buy server-optimized NICs for the server, and less-expensive client NICs for the client PCs. However, you should still purchase the same brand to simplify support issues. Some vendors use the same driver for both their server and client NICs, further simplifying your support issue.

You should record the brand name and model number of the NIC(s) you are using, as well as the driver version or source. Use Table 19.11 as a template for creating your own record.

Table 19.11 NIC Location and Information Worksheet

NIC Location & Computer ID	Brand Name	Model #	Cable Type(s)	Speed	Driver Source or Version
_____	_____	_____	_____	_____	_____
_____	_____	_____	_____	_____	_____
_____	_____	_____	_____	_____	_____
_____	_____	_____	_____	_____	_____

UTP Cable

One cable long enough to reach comfortably between the computer's NIC and the hub for each computer. Use Table 19.12 as a guide for recording necessary information regarding your cabling.

Table 19.12 UTP Cable Worksheet

Computer ID	Cable Length	Wiring Standard
_____	_____	_____
_____	_____	_____
_____	_____	_____
_____	_____	_____

Hub

Buy a hub of the correct speed with at least enough RJ-45 ports for each computer on the network. Use the worksheet shown in Table 19.13 as a guide for recording information about your hub or hubs.

Table 19.13 Hub Worksheet

Hub #	Brand	Model#	# of Ports	Uplink?	Speed(s)
_____	_____	_____	_____	_____	_____
_____	_____	_____	_____	_____	_____
_____	_____	_____	_____	_____	_____
_____	_____	_____	_____	_____	_____

Other Home Networking Solutions

If you are working at home or in a small office, you have an alternative to hole-drilling, pulling specialized network cabling, and learning how to configure TCP/IP, IPX, or NetBEUI protocols.

So-called "home" networking is designed to minimize the complexities of cabling and protocol configuration by providing users with a sort of "instant" network that requires no additional wiring and configures with little technical understanding.

HomePNA

Other than using Ethernet, the most-popular form of home networking involves adapting existing telephone wiring to networking by running network signals at frequencies above those used by the telephone system. Other, less-popular forms of home networking piggy-back on household or office electrical wiring or are wireless, taking advantage of previously unused parts of the electromagnetic spectrum.

Because it is the most-developed and most broadly supported type of home networking, this discussion focuses on the HomePNA standards created by the Home Phoneline Networking Alliance (<http://www.homepna.org>), which has most major computer hardware and telecommunications vendors among its founding and active membership.

A companion Web site focusing on products that use HomePNA standards is <http://www.homepna.com>.

The Home Phoneline Networking Alliance has developed two versions of its HomePNA standard. Both versions are designed to work over existing telephone lines, but they have big differences in speed and hardware usage.

HomePNA 1.0

The original HomePNA standard, introduced in 1998, was designed to make home networking as “no-brainer” as possible. HomePNA 1.0 has a speed of just 1Mbps, which is just 1/10 the speed of 10BaseT or other forms of standard Ethernet.

HomePNA 1.0-compatible products are available from various vendors, but can be used in combination with each other. Interface types include parallel ports, USB ports, and PCI cards for use with desktop computers, and PC Card (PCMCIA) devices for use with notebook computers.

HomePNA 1.0's primary objective is ease of use, rather than performance, and although some HomePNA 1.0-compatible products were shipped along with Internet line-sharing (proxy server) software, the connection speed made file transfers a better use for this family of products.

HomePNA 2.0

HomePNA 2.0-compatible products began to appear in late 1999. HomePNA 2.0 runs up to 10Mbps, making it comparable to standard Ethernet speeds, and is primarily implemented through 32-bit PCI network cards for desktop computers and PC Card devices for use with notebook computers.

HomePNA 2.0-compatible products are fast enough to make Internet connection sharing a workable reality and are backward-compatible with HomePNA 1.0 products.

Other Solutions

Although many studies suggest that home networking via power lines will be even better than telephone-line networking, there is no widely adopted standard for power-line networking. The leader in this field is Intelogis, whose Passport is a parallel port-based solution. This product features performance about 1/3 the speed of HomePNA 1.0-based networks, but does offer security features to prevent your neighbors from “plugging in” to your network.

Several products on the market are wireless, but as with power-line networking, there is no industry standard. The performance of products such as Proxim Symphony Cordless and WebGear Aviator Pro is faster than that of power-line networking, but slower than even HomePNA 1.0-compatible products.

Given the lack of standards for wireless and power-line networks, their slow performance, and the high cost of wireless networks, I don't recommend these types of products.

Home Networking Compared to Ethernet UTP Solutions

The pricing of home networks is comparable to Ethernet UTP solutions, but which one is best for you? Use Table 19.14 to help you determine which way to go in networking your small office or home office. Networks are listed in order of speed, from slowest to fastest.

Table 19.14 Comparing Home Networking to Ethernet UTP Networking—Hardware

Network Type	Cable Type	Parallel Port or USB?	PCI Card?	ISA Card?	Notebook?	Speed
HomePNA 1.0	Phone	Both	Yes	Yes	Yes	1Mbps
Ethernet 10BaseT	UTP	USB only	Yes	Yes	Yes	10Mbps
HomePNA 2.0	Phone	No	Yes	No	Yes	10Mbps
Fast Ethernet 100BaseTX	UTP	No	Yes	No	Yes	100Mbps

In addition to the speed and cable types, consider the issue of interconnecting a HomePNA network to a standard Ethernet network. You'll need a special PC Card or a HomePNA/Ethernet hub to interconnect the two networks, and many products of this type support only HomePNA 1.0 1Mbps speeds. You can't simply install HomePNA networking software onto a system that already has standard networking software installed; they aren't designed to coexist.

I recommend HomePNA 2.0-compatible networking only for use in a home-office environment where technical expertise is scanty and installing UTP wiring is out of the question. With the current rock-bottom pricing of Fast Ethernet 100BaseTX NICs and hubs, Fast Ethernet is very close to the pricing of HomePNA 2.0 products, and offers 10 times the speed and compatibility with a broad range of network protocols.

Putting Your Network Together

You've bought or built your cables, bought your NICs and your hub, and located your Windows 9x, NT, or Windows 2000 CD-ROM. Now it's time to make your network a reality!

Installing a NIC

First, you'll need to install your NICs into each computer. Install the NIC just like you would any other PCI or ISA device as explained below:

1. Open the case and locate an open expansion slot that matches the type of NIC you purchased (preferably PCI).
2. Using a screwdriver, remove the screw securing the slot cover at the rear of the case.
3. Insert the card gently, ensuring that edge connector is seated solidly in the slot.
4. Fasten down the card with the same screw that held the slot cover.

Tip

If you are a realist like me, you might not want to close the case until you are certain the NIC is working (see "Testing Your Connections" later in the chapter).

A NIC uses the same hardware configuration settings used by most other expansion cards:

- An IRQ
- An I/O port address range

If you are using Windows 9x, Millennium, or 2000 with a PnP (Plug and Play) BIOS, the computer and Windows will configure your card for you in most cases. In a few cases, you may need to adjust PnP settings in the BIOS, and in a rare case you might even need to remove your other PnP cards and put the NIC in first if your system doesn't recognize it after you restart the system.

Even if you are installing a standard Ethernet 10BaseT system, use PCI NICs whenever possible (you'll need to use PCI NICs for faster versions of Ethernet on desktop computers). As you saw earlier, PCI is faster than ISA by a wide margin.

If you install the card in a non-PnP system or under Windows NT, make sure the card comes with configuration software or manual switch settings for hardware configuration. A pure PnP card can't be installed on a system that lacks PnP support.

Testing Your Connections

The configuration software diskette or CD-ROM usually features diagnostic software. Some diagnostics should be performed before the card is connected to the network, and should be run from an MS-DOS prompt.

After the NIC passes these tests, connect the network cable from the card to the hub, turn on the computer and the hub and watch for signal lights to light up on the NIC's back bracket (if so equipped) and on the hub. Many hubs use green LEDs to indicate the presence of a computer on a particular RJ-45 port. Connect a second computer with NIC installed to the hub. Then, run the diagnostics program on both computers to send and receive data.

Installing Networking Software

To access network resources with a PC, whether it is connected to a client/server or a peer-to-peer network, you must install network client software on the computer. The network client can be part of the operating system or a separate product, but it is this software that enables the system to use the network interface adapter to communicate with other machines.

On a properly configured network workstation, accessing network resources is no different from accessing local ones (except that they might be slightly slower). You can open a file on a network drive just as you would open the same file on your local hard disk. This is because the network client software is completely integrated into every level of the computer's operating system.

In most cases, the network client software is part of the operating system. Windows 9x, NT, and 2000, for example, include all the software you need to participate in a peer-to-peer Windows network or to connect to Windows NT, Windows 2000, and Novell NetWare servers. To connect to a network using DOS or Windows 3.1, however, you must install a separate client software package.

Configuring Your Network Software

You might have few problems installing your NICs. They might pass their diagnostics flawlessly. But until each station on your network can speak the same language, has correct client or server software setups, and uses the same protocols, your network will not function properly.

Table 19.15 shows the minimum network software configuration you must install for a Windows 9x, Windows NT, and Windows 2000 peer-to-peer networking:

Table 19.15 Minimum Network Software for Peer-to-Peer Networking

Item	Workstation	Server
Windows Network client	Yes	No
NetBEUI protocol	Yes	Yes
File and Print Sharing for Microsoft Networks	No	Yes
NIC installed and bound to protocols and services above	Yes	Yes
Workgroup identification (same for all PCs in workgroup)	Yes	Yes
Computer name (each PC needs a unique name)	Yes	Yes

Depending on how you plan to use the computer, one or both of the following will need to be done:

- If the computer is going to access a Novell NetWare client/server network, the IPX/SPX protocol must also be installed.
- If the computer is going to be used to access the Internet or any other TCP/IP-based network, the TCP/IP protocol must also be installed.

Use the Network icon in the Windows Control Panel to choose your network settings. You'll need the following software to set up the network:

- Operating system CDs, diskettes, or hard-disk image files
- NIC drivers

(Workgroup hubs require no software.)

You'll be prompted to insert a CD or disk or browse to the appropriate files during the installation procedure, if they're not available on the Windows 9x CD-ROM or on your hard disk in the default location.

After you complete the installation of the preceding list of items, click OK in the Networks protocol. You'll need to reboot your PC to complete the process. After this is completed, you'll be ready to share resources.

Configuring Users, Groups, and Resources

Depending on the network operating system software you choose, you can control access in a variety of different ways.

Peer-to-Peer Access Control

Peer-to-peer Windows 9x-style networking (which can also be used by Windows for Workgroups, Windows NT, and Windows 2000 Professional) provides access control on a resource-by-resource basis, if desired, through the use of passwords. Passwords are optional.

Caution

If no password is used, anyone who accesses the network has full control over the shared resource.

Windows 2000 Professional will allow you to manage connections by user if you desire.

Client/Server Access Control

Client/server-based networks such as Windows NT, Windows 2000 Server, and Novell NetWare control resources on a user-permission or group-permission basis.

Caution

If the user is not listed as a permitted user or is not part of a permitted group, the user *cannot* access the shared resource.

Comparing Peer-to-Peer and Client/Server Access Control

The following example demonstrates the differences in these approaches:

- Users 1, 2, 3, and 4 need to access a CD-ROM drive, two network hard drives, a laser printer, and an inkjet printer.
- Users 1 and 4 need read/write/create access to the \Msoffice folder on hard disk #1 and access to the laser printer. User 4 also needs read-only access to the \Photoshop folder on hard disk #2 and access to the inkjet printer.
- User 3 needs read-only access to the \Msoffice folder on hard disk #1, read/write/create access to the \Photoshop folder on hard disk #2, and access to the inkjet printer.
- User 2 needs access to the laser printer only.

To limit usage, passwords *must* be used; otherwise all users on the network can access any resource.

With a peer-to-peer network, the security settings that would be required to secure the resources are shown in Table 19.16.

Table 19.16 Peer-to-Peer Security Settings

Resource	Passwords	Reason for Second Password
CD-ROM	one	
\Msoffice	two	1 password for full access 1 password for read-only access
\Photoshop	two	1 password for full access 1 password for read-only access
Laser printer	one	
Inkjet printer	one	

This means that there are a total of seven passwords on the system. The number of passwords needed by each user would be as follows:

- *User 1.* Two passwords needed
- *User 2.* One password needed
- *User 3.* Three passwords needed
- *User 4.* Four passwords needed

This simple example demonstrates the not-so-simple problem of trying to control network resources. The Windows 9x-type peer-to-peer network has no way to create user lists or group permissions and therefore must assign a password to every resource. Even if all the users can remember their passwords (or store them in a password list), the challenge isn't over. Suppose the passwords are revealed to others who shouldn't have access. The authorized users will need to memorize up to four additional (new) passwords after the passwords are changed, assuming that the unauthorized users don't take over the system first.

In addition to the limitations of what Microsoft calls share-level access control, another flaw in the peer-to-peer network scheme is that nobody is really in charge of the network. There is no administrator or "superuser" who can set up and change passwords for all resources. Instead, the user of the computer with the shared resource can add, change, or delete shared resource settings unless user profiles are set up on each machine that eliminate access to the Windows Explorer and Printers folder for the normal user(s) of that computer.

With a client/server network, a single password is assigned to each user by a network administrator, and users can be divided into groups based on similar access needs. Using the previous example, this scenario would create security settings that look like the ones in Tables 19.17 and 19.18.

Table 19.17 Client/Server Network Sample Groups

User	Groups Belonged To
User 1	OfficeCreate, Laserprinter
User 2	Laserprinter
User 3	OfficeRead, PhotoCreate, Inkjet
User 4	OfficeCreate, Laserprinter, PhotoRead, Inkjet

Table 19.18 Client/Server Network Sample Security

Group	Rights	Members
Laserprinter	Use	User 2, User 1, User 4
Inkjet	Use	User 4, User 3
OfficeCreate	Read, write, create	User 1, User 4
OfficeRead	Read	User 3
PhotoCreate	Read, write, create	User 3
PhotoRead	Read	User 4
Administrator	Full network control	

Although the client/server network looks more complex at first glance, it's actually an easier and more-secure network to control. It's easier to control because each user has a single password, regardless of the number of resources he or she will access. It's easier to administer because rights can be changed for an entire group or for any member(s) of a group. It's more secure because a full-time Network Administrator is able to set up and control all user and group rights to access all network devices. It's also more secure because access rights can be controlled more precisely than with a peer-to-peer network's full access, read-only access, or no access options. Because users can have read/write/create but not delete access to a specified resource, a program can be used without the possibility of its being deleted by the user.

This discussion is not designed to minimize the benefits of peer-to-peer networking. Fast, easy to set up, and flexible, peer-to-peer networking should be used in situations in which low cost is an important factor and security is a relatively unimportant concern. If security and performance are important, use a client/server network instead.

Note

To learn more about client/server networking, see *Upgrading and Repairing Networks, Second Edition*, published by Que.

Tips and Tricks

Use this section to help you find faster, easier, better ways to set up and use your network.

Installation

- If you are setting up several systems with identical hardware, NICs, and software, consider making an image file of the first system after you complete its installation with a program such as Drive Image Professional, and then connecting the other computers and “cloning” the first computer's hard disk to each additional system. Check with the imaging software vendor for details.
- Don't click OK in the Windows Networks properties sheet until you have made all the changes you want to make (see list above). Whenever you click OK, you are prompted to reboot the system to apply the changes.
- If you're “salvaging” old 10BaseT Ethernet cards for a network, use Category 5 UTP and dual-speed hubs to make switching to Fast Ethernet in the future easier.

Sharing Resources

- If you want to have network drives or folders show up as part of “My Computer” so you can search them and see them easily in Windows Explorer, map a drive letter to each one.
- To make it easier to keep drive mappings straight, I use the drive letter I plan to use for mapping on other workstations as the name of the shared resource on my peer server. In other words, if I want to map the D: drive on my peer server as “P:”, I'll name it “P” when I set its sharing properties. Then, as I view the folder from another computer, I'll know from its name that I should map it as “P:”. This enables multiple PCs to easily map the same resource as the same drive letter on different systems, which makes it easier if people in your office play “musical computers.”

Setting Up Security

- If you're building a peer-to-peer network, keep in mind that passwords are the only way to keep unwanted users out of your system.

Sharing Internet Connections

- If you are planning to share an Internet connection, *don't* set up file and printer sharing on the computer which does the sharing (the "proxy server"). See Chapter 18, "Internet Connectivity," for software you can add to your computer to keep your computer safe on the Internet.

Direct Cable Connections

When you have a large amount of data that you want to transfer from one computer to another in the same room, you have several possible solutions. You can copy the data to floppy disks, but for any more than a few megabytes, this is inconvenient. Zip drives and other removable disk technologies hold more data, but you must either have the same type of drive on both systems or move the drive from one system to another and install the appropriate software drivers. A network connection would be the fastest solution but is not worth setting up for occasional or one-time use. Finally, you could use modems to dial up one computer from the other and transfer files. This method also works, but it requires two modems and two telephone lines. As an alternative, you can establish a "modem" connection between the two computers without using modems! Using a special type of cable called a null modem (or laplink) cable, you can connect the serial or parallel ports on two computers, forming a simple two-node network, and transfer files between them. This is particularly useful when you have both a desktop and a laptop system on which you want to use the same data.

Null Modem Cables

A null modem cable is a special cable that has its circuits crossed so the transmit data (TD) pin on each serial port connector leads to the receive data (RD) pin on the other. A cable that connects the systems' parallel ports in this way is called a parallel data-transfer cable. Cables such as these are usually available at any computer store that sells cables. They are sometimes called laplink cables, after one of the first software products to introduce the concept of the direct cable connection. FastLynx and other parallel-connection cables supplied for MS-DOS and Windows 3.x will also work. A good rule of thumb is this: If the cable works for laplink or the MS-DOS INTERLNK file transfer utility, you can use it for Direct Cable Connection as well.

You can also build your own null modem or parallel data-transfer cable using the wiring tables that follow. Table 19.19 shows the pins that you must connect for a serial cable, using either DB-9 (9-pin) or DB-25 (25-pin) connectors. Table 19.20 shows the connections for a parallel port cable. The parallel cable is slightly harder to build, but it is recommended because of its much higher transfer speed and because it will not interfere with existing modems and mouse drivers on the computers.

Table 19.19 3-Wire Serial Null Modem Cable Pinouts

PC#1	DB-9	DB-25	DB-25	DB-9	PC#2

25	←————→ 25

Direct Connect Software

After you have the hardware in place, you need the proper software for the two systems to communicate. At one time, you had to purchase a third-party product (such as laplink) to do this, but the capability is now part of most operating systems, including DOS 6, Windows 9x, and Windows NT.

In DOS, the software consists of two executable files, called INTERSVR.EXE and INTERLNK.EXE. On Windows 9x and Windows NT, the feature is called Direct Cable Connection; Windows 2000 refers to this as direct parallel or direct serial connection. The software functions in basically the same way in any case. One computer is designated the host, and the other is the guest. The software enables a user, working at the guest machine, to transfer files to and from the host.

In the DOS version, you run the INTERSVR program on the host computer. This system can be running a different version of DOS; you simply have to copy the INTERSVR.EXE program to it from a DOS 6 machine (using a floppy disk). On Windows 9x, you click the Start menu and then select Programs, Accessories, Direct Cable Connection (on some systems it might be stored in a Communications folder beneath the Accessories folder). Then choose the Host option button. In both cases, you are prompted to select the COM or LPT port to which you have connected the cable.

On the other computer, you run the INTERLNK.EXE program in DOS or select the same Direct Cable Connection menu item in Windows 9x and choose the Guest option button. Again, you are prompted to choose the correct port, after which the software establishes a connection between the two machines. After this is done, the guest computer mounts the drives from the host in its own file system, assigning them the next available drive letters with Interlink. With the Windows 9x Direct Cable Connection, you can either access the shared drive as a folder or map a drive letter to it with Windows Explorer.

Windows 2000 uses a single wizard for all types of networking, including direct connection. However, it uses the same Host and Guest terminology as used by other forms of Windows, as well as the same types of cables.

At this point, you can use the drive letters or folders representing the host system just as though they were local resources. You can copy files back and forth using any standard file-management tool, such as the DOS COPY command or Windows Explorer. The only difference is that file transfers will, of course, be slower than local hard drive operations.

Wireless Direct Cable Connection

With Windows 98, you can skip the cable if you're content with the slow-as-molasses serial port speeds *and* if both host and guest computers have an Infrared connector. Just select the device during the setup routine (Microsoft's default Infrared Monitor utility maps the infrared port to a COM or LPT port). Check your Windows Explorer or Toolbar for the Infrared port to see if it's enabled and what ports it's mapped to. When it's enabled you can use it for slow (but cableless) file transfers.

Direct Cable Connection (and Interlink) Tricks

Because both DCC- and Interlink-shared folders can be mapped to drive letters (the mapping is automatic with Interlink; DCC requires that you use Windows Explorer), you can use either utility to perform these useful tricks:

- Use DCC/Interlink to perform backups of your host's drive to a backup device (tape, Zip, and so on) attached to your guest computer.
- Use DCC/Interlink to set up a shared CD-ROM drive on the host to install software to a guest computer.

Faster Direct Cable Connections

If you're planning to use Direct Cable Connections more than occasionally and would like to spend less time in file transfers, check with the creators of DCC for a faster and smarter cable. Parallel Technologies created Direct Cable Connection for Microsoft, and its DirectParallel cables (\$69.95) provide much faster transmission rates (up to 10× faster!) and also much greater flexibility. The DirectParallel cable comes with several useful utilities for determining parallel port type and monitoring transfers. Because the cable has a "guest" and a "host" end, the DirectParallel cable can be used to provide a guest computer a gateway into a larger network that the host is already connected to. See Parallel Technologies' Web site for further information.

Troubleshooting Network Software Setup

Problem

Duplicate computer IDs

Solution

Make sure that every computer on the network has a unique ID (use control panel, Network, Identification to view this information). Otherwise, you'll get an error message when you reboot the workstations with networking cables attached.

Problem

Different workgroup names

Solution

Make sure that every computer that's supposed to be working together has the same workgroup name. The Windows 9x/NT Network Neighborhood displays computers by workgroup name. Different workgroup names actually create different workgroups, and you'd need to access them by browsing via Entire Network. This wastes time.

Problem

Shared resources not available

Solution

Make sure that shared resources have been set for any servers on your network (including "peer servers" on Windows 9x). If you can't share a resource through Windows Explorer on the peer server, make sure that File and Printer Sharing has been installed.

Problem

Network doesn't work after making changes

Solution

Did you reboot? Any change in the Network icon in Windows 9x control panel requires a system reboot!

Did you log in? Any network resources can't be accessed unless you log in when prompted. You can use the Start, Shutdown, and Close All Programs and Logon as a New User to recover quickly from a failure to log on.

Troubleshooting Networks in Use

Problem

A user can't access any shared resources (but others can)

Solution

First, have user use Start, Close All Programs and Logon as a New User. Pressing Cancel or Esc instead of logging in would keep a user off the network.

Next, check cable connections at the server and workstation. Loose terminators or BNC T-connectors will cause trouble for all workstations on a Thinnet cable segment. A loose or disconnected RJ-45 cable will affect only the computer (or hub) using it.

Problem

Wrong access level

Solution

If you save your passwords in a password cache, entering the read-only password instead of the full-access password will limit your access with peer servers. Try unsharing the resource and try to reshare it, or have the user of that peer server set up new full-access and read-only passwords. Alternatively, don't use password caching by unchecking the Save Password box when you log on to a shared resource. With a client/server network with user lists and rights, check with your network administrator because she will need to change the rights for you.

Troubleshooting TCP/IP

Problem

Incorrect settings in Network Properties

Solution

Get the correct TCP/IP settings from the administrator and enter them; restart the PC.

Problem

Can't keep connection running in Dial-Up Networking

Solution

You might have the wrong version of PPP running (classic CompuServe uses CISPPP instead of normal PPP); change the server type in Properties under Dial-Up Networking, not Networks.

Problem

Message about duplicate IP addresses—can't connect to anything

Solution

Duplicate IP addresses will disable both TCP/IP and NetBEUI networking. If you're trying to share your Internet connection, use software such as Artisoft's Ishare, or check with your networking hardware vendor for recommendations. If your LAN uses a proxy server for connection, some sharing products might not work. A proxy server serves as a middle ground between your Internet client and the Internet. Any requests for data on the Internet are routed to the proxy server, which then fetches the data from the Internet. When your station receives the data, it's actually coming from the proxy server. Proxy servers are used by corporate networks along with security software to prevent outside access to the corporate network, as well as by filtered Internet services such as Integrity Online.

Troubleshooting Direct Cable Connections

Microsoft's Direct Cable Connection troubleshooter (Windows 95) and DCC Setup Wizard (Windows 95/98) both make a critical mistake in their coverage of setting up DCC: the lack of coverage of networking protocols (protocols aren't required for laplink or for the MS-DOS Interlink programs). If the same networking protocol isn't set up for both the host and guest PCs, DCC can't work.

To solve problems with DCC, use this checklist:

- Make sure the same networking protocols are installed on both the host and guest machines. The simplest protocol to install is NetBEUI, and that's what Parallel Technologies (creator of DCC) recommends for a basic DCC "mininetwork."
- Use the parallel (LPT) ports for DCC; although serial (COM) port transfers will work, they are unbearably slow.
- Make sure that both host and guest LPT ports are working correctly with no shared IRQ problems. Use the Windows 9x Device Manager to check for IRQ conflicts with the parallel port you're using.
- Make sure the person using the guest computer knows the network "name" of the host computer (set through the Networks icon in control panel, Identification). With a simple protocol such as NetBEUI, it might be necessary to enter the name to log on to the host machine.
- Install the client for Microsoft networks on the guest computer.
- Don't print to the printers on the port using DCC; it won't work! Also, allow any print jobs to finish (or delete them) on any port you want to use for DCC before you set up your cables.
- Make sure that the host computer is sharing a drive so that the guest computer can copy files from it or move files to it. The sharing is done in the same way that peer-to-peer network sharing is done.
- Make sure the Infrared ports on both computers are enabled for use in Windows 98 if you want to use this slow but cable-free method of DCC.

CHAPTER 20

Audio Hardware

When the PC was first created, it did not include audio capabilities other than rudimentary beeping or tone generation. Part of the reason for this was that the PC standard originated in 1981, and most of the other computers of that time had similar rudimentary capabilities. Another reason was that there really were no important applications for anything other than the most basic sounds. Computers used beeps for little other than to signal problems such as a full keyboard buffer or errors during the POST (power on self test) sequence.

Systems that were designed later, such as the Macintosh that debuted in 1984, did include high-quality audio capabilities as an integral part of the system hardware and software. Although there still is no universal audio hardware and software standard for PC-compatible systems, the inherent expandability of the PC platform enables users to easily add audio capability to existing systems, and at least one de facto audio standard has emerged.

Today's PC audio hardware might take one of the following forms:

- A sound chip on the motherboard from companies such as Crystal, Analog Devices, Sigmatel, ESS, or others
- An audio adapter on a PCI or ISA expansion card that you install into a bus slot into the computer.

Regardless of its location, the audio chip or adapter uses jacks for speakers, a microphone, and sometimes other devices such as joysticks and MIDI hardware. On the software side, the audio adapter requires the support of a driver that you install either directly from an application or in your computer's operating system. This chapter focuses on the audio products found in today's PCs, their uses, and how you install and operate them.

Development of PC Audio Adapters

At first, consumer audio adapters were used only for games. Several companies, including AdLiB, Roland, and Creative Labs, released products by the late 1980s. In 1989, Creative Labs introduced the Game Blaster, which provided stereo sound to a handful of computer games. The question for many buyers was "Why spend \$100 for a card that adds sound to a \$50 game?" More importantly, because no sound standards existed at the time, the sound card you selected might turn out to be useless with other games.

Note

About the same time as the release of the Game Blaster, hardware supporting the Musical Instrument Digital Interface (MIDI) became available for the PC. At this time, however, such hardware was used only in very specialized recording applications. As MIDI support became a more common feature in musical instruments, it also became a more affordable PC add-on.

The First De Facto Standard—Sound Blaster

A few months after releasing the Game Blaster, Creative Labs announced the Sound Blaster audio adapter. The Sound Blaster was compatible with the AdLiB sound card and the Creative Labs Game Blaster card. It included a built-in microphone jack and a MIDI port for connecting the PC to a synthesizer or other electronic musical instrument. Finally, the audio adapter had the potential for uses other than games.

Unfortunately, as of 1989, there was still no official standard for PC audio adapters. In many areas of the computer industry, standards often evolve informally due to the widespread acceptance of the market leader's products in a particular segment of the marketplace. These are called *de facto* standards, as contrasted with *de jure* standards, which are officially ratified by the manufacturers involved in the development process. *De facto* standards such as Hewlett-Packard's PCL (Printer Control Language), supported and emulated by most laser printer makers, have been as important to the development of computer products as official *de jure* standards.

Over the past few years, some manufacturers of audio adapters have fought for dominance over the market, and there are several popular brands. Historically, the leader in the field has been Creative Labs, whose Sound Blaster audio adapters continue to dominate the marketplace and have established the *de facto* Sound Blaster Pro standard for the industry.

Changing Standards in a World of Windows Gaming

Compatibility with Sound Blaster continues to be important for DOS-based games, but as Windows-based sound APIs such as Microsoft DirectX and the Creative Labs Sound Blaster Live! have surpassed DOS support in popularity, support for these newer standards might be even more important to you, especially if your games are mainly or exclusively Windows-based.

Note

Aureal's A3D is also a Windows-based sound API, but its future is uncertain due to the company's filing for Chapter 11 bankruptcy in April 2000.

The original Sound Blaster and Sound Blaster Pro became a widely supported standard because of broad software support. As the industry completes its move to Windows, choosing a sound card still means choosing the card that works best with the applications you want to run. As you'll see later, the change from the resource-gobbling ISA bus to the faster PCI bus has also changed how sound cards work and what must be done for those occasions when "classic" Sound Blaster compatibility is required.

Current Uses for Audio Adapters

Today, audio adapters have many uses, including the following:

- Adding stereo sound to multimedia entertainment (game) software
- Increasing the effectiveness of educational software, particularly for young children
- Adding sound effects to business presentations and training software
- Creating music by using MIDI hardware and software
- Adding voice notes to files
- Audio conferencing and network telephony
- Adding sound effects to operating system events
- Enabling a PC to read aloud
- Enabling PC use by handicapped individuals
- Playing audio CDs

- Playing MP3 audio files
- Playing software demonstrations
- Playing audio-video clips
- Playing DVD films with audio
- Providing support for voice-control computer software
- Providing support for voice-dictation and playback software (speech-to-text/text-to-speech)

Games

As with other multimedia technologies, audio adapters were originally designed to play games. In fact, many adapters include a game adapter interface, which is a connector for adding a game control device (usually an analog joystick, control paddles, or a steering wheel). Some adapters also use this interface to connect a plug providing a MIDI connector. The game port is a potential area of conflict because other cards, such as the multi-I/O type cards that some older PCs use to provide serial and parallel ports, also have a game interface. This can result in an I/O port address conflict because most game interfaces use the same I/O port addresses. You will need to disable one of the game interfaces if you have duplicate game ports. To learn how to disable a duplicate game port, see “Resolving Resource Conflicts” later in this chapter.

If you have invested in a high-performance game port designed for fast PCs and sophisticated controllers such as driving wheels, force-feedback joysticks, and so on, you should disable the sound card’s game port and use the separate one you installed. If you have a plain-vanilla standard game port, remove it or disable it and use the game adapter port on your audio adapter, especially if you plan to use the MIDI port.

Follow the sequence listed in Table 20.1 to determine which game port to keep.

Table 20.1 Order of Preference for Game Port Usage

Order of Preference	First Choice	Second Choice	Third Choice
Location of game port	High-performance game port card	Integrated with sound card or motherboard	Integrated with ISA or VL-Bus Multi I/O card or self-contained game port without speed control

Many “legacy-free” systems come with USB ports in place of the standard game ports and require the use of USB joysticks or other gaming controls. USB-based game controls usually offer both USB and the traditional game port connectors, allowing you to use the control with either type of connector.. This can result in an

By adding an audio adapter, game playing takes on a new dimension. Sound adds a level of realism that would otherwise be impossible even with the best graphics. For example, some games use digitized human voices or real recorded dialogue. Many TV and film actors such as *Star Wars*’ Mark Hamill have enjoyed a second career providing voiceovers or even “live” performances in interactive games such as *Wing Commander*. In addition to realistic sounds and effects, games can also have musical scores, which adds to the excitement and entertainment.

Most recent sound cards also offer 3D sound, which uses multiple speakers to provide highly realistic game play and environmental sounds. When coupled with special controllers and powerful new speakers, these sound cards make games extra realistic.

Multimedia

A sound card is a prerequisite if you want to turn your PC into a Multimedia PC (MPC). What is multimedia? The term embraces a number of PC technologies, but it primarily deals with video, sound, and storage. Basically, PC multimedia means the capability to merge images, data, and sound on a computer into a unified perceptual experience. In a practical sense, multimedia usually means adding an audio adapter and a CD-ROM drive to your system.

Although the Multimedia PC Marketing Council (MPC) established standards for multimedia PCs, its MPC 1 and MPC 2 standards, as well as the MPC 3 standard set up by the successor organization, the Software Publishers Association's Multimedia PC Working Group, have been exceeded by all systems and multimedia add-ons sold since the late 1990s, as shown in Table 20.2.

Table 20.2 MPC Multimedia Standards

	MPC Level 1	MPC Level 2	MPC Level 3
Processor	16MHz 386SX	25MHz 486SX	75MHz Pentium
RAM	2MB	4MB	8MB
Hard disk	30MB	160MB	540MB
Floppy disk	1.44MB 3 1/2-inch	1.44MB 3 1/2-inch	1.44MB 3 1/2-inch
CD-ROM drive	Single-speed	Double-speed	Quad-speed
Audio	8-bit	16-bit	16-bit
VGA video	640x480	640x480	640x480
Resolution	16KB colors	64KB colors	64KB colors
Other I/O	Serial, Parallel, MIDI, Game	Serial, Parallel, MIDI, Game	Serial, Parallel, MIDI, Game
Minimum Software	Microsoft Windows 3.1	Microsoft Windows 3.1	Microsoft Windows 3.1
Date introduced	1990	May 1993	June 1995

Exceeding MPC-3

All new and recent-model computers exceed the Level 3 specification by a substantial margin in every area. With Windows 9x or Windows Me as the standard operating system, I would normally recommend a system that includes at least 64MB of RAM, a minimum 300MHz Pentium II, Pentium III, Celeron, Athlon, Duron, or other Pentium-class processor, and 2GB of hard drive space. A 24x or faster CD-ROM drive and a video resolution of 1024x768 at 24-bit (16.8 million) color depth also enhance the multimedia experience. Note that although speakers or headphones are technically not a part of the MPC specification, they are certainly required for sound reproduction. Although low-cost powered or unpowered speakers are typically included with sound card-equipped systems, feel free to replace these often low-quality units with speakers or headphones that provide the mixture of size, frequency response, and overall sound quality you need.

In addition to hardware specifications, the MPC specifications also defined the minimum audio capabilities of a multimedia system. These capabilities must include digital audio recording and playback (linear PCM sampling), music synthesis, and audio mixing. The Software Publishers Association has a special section of its Web site devoted to MPC issues at www.spa.org/mpc, although the organization doesn't plan to provide any new MPC standards.

Beyond MPC Standards—PC Design Standards

Because the MPC specifications reflect multimedia's past, users who want to know what comes next need somewhere else to turn for guidance. Microsoft and Intel jointly manage the PC Design Guide Web site at www.pcdesignguide.com, where the PC97, PC98, and PC99 specifications and addenda can be read and reviewed. These standards are widely followed by the industry and point the way to the end of ISA-bus audio and many other enhancements for audio hardware and software in the Windows environment.

Digitized Sound Files

You can use two basic types of files to store audio on your PC. One type is generically called a sound file and uses formats such as WAV, VOC, AU, and AIFF. Sound files contain waveform data, which means they are analog audio recordings that have been digitized for storage on a computer. Just as you can store graphic images at different resolutions, you can have sound files that use various resolutions, trading off sound quality for file size. The three default sound resolution levels used in Windows 9x and Windows Me are shown in Table 20.3.

Table 20.3 Windows 9x and Windows Me Sound File Resolutions

Resolution	Frequency	Bandwidth	File Size
Telephone quality	11,025Hz	8-bit mono	11KB/sec
Radio quality	22,050Hz	8-bit mono	22KB/sec
CD quality	44,100Hz	16-bit stereo	172KB/sec

Windows Me also supports additional resolution (48,000Hz, 16-bit stereo, 188KB/sec) although you must select it manually.

This additional resolution offered by Windows Me supports the 48KHz (48,000Hz) standard used by many new sound cards to support the requirements of DVD audio playback and Dolby AC-3 audio compression technologies. As you can see, the difference in file sizes between the highest and lowest audio resolution levels is substantial. CD-quality sound files can occupy enormous amounts of disk space. At this rate, just 60 seconds of audio would require over 10MB of storage. For applications that don't require or benefit from such high resolution, such as voice annotation, telephone quality audio is sufficient and generates much smaller files.

To achieve a balance between high quality and smaller file sizes, you can also convert conventional WAV files into compressed formats such as MP3 audio files. See the following sections for details.

In addition to these standard quality designations, you can create your own combinations of frequency and bandwidth with virtually any audio recording program, including the Sound Recorder applet supplied with Windows.

MP3s and Audio Compression

By using audio-editing software such as Real's RealProducer G2, you can compress high-quality sound for use on Web sites with a minimal loss of quality, but a large reduction in file size.

The latest example of a sound format being popularized by the Web is the popular MP3 file type, a digital sound-only flavor of MPEG that has become an overwhelmingly popular downloadable sound format on the World Wide Web. MP3 files can have near-CD quality, depending on the sampling rate used to create them, but are far smaller than normal CD-quality WAV files.

MP3 enables both downloading of these compact, quality music files and transformation of the CDs you now own into individual MP3 tracks. Although MP3-creation programs (also called rippers) can work at different sampling rates, a typical rate for pop music is 120Kb/second encoding, providing a balance between reasonable sound quality and amazingly small file size. A five-minute song that rips to a CD-quality 50MB WAV file would convert to an MP3 file that is less than 4MB.

Thanks to MP3, many PCs around the country are doubling as stereo systems without the need to flip CDs and with the capability to construct custom music play lists. MP3 provides music lovers with the capability to store just the songs they want and to create customized CDs for personal use. MP3 files are being distributed legally by musicians wanting to build an audience or gain publicity for a new CD, album, or upcoming tour. Unfortunately, many MP3 Web sites are stuffed full of unauthorized MP3 tracks. Despite the problems of pirated MP3 files on the Web, MP3 has become the leading edge of a consumer-friendly music revolution: helping you get just the songs you want in the playback form you want, whether it's portable player (such as Diamond Multimedia's RIO), computer storage, or music CD.

Caution

Although MP3 is an exciting method used legally by many artists to attract new audiences, be careful about what you download. Distributing MP3 sound files from copyrighted artists without permission is both unethical and illegal. If you find MP3 files on the Web and are unsure about their legitimacy, don't download them.

What You Need to Create and Use MP3s—Legally

Many users of MP3 files are content to download the hottest, newest MP3s from legal sites such as www.mp3.com. However, if you're a fan of classical music or older pop or show tunes, your source for personal-use MP3s is as close as your stack of CDs or your rack of cassettes or vinyl LPs.

To download premade MP3 tracks, you'll just need an Internet connection (via modem or LAN).

To create your own MP3 tracks, you'll need the following items:

- Audio sources that you own (CD, cassette, LP)
- An MP3 ripper program, such as Winamp
- A sound card with speaker or headphones for output and input

Note

An industry forum called the Secure Digital Music Initiative (SDMI) has introduced new specifications for creating secure ("SDMI-compliant") downloadable music files that can be played back, stored on computer hard drives and transferred freely to CD-R by the purchaser of the original music on CD. Although this organization is still in the early stages of development, its goal is to promote portable music while still protecting the rights of the music copy-right holder.

If SDMI-compliant MP3 files become widespread, you'll need to upgrade the firmware in your MP3 players to be able to play protected music files.

For more information on SDMI, see its Web site at www.sdmi.org.

To record your own MP3 "mix" CD for personal use, you'll need the following items:

- An MP3-encoding program such as MusicMatch Jukebox
- An MP3-to-WAV conversion program such Winamp
- A CD-R or CD-RW drive with recording software (some software, such as Adaptec Easy CD Creator Pro version 4.x, might include built-in MP3-to-WAV conversion)
- CD-R media rated for the maximum speed of your recorder

Note

If you are creating data CDs for use on your computer, you can use either CD-RW or CD-R media with a CD-RW drive, but to create music CDs you can play on stereo systems, you must use CD-R media. The discussion that follows assumes that you are creating music CDs.

The MP3 Creation Process from CD

The following steps are general and should be supplemented by the detailed instructions provided with the programs and devices you choose.

1. Put the CD containing the tracks you want to rip into your CD-ROM or CD-R/CD-RW drive; your drive needs to support digital audio extraction (DAE) if you want to use digital ripping. Use whichever drive supports digital ripping at the fastest rate.
2. Start your MP3 ripper program and select the appropriate bit rate and digital or analog ripping.

Tip

If your ripper supports only a single bit rate (CBR=constant bit rate), choose at least 160Kb/second for rock and alternative; at least 192Kb/second for jazz and classical. Some rippers support a feature called VBR (variable bit rate) that adjusts the bit rate according to the amount of data being ripped at any moment. This feature can be useful, but be sure your hardware MP3 player or software MP3 player program can use VBR-type MP3s before you rip them.

If you want to get done quickly, use digital ripping, which goes directly from the music CD to the hard disk. Analog ripping (which takes place at the same speed as the song's playback and uses the rear analog sound jack on the CD-ROM drive to go to the sound card for capture) sounds better and is the only way to rip from older CD-ROM drives that don't support digital audio extraction. You can use digital ripping plus error correction to balance between speed and fidelity to the original.

3. Start the ripping process and then the audio source. You might need to practice a couple of times to get the start of the song without a long delay.
4. Each song (track) is recorded to a separate MP3 file on your hard disk. Depending on the MP3 ripping software you use, you might need to supply artist and title data yourself, or you might be able to use the Compact Disc Database Online (www.cddb.com) to get this information easily.
5. Use your MP3 player software to play back the MP3 files; if they sound okay, you can transfer them to a hardware MP3 player or make your own “mix” CD.

The MP3 CD “Mix” Creation Process

Note

If you plan to play your MP3s through an MP3 player program or hardware player, you don't need to convert your MP3 files into WAV files first. You can simply use your CD-R mastering software to create a data CD-R.

The process outlined in this section will create a CD of converted MP3 files you have legally downloaded that you can play on your own CD player. This same process, minus the conversion to MP3 format, can be used to “mix” your own CD from recordings you own.

To create an MP3 mix CD:

- If your CD-R mastering program doesn't convert MP3 files into WAV files, use a separate conversion program; allow at least 50MB of disk space for each 5MB MP3 file to hold the resulting WAV file.
- Equalize the volume level of different WAV files (“normalize the output”) with the audio editing software provided with many CD-R mastering programs.
- Sequence the tracks as desired; you can put up to 74 minutes of audio on a standard CD-R in audio use. Avoid 80-minute CD-Rs, since the extra capacity can't be used by standard stereos.
- Place an unused CD-R into your CD-R/CD-RW drive.
- Use the mastering program in audio CD mode to create your “mix” CD; save the layout for reburning in case of problems.
- Test the resulting CD on your stereos; if it sounds okay, you're all set! Save the WAV files for reuse, or delete them to save space and continue.

For more information on making CD-Rs and using external audio sources (such as cassette and LP), see Chapter 13, “Optical Storage,” and the section “Recording,” later in this chapter.

MIDI Files

The third type of audio file is a MIDI file, which is as different from a WAV or MP3 file as a vector graphic is from a bitmap. MIDI files, which use MID or RMI extensions, are wholly digital files that do not contain recordings of sound; instead, they contain the instructions that the audio hardware uses to create the sound. Just as 3D video adapters use instructions and textures to create images for the computer to display, MIDI-capable audio adapters use MIDI files as instructions to guide the synthesis of music.

MIDI is a powerful programming language developed in the 1980s to permit electronic musical instruments to communicate. MIDI was the breakthrough standard in the electronic music industry, an industry that to this day shuns nearly all attempts at hardware standardization in favor of proprietary systems. With MIDI you can create, store, edit, and play back music files on your computer either in tandem with a MIDI-compatible electronic musical instrument (typically a keyboard synthesizer) or with just the computer.

Unlike the other types of sound files, MIDI messages require relatively little storage space. An hour of stereo music stored in MIDI format requires less than 500KB. Many games use MIDI sounds instead of recorded ones to supply large amounts of music while conserving disk space. Because they are not recordings, the use of various resolutions does not apply to MIDI files.

A MIDI file is actually a digital representation of a musical score. It is composed of a collection of separate channels, each of which represents a different musical instrument or type of sound. Each channel specifies the frequencies and duration of the notes to be “played” by that instrument, just as a piece of sheet music does. Thus, a MIDI file of a string quartet contains four channels representing two violins, a viola, and a cello.

Note

MIDI files are not intended to be a replacement for sound files such as WAVs; they should be considered a complementary technology. The biggest drawback of MIDI is that the playback technology is limited to sounds that can be readily synthesized. The most obvious shortcoming is that MIDI files are incapable of producing voices (except for synthesized choir effects). Therefore, when you download a MIDI file of your favorite song from the Internet, you’ll have to do the singing.

A more significant limitation of MIDI also stems from its synthetic nature; the quality of your sound card directly influences what MIDI sounds like when you play it back. Because MIDI files can be played back with FM synthesis or wavetable synthesis, older low-cost sound cards without wavetable features will produce MIDI music that sounds like an orchestra of kazoos. Unfortunately, even with a high-quality wavetable sound card, some MIDI files still sound bad because they were produced for playback on FM-synthesis sound cards. Even though most sound cards sold today feature some form of wavetable synthesis, the number of instruments and the quality of the patch sets (the digital samples) can vary widely from card to card. Inexpensive wavetable cards might support only 32 voices, whereas better cards can support 256 or more.

Check the MIDI files you want to playback to see how many voices are needed to fully support the file before you decide you need a “better” MIDI-compatible sound card with more voices. Most readily available sound cards require no more than 20 voices.

All three MPC specifications as well as the PC9x specifications call for all audio adapters to support MIDI. The general MIDI standard used by most of the audio adapters on the market provide for up to 16 channels in a single MIDI file, but this does not necessarily limit you to 16 instruments. A single channel can represent the sound of a group of instruments, such as a violin section, enabling you to synthesize an entire orchestra.

Because MIDI files consist of digital instructions, you can edit them much more easily than you can a sound file such as a WAV file. With the appropriate software, you can select any channel of a MIDI file and change the notes, the instrument used to play them, and many other attributes that affect the sound the PC produces.

Some software packages can even produce a manuscript of the music in a MIDI file by using standard musical notation. A composer can write a piece of music directly on the computer, edit it as needed, and then print out sheet music for live musicians to read. This is an enormous benefit for professional musicians, who historically have had to either employ music copyists or publishers or spend long hours copying music by hand.

Playing MIDI Files

When you play a MIDI file on your PC, you are not playing back a recording. Your system is actually creating music from scratch. To do this, the computer requires a synthesizer, and every MIDI-capable audio adapter has one. As the system reads the MIDI file, the synthesizer generates the appropriate sound for each channel, using the instructions in the file to create the proper pitches and note lengths and using a predefined patch to simulate the sound of a specific musical instrument. A patch is a set of instructions that the synthesizer uses to create sound similar to a particular instrument. You can control the speed at which the music plays and its volume in real time with the MIDI player software.

The synthesizer on an audio adapter is similar electronically to those found in actual electronic keyboard instruments, but it is usually not as capable. The MPC specifications call for audio adapters to contain FM synthesizer chips that are capable of playing at least six melodic notes and two percussive notes simultaneously.

FM Synthesis

Until the mid-1990s, most low-cost sound boards generated sounds by using FM (frequency modulation) synthesis, a technology first pioneered in 1976. By using one sine wave operator to modify another, FM synthesis creates an artificial sound that mimics an instrument. The MIDI standard supported by the adapter specifies an array of preprogrammed sounds containing most of the instruments used by pop bands and orchestras.

Over the years, the technology has progressed (some FM synthesizers now use four operators) to a point where FM synthesis can sound moderately good, but it is still noticeably artificial. The trumpet sound, for example, is vaguely similar to that of a trumpet, but it would never be confused with the real thing. Today, virtually all new sound cards use more realistic wavetable sound (see the following section), although many still offer FM synthesis as an option.

Wavetable Synthesis

Today, few sound cards use FM synthesis for their sole method of playing MIDI files because even at its best, the sound it produces is not a realistic simulation of a musical instrument. More realistic, inexpensive sound was pioneered by Ensoniq Corp., the makers of professional keyboards, in 1984.

Using a technology that was theorized at about the same time as FM synthesis, Ensoniq developed a method of sampling any instrument—including pianos, violins, guitars, flutes, trumpets, and drums—and storing the digitized sound in a wavetable. Stored either in ROM chips or on disk, the wavetable supplies an actual digitized sound of an instrument that the audio adapter can manipulate as needed. Soon after Ensoniq's discovery, other keyboard makers replaced their FM synthesizers with wavetable synthesis.

Today, Ensoniq is owned by Creative Labs, makers of the de facto industry-standard Sound Blaster line of sound cards. Ensoniq continues to create professional keyboards while also supplying OEM sound hardware to many computer vendors. Ensoniq technology has also been added to the Sound Blaster sound-card product line.

A number of low-cost, high-quality PCI-based sound cards using Ensoniq or other chipsets supporting wavetable output are also available from various vendors.

A wavetable synthesizer can take a sample of an instrument playing a single note and modify its frequency to play any note on the scale. Some adapters produce better sound by using several samples of the same instrument. The highest note on a piano differs from the lowest note in more than just pitch, and the closer the pitch of the sample is to the note being synthesized, the more realistic the sound is.

Thus, the size of the wavetable has a powerful effect on the quality and variety of sounds that the synthesizer can produce. The best-quality wavetable adapters on the market usually have several megabytes of memory on the card for storing samples. Some support optional daughtercards for the installation of additional memory and enable you to customize the samples in the wavetable to your own specifications.

To save money without compromising quality, many current PCI-based wavetable sound cards use so-called “soft wavetable” techniques, which borrow up to 4MB or more from main computer memory for storage of wavetable samples, which are also called “patch sets.”

Tip

If your system has both a “soft wavetable” sound card and integrated AGP graphics, your usable RAM is reduced by the memory sharing performed by both devices. A 4MB patch set and AGP graphics set for 8MB of RAM will reduce a 64MB system to 52MB of usable RAM. Since memory sharing like this is common, a memory upgrade from 64MB total to 128MB total will actually more than double your usable system RAM.

MIDI Connectivity

The advantages of MIDI go beyond the internal functions of your computer. You can also use your audio adapter’s MIDI interface to connect an electronic keyboard, sound generator, drum machine, or other MIDI device to your computer. You can then play MIDI files by using the synthesizer in the keyboard instead of the one on your adapter or create your own MIDI files by playing notes on the keyboard. With the right software, you can compose an entire symphony by playing the notes of each instrument separately into its own channel and then playing back all the channels together. Many professional musicians and composers use MIDI to create music directly on computers, bypassing traditional instruments altogether.

Some manufacturers even offer high-end MIDI cards that can operate in full-duplex mode, meaning that you can play back prerecorded audio tracks as you record a new track into the same MIDI file. This is technology that only a few years ago required the services of a professional recording studio with equipment costing hundreds of thousands of dollars.

To connect a MIDI device to your PC, you need an audio adapter that has the MIDI ports defined by the MIDI specification. MIDI uses two round five-pin DIN ports (see Figure 20.1) for separate

input (MIDI-IN) and output (MIDI-OUT). Many devices also have a MIDI-THRU port that passes the input from a device directly to output, but audio adapters generally do not have this. Interestingly, MIDI sends data through only pins 1 and 3 of the connector. Pin 2 is shielded and pins 4 and 5 are unused.

Figure 20.1 The MIDI specification calls for the use of two or three five-pin DIN connectors on the MIDI device.

The primary function of the audio adapter's MIDI interface is to convert the parallel data bytes used on a computer's system bus into the serial MIDI data format. MIDI uses asynchronous serial ports that run at 31.25Kbaud. MIDI communications use 8 data bits, with one start bit and one stop bit, for a speed of 320 microseconds per serial byte.

Note

You can obtain the most recent specifications for the MIDI standard for a modest fee from the MIDI Manufacturers Association's sales-fulfillment address: MMA, PO Box 3173, La Habra, CA 90632-3173 USA.

The MIDI Manufacturers Association also has a Web site at www.midi.org.

MIDI runs over special unshielded twisted-pair cables that can have a maximum length of up to 50 feet (although most of the cables sold are 10 or 20 feet long). You can also daisy-chain multiple MIDI devices together to combine their capabilities. The total length of the MIDI chain is not limited as long as each individual cable is less than 50 feet.

Many audio adapters do not have MIDI ports directly on the adapter card. Instead, they use a separate connector that plugs into the adapter's game port and provides the MIDI ports. Unfortunately, this connector is rarely included in the box with the adapter. You have to purchase it separately from the audio-card manufacturer.

If you are using a "legacy-free" PC that doesn't include a MIDI/gameport connector, you can attach MIDI interfaces via your USB ports. For a selection of various USB-compatible MIDI devices, go to www.usbstuff.com/midi.html.

MIDI Software

Windows 9x, Me, and 2000 all include basic software that enables you to play MIDI files in the form of the Media Player application, and these versions of Windows also include a selection of MIDI music files. For full MIDI capabilities, however, you'll need sequencing software to either manipulate the tempo of MIDI files and the sounds used to play them or to cut and paste together various prerecorded music sequences.

Many audio adapters come with a selection of software products that provide some MIDI capabilities, and there are shareware and freeware tools available on the Internet, but the truly powerful software that enables you to create, edit, and manipulate MIDI files must be purchased separately.

Presentations

Businesses have discovered that integrating graphics, animation, and sound into their presentations is more impressive than a simple slide show and is more likely to keep their audiences awake. An audio adapter adds impact to any presentation or classroom.

Presentation software packages such as Microsoft PowerPoint, Corel Presentations, and Lotus Freelance Graphics support WAV, AVI, and MIDI files. With these products, you can synchronize sounds with objects. When a presentation displays a picture of your new product, for example, you can add a roaring round of applause. You can even pull in sound from an audio CD in your CD-ROM drive. Many presentation software packages also include clip-media libraries with audio files that you can use license-free.

You can even take your show on the road. Most notebook computers include sound capability and have built-in CD-ROM drives and speakers. An audio adapter can make many computing tasks (such as learning how to use software) easier. PC software manufacturers have taken an early lead in this area. Many publishers are taking advantage of the space on the CD-ROMs they now use to distribute their products by including animated tutorials and online help, replete with music and narration.

Sound has also found its place on the World Wide Web. Because of their relatively small size, MIDI files are an excellent choice for providing background music when users arrive at your Web site. A catchy tune can help people remember your site out of the many others they see each day, but setting your tune to repeat incessantly can drive Web-surfers crazy. If you want to MIDIfy your Web sites, I suggest that you choose subtle MIDI tracks and give users a control for turning the music off and on, especially if you are considering repeating the MIDI track.

If you want to add digitized voice or music to your site, the leading plug-in with very wide support is RealPlayer; use the RealProducer G2 series to process your sound files for Web use, preserving essential qualities while causing amazing reductions in file size.

Recording

Virtually all audio adapters have an audio input jack. With a microphone, you can record your voice. Using the Sound Recorder application included with all versions of Microsoft Windows, you can play, edit, or record a sound file in the WAV format. From the Windows Sounds Control Panel, you can assign specific WAV files to certain Windows events.

This capability is not just an entertaining novelty, however. You can also use specific sounds to notify you of important events, such as when your system experiences an error ("Call extension 999 for help") or when you receive new email ("You've got mail!"). The Windows operating system ships with a collection of basic WAV files that you can assign as needed. Windows 9x also includes collections of WAV files called sound schemes that provide a unified environment for your system based on a given subject. The Musica sound scheme, for example, automatically

assigns sound files of various musical instruments to many of the standard system events. Many applications add their own events to the operating system, enabling you to configure sounds for activities specific to that product.

By recording the sound of your own voice (or anything else), you can create your own WAV files and assign them to certain events, instead of using the default Windows WAVs. On most multi-media systems, you can record directly from an audio CD in your CD-ROM drive to the WAV format. You can also attach your stereo system or VCR to the audio input jack and record any sound to a WAV file.

With this simple connection, users have amassed libraries consisting of thousands of WAV files celebrating popular songs, movies, and TV shows.

Tip

By using a CD-R/CD-RW drive and recording software such as Adaptec Easy CD Creator Pro with its music-oriented Spin Doctor feature, older analog sound sources such as scratchy LPs and deteriorated cassette and eight-track tapes can be improved during the conversion to digital CD storage. Spin Doctor and similar utilities can remove or minimize the click and hiss common to old recordings. Spin Doctor can also be used to produce a customized CD of your favorite selections from recordings you already own.

Note that many sound cards have software that automatically mutes one or more of the outputs during recording. If you can't hear anything through the speakers during a recording session, check your mixer settings. You might also want to use a Y-splitter that can drive your sound card (for recording) and external speakers (for monitoring) with the same stereo output from your LP or tape source.

Voice Annotation

By using WAV files, you can record voice messages and embed them in your Windows documents. For example, a business executive could pick up a microphone and, by embedding a message in a contract or spreadsheet, give her secretary explicit instructions. This message is called a voice annotation. I like to think of it as a verbal Post-it Note.

With voice annotation, you can embed voice messages, suggestions, or questions in a document and send it to a colleague. To leave such messages, your Windows application must support object linking and embedding (OLE). OLE is a technology that enables you to take objects created by one application and embed them in a document created in another application. Activating the embedded object in the target application by double-clicking it automatically launches the object's source application. Sound files can also be distributed through the Distributed Component Object Model (DCOM), a refinement of OLE that extends the concept to ActiveX controls. For example, if you embed a portion of a Microsoft Excel spreadsheet into a Word document, you will see the grid of the spreadsheet on the page in Word. However, when you double-click the spreadsheet, Excel launches and temporarily replaces the Word menu and button bars with those of Excel. Clicking another part of the Word document returns you to the normal Word environment.

Embedding a sound in a document works the same way. Imagine that you're editing an Excel spreadsheet and you want to insert a voice note next to a total that looks questionable. Place the

cursor in the cell next to the total and then select Edit, Insert, Object, Sound to call up Windows Sound Recorder. Click the Record button and begin speaking. After you finish recording, the sound appears as an icon in the selected cell. Because the sound file is actually an embedded part of the spreadsheet file, you can copy it to a disk or email it to another user. That user can then double-click the icon and hear your voice.

Although Windows ships with the Sound Recorder applet, this utility limits original recordings to very short time periods, varying with the quality of the recording (higher quality = shorter duration). To record clips of more than about 10 or 15 seconds, use a third-party application, such as the audio editor supplied with Easy CD Creator Pro or a dedicated sound editor such as Sound Forge.

Tip

Voice annotation is typically an area where sound quality is not a major issue. Be sure to configure your system to use telephone-quality (that is, the lowest quality) audio for this purpose, or you could end up with files that are enormously inflated in size by the addition of embedded audio.

The Lotus ScreenCam program, available separately or as part of the Lotus SmartSuite for Windows 9x and NT, provides a unique use for voice annotation. ScreenCam allows you to record Windows program screens as a movie, so that you can demonstrate a new program or procedure to other users by sending them the ScreenCam file and player, or by making a standalone .EXE file they can run. During the creation of the ScreenCam movie, you can provide voiceover narration or create text captions first and display them during the creation process.

Voice Recognition

Some audio adapters are equipped with software that is capable of voice recognition. You can also get voice recognition for your current adapter in the form of add-on software. Voice recognition, as the name implies, is when your computer is “taught” to recognize spoken word forms and react to them. Voice recognition products generally take two forms: those that are designed to provide a simple voice interface to basic computer functions, and those that can accept vocal dictation and insert the spoken text into an application such as a word processor. The minimum standard for most voice-recognition software is a Sound Blaster 16 or equivalent sound card.

Voice Command Software

The voice interface application is clearly the simpler of the two, as the software only has to recognize a limited vocabulary of words. With this type of software, you can sit in front of your computer and say the words “file open” to access the menu in your active Windows application.

For the average user, this type of application is of dubious value. For a time, Compaq was shipping computers to corporate clients with a microphone and an application of this type at little or no additional cost. The phenomenon of dozens of users in an office talking to their computers was interesting, to say the least. The experiment resulted in virtually no increased productivity, a lot of wasted time as users experimented with the software, and a noisier office.

However, for users with physical handicaps that limit their ability to use a keyboard, this type of software can represent a whole new avenue of communication. For this reason alone, continued development of voice recognition technology is essential.

Note

Voice-recognition applications, by necessity, have to be somewhat limited in their scope. For example, it quickly becomes a standard office joke for someone to stick his head into another person's cubicle and call out "Format C!" as though this command would erase the user's hard drive. Obviously, the software must not be able to damage a user's system because of a misinterpreted voice command.

Voice Dictation Software

The other type of voice-recognition software is far more complex. Converting standard speech into text is an extraordinarily difficult task, given the wide variation in human speech patterns. For this reason, nearly all software of this type (and some of the basic voice command applications, as well) must be "trained" to understand a particular user's voice. You do this training by reading prepared text samples supplied with the software to the computer. Because the software knows what you're supposed to be saying beforehand, it can associate certain words with the manner in which you speak them.

Users' results with this sort of application vary widely, probably due in no small part to their individual speech patterns. I've heard people rave about being able to dictate pages of text without touching the keyboard, whereas others claim that correcting the many typographical errors is more trouble than typing the text manually.

Many variables can account for such variances in the quality of voice dictation. Early versions of these products required users to separate words and speak "robotically - like - this" to get the computer to recognize the text. These "discrete speech" products are now obsolete and should be replaced by newer "continuous speech" products.

A second factor is the "trainability" of the software. My experience with trainable and "no-training-needed" programs suggest that training a voice-dictation program to recognize your speech patterns and accent is still a good idea for best results.

A third factor is the program's active and total vocabulary. Given identical voice-recognition engines, the program with the larger active vocabulary will react more quickly to dictation, and the program with the larger total vocabulary will be able to store more user-specific words.

If you're involved in medicine or law or other professions with specialized vocabularies, you might find it saves time (and ultimately money) to purchase industry-specific versions of your favorite voice-recognition program. These programs offer enlarged vocabularies tailored to your line of work.

Other features to look for include voice commands for computer operations, text-to-speech translation to let your computer "read" to you, and a Web browser. Mobile versions of these programs use a special digital recorder to save your dictation when you're away from the computer and allow you to play it back for voice recognition when you return to the computer.

Whatever the program you choose, some prerequisites for success include the following:

- A high-quality sound card (compatible with the Sound Blaster 16 or better); check the software company's Web site for the latest list of recommended sound cards.
- A quiet room with little change in background sound.

- A microphone specially designed for voice recognition (a low-cost one normally comes with the software, but better models are available). *Using a poor-quality microphone or an inadequate sound card will cause problems for even the finest voice-dictation program.* For best results, use a microphone with noise canceling or directional features, and choose a model that's on the approved list compiled by the voice-recognition software vendor. These usually feature a headset for precise adjustment of the microphone-to-mouth distance and angle, which is a crucial element in good voice recognition.
- Completing sound setup and user training, if offered, to set software for your voice and vocabulary.
- Retraining difficult-to-distinguish words.
- Using the most advanced version of the software you can afford.

Note

The voice-dictation software versions bundled with office suites such as IBM's Lotus SmartSuite and Corel WordPerfect Suite are usually not the top-of-the-line versions, but they will usually qualify you for upgrade pricing to move to the best version available.

Voice-recognition technology is still a young technology and is sensitive to changes in a person's voice. Illness and stress can often change a person's voice enough to throw off most of the "consumer" voice-recognition products. You will also need a fast computer, at least a Pentium 200MHz with 64MB of RAM or more, to achieve response times that are quick enough to keep up with your speech. Because voice-recognition technology (especially voice-dictation) can also help users avoid the debilitating effects of repetitive stress injuries on wrists, fingers, and arms from typing too long without a break, it should become increasingly popular as system speeds increase and the software improves.

Note

As with any resource-hungry product, your system should exceed the "minimum requirements" for RAM, CPU speed, and free disk space by a factor of two or three if you want to be really happy with your software.

However, advances in this technology are rapidly developing to a point where more and more of us are able to use continuous speech to write with computers, rather than typing.

Conferencing

One of the newest applications in the world of multimedia is video and audio conferencing over the Internet. These applications range from point-to-point products, such as VocalTec's Internet Phone, to multiuser-conferencing packages, such as Microsoft's NetMeeting. Other applications, such as Real's RealPlayer and Microsoft's Media Player, can play back audio (with or without video) as it is received over the Internet, in a process called *streaming*.

For all these applications, the audio adapter is an integral part of the technology. Depending on the speed of your Internet connection, the data compression technology that the software uses, and whether you elect to stream video along with audio, the quality of the sound delivered by conferencing software can range from poor to rather good.

As with voice recognition, this is a technology that is still very young. Over a 56Kbps modem connection (which frequently does not reach a full 56), one-way audio and video streaming generally works tolerably well, but full-duplex communications, even when audio-only, tend to drop words. However, as faster Internet connections and better data compression techniques become available, audio conferencing and video conferencing are likely to become as reliable as the telephone network.

Note

Audio conferencing can also benefit from an operating system upgrade because of the way that audio drivers handle audio packets. Windows 2000 is the first Microsoft operating system to require the use of WDM (Windows Driver Model) device drivers for audio and other devices. Compared to the .VxD drivers used by Windows 95 (and by many devices under Windows 98), WDM audio drivers handle audio far better, improving the quality of audio conferencing and other audio uses.

Proofreading

You can also use an audio adapter as an inexpensive proofreading tool. Many adapters include a text-to-speech utility that you can use to read a list of numbers or text back to you. This type of software can read back highlighted words or even an entire file.

Having text read back to you enables you to more easily spot forgotten words or awkward phrases. Accountants can double-check numbers, and busy executives can listen to their email while they are doing paperwork.

As I mentioned previously, this is a popular feature of many of the leading voice-dictation programs on the market.

Audio CDs

One convenient and entertaining use of a CD-ROM drive is to play audio CDs while you are working on something else. Virtually all CD-ROM drives support audio CDs, and the music can be piped not only through a pair of speakers (and even a subwoofer) connected to the audio adapter, but also through headphones plugged into the front-mounted external jack provided on most CD-ROM drives. Most sound cards include a CD-player utility, as does Windows 9x, and free versions are available for download on the Internet. These programs usually present a visual display similar to the control panel of an audio CD player. You operate the controls with a mouse or the keyboard and can listen to audio CDs as you work on other things.

If you want to hear CDs through your system's speakers, make sure that your CD audio cable is attached to both the rear of the CD-ROM drive and your sound card. Some new systems feature digital speakers attached to the USB (Universal Serial Bus) connection. These can provide excellent sound, but if used with older or cheaper CD-ROM drives, they might produce no sound at all. USB-based speakers *must* be used with CD-ROM drives that support a feature called digital audio extraction (DAE) if you want CD-based music to play through them. Check your CD-ROM drive's spec sheet for information about this feature.

Note

If you have a CD-R/CD-RW drive as well as an IDE-based CD-ROM, don't forget to check the recordable drive. Many of these do feature digital audio extraction, enabling you to play your music in that drive and use your (normally faster) CD-ROM for program loading and data access.

If your system is equipped with a DVD drive, make sure your audio CD player software is DVD-compatible. Many vendors of software DVD playback programs provide a program that can be launched at system startup to allow you to play back music CDs with your DVD drive.

Note

See Chapter 13 to learn more about CD audio.

Sound Mixer

On a multimedia PC, it is often possible for two or more sound sources to require the services of the audio adapter at the same time. Any time you have multiple sound sources that you want to play through a single set of speakers, a mixer is necessary.

Most audio adapters include a mixer that enables all the different audio sources, MIDI, WAV, line in, and the CD to use the single line-out jack. Although a separate recording mixer was often used with Windows 3.1x systems, newer versions of Windows use a single mixer for both recording and playback features. Normally, the adapter ships with software that displays visual sliders like you would see on an actual audio mixer in a recording studio. With these controls, you can set the relative volume of each of the sound sources.

Is an Audio Adapter Necessary?

In the preceding sections, you read about the various ways that high-quality audio can improve the computing experience. Certainly, for recreational computer users, audio greatly enhances the entertainment value of games and other multimedia software. The question still remains, however, of whether audio is suited to the business world.

There are definitely applications, such as voice annotation and audio conferencing, that can be useful to business computer users. In training and other educational environments, audio can be a necessity in some cases. However, three other factors that can make the assimilation of PC audio into the business office problematic are the following:

- Expense
- Productivity
- Noise

Expense

The price of adding basic audio capabilities to a PC, like that of virtually all computer hardware, has plummeted during the past few years. In fact, most recent systems either feature built-in audio adapters on the motherboard or come standard with some sort of sound card.

Systems with preconfigured audio adapters or motherboard circuits eliminate the expense of installing and configuring sound cards.

If you want to make audio upgrades easier in the future, make sure that your systems come with removable audio cards or that you can easily disable the onboard audio. In either case, most business PCs offer either feature as a standard, making audio a virtual “standard” option on today’s computers.

Productivity

Employee productivity is another important concern. Many network administrators and company executives are only now coming to grips with the effect that Internet access has had on the workforce. Audio definitely has its uses in the business world, as does the World Wide Web, but the question remains as to whether it will be seen by many supervisors as just another time-wasting toy. Computers can be used as stereo systems for playing back MP3s or listening to Internet radio, both of which can greatly improve the productivity of users by alleviating stress. But both productivity and network bandwidth can be lost to downloading MP3s or using Internet radio. Recently, over 50 percent of Indiana University’s network bandwidth was being swallowed up by students’ use of the controversial Napster service, which searches users’ hard drives for MP3 files and makes them available to other users.

The answer to this problem is not so simple. Administrators can take steps to limit users’ access to the operating system’s sound configuration controls using Windows system policies, but they cannot easily prevent users from downloading or recording sound files and playing them back without limiting the audio hardware’s usefulness. As with the Web, however, it is likely that when the novelty of the new capabilities wears off, users will waste less time playing with audio and more time using it productively.

Noise

The final problem is the obvious one of the noise produced by the individual speakers attached to a large fleet of PCs. The degree of difficulty, of course, depends on the architectural layout of the workplace. For users working in small or private offices, the noise level should be minimal. For workers in cubicles, the situation should be tolerable, as long as the users exercise some restraint in the volume. In an open office with many computers, however, the noise could be a severe problem. Using headphones that plug into the speaker jack on the rear of the sound card or system is a solution that enables the use of sound while eliminating the “over-the-cubicle” noise-irritation factor that can be a problem in many offices. For offices where small speakers are acceptable, watch out for subwoofers. Subwoofer speakers are the biggest irritant in most offices, since their low-frequency sounds can travel a long distance.

Network administrators should consider these factors when deciding which users should be furnished with audio hardware.

Audio Adapter Concepts and Terms

To fully understand audio adapters and their functions, you need to understand various concepts and terms. Terms such as 16-bit, CD quality, and MIDI port are just a few. Concepts such as

sampling and digital-to-audio conversion (DAC) are often sprinkled throughout stories about new sound products. You've already learned about some of these terms and concepts; the following sections describe many others.

The Nature of Sound

To understand an audio adapter, you have to understand the nature of sound. Every sound is produced by vibrations that compress air or other substances. These sound waves travel in all directions, expanding in balloon-like fashion from the source of the sound. When these waves reach your ear, they cause vibrations that you perceive as sound.

Two of the basic properties of any sound are its pitch and its intensity.

Pitch is the rate at which vibrations are produced. It is measured in the number of hertz (Hz), or cycles per second. One cycle is a complete vibration back and forth. The number of Hz is the frequency of the tone; the higher the frequency, the higher the pitch.

Humans cannot hear all possible frequencies. Very few people can hear sounds with frequencies less than 16Hz or greater than about 20KHz (kilohertz; 1KHz equals 1,000Hz). In fact, the lowest note on a piano has a frequency of 27Hz, and the highest note a little more than 4KHz. Frequency-modulation (FM) radio stations can broadcast notes with frequencies as high as 15KHz.

The amazing compression ratios possible with MP3 files, compared to regular CD-quality WAV files, is due in part to the discarding of sound frequencies that are higher or lower than normal hearing range during the ripping process.

The intensity of a sound is called its *amplitude*. This intensity determines the sound's volume and depends on the strength of the vibrations producing the sound. A piano string, for example, vibrates gently when the key is struck softly. The string swings back and forth in a narrow arc, and the tone it sends out is soft. If the key is struck more forcefully, however, the string swings back and forth in a wider arc, producing a greater amplitude and a greater volume. The loudness of sounds is measured in decibels (db). The rustle of leaves is rated at 20db, average street noise at 70db, and nearby thunder at 120db.

Game Standards

Most audio adapters emulate some version of the Sound Blaster, by Creative Labs, which is the entertainment audio standard for DOS-based game and educational programs.

To hear sounds in most DOS games, you must configure the game by selecting one of the audio adapter drivers included with the program. If you plan to play the game through MS-DOS mode (from Windows), you might be able to run the game directly from its icon, or you might need to run a DOS-compatibility driver first. Emulating the Sound Blaster with a PCI-based sound card is difficult because PCI cards don't use separate DMA channels the way that ISA cards and motherboard resources do. DMA support is vital to achieve a high degree of compatibility with software written for the older Sound Blaster Pro or Sound Blaster 16 cards.

DMA Emulation for PCI-based Sound Cards

There are four methods used by PCI-based sound cards to emulate Sound Blaster at the DMA hardware level demanded by older DOS and some early Windows games:

- DDMA (Distributed DMA)
- TDMA (Transparent DMA)
- PC/PCI interface
- TSR (memory-resident) Utility Programs

Distributed DMA and Transparent DMA

Distributed DMA and Transparent DMA are similar methods for converting calls to the 8237 DMA controller (no longer present on PCI-based motherboards) into calls to a “master DMA central resource,” which converts the signals into a form compatible with the way that PCI-based systems handle DMA transfers. No external connector is required for these features.

PC/PCI Interface

Some PCI-based sound cards support a special feature found on some recent motherboards: the PC/PCI connector. A narrow ribbon cable runs from sound cards to the motherboard to provide SB-type DMA support for these cards. This method is preferred by Intel, and is implemented on many of their recent Pentium II/Celeron family motherboards.

All these methods require that the feature be built into both the motherboard and the sound card. Many recent PCI-based sound cards support all three of these features, easing the issue of finding a match between your motherboard and your sound card’s method of emulating the Sound Blaster.

SB Emulation TSR Utility

This method is used by many of the early PCI-based sound cards designed before the hardware-based methods listed earlier and is still often used. This method, unlike the others listed earlier, requires the user to load a TSR (Terminate and Stay Resident) program into RAM before starting the DOS-based game or educational program.

This method is the cheapest and easiest for sound card designers, but is the most difficult for sound card users to get working correctly. Depending on the card, you might

- Be required to run your DOS-based game in a “DOS box” (DOS session) if you don’t want to load the TSR driver into memory first
- Need to create a batch file to start the emulation program and then start the game
- Have difficulties getting some game software to recognize your sound card with automatic detection
- Not be able to use the sound card with a particular game, even if you use manual configuration to set up the sound card emulation

As this section indicates, it can be difficult for many of today’s Windows-oriented PCI-based sound cards to emulate Sound Blaster at the DMA hardware level demanded by many older

games. So, don't discard that ancient SB Pro or SB 16. You might want to leave it installed as long as you have DOS-based games and an available ISA slot. But, if your PCI-based sound card works with your older game or educational programs, you can safely set the ISA card aside. Since many of the new systems have only one or even no ISA slots, avoiding the use of an ISA sound card is a good idea if you don't absolutely need it.

Older Windows-based games will work with virtually any Windows-supported sound card. For most modern Windows-based games, for best sound quality and features, check to see whether the card is supported by Microsoft's DirectSound3D API (part of DirectX), Aureal's A3D 2.0 Positional Audio API, or Creative Labs Sound Blaster Live! standards, depending on what the game uses for its sound APIs.

The ideal combination for a versatile sound card will be one that supports Sound Blaster Pro or 16 without TSR drivers and is supported by DirectX and at least one of the third-party game APIs. Most new and recent games are now being written for the Windows 9x or Me operating systems, which eliminates the problem of audio adapter compatibility. In Windows 9x/Me, you install the driver in the operating system, and any application can take advantage of it. As long as you have a Windows 9x/Me driver for your adapter, you can run any game designed for the OS, although some games will provide enhanced sound if the card also supports the audio APIs listed previously.

Note

Using Windows 9x/Me software also means that the hardware settings used by your sound card (see the following section) need no longer match the traditional Sound Blaster defaults when running a game in a DOS box and under Windows. Legacy applications that run in real-mode DOS will still need to use the legacy defaults. Overall, Windows makes configuring today's crowded systems much easier than it was in the past.

The latest games support 3D standards such as Sound Blaster Live! and Aureal's A3D technology as well as Microsoft's DirectX/Direct Sound 3D.

Evaluating the Quality of Your Audio Adapter

The quality of an audio adapter is often measured by three criteria: frequency response (or range), total harmonic distortion, and signal-to-noise ratio.

The frequency response of an audio adapter is the range in which an audio system can record or play at a constant and audible amplitude level. Many cards support 30Hz to 20KHz. The wider the spread, the better the adapter.

The total harmonic distortion measures an audio adapter's linearity and the straightness of a frequency response curve. In layman's terms, the harmonic distortion is a measure of accurate sound reproduction. Any nonlinear elements cause distortion in the form of harmonics. The smaller the percentage of distortion, the better. This harmonic distortion factor might make the difference between cards that use the same audio chipset. Cards with cheaper components might have greater distortion, making them produce poorer quality sound.

The signal-to-noise ratio (S/N or SNR) measures the strength of the sound signal relative to background noise ("hiss"). The higher the number (measured in decibels), the better the sound quality.

These factors affect all types of audio adapter use, from WAV file playback to speech recognition. Keep in mind that low-quality microphones and speakers can degrade the performance of a high-quality sound card.

Sampling

With an audio adapter, a PC can record waveform audio. Waveform audio (also known as sampled or digitized sound) uses the PC as a recording device (like a tape recorder). Small computer chips built into the adapter, called analog-to-digital converters (ADCs), convert analog sound waves into digital bits that the computer can understand. Likewise, digital-to-analog converters (DACs) convert the recorded sounds to an audible analog format.

Sampling is the process of turning the original analog sound waves (see Figure 20.2) into digital (binary) signals that the computer can save and later replay. The system samples the sound by taking snapshots of its frequency and amplitude at regular intervals. For example, at time X the sound might be measured with an amplitude of Y. The higher (or more frequent) the sample rate, the more accurate the digital sound replicates its real-life source is and the larger the amount of disk space needed to store it is.

Figure 20.2 Sampling turns a changing sound wave into measurable digital values.

8-Bit Versus 16-Bit

The original MPC specifications required audio adapters to provide 8-bit sound. This doesn't mean the audio adapter must fit into an 8-bit instead of a 16-bit expansion slot. Rather, 8-bit audio means that the adapter uses eight bits to digitize each sound sample. This translates into 256 (2^8) possible digital values to which the sample can be pegged (less quality than the 65,536 values possible with a 16-bit sound card). Generally, 8-bit audio is adequate for recorded speech, whereas 16-bit sound is best for the demands of music. Figure 20.3 shows the difference between 8- and 16-bit sound.

Figure 20.3 16-bit resolution provides more accurate sound reproduction than 8-bit resolution.

Many of the older audio adapters did only 8-bit sound reproduction. Today, all sound cards offer 16-bit reproduction, which offers very high resolution.

Besides resolution, the sampling rate or frequency determines how often the audio adapter measures the level of the sound being recorded or played back. Basically, you have to sample at about two times the highest frequency you want to produce, plus an extra 10 percent to keep out unwanted signals. Humans can hear up to 20,000 cycles per second, or 20KHz. If you double this number and add 10 percent, you get a 44.1KHz sampling rate, the same sampling rate used by high-fidelity audio CDs.

Sound recorded at the telephone-quality rate of 11KHz (capturing 11,000 samples per second) is fuzzier than sound sampled at the radio quality rate of 22KHz. A sound sampled in 16-bit stereo (two channel) at 44KHz (CD-audio quality) requires as much as 10.5MB per minute of disk space. The same sound sample in 8-bit mono (single channel) at 11KHz takes 1/16th the space.

Remember that for best use of your disk space (and to improve Web download times for online sounds), you should match the sound quality to the type of sound you're recording.

You can experiment with the effects of different sampling rates by recording sound with the Windows Sound Recorder or a third-party application set to CD-quality sound. Save the sound and play it back at that highest quality setting. Then convert the file to a lower-quality setting. Save the sound file again with a different name. Play back the different versions, and determine the lowest-quality (and smallest file size) that you can use without serious degradation to sound quality.

Audio Adapter Features

To make an intelligent purchasing decision, you should be aware of some audio adapter basic components and the features they provide. The following sections discuss the features you should consider while evaluating audio adapters for your PC.

Connectors

Most audio adapters have the same basic connectors. These 1/8-inch minijack connectors provide the means of passing sound signals from the adapter to speakers, headphones, and stereo systems, and of receiving sound from a microphone, CD player, tape player, or stereo. The four types of connectors your audio adapter should have at a minimum are shown in Figure 20.4.

Note: Most sound cards color code the connectors as indicated.

Figure 20.4 The basic input and output connectors that most audio adapters have in common.

- *Stereo line, or audio, out connector.* The line-out connector is used to send sound signals from the audio adapter to a device outside the computer. You can hook up the cables from the line-out connector to stereo speakers, a headphone set, or your stereo system. If you hook up the PC to your stereo system, you can have amplified sound. Some adapters, such as the Microsoft Windows Sound System, provide two jacks for line out. One is for the left channel of the stereo signal; the other is for the right channel. Use this connector to attach to amplified devices.
- *Stereo line, or audio, in connector.* With the line-in connector, you can record or mix sound signals from an external source, such as a stereo system or VCR, to the computer's hard disk.

- **Speaker/headphone connector.** The speaker/headphone connector is provided on most audio adapters, but not necessarily all of them. Instead, the line out (described earlier) doubles as a way to send stereo signals from the adapter to your stereo system or speakers. When the adapter provides both a speaker/headphone and a line-out connector, the speaker/headphone connector provides an amplified signal that can power your headphones or small bookshelf speakers. Most adapters can provide up to four watts of power to drive your speakers. The signals that the adapter sends through the line-out connector are not amplified. The line-out connector generally provides better sound reproduction because it relies on the external amplifier built into your stereo system or speakers, which is typically more powerful than the small amplifier on the audio adapter.

Note

If you have only a single speaker/line-out connector, you need to carefully adjust your mixer volume control and the volume control on your amplified speakers to find the best-quality sound. Don't use powered speakers with an already-amplified sound if you can avoid it.

- **Microphone, or mono, in connector.** The mono-in connector is used to connect a microphone for recording your voice or other sounds to disk. This microphone jack records in mono, not in stereo, and is therefore not suitable for high-quality music recordings. Many audio adapters cards use Automatic Gain Control (AGC) to improve recordings. This feature adjusts the recording levels on-the-fly. A 600–10,000ohm dynamic or condenser microphone works best with this jack. Some inexpensive audio adapters use the line-in connector instead of a separate microphone jack.
- **Joystick connector.** The joystick connector is a 15-pin, D-shaped connector that can connect to any standard joystick or game controller. Sometimes the joystick port can accommodate two joysticks if you purchase an optional Y-adapter. Many computers already contain a joystick port as part of a multifunction I/O circuit on the motherboard or an expansion card. If this is the case, you must note which port your operating system or application is configured to use when connecting the game controller.
- **MIDI connector.** Audio adapters typically use the same joystick port as their MIDI connector. Two of the pins in the connector are designed to carry signals to and from a MIDI device, such as an electronic keyboard. In most cases, you must purchase a separate MIDI connector from the audio adapter manufacturer that plugs in to the joystick port and contains the two round, five-pin DIN connectors used by MIDI devices, plus a connector for a joystick. Because their signals use separate pins, you can connect the joystick and a MIDI device at the same time. You need this connector only if you plan to connect your PC to external MIDI devices. You can still play the MIDI files found on many Web sites by using the audio adapter's internal synthesizer.

Note

Many recent systems with onboard audio lack the joystick/MIDI connector, but you can use digital game controllers that feature a game port or USB connector to attach your game controllers to the USB port. And, as mentioned earlier, you can also attach MIDI devices through the same USB connector with a suitable interface box.

- **Internal CD-audio connector.** Most audio adapters have an internal four-pin connector that you can use to plug an internal CD-ROM drive directly into the adapter, using a small round cable. This connection enables you to channel audio signals from the CD-ROM directly to the audio adapter, so you can play the sound through the computer's speakers.

Note that this connector is different from the CD-ROM controller connector found on some audio adapters. This connector does not carry data from the CD-ROM to the system bus; it only provides the CD-ROM drive with direct audio access to the speakers. If your adapter lacks this connector, you can still play CD audio through the computer speakers by connecting the CD-ROM drive's headphone jack to the audio adapter's line-in jack with an external cable.

Tip

The line-in, line-out, and speaker connectors on an audio adapter all use the same 1/8-inch minijack socket. The three jacks are usually labeled, but when setting up a computer on or under a desk, these labels on the back of the PC can be difficult to read. One of the most common reasons why a PC fails to produce any sound is that the speakers are plugged into the wrong socket.

To avoid this problem, many consumer-oriented systems color-code microphone and speaker cables and the corresponding connections on the sound card. If you replace the color-coded OEM sound product, add labels if the replacements are not color-coded or use a different color code than the original products.

Before the PC99 design guide color standards were introduced, red was used for Mic, green for Line-Out, blue for Line-In, and black for Amplified (Speaker)-Out by most vendors who color-coded their audio connectors. To see the PC99 Design Guide color-coding, which uses primarily pastel colors, go to www.pcdesguide.com/documents/pc99icons.htm.

Connectors for Advanced Features

Many of the newest sound cards are designed for advanced gaming, DVD audio playback, and sound production uses, and have additional connectors.

For example, the Sound Blaster Live! CT4620 card (used in all SBLive! versions except the low-cost Value edition) offers two methods for adding extra ports to the card: the CT4660 module, which uses a PCI slot, and the Live! Drive, which fits into an empty 5 1/4-inch drive bay. Figure 20.5 shows the CT4620 and CT4660 sound cards, whereas Figure 20.6 shows the Live! Drive.

Additional connectors found on modern sound cards include the following:

- *MIDI in and MIDI out.* Some advanced sound cards don't require you to convert the game port (joystick port) to MIDI interfacing by offering these ports on a separate external connector. This permits you to use a joystick and have an external MIDI device connected at the same time. Typical location: external device.
- *SPDIF (a.k.a. SP/DIF) in and SPDIF out.* The Sony/Philips Digital Interface receives digital audio signals direct from compatible devices without converting them to analog format first. Typical location: external device. SPDIF interfaces are also referred to by some vendors as "Dolby Digital" interfaces.
- *CD SPDIF.* Connects compatible CD-ROM drives with SPDIF interfacing to the digital input of the sound card. Typical location: side of audio card.
- *TAD in.* Connects modems with Telephone Answering Device support to the sound card for sound processing of voice messages. Typical location: side of audio card.
- *Digital DIN out.* This supports multi-speaker digital speaker systems. Typical location: external device.

- *Aux in*. Provides input for other sound sources such as a TV tuner card. Typical location: side of audio card.
- *I2S in*. This allows the sound card to accept digital audio input from an external source, such as two-channel decoded AC-3 from DVD decoders and MPEG-2 Zoom Video. Typical location: side of audio card.

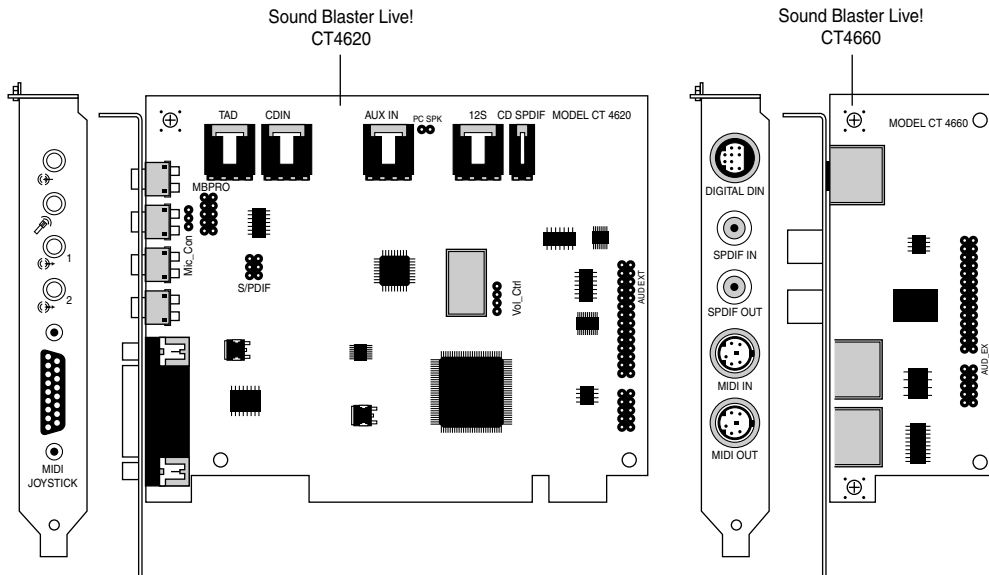

Figure 20.5 These two Sound Blaster Live! sound cards include many special input/output connectors.

Figure 20.6 The SBLive! Drive connects to the sound card through a ribbon cable (not shown).

Figure 20.7 shows a Diamond Monster card with connectors common on today's 3D sound cards.

Figure 20.7 The Diamond Monster Sound MX400's rear bracket (left), featuring a typical set of connectors for a mid-range modern 3D sound card. From the top, the SPDIF digital audio jack (RCA plug), front speaker, rear speaker, line in, and microphone jacks (all mini-plug) are visible. At the bottom is the typical 15-pin joystick port. The right-hand view shows the entire card in profile.

Volume Control

Some audio adapters include a thumbwheel volume control next to the input/output jacks, although sophisticated sound cards have no room for it. This control is usually redundant, as the operating system or the software included with the adapter typically provides a combination of keys or a visual slider control that you can use to adjust the volume. In fact, the volume wheel can be troublesome; if you aren't aware of its existence and it is turned all the way down, you might be puzzled by the adapter's failure to produce sufficient sound.

If the PC speakers are amplified, remember to check that the power is on and the volume control on the speakers is turned up.

MIDI Support Features

At one time, when evaluating audio adapters, you had to decide whether to buy a monophonic or stereophonic card. Today, virtually all audio adapters are stereophonic.

Stereophonic cards produce many voices concurrently and from two different sources. A voice is a single sound produced by the adapter. A string quartet uses four voices, one for each instrument, whereas a polyphonic instrument such as a piano requires one voice for each note of a chord. Thus, to fully reproduce the capabilities of a pianist requires ten voices, one for each finger. The more voices an audio adapter is capable of producing, the better the sound fidelity. The best audio adapters on the market today can produce up to 1024 simultaneous voices.

Most of the audio adapters that use FM synthesis to imitate musical instruments have used synthesizer chips developed by Yamaha. Older and less-expensive adapters use the 11-voice YM3812

or OPL2 chip. Better models use the stereophonic 20-voice YMF262 or OPL3 chip, but FM synthesis is rapidly being replaced by wavetable, even on low-priced audio adapters.

Imitated musical instruments are not as impressive as the real thing. Wavetable audio adapters use digital recordings of real instruments and sound effects. Often, several megabytes of these sound clips are embedded in ROM chips on the card. For example, many sound cards use chipsets from Ensoniq or Yamaha that perform wavetable synthesis of musical instruments. Instead of synthesizing the sound of a trombone playing a D flat, these chipsets access a digitized sample of an actual trombone playing that note.

The FM synthesis-versus-wavetable debate is of limited interest if you primarily use an audio adapter for DOS game play or for business audio. However, if you are a music enthusiast or work with MIDI, you'll want the best wavetable card that fits your price range.

Note

To enhance the MIDI capabilities of Sound Blaster and compatible adapters that use FM synthesis, several daughtercards have been developed.

These cards replaced the FM synthesis with wavetable output for MIDI files, greatly increasing the MIDI playback quality. The pioneer was the Creative Labs WaveBlaster, but a popular alternative was the Yamaha DB50XG, still available from some sources for about \$80. These cards provided support for hundreds of digital musical instrument samples, but recent developments and huge price cuts on PCI-based wavetable-equipped sound cards have made these daughtercards largely obsolete.

If your sound card is one of the low-priced PCI models that offers only 32 voices, check with your vendor for a software upgrade to a higher number for better MIDI reproduction. All Ensoniq-based 32-voice sound cards from any OEM vendor can be upgraded to 64 voices through software available at Ensoniq's Web site: www.ensoniq.com/audiopci.html. You should also consider replacing your sound card with a newer model, since many models now on the market support more than 500 simultaneous voices, and can be purchased for around \$100.

Data Compression

Most sound cards today can easily produce CD-quality audio, which is sampled at 44.1KHz. At this rate, recorded files (even of your own voice) can consume over 10MB for every minute of recording. To counter this demand for disk space, many audio adapters include their own data-compression capability. For example, the Sound Blaster ASP 16 includes on-the-fly compression of sound files in ratios of 2:1, 3:1, or 4:1.

Some manufacturers of audio adapters use an algorithm called Adaptive Differential Pulse Code Modulation (ADPCM) compression to reduce file size by more than 50 percent. However, a simple fact of audio technology is that when you use such compression, you lose sound quality.

Because it degrades sound quality, there is no standard for the use of ADPCM. Creative Labs uses a proprietary hardware approach, whereas Microsoft is promoting the Business Audio ADPCM design, developed with Compaq.

The most popular compression standard is the Motion Pictures Experts Group (MPEG) standard, which works with both audio and video compression and is gaining support in the non-PC world

from products such as the new crop of DVD players now hitting the market. MPEG by itself provides a potential compression ratio of 30:1, and largely because of this, full-motion-video MPEG DVD and CD-ROM titles are now available. The popular MP3 sound compression scheme is an MPEG format, and it can be played back on the latest versions of the Windows 9x Media Player, as well as by MP3-only player programs.

Multipurpose Digital Signal Processors

Many audio adapters use digital signal processors (DSPs) to add intelligence to the adapter, freeing the system processor from work-intensive tasks, such as filtering noise from recordings or compressing audio on-the-fly.

The Sound Blaster Live!'s EMU10K1 programmable DSP, for example, supports hardware sound acceleration needed by the latest version of Microsoft DirectX/DirectSound 3D, which allows multiple sounds to be played at the same time to synchronize with the onscreen action in a video game. The DSP can be upgraded with software downloads to accommodate more simultaneous audio streams. IBM uses its DSP to add a fax modem and digital answering machine to its WindSurfer Communications Adapter, found in many of its own Aptiva computers, and similar adapters sold as OEM products found in other brands of computers.

The widespread use of DSPs in better-quality audio adapters allows you to upgrade them through software instead of the time-consuming, expensive process of physical replacement.

CD-ROM Connectors

A few older audio adapters double as a CD-ROM controller, or interface, card. Before the EIDE interface made the CD-ROM a ubiquitous PC component, connecting the drive to the audio adapter was an inexpensive means of adding multimedia capabilities to a system. Although some adapters provide a SCSI port that you can theoretically use to connect any SCSI device, others used a proprietary connection that accommodates only a select few CD-ROM drives that support the same interface. The proprietary connectors once used by early Creative Labs Sound Blaster multimedia upgrade kits have long been obsolete, and cannot be used with today's standard IDE and SCSI-interface CD-ROM drives.

If you're seeking to add both an audio adapter and a CD-ROM drive to an existing system, check for an unused 40-pin IDE connector on an IDE interface cable. If your system has an unused connector, any standard IDE (ATAPI) CD-ROM can be connected there. You can then buy a sound card and IDE CD-ROM drive as a kit or separately. If your sound card has an IDE port built in, disable it to keep it from interfering with the IDE ports on your system board. This might require adjusting jumper blocks on the board, running setup software, or adding a special command added to the `CONFIG.SYS` statement for the board during system startup.

Note

In my experience, you'll usually have better, faster choices if you purchase the sound card, CD-ROM drive, and speakers separately, rather than as a kit. The only reason to purchase a multimedia kit today is to have a single source for multimedia technical support because the sound cards and CD-ROM drive typically found in kits are often low-end devices with limited features.

Although an integrated audio/CD-ROM controller can be a quick and easy multimedia solution for older systems, I generally recommend that users connect the CD-ROM through a standard EIDE or SCSI interface and avoid the CD-ROM connector on the audio adapter. All new and recent systems include an EIDE interface, and a SCSI adapter enables you to attach other devices to the same interface, such as hard disks, tape drives, and scanners. The software driver support and performance of a dedicated driver interface will be much better than those provided by audio/CD-ROM combination cards, in part because EIDE support on the motherboard allows compatible CD-ROM drives to use 32-bit data transfers, run at PCI speeds, and use advanced features such as PIO/UDMA and bus-mastering for better speed and lower CPU utilization.

◀◀ For more information on adding a CD-ROM drive to your system, see Chapter 13, p. 745.

Sound Drivers

As with many PC components, a software driver provides a vital link between an audio adapter and the application or operating system that uses it. Operating systems such as Windows 9x, Windows 2000, and Windows NT include a large library of drivers for most of the audio adapters on the market. In most cases, these drivers are written by the manufacturer of the audio adapter and only distributed by Microsoft. You might find that the drivers that ship with the adapter are more recent than those included with the operating system. As always, the best place to find the most recent drivers for a piece of hardware is the manufacturer's own Web site or other online service.

DOS applications do not usually include as wide a range of driver support as an operating system, but you should find that most games and other programs support the Sound Blaster adapters. If you are careful to buy an adapter that is compatible with Sound Blaster, you should have no trouble finding driver support for all your applications. It's preferable to have this support through hardware rather than software. If your game program locks up when you try to detect the sound card during configuration, set the card type and settings manually. This is often a symptom of inadequate emulation for Sound Blaster by a third-party card. If you have problems, check the game developer or audio adapter's Web site for patches or workarounds. Remember that with many recent audio adapters, you might need to load a Sound Blaster emulation program into RAM before you start the game.

Choosing an Audio Adapter

What are some key features to consider in a sound card? Although some aspects are subjective, the following sections describe some key buying points.

Consumer or Producer?

Different users require varying degrees of performance and different features from an audio adapter. One simple way of classifying audio users is to divide them into business consumers, game consumers, and producers of sound.

When Basic Audio Support Is Good Enough

Many users need only basic audio capabilities. They want to listen to audio CDs as they work and hear sound effects and music when they play a few games or view Web sites. These are business

consumers of sound. They obtain audio from outside sources such as CD-ROMs and the Internet and play them over their speakers. For this type of user, a modest audio adapter is all that is needed. The adapter should provide 16-bit audio, but an FM synthesizer might be sufficient for sound production. Users who want more realistic MIDI music should consider the vast array of low-cost wavetable cards on the market, but they don't need to purchase the top-of-the-line models. Users of basic audio capabilities will also be satisfied with the integrated audio found in many inexpensive desktop computers and motherboards.

Games and Sound Cards

A game consumer who lives in a "dangerous" 3D world of pixelated enemies, desktop flights around the world, or console Grand Prix racing is a far more demanding customer. The increasing realism of all types of games has changed both video and audio standards. Mere stereo playback isn't good enough for hardcore gamers who want to be able to hear monsters behind them or feel the impact of a car crash. These users should choose sound cards with support for four or more speakers and some form of "directional sound," such as Creative Labs's EAX technology used in the Sound Blaster Live! or Aureal's A3D technology. Many sound cards feature support for both standards, either through direct hardware support or through software emulation and conversion. For example, Aureal's Web site (www.aureal.com) allows users of non-A3D cards to download a driver package called A2D that allows these cards to play the audio from A3D-optimized games. As with 3D video cards (see Chapter 15, "Video Hardware"), the 3D audio standards supported by these users' favorite games will help them determine which cards to choose from.

The underlying issue common to all 3D sound cards is that of positional audio, which refers to adjusting features such as reverberation, balance, and apparent sound "location" to produce the illusion of sound coming from in front of, beside, or even behind the user. One very important element in positional audio is HRTF (Head Related Transfer Function), which refers to how the shape of the ear and the angle of the listener's head changes the perception of sound. Because HRTF factors mean that a "realistic" sound at one listener's head angle might sound artificial when the listener turns to one side or the other, the addition of multiple speakers that "surround" the user, as well as sophisticated sound algorithms that add controlled reverberation to the mix, are making computer-based sound more and more real.

A second important issue for game players is how the sound cards produce 3D audio. As with 3D video, there are two major methods:

- Host-based processing
- Processing on the audio adapter

Some 3D audio cards perform some or all of the processing necessary for 3D using the host's CPU, whereas others use a powerful DSP which performs the processing on the audio adapter itself. Cards which use host-based processing for 3D will cause major drops in frame rate (frames per second of animation displayed on screen by a 3D game) when 3D sound is enabled, whereas cards with their own 3D audio processor onboard have little change in frame rate whether 3D sound is enabled or disabled.

A good rule of thumb for realistic gaming is to have an overall average frame rate of 30fps (frames per second). With fast CPUs such as the Pentium III 550MHz, this is easy to achieve with

any recent 3D card, but gamers using slower CPUs such as the Celeron 300A (running at 300MHz) will find that cards that use the host CPU for some of the 3D processing will have frame rates that fall below the desired average of 30fps, making for clumsy game play. To see the effect of enabling 3D sound on the speed of popular games, you can use the built-in frame-rate tracking feature found in many games, or check online game-oriented hardware review sources such as www.anandtech.com.

As with 3D video, the main users of 3D sound are game developers, but business uses for ultra-realistic sound will no doubt follow.

Sound Producers

Producers are people who intend to create their own sound files. These can range from casual business users recording low-fidelity voice annotations to professional musicians and MIDI maniacs. These users need an adapter that can perform as much of the audio processing as possible itself, so as not to place an additional burden on the system processor. Adapters that use DSPs to perform compression and other tasks are highly recommended in this case. Musicians will certainly want an adapter with as many voices as possible and a wavetable synthesizer. Adapters with expandable memory arrays and the capability to create and modify custom wavetables are also preferable. Many of the best sound cards for “hardcore gamer” will also be suitable for sound producers by adding the appropriate sound-editing programs such as Sound Forge and by equipping the card with the appropriate connectors for SPDIF digital audio and MIDI interfaces. The Sound Blaster Live! Platinum Edition features a drive bay–mounted external interface for these features. This accessory can also be retrofitted to other Sound Blaster Live! models.

Most other audio cards designed for sound production features add jacks to the traditional trio of connectors on the rear card bracket.

Compatibility

Although there are no official audio adapter standards, the popular Creative Labs Sound Blaster line has become a de facto standard. The Sound Blaster—the first widely distributed audio adapter—is supported by the greatest number of software programs, especially DOS-based programs. An audio adapter advertised as Sound Blaster-compatible should be able to run with virtually any application that supports sound. All current and recent adapters support (and exceed) the old MPC Level 2 or Level 3 specifications, enabling you to play sound files in Windows and more.

Caution

Beware of audio adapters that require special drivers to be Sound Blaster compatible if you use MS-DOS–based game or educational programs with sound support. These drivers can cause problems and will take up additional memory that otherwise would be available to your applications.

Some wavetable sound cards require you to retain your Sound Blaster card for DOS game compatibility. This wastes a slot and might also create shortages of other hardware resources. I recommend that you look for PCI-based sound cards that feature good Sound Blaster game compatibility and wavetable features in a single slot instead.

Bundled Software

A software bundle can sometimes make the difference between a good buy on an audio adapter and a great one. Audio adapters usually include several sound utilities so you can begin using your adapter right away. Some of the types of software you might receive are as follows:

- Text-to-speech conversion programs
- Applications for playing, editing, and recording audio files
- Audio CD-player programs
- Stereo sound-mixer programs
- Sequencer software, which helps you create, edit, and play back MIDI music files
- Various sound clips

Some vendors sell the same basic sound card in different packages, distinguished primarily by their software bundles. Make the best deal for your needs by purchasing the card with the most suitable software bundle for your needs.

Audio Adapter Installation (Overview)

Installing an audio adapter is no more intimidating than installing an internal modem or a video adapter, especially if you are using Windows 9x and the adapter conforms to the Plug-and-Play specification, as most do. Typically, you follow these steps:

1. Open your computer.
2. Configure your sound card (if it isn't plug-and-play).
3. Insert the audio adapter into a bus slot and attach the CD-ROM drive to the CD Audio In connector, if present.
4. Close your computer.
5. Boot the system, causing Windows 9x, Me, or 2000 to locate and install the driver for the adapter (or install the sound card software for non-plug-and-play devices).
6. Attach your speakers and other sound accessories.

Tip

When Windows (9x/Me/2000) detects new hardware, it might ask you to reboot after finding a single new item. Because most sound cards today contain multiple features (Sound Blaster compatibility, MPU-401 MIDI compatibility, FM synthesis, digital signal processor, and so on), *don't* reboot when directed to after the drivers for the first item are loaded. Click No, and you'll often see the system find additional hardware items. Why? A single add-on card might contain multiple hardware components. Reboot manually, using Start, Shutdown, Restart, only after the Windows desktop has been displayed.

Installing the Sound Card (Detailed Procedure)

After your computer is open, you can install the audio adapter. A few low-cost adapters today still use a 16-bit ISA slot, although most adapters now use the PCI bus. The migration from ISA to PCI

in the audio-adaptor industry has been slower than that for other components, such as video-display adapters. The first PCI audio cards were much more expensive than standard commercial models and were intended for professional applications, but most manufacturers are now marketing low-cost PCI audio adapters for the home PC market. PCI audio adapters use fewer hardware resources, feature a lower CPU-utilization rate, and provide better support for advanced 3D gaming APIs. If you still want to use an ISA-bus audio card, make sure there's an open slot for it. Most recent systems have only one or two ISA slots.

If you have several empty bus slots from which to choose, install the audio adapter in the slot that is as far away as possible from the other cards in the computer. This reduces any possible electromagnetic interference; that is, it reduces stray radio signals from one card that might affect the sound card. The analog components on audio adapters are highly susceptible to interference, and even though they are shielded, they should be protected as well as possible. Next, you must remove the screw that holds the metal cover over the empty expansion slot you've chosen. Remove your audio adapter from its protective packaging. When you open the bag, carefully grab the card by its metal bracket and edges. Do not touch any of the components on the card. Any static electricity you might transmit can damage the card. Also, do not touch the gold-edge connectors. You might want to invest in a grounding wrist strap, which continually drains you of static build-up as you work on your computer.

If your adapter is not Plug-and-Play, you might have to set jumpers or DIP switches to configure the adapter to use the appropriate hardware resources in your computer. For example, you might have to adjust an IRQ or DMA setting or turn off the adapter's joystick port because your joystick is already connected to your PC elsewhere. See the instructions that came with your audio adapter. Use the Windows 9x/Me/2000 Device Manager to see existing hardware settings, and compare them to the sound card's default settings. Use the default settings if possible. If you're installing a Plug-and-Play sound card into an older system that doesn't have a Plug-and-Play BIOS, you'll also install a program called an "enumerator" that runs early in the startup process to set the card.

◀◀ See "Plug-and-Play BIOS," p. 424.

If your system has an internal CD-ROM drive with an analog audio cable, connect the audio cable to the adapter's CD Audio In connector. This connector is a four-pin connector, and is keyed so that you can't insert it improperly. Note that there is no true standard for this audio cable, so be sure that you get the right one that matches your drive and adapter. If you need to purchase one, you can find cables with multiple connectors designed for different brands of CD-ROM drives. This will allow you to play music CDs through the sound card's speakers and to use analog ripping if you want to create MP3 files from your CDs.

Many recent CD-ROM and DVD drives also have a digital audio connector, which supports a two-wire connector. Attach one end of the digital audio cable to the rear of the drive and the other end to the CD SPDIF or CD Digital Audio connector on the sound card. This allows you to perform digital ripping if you want to create MP3 files from your CDs.

Next, insert the adapter's edge connector in the bus slot, but first touch a metal object, such as the inside of the computer's cover, to drain yourself of static electricity. When the card is firmly in place, attach the screw to hold the expansion card and then reassemble your computer.

After the adapter card is installed, you can connect small speakers to the external speaker jack(s). Typically, sound cards provide four watts of power per channel to drive bookshelf speakers. If you are using speakers rated for less than four watts, do not turn up the volume on your sound card to the maximum; your speakers might burn out from the overload. You'll get better results if you plug your sound card into powered speakers—that is, speakers with built-in amplifiers. If your sound card supports a four-speaker system, check the documentation to see which jack is used for the front speakers, and which for the rear speakers. To use the rear speakers for 3D audio, you might need to run a utility program supplied with the sound card.

Tip

If you have powered speakers but don't have batteries in them or have them connected to an AC adapter, don't turn on the speakers! Turning on the speakers without power will prevent you from hearing anything at all. Leave the speakers turned off and use the volume control built into your sound card's mixer software instead. Powered speakers sound better, but most small models can run without power in an emergency.

Some computer power supplies feature small jacks to provide power for computer speakers.

When the sound card installation is finished, you should have a speaker icon in the Windows 9x System Tray. If the speaker icon (indicating the Volume Control) isn't visible, you can install it through the Control Panel's Add/Remove Programs icon. Choose the Windows Setup tab and open the Multimedia section. Put a check mark next to Volume Control and insert the Windows 9x or 2000 CD-ROM or diskette if requested to complete the installation.

Use the Volume Control to make sure your speakers are receiving a sound signal. The mixer sometimes defaults to Mute. You can usually adjust volume separately for wave (WAV) files, MIDI, microphone, and other components.

Using Your Stereo Instead of Speakers

Another alternative is to patch your sound card into your stereo system for greatly amplified sound. Check the plugs and jacks at both ends of the connection. Most stereos use pin plugs—also called RCA or phono plugs—for input. Although pin plugs are standard on some sound cards, most use miniature 1/8-inch phono plugs, which require an adapter when connecting to your stereo system. From Radio Shack, for example, you can purchase an audio cable that provides a stereo 1/8-inch miniplug on one end and phono plugs on the other (Cat. No. 42-2481A).

Make sure that you get stereo, not mono, plugs, unless your sound card supports only mono. To ensure that you have enough cable to reach from the back of your PC to your stereo system, get a six-foot long cable.

Hooking up your stereo to an audio adapter is a matter of sliding the plugs into the proper jacks. If your audio adapter gives you a choice of outputs—speaker/headphone and stereo line-out—choose the stereo line-out jack for the connection. This will give you the best sound quality because the signals from the stereo line-out jack are not amplified. The amplification is best left to your stereo system.

Connect this cable output from your audio adapter to the auxiliary input of your stereo receiver, preamp, or integrated amplifier. If your stereo doesn't have an auxiliary input, other input

options include—in order of preference—tuner, CD, or Tape 2. (Do not use phono inputs, however, because the level of the signals will be uneven.) You can connect the cable's single stereo miniplug to the sound card's stereo line-out jack, for example, and then connect the two RCA phono plugs to the stereo's Tape/VCR 2 Playback jacks.

The first time you use your audio adapter with a stereo system, turn down the volume on your receiver to prevent blown speakers. Barely turn up the volume control and then select the proper input (such as Tape/VCR 2) on your stereo receiver. Finally, start your PC. Never increase the volume to more than three-fourths of the way up. Any higher and the sound might become distorted.

Note

If your stereo speakers are not magnetically shielded, you might hear a lot of crackling if they are placed close to your computer. Try moving them away from the computer, or use magnetically shielded speakers.

Tricks for Using the Tape Monitor Circuit of Your Stereo

Your receiver might be equipped with something called a tape monitor. This outputs the sound coming from the tuner, tape, or CD to the tape-out port on the back, and it then expects the sound to come back in on the tape-in port. These ports, in conjunction with the line-in and line-out ports on your audio adapter, enable you to play computer sound and the radio through the same set of speakers.

Here's how you do it:

1. Turn off the tape monitor circuit on your receiver.
2. Turn down all the controls on the sound card's mixer application.
3. Connect the receiver's tape-out ports to the audio adapter's line-in port.
4. Connect the audio adapter's line-out port to the receiver's tape-in ports.
5. Turn on the receiver, select some music, and set the volume to a medium level.
6. Turn on the tape monitor circuit.
7. Slowly adjust the line-in and main-out sliders in the audio adapter's mixer application until the sound level is about the same as before.
8. Disengage and re-engage the tape monitor circuit while adjusting the output of the audio adapter so that the sound level is the same regardless of whether the tape monitor circuit is engaged.
9. Start playing a WAV file.
10. Slowly adjust up the volume slider for the WAV file in the audio adapter's mixer application until it plays at a level (slightly above or below the receiver) that is comfortable.

Now you can get sounds from your computer and the radio through the receiver's speakers.

Different connectors might be needed if you have digital surround speakers and newer PCI-based sound cards. Check your speakers and sound card before you start this project.

Troubleshooting Sound Card Problems

To operate, an audio adapter needs hardware resources, such as IRQ numbers, a base I/O address, and DMA channels that don't conflict with other devices. Most adapters come preconfigured to use the standard Sound Blaster resources that have come to be associated with audio adapters. However, problems occasionally arise even with Plug-and-Play adapters. Troubleshooting might mean that you have to change board jumpers or switches or even reconfigure the other devices in your computer. No one said life was fair.

Hardware (Resource) Conflicts

The most common problem for audio adapters is that they conflict with other devices installed in your PC. You might notice that your audio adapter simply doesn't work (no sound effects or music), repeats the same sounds over and over, or causes your PC to freeze. This situation is called a device, or hardware, conflict. What are they fighting over? Mainly the same bus signal lines or channels (called resources) used for talking to your PC. The sources of conflict in audio adapter installations are generally threefold:

- *Interrupt Requests (IRQs)*. Hardware devices use IRQs to “interrupt” your PC's CPU and get its attention.
- *Direct Memory Access (DMA) channels*. DMA channels move information directly to your PC's memory, bypassing the system processor. DMA channels enable sound to play while your PC is doing other work.
- *Input/output (I/O) port addresses*. Your PC uses I/O port addresses to channel information between the hardware devices on your audio adapter and your PC. The addresses usually mentioned in a sound card manual are the starting or base addresses. An audio adapter has several devices on it, and each one uses a range of addresses starting with a particular base address.

Most audio adapters include installation software that analyzes your PC and attempts to notify you should any of the standard settings be in use by other devices. The Windows 9x or 2000 Device Manager (accessed from the System Control Panel) can also help you to resolve conflicts. Although these detection routines can be fairly reliable, unless a device is operating during the analysis, it might not always be detectable.

Some of the newer PCI-based sound cards and Intel-chipset motherboards might not properly support ISA-type I/O addresses used by Sound Blaster-compatible software to communicate with the card. If you have problems getting older games to work with your system, see the tips listed earlier for emulation methods, check with your sound card and system board/computer supplier for help, and check with the game developer for possible patches and workarounds.

Table 20.4 shows the default resources used by the components on a typical Sound Blaster 16 card, which uses a 16-bit ISA slot.

Table 20.4 Default Sound Blaster Resource Assignments

Device	Interrupt	I/O Ports	16-Bit DMA	8-Bit DMA
Audio	IRQ 5	220h-233h	DMA 5	DMA 1
MIDI Port	—	330h-331h	—	—
FM Synthesizer	—	388h-38Bh	—	—
Game Port	—	200h-207h	—	—

All these resources are used by a single sound card in your system. No wonder many people have conflicts and problems with audio adapter installations! In reality, working out these conflicts is not all that hard, as you shall see. You can change most of the resources that audio adapters use to alternative settings, should there be conflicts with other devices; even better, you can change the settings of the other device to eliminate the conflict. Note that some devices on the audio adapter, such as the MIDI Port, FM Synthesizer, and Game Port, do not use resources such as IRQs or DMA channels.

Compare the resource settings used by a traditional ISA sound card (in Table 20.4) to those used by a typical PCI-based sound card (in Table 20.5).

Table 20.5 Default Ensoniq PCI Resource Assignments

Device	Interrupt	I/O Ports	16-Bit DMA	8-Bit DMA
Audio	IRQ 5	DC80-DCBF	—	—
MIDI Port	(included in above configuration)			
FM Synthesizer	(included in above configuration)			
Game Port	—	200h-207h	—	—

If you don't need MS-DOS game support, the PCI card uses far fewer resources than the ISA card. However, if you are using MS-DOS games, you will need to set up a number of "virtual" IRQ, I/O port, and DMA port settings for use with those games only, as in the following figure.

When using a typical PCI-based sound card's Sound Blaster Legacy settings, you will need to verify that MS-DOS software using the Sound Blaster is set for the appropriate configuration (see Figure 20.8).

It is always best to install an audio adapter (or a notebook computer's built-in sound adapter circuits) by using the default settings whenever possible. This is mainly because of poorly written software that cannot work properly with alternative settings, even if they do not cause conflicts. In other words, if you are having a conflict with another type of adapter, modify the settings of the other device, rather than those of the audio adapter. Take this from experience; otherwise, you will have to explain to your five-year old why the new Dinosaur program you just installed does not make any sounds! This problem is primarily associated with DOS-based game programs, but some older Windows-based programs have also been unable to work with alternative hardware settings.

Figure 20.8 One advantage of PCI cards is visible here, even in emulation mode: All emulations can use the same IRQ, rather than up to three different IRQs, as would be the case with most third-party ISA cards that emulate the Sound Blaster.

Note

Some of the recent chipsets for “legacy-free” systems, such as the Intel 810 and 820 chipsets, don’t decode addresses below 1000h to the PCI bus. All the Sound Blaster I/O port addresses are well below 1000h, and thus sound card manufacturers will need to adjust driver software or use TSR programs to reroute calls to these I/O port addresses by software to the correct I/O port addresses. This design choice will not be a problem for typical Windows software that uses sound, but can cause legacy (DOS-based) applications to fail.

Resolving Resource Conflicts

The audio portion of a sound card has a default IRQ setting, but it will usually also support any of several alternative interrupts. As stated earlier, you should endeavor to leave the audio IRQ at the default setting (usually IRQ 5) and change those of other adapters where possible.

If your audio adapter is set to the same IRQ as another device in your system, you might see symptoms such as skipping, jerky sound, or system lockups.

A typical ISA-based audio adapter requires the use of two simultaneous DMA channels. These are usually split into a requirement for an 8-bit DMA and a 16-bit DMA channel. Most adapters use DMA 1 for 8-bit sound (Creative Labs calls this Low DMA), and DMA 5 for 16-bit sound (High DMA). The primary symptom of a DMA conflict in your system is that you hear no sound at all.

Note

PCI-based sound cards don’t require DMA settings unless you are using them in “legacy” mode to emulate a Sound Blaster for game support.

If your sound card is part of a multifunction card such as IBM’s Mwave series (IBM Dolphin and other models), you’ll not only need to have available hardware resources for the sound card, but

you'll also need IRQs and I/O port addresses for the card's digital signal processor (DSP) and modem serial port. These cards can be difficult to install in today's resource-starved systems.

Solving Hardware Conflicts

If you use Windows 9x/Me/2000, the Device Manager application can tell you which devices are using a particular resource. If not, you might have to manually resolve any resource conflicts you find.

The best way to manually locate a hardware conflict is to gather all the documentation for your PC and its various devices, such as the SCSI interface adapters, CD-ROM drives, and so on. This topic is discussed more completely in Chapter 16, "Serial, Parallel, and Other I/O Interfaces."

The most common causes of system resource conflicts are the following:

- SCSI host adapters
- Network interface cards
- Bus mouse adapter cards
- Serial port adapter cards for COM3: or COM4:
- Parallel port adapter cards for LPT2:
- Internal modems
- Scanner interface cards
- Game ports

If your system is not running Windows 9x/Me/2000, all of which feature built-in conflict detection, you must use other methods to find the conflict. One way to find which device is conflicting with your audio adapter is to temporarily remove all the expansion cards from your system except for the audio adapter and essential devices (such as the video adapter). Then replace each of the cards you removed, one at a time, until your audio adapter no longer works. The last card you added is the troublemaker.

Having found the card that's causing the conflict, you can either switch the settings for the device that is conflicting with your audio adapter or change the settings of the audio adapter. In either case, you will have to change the IRQ, DMA, or I/O address. To do this, you might have to either set jumpers or DIP switches on the adapter or use a configuration program supplied with the adapter to change its settings.

Game-port conflicts are common on systems that feature game ports on both a multi-I/O card or the motherboard and a game port on the sound card. Since all standard game ports use all or part of the same I/O port address range—200h to 207h—you cannot adjust one game port to a different address range. Use one of the following methods to disable the duplicate game port:

- *Disable game port in CMOS/BIOS.* If the game port is attached directly to the motherboard, check the system configuration for the port and disable it there.
- *Adjust jumper blocks on multi-I/O card.* If the game port is on a multi-I/O card, adjust jumper blocks for that port to disable the game port, or use the card's software configuration program if the card is jumperless.

- *Remove the card from the Device Manager and the System.* You can remove a plain-vanilla gameport card and use the game port on the sound card. Remove the card from the Windows 9x/2000/Me Device Manager, shut down the system, and remove the card physically.
- *Disable the Card in the Windows Device Manager.* If the port is on a PnP (Plug and Play) card, you might be able to use the Windows Device Manager to disable the port, either by selecting a configuration which doesn't use the I/O port address used by the game port (200h–207h or 201h), or by viewing the port's properties and selecting "Disable in this hardware profile".

Note

If you are using an LPT2 port card for a slow-speed device such as a dot-matrix or low-end inkjet printer, you can often free up its default IRQ 5 by disabling EPP/ECP/IEEE-1284 modes. These modes require use of an IRQ (ECP also uses a DMA channel). Reverting to standard printing will cause most LPT ports to use only I/O port addresses. This will permit you to use the port for printing and its IRQ 5 for a sound card.

Other methods include switching to a PCI-based multi-I/O or parallel port card or using a USB-to-parallel adapter for your second parallel printer or device. Either method will allow you to avoid IRQ conflicts without sacrificing printer-port speed.

Other Sound Card Problems

Like the common cold, audio adapter problems have common symptoms. Use the following sections to diagnose your problem.

No Sound

If you don't hear anything from your audio adapter, consider these solutions:

- Make sure that the audio adapter is set to use all default resources and that all other devices using these resources have been either reconfigured or removed.
- Are the speakers connected? Check that the speakers are plugged into the sound card's stereo line-out or speaker jack (not the line-in or microphone jack).
- Are the speakers stereo? Check that the plug inserted into the jack is a stereo plug, not mono.
- Are the mixer settings high enough? Many audio adapters include a sound mixer application. The mixer controls the volume settings for various sound devices, such as the microphone or the CD player. There might be separate controls for both recording and playback. Increase the master volume or speaker volume when you are in the play mode.
If the Mute option is selected in your sound mixer software, you won't hear anything.
- Use your audio adapter's setup or diagnostic software to test and adjust the volume of the adapter. Such software usually includes sample sounds used to test the adapter.
- Turn off your computer for one minute and then turn it back on. A hard reset (as opposed to pressing the Reset button or pressing Ctrl+Alt+Delete) might clear the problem.
- If your computer game lacks sound, check that it is designed to work with your audio adapter. For example, some games might require the exact settings of IRQ 7 (or IRQ 5), DMA 1, and I/O address 220 to be Sound Blaster compatible.

One-Sided Sound

If you hear sound coming from only one speaker, check out these possible causes:

- Are you using a mono plug in the stereo jack? A common mistake is to use a mono plug into the sound card's speaker or stereo-out jacks. Seen from the side, a stereo connector has two darker stripes. A mono connector has only one stripe.
- If you're using amplified speakers, are they powered on? Check the strength of the batteries or the AC adapter's connection to the electrical outlet.
- Are the speakers wired correctly? When possible, use keyed and color-coded connectors to avoid mistakes, such as those found on the Altec Lansing ACS-340 and others.
- Is the audio adapter driver loaded? Some sound cards provide only left-channel sound if the driver is not loaded correctly. Rerun your adapter's setup software or reinstall it in the operating system.
- Are both speakers set to the same volume? Some speakers use separate volume controls on each speaker. Balance them for best results. Separate speaker volume controls can be an advantage if one speaker must be further away from the user than the other.

Volume Is Low

If you can barely hear your sound card, try these solutions:

- Are the speakers plugged into the proper jack? Speakers require a higher level of drive signal than headphones. Again, adjust the volume level in your mixer application.
- Are the mixer settings too low? Again, adjust the volume level in your mixer application.
- Is the initial volume too low? If your audio adapter has an external thumbwheel volume control located on the card bracket, check to make sure that it is not turned down too low.
- Are the speakers too weak? Some speakers might need more power than your audio adapter can produce. Try other speakers or put a stereo amplifier between your sound card and speakers.

Scratchy Sound

Scratchy or static-filled sound can be caused by several different problems. Improving the sound might be as simple as rearranging your hardware components. The following list suggests possible solutions to the problem of scratchy sound:

- Is your audio adapter near other expansion cards? The adapter might be picking up electrical interference from other expansion cards inside the PC. Move the audio card to an expansion slot as far away as possible from other cards.
- An ISA-based audio adapter requires a lot of CPU attention. Frequent hard disk access can cause dropouts due to the CPU's switching between managing the sound card and the hard drive.
- Are your speakers too close to your monitor? The speakers might pick up electrical noise from your monitor. Move them farther away. Subwoofers should *never* be placed near the monitor because their powerful magnets might interfere with the picture. They should be on the floor to maximize low-frequency transmission.

- Are you using a cheaper audio adapter with an FM synthesizer? Some of the adapters that use FM synthesis instead of wavetable sound generation have very poor-quality output. Many people have been fooled into thinking they had a defective sound card, when in reality it was just a poor-quality FM synthesis card that simply does not sound good. You can test this by comparing the sound of a MIDI file (which uses the FM synthesizer) with that of a sound file such as a WAV (which doesn't). If the problem is the synthesizer, I recommend upgrading to an adapter that does wavetable synthesis so you can get the full benefit of high-quality sound.

Your Computer Won't Start

If your computer won't start at all, you might not have inserted the audio adapter completely into its slot. Turn off the PC and then press firmly on the card until it is seated correctly.

If you install an Ensoniq-based PCI sound card and get an IOS error after restarting Windows 95, the installation software should include an IOS fix-up program. You can start Windows 95 in command-prompt mode to get access to the CD-ROM to install this if needed, or it might be on one of the installation diskettes. Check the sound card's Readme file for more information.

You can use the Windows "bootlog" feature to record every event during startup; this file records which hardware drivers are loaded during startup and indicates whether the file loaded successfully, didn't load successfully, or froze the computer. See the documentation for your version of Windows for details on how to create a bootlog when needed.

Parity Errors or Other Lockups

Your computer might display a memory parity error message or simply crash. This is normally caused by resource conflicts in one of the following areas:

- IRQ (Interrupt Request)
- DMA (Direct Memory Access)
- I/O (Input/Output) ports

If other devices in your system are using the same resources as your audio adapter, crashes, lock-ups, or parity errors can result. You must ensure that multiple devices in your system do not share these resources. Follow the procedures outlined earlier in this chapter to resolve the resource conflicts.

Joystick Troubleshooting

If your joystick won't work, consider the following list of cures:

- Are you using two game ports? If you already have a game port installed in your PC, the game or joystick port provided on your audio adapter might conflict with it. Usually it is best to disable any other game ports and use the one on the audio adapter. Many of the multi-I/O or Super-I/O adapters that come in PC-compatible systems feature game ports that you should disable when you install an audio adapter.
- Is your computer too fast? Some fast computers get confused by the inexpensive game ports. During the heat of virtual combat, for example, you might find yourself flying upside

down or spiraling out of control. This is one sign that your game port is inadequate. Most of the game adapters built into audio adapters work better than the ones on the multi-I/O adapters. There are also dedicated game cards available that can work with faster computers. These game cards include software to calibrate your joystick and dual ports so that you can enjoy a game with a friend. Another solution is to run your computer at a slower speed, which on some systems is as easy as pressing some type of “deturbo” button on the case.

Advanced Features

If you are having problems playing DVD audio, MP3 files, or using SPDIF connections, make sure that

- You have enabled the hardware resources on the sound card
- You are using the correct playback program
- Your mixer has the correct volume control setting for the device
- Your cabling is correct for the device

Other Problems

Sometimes sound problems can be difficult to solve. Due to quirks and problems with the way DMA is implemented in some motherboard chipsets, there can be problems interacting with certain cards or drivers. Sometimes altering the Chipset Setup options in your CMOS settings can resolve problems. These kinds of problems can take a lot of trial and error to solve.

The PC “standard” is based loosely on the cooperation among a handful of companies. Something as simple as one vendor’s BIOS or motherboard design can make the standard non-standard.

A good way to solve problems of all types with Plug-and-Play (PnP) cards, a PnP BIOS, and a PnP operating system (Windows 9x/Me/2000) is to use the Device Manager to remove the sound card, restart the system, and allow the card’s components to be redetected. This installs a “fresh” copy of the software and reinserts Registry entries.

Speakers

Successful business presentations, multimedia applications, and MIDI work demand external high-fidelity stereo speakers. Although you can use standard stereo speakers, they are often too big to fit on or near your desk. Smaller bookshelf speakers are better.

Sound cards offer little or none of the amplification needed to drive external speakers. Although some sound cards have small four-watt amplifiers, they are not powerful enough to drive quality speakers. Also, conventional speakers sitting near your display might create magnetic interference, which can distort colors and objects onscreen or jumble the data recorded on nearby floppy disks or other magnetic media.

To solve these problems, computer speakers need to be small, efficient, and self-powered. Also, they should be provided with magnetic shielding, either in the form of added layers of insulation in the speaker cabinet or electronic cancellation of the magnetic distortion.

Caution

Although most computer speakers are magnetically shielded, do not leave recorded tapes, watches, credit cards, or floppy disks in front of the speakers for long periods of time.

Quality sound depends on quality speakers. A 16-bit audio adapter might provide better sound to computer speakers, but even an 8-bit adapter sounds good from a good speaker. Conversely, an inexpensive speaker makes both 8-bit and 16-bit adapters cards sound tinny.

There are now dozens of models of PC speakers on the market ranging from inexpensive minispeakers from Sony, Koss, and LabTech to larger self-powered models from prestigious audio companies such as Bose and Altec Lansing. Many of the higher-end speaker systems even include subwoofers to provide additional bass response. To evaluate speakers, it helps to know the jargon. Speakers are measured by three criteria:

- *Frequency response.* A measurement of the range of high and low sounds a speaker can reproduce. The ideal range is from 20Hz to 20KHz, the range of human hearing. No speaker system reproduces this range perfectly. In fact, few people hear sounds above 18KHz. An exceptional speaker might cover a range of 30Hz to 23,000Hz. Lesser models might cover only 100Hz to 20,000Hz. Frequency response is the most deceptive specification because identically rated speakers can sound completely different.
- *Total Harmonic Distortion (THD).* An expression of the amount of distortion or noise created by amplifying the signal. Simply put, distortion is the difference between the sound sent to the speaker and the sound you hear. The amount of distortion is measured in percentages. An acceptable level of distortion is less than .1 percent (one-tenth of one percent). For some CD-quality recording equipment, a common standard is .05 percent. Some speakers have a distortion of 10 percent or more. Headphones often have a distortion of about two percent or less.
- *Watts.* Usually stated as watts per channel, the amount of amplification available to drive the speakers. Check that the company means “per channel” (or RMS) and not total power. Many audio adapters have built-in amplifiers, providing up to eight watts per channel (most provide four watts). This wattage is not enough to provide rich sound, however, which is why many speakers have built-in amplifiers. With the flick of a switch or the press of a button, these speakers amplify the signals they receive from the audio adapter. If you do not want to amplify the sound, you typically leave the speaker switch set to “direct.” In most cases, you’ll want to amplify the signal.

Inexpensive PC speakers often use batteries to power the amplifiers. Because these speakers require so much power, you might want to invest in an AC adapter or purchase speakers that use AC power. With an AC adapter, you won’t have to buy new batteries every few weeks. If your speakers didn’t come with an AC adapter, you can pick one up from your local Radio Shack or hardware store. Be sure that the adapter you purchase matches your speakers in voltage and polarity; most third-party adapters are multiple voltage, featuring interchangeable tips and reversible polarity.

You can control the volume and other sound attributes of your speakers in various ways, depending on their complexity and cost. Typically, each speaker has a volume knob, although some share a single volume control. If one speaker is farther away than the other, you might want to adjust the volume accordingly. Many computer speakers include a dynamic bass boost (DBB)

switch. This button provides a more powerful bass and clearer treble, regardless of the volume setting. Other speakers have separate bass and treble boost switches or a three-band equalizer to control low, middle, and high frequencies. When you rely on your audio adapter's power rather than your speakers' built-in amplifier, the volume and dynamic bass boost controls have no effect. Your speakers are at the mercy of the adapter's power.

For best audio quality, adjust the master volume on the sound card near the high end, and use the volume control on powered speakers to adjust the volume. Otherwise, your speakers will try to amplify any distortions coming from the low-power input from the PC's audio adapter.

An 1/8-inch stereo minijack connects from the audio adapter's output jack to one of the speakers. The speaker then splits the signal and feeds through a separate cable from the first speaker to the second one (often referred to as the "satellite speaker").

Before purchasing a set of speakers, check that the cables between the speakers are long enough for your computer setup. For example, a tower case sitting alongside your desk might require longer speaker wires than a desktop computer.

Beware of speakers that have a tardy built-in sleep feature. Such speakers, which save electricity by turning themselves off when they are not in use, might have the annoying habit of clipping the first part of a sound after a period of inactivity.

Speakers that are USB-based will not be able to play CD music unless the CD-ROM drive can perform digital audio extraction. Check your drive's specifications for information.

Headphones are an option when you can't afford a premium set of speakers. Headphones also provide privacy and enable you to play your PC audio as loud as you like.

For best results with newer sound cards that support four speakers or more, check the properties sheet for the audio adapter and set whether you're using headphones, stereo speakers, or a larger number of speakers.

Make sure that speakers are placed properly. If you use a subwoofer, put it on the floor for better bass sound and to reduce EMI interference with other devices.

How can you tell if wireless satellite speakers are causing interference? Watch your monitor; frequencies as high as 2KHz can interfere with your video display. Move the speakers away from the monitor and check the display again.

Microphones

Some audio adapters come complete with a microphone, but most do not. You'll need one to record your voice to a WAV file. Selecting a microphone is quite simple. You need one that has an 1/8-inch minijack to plug into your audio adapter's microphone, or audio in, jack. Most microphones have an on/off switch.

Like speakers, microphones are measured by their frequency range. This is not an important buying factor, however, because the human voice has a limited range. If you are recording only voices, consider an inexpensive microphone that covers a limited range of frequencies. An expensive microphone's recording capabilities extend to frequencies outside the voice's range. Why pay for something you won't be needing?

If you are recording music, invest in an expensive microphone, but make sure that your audio adapter can do justice to the signal produced by the microphone. A high-quality microphone can produce mediocre results when paired with a cheap 8-bit audio adapter.

Your biggest decision is to select a microphone that suits your recording style. If you work in a noisy office, you might want an unidirectional microphone that will prevent extraneous noises from being recorded. An omnidirectional microphone is best for recording a group conversation.

Most higher-priced audio adapters include a microphone of some type. This can be a small lapel microphone, a handheld microphone, or one with a desktop stand. If you want to keep your hands free, you might want to shun the traditional handheld microphone for a lapel or desktop model. If your audio adapter does not come with a microphone, see your local stereo or electronics parts store. Be sure that any microphone you purchase has the correct impedance to match the audio adapter's input.

If you're using software such as L & H's Voice Express series, Dragon Naturally Speaking, IBM Via Voice, Philips FreeSpeech, or other voice-recognition software, use the microphone supplied with the software or choose from alternative models the software vendor recommends. Run the microphone setup program again if your software has trouble recognizing your voice. Some newer models feature a battery pack to boost sound quality; be sure to check the batteries and replace them to keep recognition quality high.

If you're talking but your voice-recognition or recording software isn't responding, check the following:

- Incorrect jack; it's easy to plug the microphone into the wrong jack. Try using a magic marker to color-code the microphone wire and jack to make matching up easier.
- Check the recording volume in the mixer control. This usually defaults to Mute to avoid spurious noise.
- Make sure the microphone is on in the voice-recognition or recording software. You must click the Record button in recording software, and many voice-recognition programs let you "pick up" the microphone for use or "put it down" when you need to answer the phone. Look for an onscreen microphone icon in the Windows 9x System Tray for fast toggling between modes.

CHAPTER 21

Power Supply and Chassis/Case

Considering the Importance of the Power Supply

The power supply is not only one of the most important parts in a PC, but it is unfortunately also the most overlooked. In the immortal words of a famous comedian, the power supply gets no respect! People spend hours discussing their processor speeds, memory capacity, disk storage capacity and speed, video adapter performance, monitor size, and so forth, but rarely even mention or consider their power supply. When a system is put together to meet the lowest possible price point, what component do you think the manufacturer will skimp on? Yes, the power supply. To most people, the power supply is a rather nondescript metal box that sits inside their system, something to which they pay virtually no attention at all. The few who do pay any mind seem only concerned with how many watts of power it is rated to put out (even though there is no practical way to verify those ratings), without regard as to whether the power that is being produced is stable, direct current and not a wildly variable signal full of noise, hash, spikes, and surges.

On the other hand, I have always placed great emphasis on selecting a power supply for my systems. I consider the power supply the core of the system and am willing to spend more to get a better unit. The power supply function is critical because it supplies electrical power to every other component in the system. In my experience, the power supply is also one of the most failure-prone components in any computer system, especially due to the fact that so many system assemblers use the cheapest ones they can find. A malfunctioning power supply can not only cause other components in the system to malfunction but also damage the other components in your computer by delivering an improper or erratic voltage. Because of its importance to proper and reliable system operation, you should understand both the function and limitations of a power supply, as well as its potential problems and their solutions.

This chapter covers the power supply in detail. I will focus on the electrical functions of the supply and the mechanical form factors and physical designs that have been used in PC systems in the past as well as today. Because the physical shape (form factor) of the power supply relates to the case, some of this information also relates to the type of chassis or case you have.

Power Supply Function and Operation

The basic function of the power supply is to convert the type of electrical power available at the wall socket to the type the computer circuitry can use. The power supply in a conventional desktop system is designed to convert the American 120-volt, 60Hz, AC (alternating current) power into +3.3V, +5V, and +12V DC (direct current) power. Usually, the digital electronic components and circuits in the system (motherboard, adapter cards, and disk drive logic boards) use the +3.3V or +5V power, and the motors (disk drive motors and any fans) use the +12V power. The power supply must deliver a good, steady supply of DC power so that the system can operate properly.

Signal Functions

If you look at a specification sheet for a typical PC power supply, you can see that the supply generates not only +3.3V, +5V, and +12V, but also -5V and -12V. The positive voltages seemingly power everything in the system (logic and motors), so what are the negative voltages used for?

The answer is, not much! Some communications circuits have used the -12V power as a bias current, but rarely is the -5V used at all today. Some of the newest power supply designs like the SFX (Small form factor) design no longer include the -5V signal for that reason. The only reason it has been around at all is that it is a required signal on the ISA (Industry Standard Architecture) bus for full backward compatibility.

Note

When Intel began releasing processors that required a +3.3V power source, power supplies that supplied the additional output voltage were not yet available. As a result, motherboard manufacturers began adding voltage regulators to their boards, which convert +5V current to +3.3V. Voltage regulators, however, also generate a lot of heat in the conversion process, which should be avoided as much as possible in a PC. Newer DIMM (Dual In-line Memory Module) memory also runs on +3.3V, so to minimize the onboard voltage regulator functions, these boards are usually designed to require a +3.3V signal.

◀◀ See "CPU Operating Voltages," p. 114.

Although -5V and -12V are supplied to the motherboard via the power supply connectors, the motherboard uses only the +5V. The -5V signal is simply routed to the ISA bus on pin B5. The motherboard does not use it. Originally, the analog data separator circuits found in older floppy controllers used -5V, so it was supplied to the bus. Because modern controllers do not need the -5V, most systems no longer use it. It is still required, however, because it is part of the ISA bus standard.

Note

Power supplies in systems with a Micro Channel Architecture (MCA bus) as well as the newer SFX (Small form factor) power supplies used in micro-ATX systems do not supply -5V. If necessary for backward compatibility, the motherboard should use an onboard regulator to supply the -5V signal to the ISA bus. PCI-only systems can be produced that do not need -5V current.

The motherboard logic doesn't use the +12V and -12V signals either. They are routed to pins B9 and B7 of the ISA bus (respectively). Any adapter card on the bus can make use of these voltages if needed, but typically they are used by serial port driver/receiver circuits. If the motherboard has integrated serial ports, it can use the +12V and -12V signals for those ports.

Note

The load placed on the +12V and -12V signals by a serial port is very small. For example, the PS/2 Dual Asynch adapter uses only 35mA of +12V and 35mA of -12V (0.035 amps each) to operate two ports.

Most newer serial port circuits no longer use 12V driver/receiver circuits. Instead, they now use circuits that run on only +3.3V or +5V. If you have serial ports such as these in your system, the -12V signal from your power supply will probably not be used.

The main function of the +12V power is to run disk drive motors. Usually, a large amount of current is available, especially in systems with a large number of drive bays (such as in a tower configuration). Besides disk drive motors, the +12V supply is used by any cooling fans in the

system—which, of course, should always be running. A single cooling fan can draw between 100mA and 250mA (0.1–0.25 amps); however, most newer fans use the lower 100mA figure. Note that although most fans in desktop systems run on +12V, portable systems can use fans that run on +5V, or even +3.3V.

In addition to supplying power to run the system, the power supply also ensures that the system does not run unless the power supplied is sufficient to operate the system properly. In other words, the power supply actually prevents the computer from starting up or operating until all the correct power levels are present.

Each power supply completes internal checks and tests before allowing the system to start. If the tests are successful, the power supply sends a special signal to the motherboard called `Power_Good`. If this signal is not present continuously, the computer does not run. Therefore, when the AC voltage dips and the power supply becomes overstressed or overheated, the `Power_Good` signal goes down and forces a system reset or complete shutdown. If you have ever worked on a system that seems dead when the power switch is on and the fan and hard disks are running, you know the effects of losing the `Power_Good` signal.

►► See “The `Power_Good` Signal,” page 1176.

IBM originally implemented this conservative design so that the computer would not operate if the power became low or the supply, overheated or overstressed, caused output power to falter.

Note

You even can use the `Power_Good` feature as a method of designing and implementing a reset switch for the PC. The `Power_Good` line is wired to the clock generator circuit, which controls the clock and reset lines to the microprocessor. When you ground the `Power_Good` line with a switch, the chip and related circuitry stop the processor. They do so by killing the clock signal and then resetting the processor when the `Power_Good` signal appears after you release the switch. The result is a full hardware reset of the system. Later in this chapter, you can find instructions for installing such a reset switch in a system not already equipped with one.

Most systems with newer motherboard form factors, such as the ATX, micro-ATX, or NLX, include another special signal. This feature, called `PS_ON`, can be used to turn the power supply (and thus the system) on or off via software. It is sometimes known as the soft-power feature. `PS_ON` is most evident when you use it with an operating system that supports the Advanced Power Management (APM) or Advanced Configuration and Power Interface (ACPI) specifications such as Windows 9x. When you select the Shut Down the Computer option from the Start menu, Windows automatically turns the computer off after it completes the OS shutdown sequence. A system without this feature only displays a message that it's safe to shut down the computer.

Power Supply Form Factors

The shape and general physical layout of a component is called the form factor. Items that share a form factor are generally interchangeable, at least as far as their size and fit are concerned. When designing a PC, the engineers can choose to use one of the popular standard PSU (power supply unit) form factors, or they can elect to build their own. Choosing the former means that a virtually inexhaustible supply of inexpensive replacement parts will be available in a variety of

quality and power output levels. Going the custom route means additional time and expense for development. In addition, the PSU will be unique to the system and available only from the original manufacturer.

If you can't tell already, I am a fan of the industry-standard form factors! In the early days of PCs, the computer industry was dominated by companies—such as IBM—that manufactured most of their own proprietary components. When other manufacturers began to clone PCs on a large scale, this philosophy became increasingly impractical. The drive toward the standardization of PC components, which began at that time, continues today.

Until the introduction of Intel's ATX architecture in 1995, the form factors of the power supplies used in PC systems differed primarily in their size and their orientation in the computer case. ATX and related standards introduced some new features (such as the PS_ON signal), but virtually all the power supplies used in PCs now conform to the same basic electronic design.

Technically, the PSU in your PC is described as a *constant voltage half-bridge forward converting switching power supply*:

- *Constant voltage* means that the PSU puts out the same voltage to the computer's internal components, no matter what the voltage of AC current running it or the capacity (wattage) of the power supply.
- *Half-bridge forward converting* refers to the PSU's switching design and its power regulation technique. This type of power supply is sometimes known as a switching supply. Compared to other types of power supplies, this design provides an efficient power source and generates a minimum amount of heat. It also maintains a small size and a low price.

Note

Although two power supplies can share the same basic design and form factor, they can differ greatly in quality and efficiency. Later in this chapter, you'll learn about some of the features and specifications to look for when evaluating PC power supplies.

There have been seven main power supply form factors that can be called industry standard. Of these, only three are used in most modern systems; the others are pretty much obsolete. These different form factors are as follows:

Obsolete:	Modern:
PC/XT style	LPX style
AT/Desk style	ATX style
AT/Tower style	SFX style
Baby-AT style	

Each of these power supply styles are available in numerous different configurations and power output levels. The LPX style power supply had been the standard used on most systems up until about four years ago, when the ATX form factor came on the scene. Since then, ATX has become by far the dominant form factor for power supplies, with the new SFX style being added recently to replace ATX for use in very compact systems. The earlier form factors have been largely obsolete for some time now.

Power supply form factors relate to motherboard form factors in ways that are often not obvious. For example, most systems with Baby-AT motherboards use LPX style power supplies, and systems with NLX motherboards use ATX power supplies. Here is a cross reference showing the most common type of power supply used with different motherboards:

Motherboard Form Factor	Most Common PS Form Factor Used	Other PS Form Factors Used
Baby-AT	LPX style	Baby-AT, AT/Tower, or AT/Desk
LPX	LPX style	None
ATX	ATX style	None
Micro-ATX	ATX style	SFX style
NLX	ATX style	None

◀◀ See “Motherboard Form Factors,” p. 222.

As you can see, most systems today use the ATX form factor power supply, and some might use the SFX or LPX styles as well.

Note that although the names of these styles of supplies seem to be the same as those of motherboard form factors, the power supply form factor is more related to the system case than the motherboard. All Baby-AT, LPX, and AT/Tower type power supplies use the same two six-pin connectors to plug into the motherboard, and will therefore work with the same boards. For them to physically work in the system, they must fit the case. This can be very misleading because most all cases today that aren't a variation of ATX or NLX will use the LPX style power supply, even tower cases. The bottom line is that it is up to you to make sure the power supply you are purchasing will fit the case you will be installing it into.

PC/XT Style

IBM's XT used the same basic power supply shape as the original PC, except that the new XT supply had more than double the power output capability. Because they were identical in external appearance and the type of connectors they used, you could easily install the higher output XT supply as an upgrade for a PC system. The tremendous popularity of the original PC and XT design led a number of manufacturers to begin building systems that mimicked their shape and layout. These clones, as they have been called, could interchange virtually all components with the IBM systems, including the power supply. Numerous manufacturers then began producing these components. Most of these components follow the form factor of one or more IBM systems. The PC/XT power supply and connectors are shown in Figure 21.1. This form factor is rarely, if at all, used in modern systems today.

Figure 21.1 PC/XT form factor power supply.

AT/Desktop Style

The AT desktop system, introduced by IBM after the XT, had a larger power supply and a different form factor than the original PC/XT. This system, which was rapidly cloned, represented the basis for many IBM-compatible designs. The power supply used in these systems was called the AT/Desktop-style power supply (see Figure 21.2). Hundreds of manufacturers began making motherboards, power supplies, cases, and other components that were physically interchangeable with the original IBM AT. This form factor is rarely, if at all, used today.

Figure 21.2 AT/Desktop form factor power supply.

AT/Tower Style

The early PC-compatible market came up with some other variations on the AT theme that became quite popular. The AT/Tower configuration was basically a full-sized AT-style desktop system running on its side. The power supply and motherboard form factors were largely the same in the tower system as they were in the desktop. The tower configuration is not new; in fact, even IBM's original AT had a specially mounted logo that could be rotated when you ran the system on its side in the tower configuration.

The type of power supply used in a tower system is identical to that used in a desktop system, except for the location of the power switch. On most AT/Desktop systems, the power switch is located on the power supply (usually in the form of a large toggle switch). Most AT/Tower systems use an external switch attached to the power supply through a short four-wire cable. A full-sized AT power supply with a remote switch is called an AT/Tower form factor power supply (see Figure 21.3). This form factor is rarely, if at all, used today.

Figure 21.3 AT/Tower form factor power supply.

Baby-AT Style

Another type of AT-based form factor is the so-called Baby-AT, which is a shortened version of the full-sized AT system. The power supply in these systems is shortened in one dimension but matches the AT design in all other respects. Baby-AT-style power supplies can fit into both a Baby-AT chassis and the larger AT-style chassis; however, the full-sized AT/Tower power supply does not fit in the Baby-AT chassis (see Figure 21.4). Because the Baby-AT PSU performed all the same functions as the AT-style power supply, but was in a smaller package, it became the preferred form factor until overtaken by later designs. This form factor is rarely used today.

LPX Style

The next PSU form factor to gain popularity was the LPX style, also called the PS/2 type, Slimline, or slim style (see Figure 21.5). The LPX-style power supply has the exact same motherboard and disk drive connectors as the previous standard power supply form factors; it differs mainly in the shape. LPX systems were designed to have a smaller footprint and a lower height than AT-sized

systems. These computers used a different motherboard configuration that mounts the expansion bus slots on a “riser” card that plugs into the motherboard. The expansion cards plug into this riser and are mounted sideways in the system, parallel to the motherboard. Because of its smaller case, an LPX system needed a smaller power supply. The PSU designed for LPX systems is smaller than the Baby-AT style in every dimension and takes up less than half the space of its predecessor.

Figure 21.4 Baby-AT form factor power supply.

Note

IBM used this type of power supply in some of its PS/2 systems in the late 1980s; hence it is sometimes called a PS/2-type supply.

As with the Baby-AT design in its time, the LPX power supply does the same job as its predecessor but comes in a smaller package. The LPX power supply quickly found its way into many manufacturers' systems, soon becoming a de facto standard. This style of power supply became the staple of the industry for many years, coming in everything from low profile systems using actual

LPX motherboards to full sized towers using Baby-AT or even full-sized AT motherboards. It is still used in some of the PCs produced today; however, in the last four years the popularity of LPX has been overshadowed by the increasing popularity of the ATX design.

5.9"×5.5"×3.4"

Figure 21.5 LPX form factor power supply.

ATX Style

One of the newer standards in the industry today is the ATX form factor (see Figure 21.6). The ATX specification, now in version 2.01, defines a new motherboard shape, as well as a new case and power supply form factor. The shape of the ATX power supply is based on the LPX design, but there are some important differences worth noting.

One difference is that the ATX specification originally called for the fan to be mounted along the inner side of the supply, where it could blow air across the motherboard and draw it in from outside the case at the rear. This kind of airflow runs in the opposite direction as most standard supplies, which blow air out the back of the supply through a hole in the case where the fan protrudes. The reverse-flow cooling provided by some ATX-style power supplies forces air over the

hottest components of the board, such as the processor, memory modules, and expansion slots, which are located in such a way as to take maximum advantage of the airflow. This often eliminates the need for multiple fans in the system—including the CPU fans common in many systems today—while reducing the amount of noise produced by the system and the amount of power needed to run the system.

Another benefit of the reverse-flow cooling is that the system remains cleaner, free from dust and dirt. The case is essentially pressurized, so air is continuously forced out of the cracks in the case—the opposite of what happens with earlier designs. For this reason, the reverse-flow cooling design is often referred to as a positive-pressure-ventilation design. For example, if you held a lit cigarette in front of your floppy drive on a normal system, the smoke would be sucked in through the front of the drive and could contaminate the heads. On an ATX system with reverse-flow cooling, the smoke would be blown out away from the drive because the only air intake would be the single fan vent on the power supply at the rear. For systems that operate in extremely harsh environments, you can add a filter to the fan intake vent to further ensure that all the air entering the system is clean and free of dust.

Although this is theoretically an excellent way to ventilate a system, a properly designed positive-pressure system needs to use a more powerful fan to pull the required amount of air through a filter and to pressurize the case. Also, the filter has to be serviced on a periodic basis—depending on operating conditions, it can need changing or cleaning as often as every week. In addition, the heat load from the power supply on a fully loaded system exhausts heated air over the CPU, reducing its cooling capability. As newer CPUs create more and more heat, the cooling capability of the airflow becomes absolutely critical. In common practice, using a standard negative-pressure system with an exhaust fan on the power supply and an additional high-quality cooling fan blowing right on the CPU is the best solution. For this reason, the ATX power supply specification has been amended to allow for the older method of negative-pressure ventilation.

Despite the advantages a positive-pressure cooling system can provide, a standard negative pressure system—where air is exhausted out the rear of the power supply and ingested through various vents in the system—offers the most cooling capacity for a given fan airspeed and flow. This is why most of the newer ATX-style power supplies use the negative-pressure cooling system.

The ATX specification was first released by Intel in 1995. In 1996, it became increasingly popular in Pentium and Pentium Pro-based PCs, capturing 18% of the motherboard market. With the introduction of the Pentium II in 1997 and now the Pentium III in 1999, ATX has become the dominant motherboard form factor, displacing the previously popular Baby-AT. ATX and its derivatives are likely to remain the most popular form factor for several years to come.

5.9"x5.5"x3.4"

Figure 21.6 ATX form factor power supply, used with both ATX and NLX systems.

The ATX form factor (see Figure 21.7) addresses several problems with the Baby-AT and mini-AT form factors. Two main problems with the power supply persist. One is that the traditional PC power supply has two connectors that plug into the motherboard. If you insert these connectors backward or out of their normal sequence, you will fry the motherboard. Most responsible system manufacturers “key” the motherboard and power supply connectors so that you cannot install them backward or out of sequence. However, some vendors of cheaper systems do not feature this keying on the boards or supplies they use.

The ATX form factor includes a new power plug for the motherboard to prevent users from plugging in their power supplies incorrectly. This new connector has 20 pins and is keyed, which makes it virtually impossible to plug it in backward. Because there is one connector instead of two almost identical ones, it eliminates the problem of plugging in the connectors out of sequence. The new ATX connector also supplies +3.3V, reducing the need for voltage regulators on the motherboard to power the CPU and other +3.3V circuits.

Figure 21.7 ATX/NLX form factor power supply.

Besides the new +3.3V signals, another set of signals is furnished by the ATX PSU that is not normally seen on standard power supplies. The set consists of the Power_On (PS_ON) and 5V_Standby (5VSB) signals, known collectively as Soft Power. Power_On is a motherboard signal that operating systems such as Windows 9x use to power the system on or off via software. This allows features to be implemented such as Wake on Ring or Wake on LAN, in which a signal from a modem or network adapter can actually cause a PC to wake up and power on. Many such systems also have the option of setting a wake-up time, at which the PC can automatically turn on to perform scheduled tasks. These signals can also allow for the optional use of the keyboard to power the system on—exactly like Apple Macintosh systems. The 5V Standby signal is always active, giving the motherboard a limited source of power even when off and enabling these features. Check your BIOS Setup for control over these features.

The other problem solved by an ATX form factor power supply with reverse-cooling airflow is that of keeping today's system processors cool. But it works only in industrial applications, in which an industrial-duty power supply has been designed properly for the heat-load of the intended system and in which constant maintenance is provided. Most of the high-end Pentium and Pentium Pro systems on the market use active heat sinks on the processor, which means there is a small fan on the CPU designed to cool it. Intel and other manufacturers now package cooling fans with the CPU—some are actually permanently mounted on the CPU. For best results, use CPU fans only from reputable manufacturers because a CPU fan can be one of the most critical components for reliable operation.

Note

The cooling method described here was originally recommended by the ATX specification, but it is not required and might not even be preferred. Manufacturers can use alternative methodologies, such as the traditional outblowing (negative pressure) fan arrangement, as well as active or passive heat sinks, on a system with an ATX motherboard. In fact, this might be a better solution for nonindustrial applications for which periodic maintenance of the power supply filter is not assured.

NLX Style

The NLX specification, also developed by Intel, defines a low-profile case and motherboard with many of the same attributes as the ATX. In fact for interchangeability, NLX systems were

designed to use ATX power supplies, even though the case and motherboard dimensions might be different.

As in previous Slimline systems, the NLX motherboard uses a riser board for the expansion bus slots. The NLX motherboard is also designed for easy maintenance access; releasing a simple catch enables you to slide the entire motherboard out of the chassis in about 30 seconds! This is made possible by having nothing connect to the motherboard internally except the riser. The power supply connects to the riser, as do the disk drives, front panel, and multimedia connectors. No boards or cables have to be removed to take out the motherboard, you simply slide it out on rails and slide the replacement in place, all in less than a minute on average.

Just as the standardized ATX architecture functionally replaced the Baby-AT form factor in full-sized desktop and tower systems, NLX is intended to replace the cumbersome and semi-proprietary LPX form factor for smaller desktop systems. For interchangeability with ATX, the NLX specification does not define a new power supply form factor but uses the ATX type power supply directly instead. NLX is targeted more at the corporate computer market, which has serviceability and maintenance requirements quite different from those of home users. Adoption of the NLX standard is dragging slightly behind that of ATX, but quite a few computer manufacturers have announced systems that take advantage of the lower prices, smaller footprints, and easier maintenance that the new form factor can provide.

SFX Style (Micro-ATX Motherboards)

Intel has recently released a third new motherboard specification, called micro-ATX, that is intended for low-end systems, which are designed with an even smaller footprint than NLX and with potentially smaller power supply requirements. The new smaller micro-ATX motherboards and cases can be designed to use the ATX power supply by default, as well as a new very small power supply called *SFX* for *Small form factor* (see Figure 21.8).

The SFX power supply is specifically designed for use in small systems containing a limited amount of hardware. The PSU can provide 90 watts of continuous power (135 watts at its peak) in four voltages (+5, +12, -12, and +3.3V). This amount of power has proved to be sufficient for a small system with a Pentium II processor, an AGP interface, up to four expansion slots, and three peripheral devices—such as hard drives and CD-ROMs.

Note

The SFX power supply does not provide the -5V current required for full compliance with the ISA bus standard. Micro-ATX systems are supposed to use the PCI bus or the AGP interface for all the expansion cards installed in the computer, omitting the ISA bus entirely.

Although Intel designed the SFX power supply specification with the micro-ATX motherboard form factor in mind, SFX is a wholly separate standard that is compliant with other motherboards as well. SFX power supplies use the same 20-pin connector defined in the ATX standard and include both the Power_On and 5V_Standby signals. Whether you will use an ATX or SFX power supply with a micro-ATX system is dependent on the case or chassis, not the motherboard. Each has the same electrical connectors; the difference is which one the case is physically designed to accept.

On a standard model SFX power supply, a 60mm diameter cooling fan is located on the surface of the housing, facing the inside of the computer's case. The fan draws the air into the power supply housing from the system cavity and expels it through a port at the rear of the system. Internalizing the fan in this way reduces system noise and results in a standard negative pressure design. In many cases, additional fans might be needed in the system to cool the processor (see Figure 21.8).

Figure 21.8 SFX form factor power supply dimensions with standard internal 60mm fan.

For systems that require more cooling capability, there is also a version that allows for a larger 90mm top-mounted cooling fan. The larger fan provides more cooling capability and airflow for systems that need it (see Figure 21.9).

Figure 21.10 shows a picture of an SFX style power supply with the 90mm top-mounted cooling fan.

Figure 21.9 SFX form factor power supply dimensions with internal 90mm top-mounted fan.

Figure 21.10 SFX style supply with 90mm top-mounted cooling fan.

Power Supply Connectors

Table 21.1 shows the pinouts for most LPX-, Baby-AT-, standard AT-, and PC/XT-compatible systems. The two six-pin connectors (P8 and P9) attach the power supply to the motherboard, whereas P10 through P13 are identical four-pin connectors that you use to supply power to internal peripherals, such as floppy and hard disk drives. Figure 21.11 shows the P8 and P9 connectors (sometimes also called P1/P2).

Figure 21.11 Motherboard P8/P9 (sometimes also called P1/P2) power connectors.

All standard PC power supplies that use the P8 and P9 connectors have them installed end-to-end so that the two black-colored wires (ground connections) on both power cables are next to each other. Note the designations P8 and P9 are not fully standardized, although most use those designations because that is what IBM used on the originals. Some power supplies have them labeled as P1/P2 or possibly something else. Because these connectors usually have a clasp that prevents them from being inserted backward on the pins on the motherboards, the major concern is getting them in the correct order and not missing a pin on either side. Following the black-on-black rule keeps you safe. You must take care, however, to make sure no unconnected motherboard pins are between or on either side of the two connectors when you install them. A properly installed connector connects to and covers every motherboard power pin—if any power pins are showing on either side of the connectors, the entire connector assembly is installed incorrectly, which can result in catastrophic failure for the motherboard and everything plugged into it at the time of power-up.

Some systems might have more or fewer drive connectors. For example, IBM's AT system power supplies have only three disk drive power connectors, although most AT/Tower-type power supplies have four drive connectors. Depending on their power ratings, some ATX supplies have as many as eight drive connectors.

If you are adding drives and need additional disk drive power connectors, Y splitter cables (see Figure 21.12) are available from many electronics supply houses (including Radio Shack). These cables can adapt a single power connector to service two drives. As a precaution, make sure that your total power supply output is capable of supplying the additional power.

Table 21.1 shows typical PC/XT and AT power supply connections.

Figure 21.12 A common Y-adaptor power cable.

Table 21.1 Typical PC/XT and AT Power Supply Connections

Connector	AT Type	PC/XT Type
P8-1	Power_Good (+5V)	Power_Good (+5V)
P8-2	+5V	Key (No connect)
P8-3	+12V	+12V
P8-4	-12V	-12V
P8-5	Ground (0)	Ground (0)
P8-6	Ground (0)	Ground (0)
P9-1	Ground (0)	Ground (0)
P9-2	Ground (0)	Ground (0)
P9-3	-5V	-5V
P9-4	+5V	+5V
P9-5	+5V	+5V
P9-6	+5V	+5V
P10-1	+12V	+12V
P10-2	Ground (0)	Ground (0)
P10-3	Ground (0)	Ground (0)
P10-4	+5V	+5V

(continues)

Table 21.1 Continued

Connector	AT Type	PC/XT Type
P11-1	+12V	+12V
P11-2	Ground (0)	Ground (0)
P11-3	Ground (0)	Ground (0)
P11-4	+5V	+5V
P12-1	+12V	-
P12-2	Ground (0)	-
P12-3	Ground (0)	-
P12-4	+5V	-
P13-1	+12V	-
P13-2	Ground (0)	-
P13-3	Ground (0)	-
P13-4	+5V	-

Notice that all the power supplies from the AT/Desk through the Baby-AT and LPX power supplies use the same pin configuration. The only other industry standard PSU-to-motherboard connector is the Molex 39-29-9202 (or equivalent) 20-pin ATX style connector (see Figure 21.13). First used in the ATX form factor power supply, it is also used in the SFX form factor. This is a 20-pin keyed connector with pins configured, as shown in Table 21.2. The colors for the wires are those recommended by the ATX standard; however, they are not required for compliance to the specification (in other words, the colors could vary from manufacturer to manufacturer).

**Figure 21.13** ATX style 20-pin motherboard power connector.

Tip

Although the PC/XT power supplies do not have any signal on pin P8-2, you can still use them on AT-type motherboards, or vice versa. The presence or absence of the +5V signal on that pin has little or no effect on system operation.

Table 21.2 ATX Power Supply Connections

Color	Signal	Pin	Pin	Signal	Color
Orange*	+3.3V	11	1	+3.3V	Orange
Blue	-12V	12	2	+3.3V	Orange
Black	GND	13	3	GND	Black
Green	PS_On	14	4	+5V	Red
Black	GND	15	5	GND	Black
Black	GND	16	6	+5V	Red
Black	GND	17	7	GND	Black
White	-5V	18	8	Power_Good	Gray
Red	+5V	19	9	+5VSB (Standby)	Purple
Red	+5V	20	10	+12V	Yellow

* = Can also be Brown, indicating +3.3V Sense feedback

Note

The ATX supply features several signals not seen before, such as the +3.3V, Power_On, and +5V_Standby signals. Therefore, it is difficult to adapt a standard LPX form factor supply to make it work properly in an ATX system, even though the shapes of the power supplies themselves are virtually identical.

For power supplies of 250 watts or more, an auxiliary power connector is recommended to supply the additional 5V and 3.3V the motherboard might need. This is a 6-pin Molex-type connector, similar to one of the motherboard power connectors used on LPX supplies. It is keyed to prevent misconnection.

The pinouts of the auxiliary connector are shown in Table 21.3.

Table 21.3 Auxiliary Power Connector Pinout

Pin	Signal	Color
1	Gnd	Black
2	Gnd	Black
3	Gnd	Black
4	+3.3V	Orange
5	+3.3V	Orange
6	+5V	Red

If your motherboard does not feature a mating auxiliary connector, it probably wasn't designed to consume a large amount of power, and the auxiliary connector from the power supply can be left unconnected. If your power supply is rated at 250 watts or larger, you should ensure that it has this connector and that your motherboard is able to accept it. This eases the load on the main power connector.

ATX Auxiliary and Optional Power Connector

In addition to the main 20-pin power connector (see Figure 21.14) and the auxiliary power connector, the ATX specification defines an optional six-pin connector (two rows of three pins each) to provide the signals shown in Table 21.4. The computer can use these signals to monitor and control the cooling fan, monitor the voltage of the +3.3V signal to the motherboard, and provide power and grounding to devices compliant with the IEEE 1394 (FireWire) standard.

Table 21.4 ATX Optional Power Supply Connections

Color	Signal	Pin	Pin	Signal	Color
White/Black Stripe	1394R	4	1	FanM	White
White/Red Stripe	1394V	5	2	FanC	White/Blue Stripe
	Reserved	6	3	+3.3V sense	White/Brown Stripe

The FanM signal enables the operating system to monitor the status of the power supply's cooling fan so that it can take appropriate actions, such as shutting down the system if the fan fails.

Figure 21.14 ATX optional power supply connections.

The motherboard (under operating system control) can use the FanC signal with variable voltages to control the operation of the power supply's fan, shifting it into a low power state or shutting it off completely when the system is in sleep or standby mode. The ATX standard specifies that a voltage of +1V or less indicates that the fan is to shut down, whereas +10.5V or more instructs the fan to operate at full speed. The system designer can define intermediate voltages to operate variable-speed fans at various levels. If the power supply does not include a variable-speed fan circuit, any voltage level higher than +1V on the FanC signal is interpreted as a command to run the fan at its full (and only) speed.

The 1394 connectors are for powering an optional IEEE1394 (Firewire or iLink) bus on a motherboard. The 1394V pin provides voltages from 8 to 40V to run Firewire peripherals off the bus, and the 1394R pin is a return or ground line for this power circuit. This separate power rail keeps the 1394 bus power separate from the system main power to prevent interference.

Note

The SFX specification also defines the use of a six-pin control connector, but uses it only to provide a fan control signal on one pin. The other five pins are all reserved for future use.

Power Switch Connectors

Most of the power supplies used today employ a remote power switch that is accessible from the front of the computer case. In contrast, earlier form factors, such as the AT desktop and Baby-AT, used a switch that was integrated into the power supply housing. Because the power supply was mounted in a rear corner of the case, the switch was inconveniently located on the back of the computer case.

Pre-ATX power supplies use a remote switch that is connected to the power supply through a standard four-wire cable. The ends of the cable are fitted with spade connector lugs, which plug onto the spade connectors on the power switch. The switch is usually a part of the case, so the power supply comes with the cable and no switch.

The cable from the power supply to the switch in the case contains four color-coded wires. There might also be a fifth wire supplying a ground connection to the case.

Caution

The remote power switch leads carry 110V AC current at all times. You could be electrocuted if you touch the ends of these wires with the power supply plugged in! Always make sure the power supply is unplugged before connecting or disconnecting the remote power switch.

The four or five wires are color coded as follows:

- The brown and blue wires are the live and neutral feed wires from the 110V power cord to the power supply. These wires are always hot when the power supply is plugged in.
- The black and white wires carry the AC feed from the switch back to the power supply. These leads should be hot only when the power supply is plugged in and the switch is turned on.
- A green wire or a green wire with a yellow stripe is the ground lead. It should be connected to the PC case and should help ground the power supply to the case.

On the switch, the tabs for the leads are usually color coded; if not, you can still connect them easily. If no color coding is on the switch, plug the blue and brown wires onto the tabs that are parallel to each other and the black and white wires to the tabs that are angled away from each other. See Figure 21.15 as a guide.

Caution

Although these wire color codings are used on most power supplies, they are not necessarily 100% universal. I have encountered power supplies that did not use the same coloring scheme described here. Unless you can verify the color codes with the power supply manufacturer, always disconnect the power supply from the wall socket before handling any of these wires.

As long as the blue and brown wires are on the one set of tabs and the black and white leads are on the other, the switch and supply will work properly. If you incorrectly mix the leads, you will likely blow the circuit breaker for the wall socket, because mixing them can create a direct short circuit.

Figure 21.15 Power supply remote switch connections for two styles of switches.

All ATX and subsequent power supplies that employ the 20-pin motherboard connector use the PS_ON signal to power up the system. As a result, the remote switch does not physically control the power supply's access to the 110V AC power, as in the older style PSUs. Instead, the power supply's on or off status is toggled by a PS_ON signal received on pin 14 of the ATX connector.

The PS_ON signal can be generated physically by the computer's power switch or electronically by the operating system. PS_ON is an active low signal, meaning that all the DC power signals generated by the PSU are deactivated when PS_ON is held high, with the exception of the +5VSB (standby) signal on pin 9, which is active whenever the power supply is connected to an AC power source. The +5VSB signal provides the power for the remote switch on the case to operate while the computer is off. Thus, the remote switch in an ATX-style system (which should include most NLX and SFX systems) carries only +5V of DC power, rather than the full 110V AC current that is in the older form factors.

Caution

The continuous presence of the +5VSB signal on pin 9 of the ATX connector means that the motherboard is always receiving power from the PSU when connected to an AC source, even when the computer is turned off. As a result, it is even more crucial to unplug an ATX system from the power source before working inside the case than it is on an earlier model system.

Disk Drive Power Connectors

The disk drive connectors on power supplies are fairly universal with regard to pin configuration and even wire color. Table 21.5 shows the standard disk drive power connector pinout and wire colors.

Table 21.5 Disk Drive Power Connector Pinout

Pin	Wire Color	Signal
1	Yellow	+12V
2	Black	Gnd
3	Black	Gnd
4	Red	+5V

This information applies whether the drive connector is the larger Molex version or the smaller mini-version used on most 3 1/2-inch floppy drives. In each case, the pinouts and wire colors are the same. To determine the location of pin 1, look at the connector carefully. It is usually embossed in the plastic connector body; however, it is often tiny and difficult to read. Fortunately, these connectors are keyed and therefore difficult to insert incorrectly. Figure 21.16 shows the keying with respect to pin numbers on the larger drive power connector.

**Figure 21.16** A disk drive female power supply cable connector.**Note**

Some drive connectors might supply only two wires—usually the +5V and a single ground (pins 3 and 4)—because the floppy drives in most newer systems run on only +5V and do not use the +12V at all.

Physical Connector Part Numbers

The physical connectors used in industry-standard PC power supplies were originally specified by IBM for the supplies used in the original PC/XT/AT systems. They used a specific type of connector between the power supply and the motherboard (the P8 and P9 connectors) and specific connectors for the disk drives. The motherboard connectors used in all the industry-standard power supplies were unchanged from 1981 (when the IBM PC appeared) until 1995 (when Intel released the ATX standard). The original PC's four-pin disk drive connector was augmented by a smaller (also four-pin) power connector when 3 1/2-inch floppy drives appeared in 1986. Table 21.6 lists the standard connectors used for motherboard and disk drive power.

Table 21.6 Physical Power Connectors

Connector Description	Female (on Power Cable)	Male (on Component)
ATX/NLX/SFX (20-pin)	Molex 39-29-9202	Molex 39-01-2200
ATX Optional (6-pin)	Molex 39-01-2960	Molex 39-30-1060
PC/AT/LPX Motherboard P8/P9	Burndy GTC6P-1	Burndy GTC 6RI
Disk Drive (large style)	AMP 1-480424-0	AMP 1-480426-0
Floppy Drive (small style)	AMP 171822-4	AMP 171826-4

You can get these raw connectors through the electronics supply houses (Allied, Newark, and Digi-Key, for example) found in the Vendor List on the CD. You also can get complete cable assemblies, including drive adapters that convert the large connectors into small connectors; disk drive Y splitter cables; and motherboard power extension cables from a number of the cable and miscellaneous supply houses, such as Ci Design and Key Power.

Caution

Before you install additional connectors to your power supply using Y splitters or any other type of connector, be sure your power supply is capable of delivering sufficient power for all your internal peripherals. Overloading the power supply can cause damage to electrical components and stored data.

▶▶ See "Power Supply Ratings," p. 1179.

The Power_Good Signal

The Power_Good signal (sometimes called Power_OK or POK) is a +5V signal (with variation from +3.0 through +6.0V generally being considered acceptable) generated in the power supply when it has passed its internal self tests and the outputs have stabilized. This normally takes place anywhere from 0.1 to 0.5 seconds after you turn on the power supply switch. This power supply sends the signal to the motherboard, where it is received by the processor timer chip, which controls the reset line to the processor.

In the absence of Power_Good, the timer chip continually resets the processor, which prevents the system from running under bad or unstable power conditions. When the timer chip receives the Power_Good signal, it stops resetting the processor, and the processor begins executing whatever code is at address FFFF:0000 (usually the ROM BIOS).

If the power supply cannot maintain proper outputs (such as when a brownout occurs), the Power_Good signal is withdrawn, and the processor is automatically reset. When the power output returns to its proper levels, the PSU regenerates the Power_Good signal and the system again begins operation (as if you had just powered on). By withdrawing Power_Good, the system never sees the bad power because it is stopped quickly (reset) rather than being allowed to operate using unstable or improper power levels, which can cause memory parity errors and other problems.

▶▶ See "Parity Checking," p. 479.

On pre-ATX systems, the Power_Good connection is made via connector P8-1 (P8 Pin 1) from the power supply to the motherboard. ATX and later systems use pin 8 of the 20-pin connector.

A well-designed power supply delays the arrival of the Power_Good signal until all the PSU's voltages stabilize after you turn the system on. Badly designed power supplies, which are found in many low-cost systems, often do not delay the Power_Good signal properly and enable the processor to start too soon. (The normal Power_Good delay is from 0.1 to 0.5 seconds.) Improper Power_Good timing also causes CMOS memory corruption in some systems.

Note

If you find that a system consistently fails to boot up properly the first time you turn on the switch but that it subsequently boots up if you press the reset or Ctrl+Alt+Delete warm boot command, you likely have a problem with the Power_Good timing. You must install a new, high-quality power supply and see if that solves the problem.

Some cheaper power supplies do not have proper Power_Good circuitry and might just tie any +5V line to that signal. Some motherboards are more sensitive to an improperly designed or improperly functioning Power_Good signal than others. Intermittent startup problems are often the result of improper Power_Good signal timing. A common example is when you replace a motherboard in a system and then find that the system intermittently fails to start properly when you turn the power on. This can be very difficult to diagnose, especially for the inexperienced technician, because the problem appears to be caused by the new motherboard. Although it seems as though the new motherboard is defective, it usually turns out that the power supply is poorly designed. It either cannot produce stable enough power to properly operate the new board, or it has an improperly wired or timed Power_Good signal (which is more likely). In these situations, replacing the supply with a high-quality unit, in addition to the new motherboard, is the proper solution.

Power Supply Loading

PC power supplies are of a *switching* rather than a *linear* design. The switching type of design uses a high-speed oscillator circuit to convert the higher wall-socket AC voltage to the much lower DC voltage used to power the PC and PC components. Switching type power supplies are noted for being very efficient in size, weight, and energy in comparison to the linear design, which uses a large internal transformer to generate different outputs. This type of transformer-based design is inefficient in at least three ways. First, the output voltage of the transformer linearly follows the input voltage (hence the name *linear*), so any fluctuations in the AC power going into the system can cause problems with the output. Second, the high current level (power) requirements of a PC system require the use of heavy wiring in the transformer. Third, the 60Hz (hertz) frequency of the AC power supplied from your building is difficult to filter out inside the power supply, requiring large and expensive filter capacitors and rectifiers.

The switching supply, on the other hand, uses a switching circuit that chops up the incoming power at a relatively high frequency. This allows for the use of high-frequency transformers that are much smaller and lighter. Also, the higher frequency is much easier and cheaper to filter out at the output, and the input voltage can vary widely. Input ranging from 90 to 135 volts still produces the proper output levels, and many switching supplies can automatically adjust to 220V input.

One characteristic of all switching-type power supplies is that they do not run without a *load*. This means that you must have the supply plugged into something drawing power for the supply to work. If you simply have the power supply on a bench with nothing plugged into it, the supply either burns up or its protection circuitry shuts it down. Most power supplies are protected from no-load operation and shut down automatically. Some of the cheap clone supplies, however, lack the protection circuit and relay. They are destroyed after a few seconds of no-load operation. A few power supplies have their own built-in load resistors, so they can run even though no normal load is plugged in.

According to IBM specifications for the standard 192-watt power supply used in the original AT, a minimum load of 7.0 amps was required at +5V and a minimum of 2.5 amps was required at +12V for the supply to work properly.

Because floppy drives present no +12V load unless they are spinning, systems without a hard disk drive often do not operate properly. Some power supplies have a minimum load requirement for both the +5V and +12V sides. If you fail to meet this minimum load, the supply shuts down.

Because of this characteristic, when IBM used to ship the original AT systems without a hard disk, they plugged the hard disk drive power cable into a large 5-ohm 50-watt sandbar resistor, which was mounted in a little metal cage assembly where the drive would have been. The AT case had screw holes on top of where the hard disk would go, specifically designed to mount this resistor cage.

Note

Several computer stores I knew of in the mid-1980s would order the diskless AT and install their own 20MB or 30MB drives, which they could get more cheaply from other sources than from IBM. They were throwing away the load resistors by the hundreds! I managed to grab a couple at the time, which is how I know the type of resistor they used.

This resistor would be connected between pin 1 (+12V) and pin 2 (Ground) on the hard disk power connector. This would place a 2.4-amp load on the supply's +12V output, drawing 28.8 watts of power (it would get hot!) and thus enabling the supply to operate normally. Note that the cooling fan in most power supplies draws approximately 0.1–0.25 amps, bringing the total load to 2.5 amps or more. If the load resistor were missing, the system would intermittently fail to start up or operate properly. The motherboard would draw +5V at all times, but +12V would normally be used only by motors, and the floppy drive motors would be off most of the time.

Most of the power supplies in use today do not require as much of a load as the original IBM AT power supply. In most cases, a minimum load of 0–0.3 amps at +3.3V, 2.0–4.0 amps at +5V, and 0.5–1.0 amps at +12V is considered acceptable. Most motherboards easily draw the minimum +5V current by themselves. The standard power supply cooling fan draws only 0.1–0.25 amps, so the +12V minimum load might still be a problem for a diskless workstation. Generally, the higher the rating on the supply, the more minimum load required; however, there are exceptions, so this is a specification you want to check when evaluating power supplies.

Some high-quality switching power supplies have built-in load resistors and can run under a no-load situation because the supply loads. Other high-quality power supplies, such as those from

PC Power and Cooling, have no internal load resistors. They only require a small load on the +5V line to operate properly. Many of the cheaper clone supplies, which often do not have built-in load resistors, might require +3.3V, +5V, and +12V loads to work.

If you want to bench test a power supply, make sure you place loads on all the PSU's positive voltage outputs. This is one reason why it is best to test the supply while it is installed in the system instead of testing it separately on the bench. For impromptu bench testing, you can use a spare motherboard and hard disk drive to load the outputs.

Power Supply Ratings

A system manufacturer should be able to provide you the technical specifications of the power supplies it uses in its systems. This type of information can be found in the system's technical-reference manual, as well as on stickers attached directly to the power supply. Power supply manufacturers can also supply this data, which is preferable if you can identify the manufacturer and contact them directly or via the Web.

Tables 21.7 and 21.8 list power supply specifications for several of IBM's units, from which the power supplies of many other systems are derived. The input specifications are listed as voltages, and the output specifications are listed as amps at several voltage levels. IBM reports output wattage level as "specified output wattage." If your manufacturer does not list the total wattage, you can convert amperage to wattage by using the following simple formula:

$$\text{watts} = \text{volts} \times \text{amps}$$

For example, if a motherboard is listed as drawing 6 amps of +5V current, that would be 30 watts of power, according to the formula.

By multiplying the voltage by the amperage available at each output and then adding the results, you can calculate the total capable output wattage of the supply.

Table 21.7 Power Supply Output Ratings for IBM Classic Systems

	PC	Port-PC	XT	XT-286	AT
Minimum input voltage	104	90	90	90	90
Maximum input voltage	127	137	137	137	137
110/220V switching	No	Yes	No	Auto	Yes
Output current (amps):					
+5V	7.0	11.2	15.0	20.0	19.8
+12V	2.0	4.4	4.2	4.2	7.3
-5V	0.3	0.3	0.3	0.3	0.3
-12V	0.25	0.25	0.25	0.25	0.3
Calculated output (watts)	63.5	113.2	129.9	154.9	191.7
Specified output (watts)	63.5	114.0	130.0	157.0	192.0

Table 21.7 shows the standard power supply output levels available in industry-standard form factors. Most manufacturers offer supplies with ratings from 100 watts to 450 watts or more. Table

21.8 shows the rated outputs at each of the voltage levels for supplies with different manufacturer-specified output ratings. To compile the table, I referred to the specification sheets for supplies from Astec Standard Power and PC Power and Cooling. Although most of the ratings are accurate, they are somewhat misleading for the higher wattage units.

Table 21.8 Typical Non-ATX Power Supply Output Ratings

Rated Output (Watts)	100W	150W	200W	250W	300W	375W	450W
Output current (amps):							
+5V	10.0	15.0	20.0	25.0	32.0	35.0	45.0
+12V	3.5	5.5	8.0	10.0	10.0	13.0	15.0
-5V	0.3	0.3	0.3	0.5	1.0	0.5	0.5
-12V	0.3	0.3	0.3	0.5	1.0	0.5	1.0
Calc. output (watts)	97.1	146.1	201.1	253.5	297.0	339.5	419.5

Adding a +3.3V signal to the power supply modifies the equation significantly. Table 21.9 contains data for various ATX power supplies from PC Power and Cooling that include a +3.3V signal.

Table 21.9 PC Power and Cooling ATX Power Supply Output Ratings

Rated Output	235W	275W	300W	350W	400W	425W
Output current (amps):						
+5V	22.0	30.0	30.0	32.0	30.0	50.0
+3.3V	14.0	14.0	14.0	28.0	28.0	40.0
Max watts +5V & +3.3V:	125W	150W	150W	215W	215W	300W
+12V	8.0	10.0	12.0	10.0	14.0	15.0
-5V	0.5	0.5	0.5	0.3	1.0	0.3
-12V	1.0	1.0	1.0	0.8	1.0	1.0

If you compute the total output using the formula described earlier, these PSUs seem to produce an output that is much higher than their ratings. The 300W model, for example, comes out at 354.7 watts. However, notice that the supply also has a maximum combined output for the +3.3V and +5V signals of 150 watts. This means you cannot draw the maximum rating on both the 5V and 3.3V lines simultaneously, but must keep the total combined draw between them at 150W. This brings the total output to a more logical 308.5 watts.

Most PC power supplies have ratings between 150 and 300 watts. Although lesser ratings are not usually desirable, it is possible to purchase heavy-duty power supplies for most systems that have outputs as high as 600 watts or more.

The 300-watt and larger units are excellent for enthusiasts who are building fully optioned desktops or tower systems. These supplies run any combination of motherboard and expansion card, as well as a large number of disk drives and other peripherals. In most cases, you cannot exceed the ratings on these power supplies—the system will be out of room for additional items first!

Most power supplies are considered to be universal, or worldwide. That is, they can also run on the 220V, 50-cycle current used in Europe and many other parts of the world. Many power supplies that can switch from 110V to 220V input do so automatically, but a few require you to set a switch on the back of the power supply to indicate which type of power you will access.

Caution

If your supply does not switch input voltages automatically, make sure the voltage setting is correct. If you plug the power supply into a 110V outlet while set in the 220V setting, no damage will result, but the supply will certainly not operate properly until you correct the setting. On the other hand, if you are in a foreign country with a 220V outlet and have the switch set for 110V, you might cause damage.

Power Supply Specifications

In addition to power output, many other specifications and features go into making a high-quality power supply. I have had many systems over the years. My experience has been that if a brownout occurs in a room with several systems running, the systems with higher-quality power supplies and higher output ratings are far more likely to make it through the power disturbances unscathed, whereas others choke.

High-quality power supplies also help protect your systems. A power supply from a vendor such as Astec or PC Power and Cooling will not be damaged if any of the following conditions occur:

- A 100% power outage of any duration
- A brownout of any kind
- A spike of up to 2,500V applied directly to the AC input (for example, a lightning strike or a lightning simulation test)

Decent power supplies have an extremely low current leakage to ground of less than 500 microamps. This safety feature is important if your outlet has a missing or improperly wired ground line.

As you can see, these specifications are fairly tough and are certainly representative of a high-quality power supply. Make sure that your supply can meet these specifications.

You can also use many other criteria to evaluate a PSU. The power supply is a component many users ignore when shopping for a PC, and it is therefore one that some system vendors might choose to skimp on. After all, a dealer is far more likely to be able to increase the price of a computer by spending money on additional memory or a larger hard drive than by installing a better power supply.

When buying a computer (or a replacement PSU), it is always a good idea to learn as much as possible about the power supply. However, many consumers are intimidated by the vocabulary and the statistics found in a typical PSU specification. Here are some of the most common parameters found on power supply specification sheets, along with their meanings:

- *Mean Time Between Failures (MTBF) or Mean Time To Failure (MTTF)*. The (calculated) average interval, in hours, that the power supply is expected to operate before failing. Power supplies typically have MTBF ratings (such as 100,000 hours or more) that are clearly not the

result of real-time empirical testing. In fact, manufacturers use published standards to calculate the results, based on the failure rates of the power supply's individual components. MTBF figures for power supplies often include the load to which the PSU was subjected (in the form of a percentage) and the temperature of the environment in which the tests were performed.

- **Input Range (or Operating Range).** The range of voltages that the power supply is prepared to accept from the AC power source. For 110V AC current, an input range of 90–135V is common; for 220V current, a 180–270V range is typical.
- **Peak Inrush Current.** The greatest amount of current drawn by the power supply at a given moment immediately after it is turned on, expressed in terms of amps at a particular voltage. The lower the current, the less thermal shock the system experiences.
- **Holdup Time.** The amount of time (in milliseconds) that a power supply's output remains within the specified voltage ranges after its input ceases. Values of 15–25 milliseconds are common for today's PSUs.
- **Transient Response.** The amount of time (in microseconds) a power supply takes to bring its output back to the specified voltage ranges after a steep change of the output current. In other words, the amount of time it takes for the output power levels to stabilize after a device in the system starts or stops drawing power. Power supplies sample the current being used by the computer at regular intervals. When a device stops drawing power during one of these intervals (such as when a floppy drive stops spinning), the PSU might supply too high a voltage to the output for a brief time. This excess voltage is called overshoot, and the transient response is the time that it takes for the voltage to return to the specified level. Once a major problem that came with switching power supplies, overshoot has been greatly reduced in recent years. Transient response values are sometimes expressed in time intervals, and at other times are expressed in terms of a particular output change, such as "power output levels stay within regulation during output changes of up to 20 percent."
- **Overvoltage Protection.** The trip points for each output at which the power supply shuts down or squelches the signal for that output. Values can be expressed as a percentage (for example, 120% for +3.3 and +5V) or as raw voltages (for example, +4.6V for the +3.3V output and +7.0V for the +5V output).
- **Maximum Load Current.** The largest amount of current (in amps) that can be safely delivered through a particular output. Values are expressed as individual amperages for each output voltage. With these figures, you can calculate not only the total amount of power the PSU can supply, but also how many devices using those various voltages it can support.
- **Minimum Load Current.** The smallest amount of current (in amps) that must be drawn from a particular output for that output to function. If the current drawn from an output falls below the minimum, the power supply could be damaged or could automatically shut down.
- **Load Regulation (or Voltage Load Regulation).** When the current drawn from a particular output increases or decreases, the voltage changes slightly as well, usually increasing as the current rises. Load regulation is the change in the voltage for a particular output as it transitions from its minimum load to its maximum load (or vice versa). Values, expressed in terms of a +/- percentage, typically range from +/-1% to +/-5% for the +3.3, +5, and +12V outputs.
- **Line Regulation.** The change in output voltage as the AC input voltage transitions from the lowest to the highest value of the input range. A power supply should be capable of handling any AC voltage in its input range with a change in its output of 1% or less.

- *Efficiency.* The ratio of a PSU's power input to its power output, expressed in terms of a percentage. Values of 65–85% are common for power supplies today. The remaining 15–35% of the power input is converted to heat during the AC/DC conversion process. Although greater efficiency means less heat inside the computer (always a good thing) and lower electric bills, it should not be emphasized at the expense of precision, as evidenced in the PSU's load regulation and other parameters.
- *Ripple (or Ripple and Noise, or AC Ripple, or PARD [Periodic and Random Deviation]).* The average voltage of all AC components' effects on the power supply's outputs, measured in millivolts peak-to-peak (RMS) for each output voltage. The effects can be caused by internal switching transients, feed through of the rectified line frequency, and other random noise.

Power Supply Certifications

Many agencies around the world certify electric and electronic components for safety and quality. The most commonly known agency in the United States is Underwriters Laboratories, Inc. (UL). UL standard #1950—the *Standard for Safety of Information Technology Equipment, Including Electrical Business Equipment, Third Edition*—covers power supplies and other PC components. It is always a good idea to purchase power supplies and other devices that are UL-certified. It has often been said that, although not every good product is UL-certified, no bad products are.

In Canada, electric and electronic products are certified by the Canadian Standards Agency (CSA). The German equivalents are TÜV Rheinland and VDE. NEMKO operates in Norway. These agencies are responsible for certification of products throughout Europe. Power supply manufacturers that sell to an international market should have products that are certified at least by UL, the CSA, and TÜV—if not by all the agencies listed, and more.

Apart from UL-type certifications, many power supply manufacturers, even the most reputable ones, claim that their products have a Class B certification from the Federal Communications Commission, meaning that they meet FCC standards for electromagnetic and radio frequency interference (EMI/RFI). This is a contentious point, however, because the FCC does not certify power supplies as individual components. Title 47 of the Code of Federal Regulations, Part 15, Section 15.101(c) states as follows:

“The FCC does NOT currently authorize motherboards, cases, and internal power supplies. Vendor claims that they are selling ‘FCC-certified cases,’ ‘FCC-certified motherboards,’ or ‘FCC-certified internal power supplies’ are false.”

In fact, an FCC certification can be issued collectively only to a base unit consisting of a computer case, motherboard, and a power supply. Thus, a power supply purported to be FCC-certified was actually certified along with a particular case and motherboard—not necessarily the same case and motherboard you are using in your system. This does not mean, however, that the manufacturer is being deceitful or that the power supply is inferior. If anything, this means that when evaluating power supplies, you should place less weight on the FCC certification than on other factors, such as UL certification.

Power-Use Calculations

When expanding or upgrading your PC, it is important to be sure your power supply is capable of providing sufficient current to power all the system's internal devices. One way to see whether

your system is capable of expansion is to calculate the levels of power drain in the different system components and deduct the total from the maximum power supplied by the PSU. This calculation can help you decide whether you must upgrade the power supply to a more capable unit. Unfortunately, these calculations can be difficult to make because many manufacturers do not publish power consumption data for their products.

It can be difficult to get power-consumption data for many +5V devices, including motherboards and adapter cards. Motherboards can consume different power levels, depending on numerous factors. Most motherboards consume about 5 amps or so, but try to get information on the one you are using. For adapter cards, if you can find the actual specifications for the card, use those figures. To be on the conservative side, however, I usually go by the maximum available power levels set forth in the respective bus standards.

For example, consider the power-consumption figures for components in a modern PC, such as a desktop or Slimline system with a 200-watt power supply rated for 20 amps at +5V and 8 amps at +12V. The ISA specification calls for a maximum of 2.0 amps of +5V and 0.175 amps of +12V power for each slot in the system. Most systems have eight slots, and you can assume that four are filled for the purposes of calculating power draw. The calculation shown in Table 21.10 shows what happens when you subtract the amount of power necessary to run the different system components:

Table 21.10 Power Consumption Calculation

Available 5V Power (Amps):		20.0A
less:	Motherboard	-5.0A
	4 slots filled at 2.0 each	-8.0A
	3 1/2-inch floppy drive logic	-0.5A
	3 1/2-inch hard disk drive logic	-0.5A
	CD-ROM/DVD drive logic	-1.0A
	Remaining power (amps):	5.0A
Available 12V Power (Amps):		8.0A
less:	4 slots filled at 0.175 each	-0.7A
	3 1/2-inch hard disk drive motor	-1.0A
	3 1/2-inch floppy drive motor	-1.0A
	Cooling fan motor	-0.1A
	CD-ROM/DVD drive motor	-1.0A
	Remaining power (amps):	4.2A

In the preceding example, everything seems all right for the present. With half the slots filled, a floppy drive, and one hard disk, the system still has room for more. Problems with the power supply could come up, however, if this system were expanded to the extreme. With every slot filled and two or more hard disks, there definitely would be problems with the +5V current. However, the +12V does seem to have room to spare. You could add a CD-ROM drive or a second hard disk without worrying too much about the +12V power, but the +5V power would be strained.

If you anticipate loading up a system to the extreme—as in a high-end multimedia system, for example—you might want to invest in the insurance of a higher output power supply. For example, a 250-watt supply usually has 25 amps of +5V and 10 amps of +12V current, whereas a 300-watt unit usually has 32 amps of +5V current available. These supplies enable you to fully load the system and are likely to be found in full-sized desktop or tower case configurations in which this type of expansion is expected.

Motherboards can draw anywhere from four to fifteen amps or more of +5V power to run. In fact, a single Pentium 66MHz CPU draws up to 3.2 amps of +5V power all by itself. A 200MHz Pentium Pro CPU or 400MHz Pentium II consumes up to 15 amps. Considering that systems with two or more processors are now becoming common, you could have 30 amps or more drawn by the processors alone. A motherboard such as this—with two CPUs and 128MB or more of RAM for each CPU—might draw more than 40 amps all by itself. Very few “no-name” power supplies can supply this kind of current. For these applications, you should consider only high-quality, high-capacity power supplies from a reputable manufacturer, such as PC Power and Cooling.

In these calculations, bus slots are allotted maximum power in amps, as shown in Table 21.11.

Table 21.11 Maximum Power Consumption in Amps per Bus Slot

Bus Type	+5V Power	+12V Power	+3.3V Power
ISA	2.0	0.175	n/a
EISA	4.5	1.5	n/a
VL-bus	2.0	n/a	n/a
16-bit MCA	1.6	0.175	n/a
32-bit MCA	2.0	0.175	n/a
PCI	5	0.5	7.6

As you can see from the table, ISA slots are allotted 2.0 amps of +5V and 0.175 amps of +12V power. Note that these are maximum figures; not all cards draw this much power. If the slot has a VL-bus extension connector, an additional 2.0 amps of +5V power are allowed for the VL-bus.

Floppy drives can vary in power consumption, but most of the newer 3 1/2-inch drives have motors that run on +5V current in addition to the logic circuits. These drives usually draw 1.0 amps of +5V power and use no +12V at all. 5 1/4-inch drives use standard +12V motors that draw about 1.0 amps. These drives also require about 0.5 amps of +5V for the logic circuits. Most cooling fans draw about 0.1 amps of +12V power, which is negligible.

Typical 3 1/2-inch hard disks today draw about 1 amp of +12V power to run the motors and only about 0.5 amps of +5V power for the logic. 5 1/4-inch hard disks, especially those that are full-height, draw much more power. A typical full-height hard drive draws 2.0 amps of +12V power and 1.0 amps of +5V power.

Another problem with hard disks is that they require much more power during the spinup phase of operation than during normal operation. In most cases, the drive draws double the +12V power during spinup, which can be 4.0 amps or more for the full-height drives. This tapers off to normal after the drive is spinning.

The figures that most manufacturers report for maximum power supply output are full duty-cycle figures. The PSU can supply these levels of power continuously. You usually can expect a unit that continuously supplies a given level of power to be capable of exceeding this level for some noncontinuous amount of time. A supply usually can offer 50% greater output than the continuous figure indicates for as long as one minute. Systems often use this cushion to supply the necessary power to spin up a hard disk drive. After the drive has spun to full speed, the power draw drops to a value within the system's continuous supply capabilities. Drawing anything over the rated continuous figure for any extended length of time causes the power supply to run hot and fail early and can also create nasty symptoms in the system.

Tip

If you are using internal SCSI hard drives, you can ease the startup load on your power supply. The key is to enable the SCSI drive's Remote Start option, which causes the drive to start spinning only when it receives a startup command over the SCSI bus. The effect is that the drive remains stationary (drawing very little power) until the very end of the POST and spins up right when the SCSI portion of the POST is begun.

If you have multiple SCSI drives, they all spin up sequentially based on their SCSI ID setting. This is designed so that only one drive is spinning up at any one time and so that no drives start spinning until the rest of the system has had time to start. This greatly eases the load on the power supply when you first power the system on.

In most cases, you enable Remote Start through your SCSI host adapter's setup program. This program might be supplied with the adapter on separate media, or it might be integrated into the adapter's BIOS and activated with a specific key combination at boot time.

The biggest cause of power supply overload problems has historically been filling up the expansion slots and adding more drives. Multiple hard drives, CD-ROM drives, and floppy drives can create quite a drain on the system power supply. Make sure that you have enough +12V power to run all the drives you plan to install. Tower systems can be especially problematic because they have so many drive bays. Just because the case has room for the devices doesn't mean the power supply can support them. Make sure you have enough +5V power to run all your expansion cards, especially PCI cards. It pays to be conservative, but remember that most cards draw less than the maximum allowed. Today's newest processors can have very high current requirements for the +5- or +3.3-volt supplies. When selecting a power supply for your system, be sure to take into account any future processor upgrades.

Many people wait until an existing component fails before they replace it with an upgraded version. If you are on a tight budget, this "if it ain't broke, don't fix it" attitude might be necessary. Power supplies, however, often do not fail completely all at once; they can fail in an intermittent fashion or allow fluctuating power levels to reach the system, which results in unstable operation. You might be blaming system lockups on software bugs when the culprit is an overloaded power supply. If you have been running your original power supply for a long time and have upgraded your system in other ways, you should expect some problems.

Although there is certainly an appropriate place for the exacting power-consumption calculations you've read about in this section, a great many experienced PC users prefer the "don't worry about it" power calculation method. This technique consists of buying or building a system with a good quality 300-watt or higher power supply (or upgrading to such a supply in an existing system) and then upgrading the system freely, without concern for power consumption.

Tip

My preference is the 425W supply from PC Power and Cooling, which is probably overkill for most people but for those who keep a system for a long time and put it through a number of upgrades it is an excellent choice.

Unless you plan to build a system with arrays of SCSI drives and a dozen other peripherals, you will probably not exceed the capabilities of the PSU, and this method certainly requires far less effort.

Power Off When Not in Use

Should you turn off a system when it is not in use? To answer this frequent question, you should understand some facts about electrical components and what makes them fail. Combine this knowledge with information on power consumption, cost, and safety to come to your own conclusion. Because circumstances can vary, the best answer for your own situation might be different than for others, depending on your particular needs and applications.

Frequently, powering a system on and off does cause deterioration and damage to the components. This seems logical, but the simple reason is not obvious to most people. Many believe that flipping system power on and off frequently is harmful because it electrically “shocks” the system. The real problem, however, is temperature or thermal shock. As the system warms up, the components expand; as it cools off, the components contract. In addition, various materials in the system have different thermal expansion coefficients, which means that they expand and contract at different rates. Over time, thermal shock causes deterioration in many areas of a system.

From a pure system-reliability viewpoint, it is desirable to insulate the system from thermal shock as much as possible. When a system is turned on, the components go from ambient (room) temperature to as high as 185° F (85° C) within 30 minutes or less. When you turn the system off, the same thing happens in reverse, and the components cool back to ambient temperature in a short period of time.

Thermal expansion and contraction remain the single largest cause of component failure. Chip cases can split, allowing moisture to enter and contaminate them. Delicate internal wires and contacts can break, and circuit boards can develop stress cracks. Surface-mounted components expand and contract at different rates than the circuit board they are mounted on, which causes enormous stress at the solder joints. Solder joints can fail due to the metal hardening from the repeated stress, resulting in cracks in the joint. Components that use heat sinks, such as processors, transistors, or voltage regulators, can overheat and fail because the thermal cycling causes heat sink adhesives to deteriorate, breaking the thermally conductive bond between the device and the heat sink. Thermal cycling also causes socketed devices and connections to loosen or “creep,” which can cause a variety of intermittent contact failures.

◀◀ See “SIMMs and DIMMs,” p. 455.

Thermal expansion and contraction affect not only chips and circuit boards, but also things such as hard disk drives. Most hard drives today have sophisticated thermal compensation routines that make adjustments in head position relative to the expanding and contracting platters. Most

drives perform this thermal compensation routine once every five minutes for the first 30 minutes the drive is running, and then every 30 minutes thereafter. In many drives, this procedure can be heard as a rapid “tick-tick-tick-tick” sound. In essence, anything you can do to keep the system at a constant temperature prolongs the life of the system, and the best way to accomplish this is to leave the system either permanently on or off. Of course, if the system is never turned on in the first place, it should last a long time indeed!

Now, I am not saying that you should leave all systems on 24 hours a day. A system powered on and left unattended can be a fire hazard (I have had monitors spontaneously catch fire—luckily, I was there at the time), is a data security risk (from cleaning crews and other nocturnal visitors), can be easily damaged if moved while running, and wastes electrical energy.

I currently pay 11 cents for a kilowatt-hour of electricity. A typical desktop-style PC with display consumes at least 300 watts (0.3 kilowatt) of electricity (and that is a conservative estimate). This means that it would cost 3.3 cents to run my typical PC for an hour. Multiplying by 168 hours in a week means that it would cost \$5.54 per week to run this PC continuously. If the PC were turned on at 9 a.m. and off at 5 p.m., it would be on only 40 hours per week and would cost only \$1.32—a savings of \$4.22 per week! Multiply this savings by 100 systems, and you are saving \$422 per week. Multiply this by 1,000 systems, and you are saving \$4,220 per week! Using systems certified under the new EPA Energy Star program (so-called green PCs) would account for an additional savings of around \$1 per system per week—or \$1,000 per week for 1,000 systems. The great thing about Energy Star systems is that the savings are even greater if the systems are left on for long periods of time because the power management routines are automatic.

Based on these facts, my recommendations are that you power the systems on at the beginning of the workday and off at the end of the workday. Do not power the systems off for lunch, breaks, or any other short periods of time. If you are a home user, leave your computer on if you are going to be using it later in the day or if instant access is important. I'd normally recommend home users turn the system off when leaving the house or when sleeping. Servers, of course, should be left on continuously. This seems to be the best compromise of system longevity with pure economics. No matter what, these are just guidelines; if it works better for you to leave your system on 24 hours a day, seven days a week, make it so.

Power Management

As the standard PC configuration has grown to include capabilities formerly considered options, the power requirements of the system have increased steadily. Larger displays, CD-ROM drives, and audio adapters all need more power to run, and the cost of operating a PC rises steadily. To address these concerns, several programs and standards are now being developed that are intended to reduce the power needed to run a PC as much as possible.

For standard desktop systems, power management is a matter of economy and convenience. By turning off specific components of the PC when they are not in use, you can reduce the electric bill and avoid having to power the computer up and down manually.

For portable systems, power management is far more important. Adding CD-ROMs, speakers, and other components to a laptop or notebook computer reduces what is in many cases a short battery life even further. By adding new power management technology, a portable system can

supply power only to the components it actually needs to run, thus extending the life of the battery charge.

Energy Star Systems

The EPA has started a certification program for energy-efficient PCs and peripherals. To be a member of this program, the PC or display must drop to a power draw at the outlet of 30 watts or less during periods of inactivity. Systems that conform to this specification get to wear the Energy Star logo. This is a voluntary program; however, many PC manufacturers are finding that it helps them sell their systems if they can advertise these systems as energy efficient.

One problem with this type of system is that the motherboard and disk drives can go to sleep, which means they can enter a standby mode in which they draw very little power. This causes havoc with some of the older power supplies because the low power draw does not provide enough of a load for them to function properly. Most of the newer supplies on the market, which are designed to work with these systems, have a very low minimum load specification. I suggest that you ensure that the minimum load will be provided by the equipment in your system if you buy a power supply upgrade. Otherwise, when the PC goes to sleep, it might take a power switch cycle to wake it up again. This problem would be most noticeable if you invested in a very high output supply and used it in a system that draws very little power to begin with.

Advanced Power Management

Advanced Power Management (APM) is a specification jointly developed by Intel and Microsoft that defines a series of interfaces between power management-capable hardware and a computer's operating system. When it is fully implemented, APM can automatically switch a computer between five states, depending on the system's current activity. Each state represents a further reduction in power use, accomplished by placing unused components into a low-power mode. The five system states are as follows:

- *Full On.* The system is completely operational, with no power management occurring.
- *APM Enabled.* The system is operational, with some devices being power managed. Unused devices can be powered down and the CPU clock slowed or stopped.
- *APM Standby.* The system is not operational, with most devices in a low-power state. The CPU clock can be slowed or stopped, but operational parameters are retained in memory. When triggered by a specific user or system activities, the system can return to the APM Enabled state almost instantaneously.
- *APM Suspend.* The system is not operational, with most devices unpowered. The CPU clock is stopped and operational parameters are saved to disk for later restoration. When triggered by a wakeup event, the system returns to the APM Enabled state relatively slowly.
- *Off.* The system is not operational. The power supply is off.

APM requires support from both hardware and software to function. In this chapter, you've already seen how ATX-style power supplies can be controlled by software commands using the Power_On signal and the six-pin optional power connector. Manufacturers are also integrating the same sort of control features into other system components, such as motherboards, monitors, and disk drives.

Operating systems that support APM, such as Windows 9x, trigger power management events by monitoring the activities performed by the computer user and the applications running on the system. However, the OS does not directly address the power management capabilities of the hardware.

A system can have many different hardware devices and many different software functions participating in APM functions, which makes communication difficult. To address this problem, both the operating system and the hardware have an abstraction layer that facilitates communication between the various elements of the APM architecture.

The operating system runs an APM driver that communicates with the various applications and software functions that trigger power management activities, while the system's APM-capable hardware devices all communicate with the system BIOS. The APM driver and the BIOS communicate directly, completing the link between the OS and the hardware.

Thus, for APM to function, there must be support for the standard built into the system's individual hardware devices, the system BIOS, and the operating system (which includes the APM driver). Without all these components, APM activities cannot occur.

Advanced Configuration and Power Interface (ACPI)

ACPI is a newer power management and system configuration standard supported by newer system BIOS software running Windows 98 and later operating systems. If your BIOS and operating system support ACPI, full power management control is now done by the operating system, rather than by the BIOS. ACPI is intended to offer a single place for power management and system configuration control; in the past, with APM you would often be able to make power management settings in the BIOS setup as well as the operating system that often overlapped or could have conflicting settings. ACPI is supported in newer systems in lieu of APM.

Tip

If, for any reason, you find that power management activities cause problems on your system, such as operating system freeze-ups or hardware malfunctions, the easiest way to disable APM is through the system BIOS. Most BIOSes that support APM include an option to disable it. This breaks the chain of communication between the operating system and the hardware, causing all power management activities to cease. Although it is also possible to achieve the same end by removing the APM driver from the operating system, Windows 9x's Plug-and-Play (PnP) feature detects the system's APM capabilities whenever you restart the computer and attempts to reinstall the APM driver.

If you have a newer system with ACPI, you can disable the power management settings via the Power Management icon in the Windows control panel.

Power Supply Troubleshooting

Troubleshooting the power supply basically means isolating the supply as the cause of problems within a system and, if necessary, replacing it.

Caution

It is rarely recommended that an inexperienced user open a power supply to make repairs because of the dangerous high voltages present. Even when unplugged, power supplies can retain dangerous voltage and must be discharged (like a monitor) before service. Such internal repairs are beyond the scope of this book and are specifically not recommended unless the technician knows what he or she is doing.

Many symptoms lead me to suspect that the power supply in a system is failing. This can sometimes be difficult for an inexperienced technician to see because at times there appears to be little connection between the symptom and the cause—the power supply.

For example, in many cases a parity check error message can indicate a problem with the power supply. This might seem strange because the parity check message specifically refers to memory that has failed. The connection is that the power supply powers the memory, and memory with inadequate power fails.

It takes some experience to know when this type of failure is power related, not caused by the memory. One clue is the repeatability of the problem. If the parity check message (or other problem) appears frequently and identifies the same memory location each time, I would suspect that defective memory is the problem. However, if the problem seems random, or if the memory location the error message cites as having failed seems random, I would suspect improper power as the culprit. The following is a list of PC problems that often are related to the power supply:

- Any power-on or system startup failures or lockups
- Spontaneous rebooting or intermittent lockups during normal operation
- Intermittent parity check or other memory-type errors
- Hard disk and fan simultaneously failing to spin (no +12V)
- Overheating due to fan failure
- Small brownouts cause the system to reset
- Electric shocks felt on the system case or connectors
- Slight static discharges disrupt system operation

In fact, just about any intermittent system problem can be caused by the power supply. I always suspect the supply when flaky system operation is a symptom. Of course, the following fairly obvious symptoms point right to the power supply as a possible cause:

- System is completely dead (no fan, no cursor)
- Smoke
- Blown circuit breakers

If you suspect a power supply problem, some of the simple measurements and the more sophisticated tests outlined in this section can help you determine whether the power supply is at fault. Because these measurements might not detect some intermittent failures, you might have to use a spare power supply for a long-term evaluation. If the symptoms and problems disappear when a “known good” spare unit is installed, you have found the source of your problem.

Following is a simple flowchart to help you zero in on common power supply related problems:

1. Check AC power input. Make sure the cord is firmly seated in the wall socket and in the power supply socket. Try a different cord.
2. Check DC power connections. Make sure the motherboard and disk drive power connectors are firmly seated and making good contact. Check for loose screws.
3. Check DC power output. Use a digital multimeter to check for proper voltages. If below spec, replace the power supply.
4. Check installed peripherals. Remove all boards and drives and retest the system. If it works, add back in items one at a time until the system fails again. The last item added before the failure returns is likely defective.

Many different types of symptoms can indicate problems with the power supply. Because the power supply literally powers everything else in the system, everything from disk drive problems to memory problems to motherboard problems can often be traced back to the power supply as the root cause.

Overloaded Power Supplies

A weak or inadequate power supply can put a damper on your ideas for system expansion. Some systems are designed with beefy power supplies, as if to anticipate a great deal of system add-ons and expansion components. Most desktop or tower systems are built in this manner. Some systems have inadequate power supplies from the start, however, and cannot adequately service the power-hungry options you might want to add.

The wattage rating can sometimes be very misleading. Not all 300-watt supplies are created the same. People familiar with high-end audio systems know that some watts are better than others. This goes for power supplies, too. Cheap power supplies might in fact put out the rated power, but what about noise and distortion? Some of the supplies are under-engineered to just barely meet their specifications, whereas others might greatly exceed their specifications. Many of the cheaper supplies provide noisy or unstable power, which can cause numerous problems with the system. Another problem with under-engineered power supplies is that they can run hot and force the system to do so as well. The repeated heating and cooling of solid-state components eventually causes a computer system to fail, and engineering principles dictate that the hotter a PC's temperature, the shorter its life. Many people recommend replacing the original supply in a system with a heavier duty model, which solves the problem. Because power supplies come in common form factors, finding a heavy-duty replacement for most systems is easy, as is the installation process.

Inadequate Cooling

Some of the available replacement power supplies have higher capacity cooling fans than the originals, which can greatly prolong system life and minimize overheating problems, especially for the newer, hotter-running processors. If system noise is a problem, models with special fans can run more quietly than the standard models. These PSUs often use larger-diameter fans that spin more slowly, so they run more quietly and move the same amount of air as the smaller fans. PC Power and Cooling specializes in heavy-duty and quiet supplies; Astec has several heavy-duty models as well.

Ventilation in a system is also important. You must ensure adequate airflow to cool the hotter items in the system. Many processors today use passive heat sinks that require a steady stream of air to cool the chip. If the processor heat sink has its own fan, this is not much of a concern. If you have free expansion slots, it's a good idea to space out the boards in your system to permit airflow between them. Place the hottest running boards nearest the fan or the ventilation holes in the system. Make sure that there is adequate airflow around the hard disk drive, especially for those that spin at high rates of speed. Some hard disks can generate quite a bit of heat during operation. If the hard disks overheat, data can be lost.

Always make sure you run your computer with the case cover on, especially if you have a loaded system. Removing the cover can actually cause a system to overheat. With the cover off, the power supply fan no longer draws air through the system. Instead, the fan ends up cooling the supply only, and the rest of the system must be cooled by simple convection. Although most systems do not immediately overheat for this reason, several of my own systems, especially those that are fully expanded, have overheated within 15–30 minutes when run with the case cover off.

In addition, be sure that any empty slot positions have the filler brackets installed. If you leave these brackets off after removing a card, the resultant hole in the case disrupts the internal airflow and might cause higher internal temperatures.

If you experience intermittent problems that you suspect are related to overheating, a higher-capacity replacement power supply is usually the best cure. Specially designed supplies with additional cooling fan capacity also can help. At least one company sells a device called a fan card, but I am not convinced these are a good idea. Unless the fan is positioned to draw air to or from outside the case, all it does is blow hot air around inside the system and provide a spot cooling effect for anything it is blowing on. In fact, adding fans in this manner contributes to the overall heat inside the system because the fan consumes power and generates heat.

CPU-mounted fans are an exception because they are designed only for spot cooling of the CPU. Many newer processors run so much hotter than the other components in the system that a conventional finned aluminum heat sink cannot do the job. In this case, a small fan placed directly over the processor provides a spot cooling effect that keeps the processor temperatures down. One drawback to these active processor cooling fans is that the processor overheats instantly and can be damaged if they fail. Whenever possible, try to use the biggest passive (finned aluminum) heat sink you can find and purchase a CPU fan from a reputable vendor.

Using Digital Multi-Meters

One simple test you can perform on a power supply is to check the output voltages. This shows whether a power supply is operating correctly and whether the output voltages are within the correct tolerance range. Note that you must measure all voltages with the power supply connected to a proper load, which usually means testing while the power supply is still installed in the system.

Selecting a Meter

You need a simple Digital Multi-Meter (DMM) or Digital Volt-Ohm Meter (DVOM) to perform voltage and resistance checks on electronic circuits (see Figure 21.17). You should use only a

DMM instead of the older needle-type multimeters because the older meters work by injecting a 9V signal into the circuit when measuring resistance, which damages most computer circuits.

Figure 21.17 A typical DMM.

A DMM uses a much smaller voltage (usually 1.5V) when making resistance measurements, which is safe for electronic equipment. You can get a good DMM with many different features from several sources. I prefer the small pocket-sized meters for computer work because they are easy to carry around.

Some features to look for in a good DMM are as follows:

- *Pocket size.* This is self-explanatory, but small meters are available that have many, if not all, of the features of larger ones. The elaborate features found on some of the larger meters are not really needed for computer work.
- *Overload protection.* This means that if you plug the meter into a voltage or current beyond the meter's capability to measure, the meter protects itself from damage. Cheaper meters lack this protection and can be easily damaged by reading current or voltage values that are too high.
- *Autoranging.* This means that the meter automatically selects the proper voltage or resistance range when making measurements. This is preferable to the manual range selection; however, really good meters offer both autoranging capability and a manual range override.
- *Detachable probe leads.* The leads can be easily damaged, and sometimes a variety of differently shaped probes are required for different tests. Cheaper meters have the leads permanently attached, which means that you cannot easily replace them. Look for a meter with detachable leads that plug into the meter.
- *Audible continuity test.* Although you can use the ohm scale for testing continuity (0 ohms indicates continuity), a continuity test function causes the meter to produce a beep noise when continuity exists between the meter test leads. By using the sound, you can quickly test cable assemblies and other items for continuity. After you use this feature, you will never want to use the ohms display for this purpose again.
- *Automatic power off.* These meters run on batteries, and the batteries can easily be worn down if the meter is accidentally left on. Good meters have an automatic shutoff that turns off the unit when it senses no readings for a predetermined period of time.

- *Automatic display hold.* This feature enables you to hold the last stable reading on the display even after the reading is taken. This is especially useful if you are trying to work in a difficult-to-reach area single-handedly.
- *Minimum and maximum trap.* This feature enables the meter to trap the lowest and highest readings in memory and hold them for later display, which is especially useful if you have readings that are fluctuating too quickly to see on the display.

Although you can get a basic pocket DMM for as little as \$20, one with all these features is priced in the \$100–\$200 range. Radio Shack carries some nice inexpensive units, and you can purchase the high-end models from electronics supply houses, such as Newark or Digi-Key.

Measuring Voltage

To measure voltages on a system that is operating, you must use a technique called *back probing* on the connectors (see Figure 21.18). You cannot disconnect any of the connectors while the system is running, so you must measure with everything connected. Nearly all the connectors you need to probe have openings in the back where the wires enter the connector. The meter probes are narrow enough to fit into the connector alongside the wire and make contact with the metal terminal inside. The technique is called *back probing* because you are probing the connector from the back. You must use this back probing technique to perform virtually all the following measurements.

Figure 21.18 Back probing the power supply connectors.

To test a power supply for proper output, check the voltage at the Power_Good pin (P8-1 on AT, Baby-AT, and LPX supplies; pin 8 on the ATX-type connector) for +3V to +6V of power. If the measurement is not within this range, the system never sees the Power_Good signal and therefore does not start or run properly. In most cases, the power supply is bad and must be replaced.

Continue by measuring the voltage ranges of the pins on the motherboard and drive power connectors. If you are measuring voltages for testing purposes, any reading within 10% of the specified voltage is considered acceptable, although most manufacturers of high-quality power supplies specify a tighter 5% tolerance. For ATX power supplies, the specification requires that voltages must be within 5% of the rating, except for the 3.3V current, which must be within 4%. The following table shows the voltage ranges within these tolerances.

Desired Voltage	Loose Tolerance		Tight Tolerance	
	Min. (-10%)	Max. (+8%)	Min. (-5%)	Max. (+5%)
+3.3V	2.97V	3.63V	3.135	3.465
+/-5.0V	4.5V	5.4V	4.75	5.25
+/-12.0V	10.8V	12.9V	11.4	12.6

The Power_Good signal has tolerances that are different from the other signals, although it is nominally a +5V signal in most systems. The trigger point for Power_Good is about +2.5V, but most systems require the signal voltage to be within the tolerances listed:

Signal	Minimum	Maximum
Power_Good (+5V)	3.0V	6.0V

Replace the power supply if the voltages you measure are out of these ranges. Again, it is worth noting that any and all power supply tests and measurements must be made with the power supply properly loaded, which usually means that it must be installed in a system and the system must be running.

Specialized Test Equipment

You can use several types of specialized test gear to test power supplies more effectively. Because the power supply is one of the most failure-prone items in PCs today, it is wise to have these specialized items if you service many PC systems.

Load Resistors for Bench Testing a Power Supply

Bench testing a power supply requires some special setup because all PC power supplies require a load to operate.

Variable Voltage Transformer

When testing power supplies, it is sometimes desirable to simulate different AC voltage conditions at the wall socket to observe how the supply reacts. A variable voltage transformer is a useful test device for checking power supplies because it enables you to exercise control over the AC line voltage used as input for the power supply (see Figure 21.19). This device consists of a large transformer mounted in a housing with a dial indicator that controls the output voltage. You

plug the line cord from the transformer into the wall socket and plug the PC power cord into the socket provided on the transformer. The knob on the transformer can be used to adjust the AC line voltage received by the PC.

Most variable transformers can adjust their AC output from 0V to 140V, no matter what the AC input (wall socket) voltage is. Some can cover a range from 0V to 280V as well. You can use the transformer to simulate brownout conditions, enabling you to observe the PC's response. Thus, you can check a power supply for proper Power_Good signal operation, among other things.

Figure 21.19 A variable voltage transformer.

By running the PC and dropping the voltage until the PC shuts down, you can see how much reserve is in the power supply for handling a brownout or other voltage fluctuations. If your transformer can output voltages in the 200V range, you can test the capability of the power supply to run on foreign voltage levels. A properly functioning supply should operate between 90V to 135V but should shut down cleanly if the voltage is outside that range.

One indication of a problem is seeing parity check-type error messages when you drop the voltage to 80V. This indicates that the Power_Good signal is not being withdrawn before the power supply output to the PC fails. The PC should simply stop operating as the Power_Good signal is withdrawn, causing the system to enter a continuous reset loop.

Variable voltage transformers are sold by a number of electronic parts supply houses, such as Newark and Digi-Key. You should expect to pay anywhere from \$100 to \$300 for this device.

Repairing the Power Supply

Hardly anyone actually repairs power supplies anymore, primarily because it is usually cheaper simply to replace the supply with a new one. Even high-quality power supplies are not that expensive when compared to the labor required to repair them.

A defective power supply is usually discarded unless it happens to be one of the higher quality or more expensive units. In that case, it is usually wise to send the supply out to a company that specializes in repairing power supplies and other components. These companies usually provide what is called depot repair, which means you send the supply to them, and they repair it and return it to you. If time is of the essence, most of the depot repair companies immediately send you a functional equivalent to your defective supply and take yours in as a core charge. Depot repair is the recommended way to service many PC components, such as power supplies, monitors, and printers. If you take your PC in to a conventional service outlet, they often determine which component has the problem and send it out to be depot repaired. You can do that yourself and save the markup that the repair shop normally charges in such cases.

For those with experience around high voltages, it might be possible to repair a failing supply with two relatively simple operations; however, these require opening the supply. I do not recommend doing so but I mention it only as an alternative to replacement in some cases.

Most manufacturers try to prevent you from entering the supply by sealing it with special tamper-proof Torx screws. These screws use the familiar Torx star driver, but also have a tamper-prevention pin in the center that prevents a standard driver from working. Most tool companies such as Jensen or Specialized sell sets of TT (tamperproof Torx) bits, which remove the tamper-resistant screws. Other manufacturers rivet the power supply case shut, which means you must drill out the rivets to gain access.

Caution

The manufacturers place these obstacles there for a reason—to prevent entry by those who are inexperienced with high voltage. Consider yourself warned!

Most power supplies have an internal fuse that is part of the overload protection. If this fuse is blown, the supply does not operate. It is possible to replace this fuse if you open the supply. Be aware, however, that in most cases an underlying power supply problem caused the fuse to blow, and replacing it only causes it to blow again until you address the root cause of the problem. In this case, you are better off sending the unit to a professional depot repair company. The Vendor List on the CD lists several companies that do depot repair on power supplies and other components.

PC power supplies have an internal voltage adjustment control that the manufacturer calibrates and sets at the factory. Over time, the condition of some of the components in the supply can change, thus altering the output voltages. If this is the case, you might be able to access the adjustment control and tweak it to bring the voltages back to where they should be.

Several adjustable controls are in the supply—usually small variable resistors that you can turn with a screwdriver.

Caution

You should use a nonconductive tool, such as a fiberglass or plastic screwdriver designed for this purpose. If you dropped a metal tool into an operating supply, dangerous sparks and possibly fire could result—not to mention the danger of electrocution and damage to the supply.

You also have to figure out which of the adjustments are for voltage and which are for each voltage signal. This requires some trial-and-error testing. You can mark the current positions of all the resistors, begin measuring a single voltage signal, and try moving each adjuster slightly until you see the voltage change. If you move an adjuster and nothing changes, put it back to the original position you marked. Through this process, you can locate and adjust each of the voltages to the standard 3.3V, 5V, and 12V levels.

Obtaining Replacement Units

Most of the time, it is simply easier, safer, or less expensive (considering the time and materials involved) to replace the power supply rather than to repair it. As mentioned earlier, replacement power supplies are available from many manufacturers. Before you can shop for a supplier, however, you should consider other purchasing factors.

Deciding on a Power Supply

When you are shopping for a new power supply, you should take several factors into account. First, consider the power supply's shape, or form factor. For example, the power supply used in an AT-style system differs in size from the one used in a Slimline computer. The larger AT form factor power supplies simply will not fit into a Slimline case designed for an LPX supply. ATX supplies are consistent in size, so any ATX supply should fit any ATX chassis.

Apart from electrical considerations, power supply form factors can differ physically in their size, shape, screw-hole positions, connector type, number of connectors, fan location, and switch position. However, systems that use the same form factor can easily interchange power supplies. When ordering a replacement supply, you need to know which form factor your system requires.

Some systems use proprietary power supply designs, which makes replacement more difficult. If a system uses one of the common form factor power supplies, replacement units are available from hundreds of vendors. An unfortunate user of a system with a nonstandard form factor supply does not have this kind of choice and must get a replacement from the original manufacturer of the system—and usually pay through the nose for the unit. Although you can find standard form factor supplies for under \$100, the proprietary units from some manufacturers run as high as \$400 or more. PC buyers often overlook this and discover too late the consequences of having nonstandard components in a system.

◀◀ See "Power Supply Form Factors," p. 1154.

Companies such as Hewlett-Packard and Compaq are notorious for using proprietary form factor power supplies. Be sure you consider this if you intend on owning these types of systems out of warranty. Personally, I always insist on systems that use industry standard power supplies such as the ATX form factor supply found in many systems today.

Sources for Replacement Power Supplies

Because one of the most failure-prone items in PC systems is the power supply, I am often asked to recommend a replacement. Literally hundreds of companies manufacture PC power supplies, and I certainly have not tested them all. I can, however, recommend some companies whose products I have come to know and trust.

Although other high-quality manufacturers are out there, at this time I recommend power supplies from either Astec Standard Power or PC Power and Cooling.

Astec makes the power supplies used in most of the high-end systems by IBM, Hewlett-Packard, Apple, and many other name-brand systems. They have power supplies available in a number of standard form factors (AT/Tower, Baby-AT, LPX, and ATX) and a variety of output levels. They have power supplies with ratings of up to 450 watts and power supplies especially designed for Green PCs, which meet the EPA Energy Star requirements for low-power consumption. Their Green power supplies are specifically designed to achieve high efficiency at low-load conditions. Be aware that high-output supplies from other manufacturers might have problems with very low loads. Astec also makes a number of power supplies for laptop and notebook PC systems and has numerous non-PC type supplies.

PC Power and Cooling has a complete line of power supplies for PC systems. They make supplies in all the standard PC form factors used today. Versions are available in a variety of different quality and output levels, from inexpensive replacements to very high-quality high-output models with ratings of up to 600 to 850 watts. They even have versions with built-in battery backup, redundant power systems, and a series of special models with high-volume, low-speed (quiet) fan assemblies. Their quiet models are especially welcome to people who work in quiet homes or offices and are annoyed by the fan noise that some power supplies emanate. My favorite is their 425W ATX supply, which has specs that put most others to shame.

PC Power and Cooling also has units available that fit some of Compaq's proprietary designs. This can be a real boon if you have to service or repair Compaq systems because the PC Power and Cooling units are available in higher output ratings than Compaq's. These units cost much less than Compaq's and bolt in as direct replacements.

Tip

They also have SFX style supplies which can be used to upgrade systems with Flex-ATX boards and chassis, including E-machines and other low-cost systems. If you have one of these systems and need a high quality replacement supply to support your upgrades, PC Power and Cooling can help.

The support offered by PC Power and Cooling is excellent also, and they have been in business a long time, which is rare in this industry. Besides power supplies, they also have an excellent line of cases.

A high-quality power supply from either of these vendors can be one of the best cures for intermittent system problems and can go a long way toward ensuring trouble-free operation in the future.

Custom Cases

There are several companies making specialized cases for unique systems. These cases offer features such as multiple drive bays, unique appearance, and specialized cooling.

Perhaps the most unique cases on the market are those by Kryotech. They market a case with a built-in refrigeration unit in the base, connected directly to a thermal plate which mounts on the CPU. The plate runs at +80 degrees F (+27C) and can maintain a CPU temperature in the 90-100

degrees F range with processors generating up to 45W. These cases also feature an LCD temperature display on the front for monitoring the temperature. A safety system shutdown is designed to trip if processor overheats. They have models available for Socket 7, Socket 370, Slot 1, or Slot A processors.

The only drawback to these cases is the expense; they cost about \$400 each. They also do not include a power supply which would cost another \$100 to \$200 for something 300W or greater to go with it.

Note that Kryotech does make a specialized cooling system that cools the CPU down to -40F (-40C), but these are only sold complete with motherboards and processors due to their specialized nature.

Another company offering special cases is PC Power and Cooling. They have a line of heavy-duty solid steel cases with multiple drive bays for serious expansion and or server use. For those who want something different and sure to evoke stares from all that see it, they also offer a tower case with a chrome plated front bezel and black cover.

Using Power-Protection Systems

Power-protection systems do just what the name implies: They protect your equipment from the effects of power surges and power failures. In particular, power surges and spikes can damage computer equipment, and a loss of power can result in lost data. In this section, you learn about the four primary types of power-protection devices available and when you should use them.

Before considering any further levels of power protection, you should know that a good quality power supply already affords you a substantial amount of protection. High-end power supplies from the vendors I recommend are designed to provide protection from higher-than-normal voltages and currents, and they provide a limited amount of power-line noise filtering. Some of the inexpensive aftermarket power supplies probably do not have this sort of protection. If you have an inexpensive computer, further protecting your system might be wise.

Caution

All the power protection features in this chapter and the protection features in the power supply inside your computer require that the computer's AC power cable be connected to a ground.

Many older homes do not have three-prong (grounded) outlets to accommodate grounded devices.

Do not use a three-pronged adapter (that bypasses the three-prong requirement and enables you to connect to a two-prong socket) to plug in a surge suppressor, computer, or UPS into a two-pronged outlet. They often don't provide a good ground and can inhibit the capabilities of your power-protection devices.

It is also a good idea to test your power sockets to make sure they are grounded. Sometimes outlets, despite having three-prong sockets, are not connected to a ground wire; an inexpensive socket tester (available at most hardware stores) can detect this condition.

Of course, the easiest form of protection is to turn off and unplug your computer equipment (including your modem) when a thunderstorm is imminent. When this is not possible, however, there are other alternatives.

Power supplies should stay within operating specifications and continue to run a system if any of these power line disturbances occur:

- Voltage drop to 80V for up to 2 seconds
- Voltage drop to 70V for up to .5 seconds
- Voltage surge of up to 143V for up to 1 second

IBM also states that neither their power supplies nor systems will be damaged by the following occurrences:

- Full power outage
- Any voltage drop (brownout)
- A spike of up to 2,500V

Because of their internal protection, many computer manufacturers that use high-quality PSUs state in their documentation that external surge suppressors are not needed with their systems.

To verify the levels of protection built into the existing power supply in a computer system, an independent laboratory subjected several unprotected PC systems to various spikes and surges of up to 6,000V—considered the maximum level of surge that can be transmitted to a system through an electrical outlet. Any higher voltage would cause the power to arc to the ground within the outlet. None of the systems sustained permanent damage in these tests. The worst thing that happened was that some of the systems rebooted or shut down if the surge was more than 2,000V. Each system restarted when the power switch was toggled after a shutdown.

I do not use any real form of power protection on my systems, and they have survived near-direct lightning strikes and powerful surges. The most recent incident, only 50 feet from my office, was a direct lightning strike to a brick chimney that blew the top of the chimney apart. None of my systems (which were running at the time) were damaged in any way from this incident; they just shut themselves down. I was able to restart each system by toggling the power switches. An alarm system located in the same office, however, was destroyed by this strike. I am not saying that lightning strikes or even much milder spikes and surges cannot damage computer systems—another nearby lightning strike did destroy a modem and serial adapter installed in one of my systems. I was just lucky that the destruction did not include the motherboard.

This discussion points out an important oversight in some power-protection strategies: Do not forget to provide protection from spikes and surges on the phone line.

The automatic shutdown of a computer during power disturbances is a built-in function of most high-quality power supplies. You can reset the power supply by flipping the power switch from on to off and back on again. Some power supplies even have an auto-restart function. This type of power supply acts the same as others in a massive surge or spike situation: It shuts down the system. The difference is that after normal power resumes, the power supply waits for a specified delay of three to six seconds and then resets itself and powers the system back up. Because no manual switch resetting is required, this feature might be desirable in systems functioning as network servers or in those found in other unattended locations.

The first time I witnessed a large surge cause an immediate shutdown of all my systems, I was extremely surprised. All the systems were silent, but the monitor and modem lights were still on. My first thought was that everything was blown, but a simple toggle of each system-unit power switch caused the power supplies to reset, and the units powered up with no problem. Since that first time, this type of shutdown has happened to me several times, always without further problems.

The following types of power-protection devices are explained in the sections that follow:

- Surge suppressors
- Line conditioners
- Standby power supplies (SPS)
- Uninterruptible power supplies (UPS)

Surge Suppressors (Protectors)

The simplest form of power protection is any one of the commercially available surge protectors—that is, devices inserted between the system and the power line. These devices, which cost between \$20 and \$200, can absorb the high-voltage transients produced by nearby lightning strikes and power equipment. Some surge protectors can be effective for certain types of power problems, but they offer only very limited protection.

Surge protectors use several devices, usually metal-oxide varistors (MOVs), that can clamp and shunt away all voltages above a certain level. MOVs are designed to accept voltages as high as 6,000V and divert any power above 200V to ground. MOVs can handle normal surges, but powerful surges such as a direct lightning strike can blow right through them. MOVs are not designed to handle a very high level of power and self-destruct while shunting a large surge. These devices therefore cease to function after either a single large surge or a series of smaller ones. The real problem is that you cannot easily tell when they no longer are functional. The only way to test them is to subject the MOVs to a surge, which destroys them. Therefore, you never really know if your so-called surge protector is protecting your system.

Some surge protectors have status lights that let you know when a surge large enough to blow the MOVs has occurred. A surge suppressor without this status indicator light is useless because you never know when it has stopped protecting.

Underwriters Laboratories has produced an excellent standard that governs surge suppressors, called UL 1449. Any surge suppressor that meets this standard is a very good one and definitely offers a line of protection beyond what the power supply in your PC already offers. The only types of surge suppressors worth buying, therefore, should have two features:

- Conformance to the UL 1449 standard
- A status light indicating when the MOVs are blown

Units that meet the UL 1449 specification say so on the packaging or directly on the unit. If this standard is not mentioned, it does not conform. Therefore, you should avoid it.

Another good feature to have in a surge suppressor is a built-in circuit breaker that can be manually reset rather than a fuse. The breaker protects your system if it or a peripheral develops a short. These better surge suppressors usually cost about \$40.

Phone Line Surge Protectors

In addition to protecting the power lines, it is critical to provide protection to your systems from any connected phone lines. If you are using a modem or fax board that is plugged into the phone system, any surges or spikes that travel through the phone line can damage your system. In many areas, the phone lines are especially susceptible to lightning strikes, which are the largest cause of fried modems and damage to the computer equipment attached to them.

Several companies manufacture or sell simple surge protectors that plug in between your modem and the phone line. These inexpensive devices can be purchased from most electronics supply houses. Most of the cable and communication products vendors listed in the Vendor List sell these phone line surge protectors. Some of the standard power line surge protectors include connectors for phone line protection as well.

Line Conditioners

In addition to high-voltage and current conditions, other problems can occur with incoming power. The voltage might dip below the level needed to run the system, resulting in a brownout. Forms of electrical noise other than simple voltage surges or spikes might travel through the power line, such as radio-frequency interference or electrical noise caused by motors or other inductive loads.

Remember two things when you wire together digital devices (such as computers and their peripherals):

- Any wire can act as an antenna and have voltage induced in it by nearby electromagnetic fields, which can come from other wires, telephones, CRTs, motors, fluorescent fixtures, static discharge, and, of course, radio transmitters.
- Digital circuitry responds with surprising efficiency to noise of even a volt or two, making those induced voltages particularly troublesome. The electrical wiring in your building can act as an antenna, picking up all kinds of noise and disturbances.

A line conditioner can handle many of these types of problems. A line conditioner is designed to remedy a variety of problems. It filters the power, bridges brownouts, suppresses high-voltage and current conditions, and generally acts as a buffer between the power line and the system. A line conditioner does the job of a surge suppressor, and much more. It is more of an active device, functioning continuously, rather than a passive device that activates only when a surge is present. A line conditioner provides true power conditioning and can handle myriad problems. It contains transformers, capacitors, and other circuitry that can temporarily bridge a brownout or low-voltage situation. These units usually cost from \$100 to \$300, depending on the power-handling capacity of the unit.

Backup Power

The next level of power protection includes backup power-protection devices. These units can provide power in case of a complete blackout, which provides the time needed for an orderly system shutdown. Two types are available: the standby power supply (SPS) and the uninterruptible power supply (UPS). The UPS is a special device because it does much more than just provide backup power: It is also the best kind of line conditioner you can buy.

Standby Power Supplies (SPS)

A standby power supply is known as an offline device: It functions only when normal power is disrupted. An SPS system uses a special circuit that can sense the AC line current. If the sensor detects a loss of power on the line, the system quickly switches over to a standby battery and power inverter. The power inverter converts the battery power to 110V AC power, which is then supplied to the system.

SPS systems do work, but sometimes a problem occurs during the switch to battery power. If the switch is not fast enough, the computer system shuts down or reboots anyway, which defeats the purpose of having the backup power supply. A truly outstanding SPS adds to the circuit a ferroresonant transformer, a large transformer with the capability to store a small amount of power and deliver it during the switch time. This device functions as a buffer on the power line, giving the SPS almost uninterruptible capability.

SPS units also might have internal line conditioning of their own. Under normal circumstances, most cheaper units place your system directly on the regular power line and offer no conditioning. The addition of a ferroresonant transformer to an SPS gives it additional regulation and protection capabilities because of the buffer effect of the transformer. SPS devices without the ferroresonant transformer still require the use of a line conditioner for full protection. SPS systems usually cost from a couple hundred to several thousand dollars, depending on the quality and power-output capacity.

Uninterruptible Power Supplies (UPS)

Perhaps the best overall solution to any power problem is to provide a power source that is conditioned and that cannot be interrupted—which is the definition of an uninterruptible power supply. UPSes are known as online systems because they continuously function and supply power to your computer systems. Because some companies advertise ferroresonant SPS devices as though they were UPS devices, many now use the term *true UPS* to describe a truly online system. A true UPS system is constructed in much the same way as an SPS system; however, because the computer is always operating from the battery, there is no switching circuit.

In a true UPS, your system always operates from the battery. A voltage inverter converts from 12V DC to 110V AC. You essentially have your own private power system that generates power independently of the AC line. A battery charger connected to the line or wall current keeps the battery charged at a rate equal to or greater than the rate at which power is consumed.

When the AC current supplying the battery charger fails, a true UPS continues functioning undisturbed because the battery-charging function is all that is lost. Because the computer was already running off the battery, no switch takes place, and no power disruption is possible. The battery begins discharging at a rate dictated by the amount of load your system places on the unit, which (based on the size of the battery) gives you plenty of time to execute an orderly system shutdown. Based on an appropriately scaled storage battery, the UPS functions continuously, generating power and preventing unpleasant surprises. When the line power returns, the battery charger begins recharging the battery, again with no interruption.

Note

Occasionally, a UPS can accumulate too much storage and not enough discharge. When this occurs, the UPS emits a loud alarm, alerting you that it's full. Simply unplugging the unit from the AC power source for a while can discharge the excess storage (as it powers your computer) and drain the UPS of the excess.

Many SPS systems are advertised as though they are true UPS systems. The giveaway is the unit's switch time. If a specification for switch time exists, the unit cannot be a true UPS because UPS units never switch. However, a good SPS with a ferroresonant transformer can virtually equal the performance of a true UPS at a lower cost.

Note

Many UPSes today come equipped with a cable and software that enables the protected computer to shut down in an orderly manner on receipt of a signal from the UPS. This way, the system can shut down properly even if the computer is unattended. Some operating systems, such as Windows NT, contain their own UPS software components.

UPS cost is a direct function of both the length of time it can continue to provide power after a line current failure and how much power it can provide. You should therefore purchase a UPS that provides you with enough power to run your system and peripherals and enough time to close files and provide an orderly shutdown. Remember, however, to manually perform a system shutdown procedure during a power outage. You will probably need your monitor plugged into the UPS and the computer. Be sure the UPS you purchase can provide sufficient power for all the devices you must connect to it.

Because of a true UPS's almost total isolation from the line current, it is unmatched as a line conditioner and surge suppressor. The best UPS systems add a ferroresonant transformer for even greater power conditioning and protection capability. This type of UPS is the best form of power protection available. The price, however, can be high. To find out just how much power your computer system requires, look at the UL sticker on the back of the unit. This sticker lists the maximum power draw in watts, or sometimes in just volts and amperes. If only voltage and amperage are listed, multiply the two figures to calculate the wattage.

As an example, if the documentation for a system indicates that the computer can require as much as 110V at a maximum current draw of 5 amps, the maximum power the system can draw is about 550 watts. This wattage is for a system with every slot full, two hard disks, and one floppy—in other words, a system at the maximum possible level of expansion. The system should

never draw any more power than that; if it does, a 5-amp fuse in the power supply will blow. This type of system normally draws an average of 300 watts; to be safe when you make calculations for UPS capacity, however, be conservative. Use the 550-watt figure. Adding a monitor that draws 100 watts brings the total to 650 watts or more. Therefore, to run two fully loaded systems, you'll need an 1,100-watt UPS. Don't forget two monitors, each drawing 100 watts. Therefore, the total is 1,300 watts. A UPS of that capacity or greater will cost approximately \$500–\$700. Unfortunately, that is what the best level of protection costs. Most companies can justify this type of expense only for critical-use PCs, such as network servers.

Note

The highest-capacity UPS sold for use with a conventional 15-amp outlet is about 1,400 watts. If it's any higher, you risk tripping a 15-amp circuit when the battery is charging heavily and the inverter is drawing maximum current.

In addition to the total available output power (wattage), several other factors can distinguish one UPS from another. The addition of a ferroresonant transformer improves a unit's power conditioning and buffering capabilities. Good units also have an inverter that produces a true sine wave output; the cheaper ones might generate a square wave. A square wave is an approximation of a sine wave with abrupt up-and-down voltage transitions. The abrupt transitions of a square wave signal are not compatible with some computer equipment power supplies. Be sure that the UPS you purchase produces a signal compatible with your computer equipment. Every unit has a specification for how long it can sustain output at the rated level. If your systems draw less than the rated level, you have some additional time.

Caution

Be careful! Most UPS systems are not designed for you to sit and compute for hours through an electrical blackout. They are designed to provide power only to essential components and to remain operating long enough to allow for an orderly shutdown. You pay a large amount for units that provide power for more than 15 minutes or so. At some point, it becomes more cost effective to buy a generator than to keep investing in extended life for a UPS.

Some of the many sources of power protection equipment include American Power Conversion (APC), Tripp Lite, and Best Power. These companies sell a variety of UPS, SPS, line, and surge protector products.

Caution

Don't connect a laser printer to a backed-up socket in any SPS or UPS unit. Such printers are electrically noisy and have widely varying current draws. This can be hard on the inverter in an SPS or UPS, frequently causing the inverter to fail or detect an overload and shut down. Either case means that your system will lose power, too.

Printers are normally noncritical because whatever is being printed can be reprinted. Don't connect them to a UPS unless there's a good business need to do so.

Some UPSes and SPSes have sockets that are conditioned but not backed up—that is, they do not draw power from the battery. In cases such as this, you can safely plug printers and other peripherals into these sockets.

RTC/NVRAM Batteries (CMOS Chips)

All 16-bit and higher systems have a special type of chip in them that combines a real-time clock (RTC) with at least 64 bytes (including the clock data) of Non-Volatile RAM (NVRAM) memory. This chip is officially called the RTC/NVRAM chip but is often referred to as the CMOS chip or CMOS RAM because the type of chip used is produced using a CMOS (Complementary Metal Oxide Semiconductor) process. CMOS design chips are known for very low power consumption. This special RTC/NVRAM chip is designed to run off of a battery for several years.

The original chip of this type used in the IBM AT was the Motorola 146818 chip. Although the chips used today have different manufacturers and part numbers, they are all designed to be compatible with this original Motorola part.

These chips include a real-time clock. Its function should be obvious. The clock enables software to read the date and time and preserves the date and time data even when the system is powered off or unplugged.

The NVRAM portion of the chip has another function. It is designed to store basic system configuration, including the amount of memory installed, types of floppy and hard disk drives, and other information. Some of the more modern motherboards use extended NVRAM chips with as much as 2KB or more of space to hold this configuration information. This is especially true for Plug-and-Play systems, which store not only the motherboard configuration but also the configuration of adapter cards. This system can then read this information every time you power on the system.

These chips are normally powered by some type of battery while the system is off. This battery preserves the information in the NVRAM and powers the clock. Most systems use a lithium-type battery because they have a very long life, especially at the low power draw from the typical RTC/NVRAM chip.

Most of the higher-quality modern systems sold today have a new type of chip that has the battery embedded within it. These are made by several companies—including Dallas Semiconductor and Benchmarq. These chips are notable for their long life. Under normal conditions, the battery will last for 10 years—which is, of course, longer than the useful life of the system. If your system uses one of the Dallas or Benchmarq modules, the battery and chip must be replaced as a unit because they are integrated. Most of the time, these chip/battery combinations are installed in a socket on the motherboard just in case a problem requires an early replacement. You can get new modules direct from the manufacturers for \$18 or less, which is often less than the cost of the older separate battery alone.

Some systems do not use a battery at all. Hewlett-Packard, for example, includes a special capacitor in many of their systems that is automatically recharged anytime the system is plugged in. Note that the system does not have to be running for the capacitor to charge; it only has to be plugged in. If the system is unplugged, the capacitor will power the RTC/NVRAM chip for up to a week or more. If the system remains unplugged for a duration longer than that, the NVRAM information is lost. In that case, these systems can reload the NVRAM from a backup kept in a

special flash ROM chip contained on the motherboard. The only pieces of information that will actually be missing when you repower the system will be the date and time, which will have to be reentered. By using the capacitor combined with a NVRAM backup in flash ROM, these systems have a very reliable solution that will last indefinitely.

Many systems use only a conventional battery, which can be either directly soldered into the motherboard or plugged in via a battery connector. For those systems with the battery soldered in, there is normally a spare battery connector on the motherboard where you can insert a conventional plug-in battery, should the original ever fail. In most cases, you would never have to replace the motherboard battery, even if it were completely dead.

Conventional batteries come in many forms. The best are of a lithium design because they will last from two to five years or more. I have seen systems with conventional alkaline batteries mounted in a holder; these are much less desirable because they fail more frequently and do not last as long. Also, they can be prone to leak, and if a battery leaks on the motherboard, the motherboard might be severely damaged.

Besides the different battery types, the chip can require any one of several different voltages. The batteries in PCs are normally 3.0V, 3.6V, 4.5V, or 6V. If you are replacing the battery, make sure that your replacement is the same voltage as the one you removed from the system. Some motherboards can use batteries of several different voltages. Use a jumper or switch to select the different settings. If you suspect your motherboard has this capability, consult the documentation for instructions on changing the settings. Of course, the easiest thing to do is to replace the existing battery with another of the same type.

Symptoms that indicate that the battery is about to fail include having to reset the clock on your PC every time you shut down the system (especially after moving it) and problems during the system's POST, such as drive-detection difficulties. If you experience problems such as these, it is a good idea to make note of your system's CMOS settings and replace the battery as soon as possible.

Caution

When you replace a PC battery, be sure that you get the polarity correct or you will damage the RTC/NVRAM (CMOS) chip. Because the chip is soldered onto most motherboards, this can be an expensive mistake! The battery connector on the motherboard and the battery are normally keyed to prevent a backward connection. The pinout of this connector is on the CD, but should also be listed in your system documentation.

When you replace a battery, in most cases the existing data stored in the NVRAM is lost. Sometimes, however, the data will remain intact for several minutes (I have observed NVRAM retain information with no power for an hour or more), so if you make the battery swap quickly, the information in the NVRAM might be retained. Just to be sure, I recommend that you record all the system configuration settings stored in the NVRAM by your system Setup program. In most cases, you would want to run the BIOS Setup program and copy or print out all the screens showing the different settings. Some Setup programs offer the capability to save the NVRAM data to a file for later restoration if necessary.

Tip

If your system BIOS is password protected and you forget the password, one possible way to bypass the block is to remove the battery for a few minutes and then replace it. This will reset the BIOS to its default settings, removing the password protection.

After replacing a battery, power up the system and use the Setup program to check the date and time setting and any other data that was stored in the NVRAM.

CHAPTER 22

Printers and Scanners

The Evolution of Printing and Scanning Technology

The capability to produce a printed version (often called a hard copy) of a document is a primary function of a PC, and along with modems, printers have become a required accessory. Whether the printer is connected directly to the computer or is accessed via a network, printers are essential. Network access to printers allows a single high-performance printer to serve many users, and printing can now take place remotely via the Internet.

Scanners, once a specialized device found only in the art department of major companies, have their way onto corporate and SOHO (small office, home office) desks alike. Because their use, features, and most common interface (parallel) complement printers, they will also be discussed in this chapter.

Whether you are a corporate buyer looking for a single printer to serve a department, a “road warrior” looking for a portable printer, or a SOHO user looking for the best bang for the buck, there are a huge and ever-increasing variety of printers on the market supporting a multitude of both features and speeds. This chapter examines the underlying concepts of all printer technology, the basic types of printers available today and how they function, and how to install and troubleshoot a printer on your PC.

Printer Technology

Three basic types of printer technologies are used with PCs, defined by the method in which the image is produced on the paper. These three technologies are as follows:

- **Laser.** Laser printers function by creating an electrostatic image of an entire page on a photosensitive drum with a laser beam. When an ultrafine colored powder called *toner* is applied to the drum, it adheres only to the sensitized areas corresponding to the letters or images on the page. The drum spins and is pressed against a sheet of paper, transferring the toner to the page and creating the image. This technology is similar to that used by photocopiers, although there are differences in the details of image transfer and in the internal temperatures of the units.

A similar technology is the LED printer pioneered by Okidata and also produced by Lexmark. These printers replace the laser beam with a fixed array of light-emitting diodes (LEDs) for imaging but are otherwise similar in performance. See the section, “LED Page Printers,” later in this chapter.

- **Inkjet.** Inkjet printers, as their name implies, have tiny nozzles that spray specially formulated ink onto a page. One method uses heated ink (as used by Canon’s BubbleJet line) and another method uses piezo-electric print heads (as in Epson’s Stylus and Stylus Color line).
- **Dot matrix.** Dot-matrix printers use an array of round-headed pins to press an inked ribbon against a page. The pins are arranged in a rectangular grid (called a matrix); different combinations of pins form the various characters and images. A few non-impact printers also use a dot-matrix print head with heat-sensitive ribbons, but these printers are primarily for portable use.

Note

A fourth option, daisywheel, which created fully formed characters similar to typewriting, was popular in law offices during the early days of PCs but has been replaced by laser printers.

In general, laser printers provide the best quality output, followed closely by inkjet, with dot-matrix printers coming in a distant third. Dot-matrix printers have become largely relegated to commercial applications requiring continuous feed and multipart forms. Inkjet printers have become important parts of SOHO (small office, home office) printing because of their high print quality (rivaling less-expensive lasers for text), color capabilities, versatility, and inclusion in many popular “all-in-one” printer-scanner-fax units. Laser printers continue to be the best choice for text-based applications because of their speed, print quality, and low cost-per-page.

Unless you need a low-cost color printer, laser printers are superior to inkjet and dot-matrix printers in almost every way. Most printers use the same basic terminology to describe their features and capabilities. The following sections examine some of this technology, how (or if) it applies to the various printer types, and what you should look for when shopping for a printer.

Print Resolution

The term *resolution* is used to describe the sharpness and clarity of the printed output. All these printer technologies create images by laying down a series of dots on the page. The size and number of these dots determine the printer’s resolution and the quality of the output. If you look at a page of text produced by a low-resolution dot-matrix printer, for example, the pattern of dots that forms the individual characters is immediately obvious to the naked eye. This is because the dots are relatively large and of a uniform size. On high-resolution laser printer output, however, the characters look solid because the dots are much smaller and often can be of different sizes.

Printer resolution is usually measured in dots per inch (dpi). This refers to the number of separate dots that the printer can produce in a straight line one inch long. Most printers function at the same resolution both horizontally and vertically, so a specification such as 300dpi implies a 300×300 dot one-inch square. A 300dpi printer can therefore print 90,000 dots in a square inch of space. There are some printers, however, that specify different resolutions in each direction, such as 600×1,200dpi, which means that the printer can produce 720,000 dots in one square inch.

It’s important to realize that the resolution of a printed page is far higher than that of a typical PC monitor. The word *resolution* is used to quantify PC video displays also, usually in terms of the number of pixels, such as 640×480 or 800×600. By print standards, however, the typical PC video display has a resolution of only 50–80dpi. By measuring the actual height and width of an image on your screen and comparing it to the image’s dimensions in pixels, you can determine the dpi for your display.

As a result, the claims of WYSIWYG (what you see is what you get) output by software and hardware manufacturers are valid only in the roughest sense. All but the lowest-resolution printers should produce output that is far superior to that of your screen display.

Increasing Print Resolution

It might seem that 90,000 dots per square inch is an extraordinary amount of detail, but at 300dpi, printed characters can have noticeably jagged diagonal lines. There are two ways to improve the quality of the printed output and eliminate the “jaggies.” One way is to increase the resolution. Today’s laser printers usually operate at a minimum of 600dpi, with some high-end models reaching as high as 1,200dpi. Commercial offset printing (as used in the printing of this book, for example), by contrast, usually runs from 1,200 to 2,400dpi. By itself, 600dpi resolution is sufficient to eliminate the obvious jaggedness in the print output. This reduce in jaggedness is the first benefit of improving resolution.

A second benefit of improved print resolution is the effect that higher resolutions have on photographic reproduction. Higher resolutions enable laser and inkjet printers in particular to create more detailed and finer-grained photo printouts. The newest photo-realistic inkjet printers combine high resolutions (600dpi and above) with smaller ink droplets and special color printing techniques to create prints that rival snapshot quality when viewed from a short distance.

600dpi and above laser printers also achieve better photographic reproduction, but through different means. The higher resolution enables them to use smaller dots to simulate half-toning, thus producing better quality photo printing.

As you’ll see later, high printer resolutions for inkjet printers are also heavily media-dependent; you can’t get the best print quality unless you use paper or other media made for high-resolution printing.

Resolution Enhancement

It is also possible to increase the quality of the print output without increasing the resolution by varying the size of the dots. This technique was originated by Hewlett-Packard and is called *Resolution Enhancement Technology (RET)*. RET uses smaller dots to fill in the jagged edges created by larger dots.

Because the dots are so small, the cumulative effect to the naked eye is a straight diagonal line. Other manufacturers have developed their own versions of this concept by using other names, such as *edge enhancement*. This type of enhancement is only possible for laser and inkjet printers. Because dot-matrix printers produce images by having pins physically strike the page (through an inked ribbon), they cannot use variable-sized dots.

Inkjet printers use variable-size ink droplets during the dithering process, which produces colors such as orange which must be mixed from the cyan, magenta, and yellow inks used by the printer. The ability to mix colors and vary the size of droplets allows today’s best inkjet printers to come incredibly close to photographic quality.

Interpolation

There are also many printers that produce higher resolution output by means of a process called *interpolation*. Printer resolution is not just a physical matter of how small the dots created by a laser or inkjet can be; a higher-resolution image also means that the printer must process more data. A 600dpi printer has to work with up to 360,000 dots per square inch, whereas a 300dpi printer uses only 90,000 dots.

The higher-resolution image, therefore, requires four times the memory of its lower-resolution counterpart (at minimum) and a great deal more processing time. Some printers are built with the capability to physically print at a higher resolution but without the required memory and processing power. Thus, the printer can process an image at 600dpi and then interpolate (or scale) the results up to 1,200dpi. Although an interpolated 1,200dpi image is better than a 600dpi image without interpolation, a printer that operates at a true 1,200dpi resolution should produce noticeably better output than an interpolated 1,200dpi, and it will probably cost significantly more as well. It is important when you evaluate printers that you check to see whether the resolution specified by the manufacturer is interpolated.

Paper Quality

Whereas laser printers produce their images by fusing toner to the paper, inkjet printers place the ink on top of the paper. While many general-purpose papers supposedly suitable for laser, copier, and inkjet printers are sold, using anything less than true inkjet paper will degrade the actual print resolution. This is because inkjet paper should be smoother than laser/copier paper and promote rapid drying of ink. Paper that lacks these features will have loose fibers causing the ink to “wick,” causing a fuzzy appearance to inkjet printing. Photorealistic printing at resolutions above 720dpi requires the use of photo-quality paper that is heavy, very smooth, and very fast drying. Many users’ disappointments with inkjet print quality stem from improper paper choices or from incorrect matching of paper with printer modes.

Dot-Matrix Print Quality

Dot-matrix printers are different from inkjet and laser printers in several fundamental ways. Most importantly, dot-matrix printers do not process an entire page’s worth of data at a time like lasers, but rather work with streams of characters. The print resolution of a dot-matrix printer is based not on its memory or its processing power, but rather on its mechanical capabilities. The grid of dots that a dot-matrix printer uses to create characters is not a data set in a memory array or a pattern on a photosensitive drum; rather, the grid is formed by a set of metal pins that physically strike the page in various combinations. The resolution of the printer is therefore determined by the quantity of its pins, which usually number either 9 or 24. Because it uses more pins to create characters of the same size, a 24-pin printer has pins that are necessarily smaller than those of a 9-pin printer, and the dots they create are smaller as well. As with the other printer types, smaller dots result in fewer jagged edges to the printed characters and a better appearance to the document overall. However, techniques such as resolution enhancement and interpolation do not apply to dot-matrix technology, making the resolution of the printer a far less important statistic. Beyond checking to see whether the printer has 9 or 24 pins, you will not see differences in print quality that are the result of print resolution technology.

Instead, the freshness of the ribbon and the character set used by the printer are the biggest determinants of a dot-matrix printer’s print quality.

Note

Manufacturers often describe 24-pin dot-matrix printers as producing “near letter quality” output. In an era of 600dpi and higher-resolution laser and inkjet printers, “near letter quality” is no longer accurate. Dot-matrix printers

(continues)

(continued)

still have their place in the professional world, such as for printing multipart forms and carbon copies, but when it comes to printing letters and other general office documents, they lack the resolution needed to produce a professional-looking product.

While any dot-matrix printer is vulnerable to print head damage (the “pins” are actually fine wires), 24-pin dot-matrix printers are particularly sensitive to incorrectly set head gaps or worn ribbons. These problems can cause the extra-fine wires to break, causing gaps in the printing. When evaluating dot-matrix printers for heavy-duty printing, find out what the replacement or repair costs of a print head will be.

Page Description Languages (PDL)

Both laser and inkjet printers are known as *page printers* because they assemble an entire page in memory before committing it to paper; the laser printer assembles the page within its own memory, whereas most inkjet printers use the computer’s memory to assemble the page. This is in contrast to dot-matrix printers, which are character-based. When your PC communicates with a page printer, it does so using a specialized language called a *page description language*, or *PDL*. A PDL is simply a means of coding every aspect of a printed document into a data stream that can be transmitted to the printer. After the PDL code arrives at the printer, internal firmware converts the code to the pattern of dots that are printed on the page. There are currently two PDLs in use today that have become de facto standards in the computer industry: PCL and PostScript. These languages are discussed in the following sections.

Printers that do not support a PDL use escape code sequences to control the printer’s features in combination with standard ASCII text for the body of the document (see the section, “Escape Codes,” later in this chapter). It is the printer driver loaded on your PC that is responsible for producing print output that is understood by your printer, whether it uses escape codes or a PDL. No matter what the source of the document you are printing and no matter what format is used to store the original document, the data must be converted into a PDL data stream or an ASCII text stream with escape codes to be printed.

PCL (Printer Control Language)

PCL is a page description language that was developed by Hewlett-Packard for use in its printers in the early 1980s. As a result of HP’s dominance in the printer market, PCL has become a standard that is emulated by many other printer manufacturers. Apart from the actual text being printed, PCL consists largely of commands that are designed to trigger various features and capabilities of the printer. These commands fall into four categories:

- *Control codes.* Standard ASCII codes that represent a function rather than a character, such as Carriage Return (CR), Form Feed (FF), and Line Feed (LF).
- *PCL commands.* Basically the same type of escape code sequences used by dot-matrix printers. These commands comprise the majority of a PCL file’s control code and include printer-specific equivalents to document parameters, such as page formatting and font selection.
- *HP-GL/2 (Hewlett-Packard Graphics Language) commands.* Commands that are specific to the printing of vector graphics as part of a compound document. An HP-GL/2 command

consists of a two-letter mnemonic that might be followed by one or more parameters that specify how the printer should process the command.

- *PJL (Printer Job Language) commands.* Enable the printer to communicate with the PC bidirectionally, exchange job status and printer identification information, and control the PDL that the printer should use for a specific job and other printer control panel functions. PJL commands are limited to job-level printer control and are not involved in the printing of individual documents.

PCL has evolved over the years as printer capabilities have improved. PCL versions 1 and 2 were used by Hewlett-Packard inkjet and daisywheel impact printers in the early 1980s and could not be considered to be full-fledged page description languages. The first LaserJet printer released in 1984 used PCL 3, and the latest models contain PCL 6. Table 22.1 lists the various versions of PCL, the major capabilities added to each new version, and the HP laser printer models that use them.

Table 22.1 Hewlett-Packard Printer Control Language (PCL) Versions

Version	Date	Models	Benefits
PCL 3	May 1984	LaserJet, LaserJet Plus	Full page formatting; vector graphics
PCL 4	Nov 1985	LaserJet Series II	Added typefaces; downloadable macros; support for larger bitmapped fonts and graphics
PCL 4e	Sep 1989	LaserJet IIP, IIP Plus	Compressed bitmap raster fonts; images
PCL 5	Mar 1990	LaserJet III, IIID, IIIP, IIIsi, HP-GL/2	Scalable typefaces; outline fonts; (vector) graphics
PCL 5e	Oct 1992	LaserJet 4, 4M, 4L, 4ML, 4P, 4MP, 4 Plus, 4M Plus, 5P, 5MP, 5L, 5LFS, 5Lxtra, 6L, 6Lxi, 6Lse, 6P, 6MP, 6Psi, 6Pse	600dpi support; bidirectional communication between printer and PC; additional fonts for Microsoft Windows
PCL 5c	Oct 1994	Color LaserJet Color LaserJet 5, 5M	Color extensions
PCL 6	Apr 1996	LaserJet 5, 5se, LaserJet 6, 6Pse, 6Psi, 6MP	Redesigned, object-oriented graphics handlers for faster printing and font synthesis for better document fidelity
PCL XL	1996	LaserJet 6P, 6MP	Enhanced graphics commands, multipage printing on one sheet, watermark, smaller file sizes

Although PCL is wholly owned and developed by Hewlett-Packard, this company's long-term dominance in the printer market has made it a de facto standard. Many other companies manufacture printers that use PCL and often advertise these printers as being compatible with a specific Hewlett-Packard model.

Note

Most HP inkjet printers use stripped-down versions of PCL; see the particular printer's documentation for information on which PCL features it supports.

PostScript

PostScript is a page description language that was developed by Adobe and first introduced in the Apple LaserWriter printer in 1985. PostScript possessed capabilities at its inception, such as scalable type and vector graphics support, that were only added to PCL years later. For this reason, PostScript quickly became and still remains the industry standard for desktop publishing and graphics work. Adobe licenses the PostScript language to many different printer manufacturers, including those that make the high-resolution image setters used by service bureaus to produce camera-ready output for the offset printing processes used by newspaper, magazine, and book printers.

PostScript does not use escape code sequences such as PCL; it is more like a standard programming language. PostScript is called an object-oriented language because the printer sends images to the printer as geometrical objects rather than bitmaps. This means that to produce type using a particular font, the printer driver specifies a font outline and a specific size. The font outline is a template for the creation of the font's characters at any size. The printer actually generates the images of the characters from the outline, rather than calling on a stored bitmap of each character at each size. This type of image that is generated specifically for use on a particular page is called a vector graphic, as opposed to a bitmap graphic, which arrives at the printer as a fully formed dot pattern. PCL did not have the capability to print scalable type until version 5 was introduced in 1990.

When it comes to printing fonts, outlines simplify the process by enabling printers to be equipped with more internal fonts that can be printed at any size. Bitmapped fonts, on the other hand, usually must be downloaded to the printer from the PC. When graphic images are involved, the difference between a vector-based object and a bitmap can often be seen in the printed output. Because a vector image is actually generated inside the printer, its quality is based on the printer's capabilities. Printing a vector image on a 600dpi printer produces a much better quality product than printing the same image on a 300dpi printer. A bitmap image, on the other hand, will generate the same output on either printer.

At first, modifications to the PostScript language were based on the evolving capabilities of the Apple laser printers that were its primary outlet. These minor modifications eventually became numerous enough for Adobe to release a new baseline version of the language called PostScript Level 2 in 1992. The evolution continued, and PostScript 3 was introduced in 1997. These updates improved the speed and performance of PostScript printers and accommodated their physical changes, such as increased amounts of memory and added paper trays, but they did not introduce revolutionary new features the way that the PCL updates did. PostScript had its most powerful features from the very beginning, and the succeeding revisions of the language remain backward compatible.

Note

PostScript provides the basis for the PDF (Portable Document Format) files you can create with Adobe Acrobat, and PostScript level 3 can print PDF files directly, without the need for an application to process the print job.

For more information about PostScript's standard and optional features and uses, see Adobe's Web site.

Note

For users who want to retrofit the graphics power of PostScript to an existing printer but cannot get a hardware upgrade, there are many RIP (Raster Image Processing) programs available that provide for PostScript imaging on common SOHO and office laser and inkjet printers. These programs serve two purposes: They improve printed output, and they enable a user with a low-cost color or monochrome inkjet or laser printer to be able to use that printer as an accurate preview device for preparing PostScript files for output by a high-end typesetter. One of the leading low-cost RIPs that supports most inkjet and laser printers is Zenographics' SuperPrint, which supports PostScript level 2. Get more information from Zenographics' Web site at www.zeno.com. For other RIPs, see the comparison chart available at www.islandartcards.com/epson/RIPcompare.html.

PDL Support

When you are evaluating printers, the decision as to what PDL you want to use should be based primarily on your interaction with other parties, their documents, and their printers. Today, PCL and PostScript are comparable in their capabilities (although this was not always the case), and for your own personal use, either one can produce excellent printed output. However, if you plan to produce documents that are to be passed on to other parties, such as service bureaus for pre-press work, PostScript support is strongly recommended because it is still the dominant standard in the world of professional graphics, printing, and publishing.

You might also come across documents on the Internet and in other places that are provided in the PostScript format. For a long time, a PostScript output file (usually with a PS extension) was the most convenient, platform-independent format for distributing a document containing graphical content.

For example, the specifications for the TCP/IP networking protocols are freely distributed on the Internet in ASCII text form. A few of the documents, however, have diagrams and other graphics that can't be represented in ASCII, so they are published in PostScript format. Any user with a PostScript printer, regardless of the computing platform, can simply copy the file to the printer and produce a hard copy of the document, including all the graphics and fonts found in the original. Although the practice of releasing raw PostScript files is less frequent now that platform-independent formats such as Adobe Acrobat (.PDF format) are available, this can still be a valid reason for having a PostScript printer available or for using a PostScript interpreter (RIP) with a non-PostScript printer (see the preceding note). Keep in mind that a raw PostScript file cannot be viewed. However, you can convert PostScript .PS files into Acrobat-compatible .PDF files with the Aladdin Ghostscript program for Windows, UNIX, VMS, Linux, MS-DOS, OS/2, and Macintosh. For more information about Ghostscript, go to www.cs.wisc.edu/~ghost/.

Both PCL and PostScript are available in a variety of printers. The Macintosh printing platform is designed around PostScript, which is standard equipment in all Apple's laser printers. Obviously because Hewlett-Packard developed the PCL standard, all their printers use that PDL by default. However, most of the HP laser printers are available in a version with PostScript as well. In addition, most HP laser printers can accept a special add-on module that provides the printer with PostScript support. Very few inkjet printer models contain a PostScript interpreter, and those few are normally B-size (11"×17" paper) or larger units designed for graphic-arts prepress work.

Note

Different HP printers use different levels of PCL. You should also know that printers that nominally use the same level of PCL might vary in their implementations of PCL commands. Search HP's Web site for details about an HP printer model's use of PCL.

Many other manufacturers also use PCL or PostScript (or both), which they have either licensed from HP or Adobe or emulated themselves for their printers. The question of whether a printer has genuine, licensed versions of its PDLs can be very important. There have been numerous instances throughout the history of these PDLs in which unauthorized or poorly emulated versions of PCL and PostScript have been foisted on the public as the real thing. In the mid-1980s, the term "LaserJet Plus Emulation" came to have as little meaning as "Hayes compatible" did for modems. Nowadays, most of the PCL (usually version 5) emulations used in other manufacturers' printers are quite good, but PostScript is a far more complex language and is more difficult to emulate. It is still possible to find discrepancies between an emulated version of a PDL and the real thing that result in visible differences in the printed output.

Here again, the PDL emulation issue largely depends on your interactions with other users. If you have a printer with an emulated version of PostScript and a printer driver that accurately addresses that emulated printer firmware, it matters little if the language does not conform precisely to the Adobe specifications. If you are sending your PostScript output to a service bureau for printing on an image setter, however, the discrepancies between an emulated PostScript and the real thing can make a vast difference.

Whenever possible, it is recommended that you purchase a printer that uses the genuine PDL licensed from its creator. A minimum of PCL 5 or PostScript Level 2 is preferable.

Many laser printers support both PCL and PostScript, and you should check to see how a printer handles mixed jobs using different PDLs. The best printers detect the PDL of each job as it arrives in the printer and automatically switch to the appropriate language. If a printer does not have this feature, you might have to send a command with each print job triggering the mode change. For a single user on a standalone system, this is not much of a problem. For a printer connected to a network, it is often hard to be certain of the order in which jobs are printed unless someone constantly monitors the print queue, and manual mode changes can be difficult to organize.

Escape Codes

Virtually all laser printers and most inkjet printers support at least one page-description language, but some printers (especially dot-matrix) do not, and in this case the printer driver usually communicates with the printer using escape code sequences. Similar to the PCL commands described earlier, escape codes are control sequences used to activate the features of a particular printer. Escape codes are so named because the ASCII value for the Esc key (decimal 027) is used as the first character of the code to signal to the printer that what follows is an instruction code and not a textual element of the document being printed.

On a dot-matrix printer, it might be possible to select different resolutions, fonts, and speeds, depending on the printer's capabilities. The printer driver that you install on your PC is designed

to generate the appropriate escape codes based on the options you specify in your application and your printer driver configuration. If your printer driver cannot generate the codes you desire, you can normally set a particular font, size, and enhancement for an entire document through the printer's control panel or control software.

Escape codes are not as standardized as PDLs; you might see different printers use different codes for the same function. Epson, for example, has long been a market leader in the dot-matrix printer industry, and its escape codes have come to be accepted by some other manufacturers, but the acceptance of the codes has not been general enough for them to be called an industry standard.

Epson's escape code standards are ESC/P for their older dot-matrix printers and ESC/P2 for newer dot-matrix printers and most inkjet printer models. ESC/P was the original Epson version and didn't support built-in scalable fonts. ESC/P2 does support built-in scalable fonts found in Epson's newer dot-matrix and inkjet printers and works well with Windows 3.x and 9x.

Host-Based/GDI

Some inkjet and dot-matrix printers don't use either "classic" PDL (PostScript or HP-PCL) but instead use the computer to render the page for printing. These printers are called *host-based* printers. Some variations on host-based printing include printers that use the Windows GDI (graphics device interface) engine to image the page (GDI printers) and Hewlett-Packard's line of Printing Performance Architecture (PPA) printers. In theory, these printers have some advantages:

- *Low cost.* Because the computer has already rendered the page, the printer doesn't need to include a PDL, reducing the printer price.
- *Faster computer means faster printing.* Because most of the printing work is being done by the host computer, speeding up the computer by adding RAM, increasing processor speed, or using IEEE-1284 bidirectional printer connections (EPP/ECP ports and cables) can improve printing speed. In 1996 tests by *PC Magazine*, the improvements ranged from a modest 5 percent to 87 percent, with complex images showing a bigger improvement than simple text-only print jobs.
- *Flexible architecture with PPA.* Hewlett-Packard's PPA, depending on the printer, might have virtually all printer functions performed in the computer (for economy) or might move some features into the printer (for performance).

Although host-based printing has its advantages, there are several key disadvantages:

- *No direct connection equals no printing.* Host-based printers *must* be tied directly to the host for printing because all they do is produce the finished image. This "gotcha" becomes apparent when your new SOHO or departmental network can't print because the printers no longer have a true host to work with. This affects both GDI-based printers and HP's PPA product line. The need for a host prevents these printers from working with network print servers such as HP's JetDirect series. This can also be an issue with sharing a printer via peer networking.
- *Problems with printing from non-Windows applications.* Depending on how the host-based printer is designed, it might not be able to print from any operating system other than Windows. Some printers can print from a "DOS box"—an MS-DOS session that runs within Windows. The issue of support for increasingly popular operating systems such as Linux could also be a big problem for some users.

- *Lower performance levels.* Many vendors of host-based printers built these printers for casual users. While the print resolutions of a host-based printer may equal that of a printer with a true PDL, print speeds are often slower.

The more flexible your printing needs, the less likely it is that a host-based printer can meet them. If you plan to use nothing but Windows or Macintosh as an environment, a host-based printer might suffice. Choose carefully.

Printer Memory

Printers have memory chips in them just as PCs do, and laser and inkjet printers usually have a processor as well, making the printer a computer unto itself, albeit a highly specialized one. Printers can use their internal memory for several purposes: as a buffer to hold print job data while it is being fed to the actual print engine; as a workspace to hold data during the processing of images, fonts, and commands; and as permanent and semipermanent storage for outline fonts and other data.

For a page printer (laser or LED), the amount of memory on-board is an extremely important gauge of its capabilities. The printer must be able to assemble a bitmap image of an entire page to print it, and the graphic images and fonts that are used on that page all take up memory. Even vector graphics and outline fonts must be processed into bitmaps before they can be printed. The larger the graphics on the page and the more fonts used, the more memory is required. This is in addition to the memory needed to store the PDL interpreter and the printer's permanent fonts.

You might find that your printer has sufficient memory to print an average page of mixed text and graphics, but not enough to print a full-page graphic or a page with many different fonts. The result of this might be a graphic split in half over two pages (a problem sometimes referred to as *guillotining*), missing fonts, or even no output at all. Fortunately, most printers can accept additional memory to extend their capabilities.

Expansion memory for printers can come in many different forms. Some printers use standard memory modules such as SIMMs or DIMMs, whereas others use proprietary designs that you must purchase from the manufacturer (at an inflated price, of course). As with a PC, extra memory installed in a printer is almost never wasted. In addition to the capability of processing larger graphics and more fonts, printers might be able to use extra memory to process the data for one page while printing another and to buffer larger amounts of data received from the PC.

Tip

Because many laser printers use data-compression techniques to print graphics with a small amount of memory, some laser printers print graphics-rich pages much faster after a memory upgrade. This is because the printer needs to spend less time calculating whether the page will fit into memory and little or no time compressing the data to fit.

A printer with additional memory can accept more data from the PC at one time. Depending on your PC's operating system and its printer driver configuration, this can result in a noticeable difference to your system's performance. When you print a document in a DOS application, you cannot proceed with your work (in most cases) until the entire print job has been transmitted to

the printer. Multitasking operating systems such as Windows 9x can usually print in the background, enabling work to proceed as the PC processes the print job, but performance might still suffer until the print job is completed. The larger the printer's memory buffer, the faster the print job data leaves the PC, returning the PC to its normal operation.

Simply learning how much memory is installed in the printer you plan to buy is insufficient to make an intelligent purchasing decision. You must also be aware of how much memory is used by the PDLs and resident fonts and how much is left free for print job data. Different PDLs, page sizes, and resolutions require different amounts of memory. As an example, for a 300dpi letter size (8 1/2"×11") printer using PCL, 12MB is a great deal of memory. For a 600dpi tabloid size (11"×17") PostScript printer, it is barely enough. Check with the printer manufacturer and the application software developer for memory guidelines, but keep in mind that one of the best upgrades for a laser printer, as well as for a computer, is more RAM.

The SIMM module sockets on some printers, notably some HP LaserJet models, can be used for more than memory expansion. HP offers PostScript upgrades for certain models that are packaged as a SIMM.

Note

The issue of memory expansion is applicable primarily to page printers such as lasers. Most dot-matrix and inkjet printers receive data from the PC as a stream of ASCII characters, and because they do not have to assemble an entire page at a time, they can maintain a much smaller buffer, usually only a few kilobytes. Even graphic images are processed by the PC and transmitted to the printer as a bit stream, so it is rarely possible to augment a dot-matrix printer's memory.

Some large-format inkjet printers such as HP's DesignJet series offer memory expansion, but this is uncommon on normal SOHO and office inkjet printers using letter-sized paper.

Fonts

Fonts are one of the most commonly used and most entertaining printer features. Having quality fonts and using them correctly can make the difference between a professional-looking document and an amateurish one. The term *font* refers to a particular typeface in a particular typestyle at a particular size. A typeface is a design for a set of alphanumeric characters in which the letters, numbers, and symbols all work well together to form an attractive and readable presentation. Thousands of typefaces are available, with many new designs being produced all the time. Some basic typefaces included with the Windows operating systems are Times New Roman, Arial, and Courier. A *typestyle* is a variation on a typeface, such as bold or italic. A typeface might have only one style, or it might have a dozen or more.

Typefaces are often classified by characteristics they have in common. For example, Times New Roman is known as a serif typeface because all its characters have little decorative strokes known as serifs. A typeface such as Arial, which lacks these strokes, is called a sans serif typeface. Courier is called a monospaced typeface because all its letters occupy the same width on the page, as on a typewriter. In contrast, Arial and Times New Roman are both proportional typefaces because the characters are designed to fit together based on their widths. The letter *i* in a proportional typeface occupies less horizontal space on the page than the letter *w*.

Technically, the term *font* refers to a typeface at a particular size, usually measured in points (72 points equals one inch). 10-point Courier and 12-point Courier would be considered two separate fonts. This is because in traditional printing and in the first PC printers, each size of a particular typeface was a separate entity. On an old-time printing press, each character on a page was printed by a separate wood or metal slug that would be pressed against the paper to make an impression. Slugs of different sizes were needed to produce different sized characters. In the same way, printers originally used bitmaps to create type. In this printing technique, every character of a typeface exists as a separate pattern of dots ready to be sent to the printer. In essence, each character existed as an individual, tiny graphic. To print the same typeface at various sizes requires individual graphics for each different size. These are called *bitmap fonts*.

Today, printers nearly always use *scalable* fonts. This is a technology in which a typeface requires only a single outline for each character to produce type of any size. The printer retains the outline in memory and generates bitmaps of the text characters at the size required for each job. The bitmaps are stored in a temporary font cache, but only for the duration of the job. The printer can also rotate a scalable font to any angle, whereas bitmaps can be rotated only in 90 degree increments. Outline fonts take up less memory space in the printer and provide a wider range of variations for each typeface. Also because they use what amounts to a vector graphic technology, scalable fonts can take advantage of the printer's full resolution, whereas bitmap fonts look the same at any resolution. The drawback to scalable fonts is that they require more processing power from the print engine, but when compared to the advantages they offer, this is a small sacrifice.

Note

Although bitmap fonts are seldom used any longer for normal business documents, some professionals prefer them for certain high-resolution printing tasks because they can be customized to suit a particular need. Bitmap fonts are also sometimes used by graphical operating systems such as Windows 3.1 for screen displays because scalable fonts do not look good at the low resolution of the typical monitor. However, a technology called antialiasing, which uses pixels of varying shades of gray (instead of just black and white) to smooth out jagged lines, has largely replaced the use of bitmap fonts on screen displays. Popularized by Adobe Type Manager (with Type 1 fonts), antialiasing has become more widespread for Windows users thanks to the font smoothing features in the Microsoft Plus! add-on for Windows 95 and the built-in font smoothing in Windows 98.

Because antialiasing can occasionally cause problems because of incompatibilities with a few display drivers, it can be turned off.

As a result of this evolution in technology, the terms *font* and *typeface* have come to be confused. In the old days, when you purchased a typeface, you would receive the same character set in a variety of sizes, with each size being called a font. Today, when you purchase a typeface, you receive only a single outline font that your printer can scale to any size.

Before TrueType scalable fonts were common, bitmap fonts were commonly used on laser printers. Many LaserJet and compatible printers such as the HP LaserJet II and LaserJet III were designed to handle removable font cartridges. Virtually all laser printers could also use bitmap fonts on diskette which needed to be downloaded to the laser printer's memory.

Today, scalable type is all but universal, and although printers are usually equipped with a selection of font outlines permanently stored in memory, this is more for reasons of speed and convenience than necessity. The printer driver on your PC can automatically download font outlines to the printer as needed or generate scalable type just as your printer can. Technologies such as the TrueType fonts found on both Windows and Macintosh systems can provide you with access to hundreds of typefaces in many styles and at almost any size.

▶▶ See “Driver Problems,” p. 1262.

Although all outline fonts function in basically the same way, different types of scalable fonts are available. PostScript was the original scalable font technology, and Adobe has built up a library of typefaces over the years that is without peer in the digital type industry. Most PostScript printers are equipped with a collection of 39 or more basic fonts stored internally, but you can choose from thousands of others by browsing Adobe’s online services or its Type On Call CD-ROM. In either case, after you purchase these PostScript Type 1 font outlines, you install them on your computer along with a utility called Adobe Type Manager, which is responsible for downloading the appropriate font outlines to your printer as needed. PostScript Type 3 font outlines were once widely used but produce poor results and should be avoided. Type 3 outlines lack the “hinting” necessary to getting top-quality results from a single font outline at any size. This “hinting” feature is used by Type 1 and TrueType fonts.

Note

Adobe Type Manager can also be used with non-PostScript printers, allowing laser and inkjet printers to access the wide world of Type 1 fonts.

The other major scalable font technology in use today is TrueType. Developed about six years after PostScript, TrueType is the result of a joint project between Apple and Microsoft. Both companies wanted to integrate a PostScript-style scalable font engine into their respective operating systems, but neither of them wanted to delegate the control over an important element of their OS to a third-party company such as Adobe. Microsoft Windows 9x makes it easy to view your existing TrueType fonts and to compare fonts to each other by using the Windows Explorer’s special menus in the Fonts folder.

Although there are substantial technical differences in the way that their font outlines are created, PostScript and TrueType function in much the same way. The primary advantage of TrueType is that it is already integrated into the Windows and Macintosh operating systems and does not require external software such as Adobe Type Manager. Most type foundries now produce their fonts in both PostScript Type 1 and TrueType versions, and any difference between the two in the final product is usually quite difficult to spot.

As with PostScript, many printers include an internal collection of TrueType fonts that the operating system makes available to your applications. You should consider the number of fonts supplied with your printer primarily as a bonus when you evaluate various products. Any typeface provided as an internal TrueType font in your printer can just as easily be produced using a software version, although you might have to purchase it separately.

Note

Thousands of TrueType and PostScript Type 1 fonts are available today at a wide range of prices. Many fonts are available free for the downloading from the Internet or on bargain CD-ROMs, whereas others (such as those offered by Adobe) are quite expensive by comparison. Be aware that there can be profound differences in the quality of these fonts, and although it is not always true that more expensive is better, there are a great many more cheap bad fonts than there are expensive bad fonts.

Printer Drivers

As with many peripherals, printers are highly reliant on a driver installed on the PC. The printer driver provides the software interface between the printer and your application or operating system. The primary function of the driver is to inform the PC about the capabilities of the printer, such as the PDLs it uses, the types of paper it handles, and the fonts installed. When you print a document in an application, the print options you select are supplied by the printer driver, although they appear to be part of the application.

In DOS, printer drivers are integrated into individual applications. A few major software packages provide drivers for a full range of printers, but most include only a few generic drivers. At times like these, the best thing to do is to select a driver that supports the same PDL revision as your printer. For example, a LaserJet III driver uses PCL 5, which will support all the LaserJet III and 4 models, even if it does not use all the printer's features. It is quite possible that a DOS application that doesn't have a driver for your exact printer model might not be able to take advantage of all your printer's capabilities.

In all versions of Windows, you install the printer driver as part of the operating system, not in the individual applications. The Windows product includes drivers for a range of printers, and individual drivers are almost always available from the printer manufacturer's online services. Note that the drivers included with Windows are usually developed by the manufacturer of the printer, not by Microsoft, and are included in the Windows package for the sake of convenience.

Although the printer manufacturer develops the drivers for any printer model used with Windows, there might be significant differences between the printer drivers included with Windows and those shipped with the printer or available online. Drivers included with Windows normally provide access to a printer's basic features, whereas the enhanced drivers provided by the manufacturer on CD-ROMs included with the printer or via download might include deluxe color-matching, enhanced spooling, improved dialog boxes, or other benefits. Be sure to try both types of drivers to see which one works best for you. Check the printer manufacturer's Web site for the latest version of the driver. Note that in some cases printer manufacturers no longer support older printers with enhanced drivers, forcing you to use the ones supplied with Windows.

PostScript Printer Descriptions (PPDs)

Whereas printers that use PCL or escape sequences all have completely separate Windows drivers, PostScript printers use a single generic driver to support the PDL. For all versions of Windows, this driver is called PSCRIPT.DRV. To support the various capabilities of individual printers, the driver uses plug-in modules called PPDs (PostScript Printer Descriptions). The PPD provides

information on the specific mechanical capabilities of the printer, such as paper trays and sizes, whereas the language support is provided by the PostScript driver. To support multiple PostScript printers in Windows, you install additional PPDs to the existing driver architecture.

In addition to the module included with Windows, there is also a PostScript driver called AdobePS that is freely available from Adobe, the owners of the PostScript language. If you have a printer that uses true Adobe PostScript, this driver is recommended because it provides more complete support for the language and all its capabilities. Although the PostScript driver is provided by Microsoft or Adobe, you typically obtain new PPDs from the manufacturer of your printer.

How Printers Operate

Each of the three main printer types uses a different method to create images on a page, as well as a different substance: powdered toner, liquid ink, or a fabric ribbon. The following sections examine how each type of printer creates images on the page.

Laser Printers

The process of printing a document on a laser printer consists of the following stages:

- Communications
- Processing
- Formatting
- Rasterizing
- Laser scanning
- Toner application
- Toner fusing

Different printers perform these procedures in various ways, but the steps are fundamentally the same. Less expensive printers, for example, might rely on the PC to perform more of the processing tasks, whereas others have the internal hardware to do the processing themselves.

Communications

The first step in the printing process is to get the print job data from the PC to the printer. PCs traditionally use the parallel port to communicate with a printer, although many printers can use a serial port. Some devices can even use both types of ports at the same time to connect to two different computers. Network printers often bypass these ports entirely and use an internal Ethernet adapter to connect directly to the network cable. The newest SOHO and office printers offer USB connections, either as their only port or along with a parallel port.

◀◀ See "Parallel Ports," p. 932.

◀◀ See "IEEE 1284 Parallel Port Standard," p. 933.

Communications between the printer and the PC obviously consist largely of print job data sent from the computer to the printer. However, communications flow in the other direction, as well.

The printer also sends signals back to the PC for the purpose of flow control—that is, to inform the computer when to stop sending data and when to resume. These signals can also indicate error conditions, such as paper out. The printer typically has an internal memory buffer that is smaller than the average print job and can only handle a certain amount of data at a time. As pages are actually printed, the printer purges data from its buffer and signals the PC to continue transmitting. This is commonly called *handshaking*. The handshaking protocols used for this communication depend on the port used to connect the printer to the PC.

The amount of data that a printer can hold varies widely, and you read earlier in this chapter how you can often enlarge the buffer by installing additional memory. Some printers even contain internal hard disk drives and can store large amounts of print data and collections of fonts. The process of temporarily storing multiple print jobs as they await processing is known as print *spooling*. Spooling can also take place in the computer or on the network, using the client PC or print server's hard drive to store print jobs.

Almost all printers today support even more advanced communications with a PC, enabling a user to interrogate the printer for its current status using a software application and even to configure parameters that previously were accessible only from the control panel on the printer. This type of communication requires that the PC have a bidirectional, ECP, or EPP port and the appropriate cable IEEE-1284 parallel cable or be connected via the USB port. If the printer is shared through a switchbox, the extension cables and switchbox must also be IEEE-1284 compliant. Bidirectional modes allow the printer to transmit more advanced status information such as ink levels, toner levels, or error messages.

Processing

After the printer receives the data from the PC, it begins the process of interpreting the code. Most laser printers are really computers in themselves, containing a microprocessor and a memory array that functions much like the equivalent components in your PC. This part of the printer is often called the controller or the interpreter and includes the firmware supporting the page description languages that the printer uses.

The first step of the interpretation process is the examination of the incoming data to distinguish the control commands from the actual content of the document. The printer's processor reads the code and evaluates the commands that it finds, organizing those that are to be part of the formatting process and executing others that require physical adjustments to the printer configuration, such as paper tray selection and simplex (single sided) or duplex (double sided) printing. Some printers also convert the document formatting commands into a specialized code that streamlines the formatting process to come, whereas others leave these commands in their raw form.

Note

A common error after changing printers is failing to set the new printer as the default printer. This often leads to sending the wrong printer commands to the new printer, resulting in many sheets of paper covered with gibberish because the printer doesn't understand the (incorrect) commands being sent to it. This is also a concern when using a two-printer-to-one-PC switchbox.

Formatting

The formatting phase of the data interpretation process involves the interpretation of the commands that dictate how the content is to be placed on the page. Again, this is a process that can differ depending on the processing capabilities of the printer. With low-end printers, the PC does much of the formatting, sending highly specific instructions to the printer that describe the exact placement of every character on the page. More capable printers perform these formatting tasks themselves, and you might be surprised to find just how much work your printer does in this respect.

Your application might display your document in a WYSIWYG format that looks very much like the printed output, but this is not necessarily how the printer driver sends the document data to the printer. In most cases, the printer actually lays out the document all over again by interpreting a series of commands that dictate parameters such as the paper size, the location of the margins, and the line spacing. The controller then places the text and graphics on the page within these guidelines, often performing complex procedures such as text justification within the printer.

The formatting process also includes the processing of outline fonts and vector graphics to convert them into bitmaps. In response to a command specifying the use of a particular font at a particular size, for example, the controller accesses the font outline and generates a set of character bitmaps at the correct size. These bitmaps are stored in a temporary font cache where the controller can access them as needed while laying out the text on the page.

Rasterizing

The result of the formatting process is a detailed set of commands defining the exact placement of every character and graphic on each page of the document. In the final stage of the data interpretation process, the controller processes the formatting commands to produce the pattern of tiny dots that will be applied to the page. This process is called *rasterization*. The array of dots is typically stored in a page buffer while it awaits the actual printing process.

The efficiency of this buffering process depends on the amount of memory in the printer and the resolution of the print job. On a monochrome printer, each dot requires one bit of memory, so a letter-sized page at 300dpi requires 1,051,875 bytes of memory $\{(8 \frac{1}{2} \times 11) \times 300^2\} / 8$, or just over 1MB. At 600dpi, the memory requirement jumps to 4,207,500 bytes—over 4MB. Some printers have sufficient memory to buffer an entire page while the formatting of the next page proceeds. Others might lack enough memory to store even one full page and use what are called *band buffers* instead.

Printers that use band buffers divide a page into several horizontal strips, or bands. The controller rasterizes one band's worth of data at a time and sends it to the print engine, clearing the buffer for the next band. This way, the printer can process a page gradually, with the entire array only coming together on the photosensitive drum in the print engine. The band buffer method is cheaper than a full page buffer because it uses less memory, but it is also slower and more prone to errors. In recent years, the price of memory has dropped so much that band buffers are rarely used in laser printers.

Band buffers are used primarily by inkjet printers, which convert each line of text or graphics into a band.

Tip

Some printer drivers enable you to control whether graphics are sent to the printer in vector or raster form. In general, vector graphics provide better speed, but if you experience problems with the placement of the graphics on the page, you can switch to the raster option. Most printer drivers that offer this feature place the control on the Graphics page of the printer's Properties dialog box. However, some drivers might place the control elsewhere or not provide it at all.

A common reason for switching to raster graphics is when a multilayer graphic doesn't print properly. This can be a problem with PCL5 laser printers and some presentation programs such as Microsoft PowerPoint or Lotus Freelance Graphics.

Laser Scanning

After the rasterized image of a page is created by the controller and stored in memory, the processing of that page passes to the print engine, the physical part of the printing process. *Print engine* is a collective term that is used to refer to the actual imaging technology in the printer, including the laser scanning assembly, the photoreceptor, the toner container, the developer unit, the corotrons, the discharge lamp, the fuser, and the paper transport mechanisms. These components are often treated as a collective unit because the print engine is essentially the same hardware that is used in copy machines. Most printer manufacturers build their products around a print engine that they obtain from another manufacturer, such as Canon. A PC printer differs from a copy machine primarily in its data-acquisition and processing procedures. A copier has a built-in scanner, whereas a printer receives and processes digital data from the PC. After the raster image reaches the print engine, however, the procedure that produces the actual document is very similar.

Figure 22.1 illustrates the laser writing process.

The laser assembly in a laser printer, sometimes called a raster output scanner (ROS), is used to create an electrostatic pattern of dots on a photosensitive drum (called the photoreceptor) that corresponds to the image stored in the page buffer. The laser assembly consists of the laser, a rotating mirror, and a lens. The laser always remains stationary. To create the pattern of dots across the horizontal width of the drum, the mirror rotates laterally, and the lens adjusts to focus the beam so that the dots on the outer edges of the drum are not distorted by having been farther from the light source. The vertical motion is provided by the slow and steady turning of the drum.

Caution

Because the drum is sensitive to any form of light, it should not be exposed to room light or daylight for extended periods of time. Some printers have a protective mechanism that shields the drum from exposure to light whenever you open up the printer's service compartment. Even when this is the case, however, you should leave the compartment open long enough only to service the printer or change the toner cartridge.

Figure 22.1 The stages of laser imaging with a typical laser printer are shown here.

The photoreceptor drum, which in some printers might actually be a belt, is coated with a smooth material that holds an electrostatic charge that can be discharged on specific areas of its surface by exposure to light. The initial charge over the entire surface of the drum may be applied by either a *charger corotron* or *conditioning rollers*. A corotron is a wire carrying a very high voltage that causes the air immediately around it to ionize. This ionization charges the drum's surface and also produces ozone, the source of the smell that is characteristic of laser printers. Most recent laser printers use charged rollers instead of corotrons specifically to avoid the production of ozone.

Note

Some laser printer manufacturers such as HP refer to *coronas* instead of *corotrons*. They perform the same functions.

Caution

Ozone is a noxious and corrosive gas that should be avoided in closed, unventilated spaces. Although ozone is used to deodorize air and purify water, working in close proximity to laser printers for extended periods of time without a sufficient fresh air supply can cause health problems.

Many laser printers have replaceable ozone filters that should be changed after several thousand pages have been printed. Check your printer documentation to determine when the ozone filter should be changed. Use the self-test feature on the printer to print a page showing the number of pages the printer has produced to help you determine how many more pages you can print before you change the filter (or if you're overdue).

HP's Web site has detailed information on which of its laser printers require ozone filter changes and the relevant part numbers

The drum is sensitive to any type of light, but a laser can produce fine enough dots to support the high resolutions required for professional-looking documents. Every spot that the laser light touches on the drum is electrically discharged, leaving the pattern of the page's characters and images on its surface. The laser in a printer discharges the areas of the drum corresponding to the black parts of the page—that is, the characters and images that comprise the document's content. This is known as write-black printing. By contrast, copiers discharge the background areas of the page, a process called write-white printing.

Toner Application

As the photoreceptor drum rotates, the portion of its surface that the laser has discharged next passes by the developer unit (see Figure 22.2). The developer is a roller coated with fine magnetic particles that function as a “brush” for the toner. Toner is an extremely fine black plastic powder that will actually form the image on the printed page. As the developer roller rotates, it passes by the toner container and picks up an even coating of the particles on its magnetic surface. This same developer roller is also located right next to the photoreceptor drum. When its surface passes by the roller, the toner particles are attracted to the areas that have been discharged by the laser, thus forming the image of the page on the drum using the toner particles as a color medium.

As the drum continues its slow rotation, it next passes close to the surface of the paper. The printer has an entirely separate mechanism for extracting one sheet of paper at a time from the supply tray and passing it through the print engine so that its flat surface passes underneath the drum (without actually touching it) at the same speed that the drum is rotating. Beneath the sheet of paper, there is another corotron (called the *transfer corotron*) that charges the paper, causing it to attract the toner particles from the drum in the exact pattern of the document image. After the toner is transferred to the page, the continued rotation of the drum causes it to pass by a discharge lamp (usually a row of LEDs) that “erases” the image of the page by completely discharging the surface of the drum. By this time, the drum has completed a full revolution, and the entire charging and discharging process can begin again for the next page of the document.

As you might imagine, these processes leave little margin for error when it comes to the proximity of the components involved. The drum must pass very close to the corotrons, the developer roller, and the paper surface for the toner to be applied properly. For this reason, many print engines (including Canon and HP) combine these components into a single integrated cartridge that you replace every time you replenish the printer's toner supply. This increases the price of the toner cartridge, but it also enables you to easily replace the most sensitive parts of the printer on a regular basis, thus keeping the printer in good repair.

Toner Fusing

After the toner is transferred from the photoreceptor drum to the page, the page continues its journey through the printer by passing over yet another corotron, called the *detrac corotron*. This corotron essentially cancels the charge that was originally applied by the transfer corotron just before the application of the toner. This is necessary because an electrostatically charged piece of paper tends to stick to anything it contacts, such as the printer's paper handling rollers or other pieces of paper.

Figure 22.2 A laser printer's print engine largely revolves around a photoreceptor drum that receives the document image from the laser and applies it to the page as it slowly rotates.

At this point in the printing process, you have a sheet of paper with toner sitting on it in the pattern of the printed page (see Figure 22.3). The toner is still in its powdered form, and because the page is no longer statically charged, there is nothing holding it in place except gravity. A slight breeze or tremor can ruin the image at this point. To permanently fuse the toner to the page, it passes through a pair of rollers heated to 400° Fahrenheit or more. This heat causes the plastic toner particles to melt and adhere to the fibers of the paper. At this point, the printing process is complete, and the page exits the printer. It is the nature of the toner and the fusing process that causes the characters of a laser-printed document to have a raised feel and appearance to them that is very attractive, whereas an inked page feels perfectly flat.

Figure 22.3 Laser printing produces an attractive “embossed” appearance because the toner is fused to the surface of the paper. Extremely rough paper can cause imaging problems, although laser printers can handle many more types of paper than inkjet printers can.

LED Page Printers

LED page printers, pioneered by Okidata and produced by Okidata and Lexmark, represent an excellent alternative to a “true” laser printer. Both technologies use a rotating drum and copier-like fusing mechanism to create high-quality printing. The difference is that LED page printers use an LED (light-emitting diode) array, rather than a laser beam, to place the image data on the imaging drum (see Figure 22.4). This difference in imaging provides three advantages:

- A straight-through paper path
- A longer warranty on the print head compared to laser printers
- Faster color printing, since all colors can be placed in a single pass, compared to the four-pass method that must be used by color laser printers (one color per pass)

Figure 22.4 LED printers use a light-emitting diode array to place the image on the imaging drum.

From the standpoint of print quality and speed, LED page printers produce quality comparable to similar laser printers. In essence, LED page printers are “laserless laser printers.”

Inkjet Printers

The data interpretation stages of the inkjet printing process are fundamentally similar to those of a laser printer. The main difference is that because many inkjets tend to occupy the low end of the printer market, they are less likely to have the powerful processors and large amounts of memory found in lasers. You are therefore likely to find more inkjet printers on the market with relatively small memory buffers that rely on the PC for the majority of their processing activities. These printers can print graphics using band buffers instead of full page buffers. Higher-end inkjets, however, can have virtually the same processing capabilities and memory capacities as laser printers.

The primary difference between an inkjet printer and a laser printer, however, is the way that the image is applied to the page. Inkjet printing technology is far simpler than laser printing, requires fewer and less expensive parts, uses less power, and takes up much less space. Instead of an elaborate process by which toner is applied to a drum and then transferred from the drum to the page, inkjet printers use tiny nozzles to spray liquid ink directly onto the paper in the same dot patterns used by laser printers. For these reasons, inkjet technology is more easily adapted for use in portable printers.

There are two basic types of inkjet printing in use today: thermal and piezo (discussed in the following sections). These terms describe the technology used to force the ink out of the cartridge through the nozzles. The inkjet cartridge typically consists of a reservoir for the liquid ink and the tiny (as small as one micron) nozzles through which the ink is expelled onto the page. The number of nozzles is dependent on the printer's resolution; configurations using anywhere from 21 to 256 nozzles per color are common. Some printers provide more nozzles in their black-printing cartridges to improve printing speed. Color inkjet printers use four or more reservoirs with different color inks (cyan, magenta, yellow, and black are the most common; light cyan and light magenta are added for six-color printing by some printers for better photo quality). By mixing the different-colored inks, the printer can produce virtually any color. (Most inkjets use one replaceable cartridge to hold the reservoirs for the three basic colors: cyan, magenta, and yellow.)

Thermal Inkjet Printing

Thermal inkjet printers function by superheating the ink in the cartridge to approximately 400°. This causes vapor bubbles to form inside the cartridge that rise to the top of the reservoir. The pressure from the vapor forces ink out of the cartridge through the nozzles in tiny droplets that form the dots on the page. The vacuum caused by the expelled ink draws more ink down into the nozzles, making a constant stream of droplets as needed.

The thermal type of inkjet printing was the first to be developed and is still the most popular. Because of the vapor bubbles that form in the cartridge, Canon began calling its inkjet printers BubbleJet, a name that has become almost synonymous with this technology. This method is also used by Hewlett-Packard and others. Because of the high heat used by this method, printers that use thermal inkjet printing normally use an ink cartridge that also contains the print head, or, as in the case of Canon BubbleJet printers, a removable and replaceable print head with a removable ink cartridge insert.

Piezo Inkjet Printing

Piezo inkjet printing is a newer technology than thermal printing, and it presents distinct advantages. Instead of heat, these printers apply an electric charge to piezoelectric crystals inside the cartridge nozzles. These crystals change their shape as a result of the electric current, forcing the ink out through the nozzles.

Removing the high temperatures from the inkjet printing process presents two important advantages. First, the selection of inks that can withstand 400° heat is very limited; piezo technology enables printers to use ink formulations that are better suited to the printing process and less prone to smearing, which is a traditional problem with inkjet printing. Second, spray nozzles that are not exposed to extreme heat can last far longer than those traditional thermal cartridges. Epson pioneered the use of piezo inkjet printing, and this method is also used by Lexmark.

Improving the Quality of Inkjet Printing

The early inkjet printers from companies such as Canon, Hewlett-Packard, and Epson could print at a maximum resolution of only 300–360dpi. Since the mid-1990s, though, resolutions have climbed to 600dpi and beyond. Today's lowest-cost inkjet printers typically have print resolutions of 600–720dpi, and the newest high-performance printers feature resolutions such as 1,200 or 1,440×720dpi.

Several developments have made these very visible improvements in print quality possible:

- *Improved ink nozzles.* By reducing the size of the ink nozzles, a smaller dot is possible, improving the look of both black text printing and color images. Canon's BJC-8200 has introduced a star-shaped nozzle able to produce a truly round dot with more precise ink placement to further improve print quality (see Figure 22.5).

Figure 22.5 Canon's BJC-8200 uses a star-shaped nozzle to improve the placement and shape of droplets for improved resolution and better print quality.

- *Multi-color layering.* Hewlett-Packard pioneered the use of multi-color layering with its DeskJet 850C printer in a process it refers to as PhotoREtII. This process can place up to sixteen colors of ink in a single dot, compared to eight for other types of inkjet printers. HP's newest printers have an improved process called PhotoREtIII, which uses a five-picoliter droplet and 29 colors of ink in a single dot to print as many as 3,500 color combinations per dot.
- *Reduced ink volume.* Even though some inkjet printers of 1997–98 featured print resolutions comparable to today's best inkjet printers, current models often provide better-looking print quality because they use less ink per droplet, which is measured in picoliters. The Epson Stylus Photo 1200, for example, has the same print resolution as the Epson Stylus Photo EX it replaced in 1999, but the Photo 1200 uses only six picoliters of ink per droplet, compared with the Photo EX's 11 picoliters per droplet. Other models from Lexmark, Epson, Canon, and Hewlett-Packard have ink volumes ranging from seven picoliters to as low as three picoliters per droplet, creating pages that can dry more quickly as well as display finer print details than older printers.
- *Improved printer-control software.* Getting the best results with inkjet printers can be confusing, because of the wide variety of options for paper type, image type, and print resolutions. Enhanced printer drivers supplied with the newest inkjet printers provide better control with less possibility of error in printing. Rather than selecting from a variety of print resolutions and paper types, these printer drivers often provide a few preselected combinations, as well as providing customization for users with special needs.

Inkjet Limitations

The latest inkjet printers can provide features once found only on laser printers:

- Full-duplex printing (printing on both sides of the paper) is available with the Hewlett-Packard DeskJet 970Cxi and HP PhotoSmart P1100.

- Rated black-ink text print speeds of 10ppm or above are available from the best printer models available from HP, Epson, Canon, and Lexmark.

These features make inkjet printers, with their combination of black-and-white and color print capabilities, better choices than ever before for more and more SOHO and corporate office users. However, the biggest problem remains the need for specially coated or designed papers and transparency stocks to avoid smearing and achieve the high-quality results the printers are designed to produce.

There are special inkjet papers that prevent this problem, but they are more expensive and offer far less variety than the laser printer papers on the market.

Inkjet printers must also use special transparency stock with a roughened (sandpaper-like) surface to promote proper ink drying. The extra cost of special paper and other print media, along with the relatively high cost and limited print life of inkjet cartridges, makes them a high cost-per-page type of printing. Figure 22.6 illustrates Canon's four-layer paper, which is ideal for inkjet printing.

Figure 22.6 Special papers, such as Canon's four-layer inkjet photo-quality paper shown here, are essential to getting the best possible print quality from today's high-resolution inkjet printers. Match the paper to the resolution you use for printing for best results.

Portable Printers

Portable printers typically use two different imaging technologies: Models made by Citizen use a nonimpact thermal transfer technique that uses special ribbons and a 60-cell print head to fuse the image to the paper. This "thermal fusion" process provides for a very quiet (under 50db) printer and a nonsmear image, but a limited ribbon life (30 pages maximum for black, five pages maximum for color) and relatively low print resolution (360dpi maximum). Portable printers made by Canon and Brother represent a miniaturization of normal desktop inkjet printers and provide for resolutions up to 720dpi with an ink cartridge life of hundreds of pages. Canon's portable printers use the same thermal inkjet print head technology used by their desktop and multifunction inkjet printers, whereas Brother uses the piezo-electric technology originally created by Epson.

Although portable printers offer high print quality similar to their desktop siblings of a similar technology, they must make compromises in other areas to reach the desired goals of light

weight (under five pounds) and compact size. They normally feature limited paper-handling with small-capacity paper trays or sometimes manual feed only. They often use only a single ink cartridge, requiring a swap to print in color. A rechargeable battery might be included, or the printer might use a PC card (PCMCIA) interface for both power and data transfer. Other typical features include infrared printing and optional scanning heads (which replace the normal print head). Although portable printers can't compete in features or speed with desktop printers, they enable travelers to deliver a high-quality printout anywhere.

Dot-Matrix Printers

Dot-matrix printers were, at one time, the most popular type of printer on the market because they were small, inexpensive to buy and to run, and fairly reliable. As the price of laser printers steadily dropped, however, and inkjet printers came to market that offered far superior output quality at virtually the same price, the market for dot-matrix printers reduced dramatically. Although they continue to perform certain tasks quite well, dot-matrix printers generally are too noisy, offer mediocre print quality, and have poor paper handling for single-sheet paper.

Unlike lasers and most inkjets, dot-matrix printers do not process documents a page at a time. Instead, they work primarily with a stream of ASCII characters up to a line at a time and therefore require very small memory buffers. As a result, their speed is measured in characters per second (cps) instead of pages per minute. There is also very little processing performed in the printer when compared to a laser printer. Dot-matrix printers do not use complex page description languages such as PCL and PostScript. The data stream from the computer contains escape sequences used to set basic printer parameters such as page size and print quality, but any complex processing required is performed by the PC.

Dot-matrix printers work by advancing paper vertically around a rubberized roller, called a *platen*, one line at a time. At the same time, a print head travels back and forth horizontally on a metal bar. The print head contains a matrix of metal pins (usually either 9 or 24) that it extends in various combinations to make a physical impression on the paper. Between the pins and the paper is an inked ribbon, much like that used in a typewriter. The pins pressing through the ribbon onto the page make a series of small dots, forming typographic characters on the page. Dot-matrix printers also usually have rudimentary graphical capabilities, enabling them to produce low-resolution bitmaps using their limited memory as a band buffer.

Dot-matrix printers are usually associated with continuous sheet paper, driven by pinholes on the edges. Most models can also handle single sheets, although rarely with the accuracy found in most laser or inkjet printers. Because they are impact printers, meaning that there is actual physical contact between the print head and the paper, dot-matrix printers can do one thing that lasers and inkjets can't: print multipart forms and carbon copies. Many printers enable you to adjust the pressure of the impact to support various numbers of copies. Dot-matrix printers are rarely used for correspondence and general office printing anymore. Instead, they have found their place in commercial applications, such as for banks and hotels.

Note

Visit the Epson Web site for an interactive product finder for its impact printers. Okidata offers a similar service, which also includes its LED printers and fax machines. Both of these services will ask you detailed questions about your printer requirements and match your answers to the models that fit your requirements most closely.

Color Printing

At one time limited to graphics professionals and other high-end users, color printers have now become a commonplace PC accessory. The simplicity of inkjet printer technology has made it possible for manufacturers to build very low-cost printers that produce color output that, although not up to professional standards, is sufficient for basic personal and business needs. New revolutionary technologies are now bringing color printing down in cost and way up in quality and speed.

There are several different types of color printers; most of them are adaptations of existing monochrome technologies. In most cases, color printers function by using the same printing medium in several colors (usually four). Thus, a color inkjet printer or color solid-ink printer uses four or more colored inks, and a color laser uses toner in four colors. As in process color offset printing, it is possible to create virtually any color by combining cyan, magenta, yellow, and black in various proportions. This is called the *CMYK color model* and is referred to as four-color printing. Some inexpensive inkjet printers use only three colors, eliminating the black. These printers create a simulated black by combining the maximum proportions of the other three colors, but the result is far less effective than a true black medium as well as costly.

Depending on the color medium, there are different processes for combining the four colors (see Figure 22.7). For most color printers, it is not possible to actually mix the four colors to achieve the desired result as you would mix paint. Instead, the printer applies the four colors very close to one another in the correct proportion to achieve the desired result. For example, an inkjet printer works by creating an interlaced pattern of dots, with each dot using one of the four inks. This is known as *bilevel printing*. The proportion of dots of each color and the pattern in which they're interlaced dictates the final color. This process of mixing different colored dots to form another color is called *dithering*. The process is similar to the display on your color monitor that creates the color for each pixel by placing red, green, and blue dots of varying intensities very close to one another.

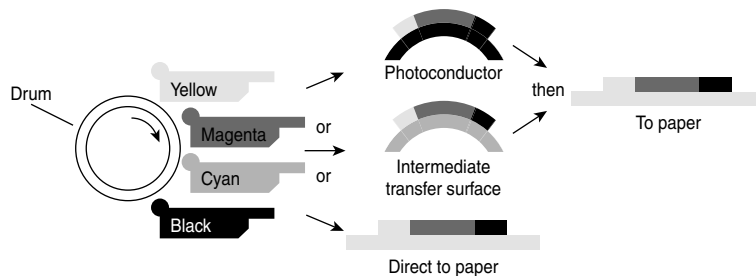

Figure 22.7 Color laser and LED printers transfer the ink (left) to a photo-conductor surface (top center) before it can be transferred to paper. Since there are four colors, this process requires four passes to print a single page with laser printers, but LED printers can print all four colors with a single pass. Color inkjet printers spray the colored inks directly onto the paper surface (bottom center), printing all colors in a single pass. In either case, the printer must control the placement of primary colors to accurately reproduce the original document.

In most cases, dithering is only a moderately successful color process. The resolution of many color printers is not high enough to prevent you from seeing the individually colored dots if you look carefully. The cumulative effect is of a solid color when seen from a distance, but close up, the dithering pattern is discernible to the naked eye. Some methods of overcoming these limitations include HP's use of color layering, Canon's use of variable-sized ink droplets (similar to laser printer "font smoothing" technologies), and Xerox/Tektronix use of solid ink with superfine pitch, many vendors' use of more ink colors, and increasing printer resolution used along with high-gloss papers.

Printing in color necessarily complicates the language that the printer uses to communicate with the PC. Only the PostScript page description language has supported color from its inception. A version of PCL 5 with extensions to accommodate color, called PCL 5c, was introduced by Hewlett-Packard in 1994. Many printer manufacturers, however, have their own proprietary color printing technologies, usually employing the printer driver to perform the additional processing required within the PC.

There are obviously many different applications for color printing, but the true test of any color printer is photographic reproduction. Dithered color that is acceptable for use in a bar chart, for example, might be totally inappropriate for printing photographs. Some relatively low-cost printers use special techniques, such as six inks instead of four, to produce better photographic reproductions, but the general rule is that to achieve photographic color prints that are comparable with those you see every day in magazines, you need equipment that is far beyond that which is typically used with PCs. One exception to the rule is the solid-ink technology pioneered by Tektronix and now owned by Xerox. Solid-ink technology allows the widest range of colors of any office duty color printer, far exceeding that of inkjet and color laser.

Graphics professionals, in most cases, use PC-based color printers as a proofing medium. In the past, it would often be necessary for an artist or designer to send a file to a service bureau for color printing to see a proof of the results of their work in hard copy. Now, rather than endure the delay and expense of that process, a relatively low-cost color printer can streamline the entire creative process. PostScript RIP software makes proofing more realistic if the printer doesn't have PostScript built in.

Note

In the world of color printing, *low-cost* is a highly relative term. To a professional graphic artist or designer, a \$5,000 color laser printer is a low-cost alternative to the enormously expensive printing systems used by service bureaus. To the average PC user with far more modest color requirements, low-cost color inkjet printers are available in the \$150–300 range.

Most color printing technology suffers in comparison to monochrome printing in two significant areas: speed and cost. In most cases, color printers are designed to sacrifice speed to achieve the best possible printing quality. For this reason, it is a good idea to separate your color from your monochrome printing tasks in any sort of production environment. If you use inkjet printers in a business office, for example, it is usually better to have a separate printer dedicated to color output than to force users to wait for a color job to complete to print a simple letter. Although the best inkjet printers today produce black printing that's as good as color printing, the speed of

color printing still lags behind black printing. Also, Canon has pioneered the use of an extra-large black cartridge with a wider print head for extra-fast black printing. Printers from Canon and other vendors that use this feature replace the normal black-and-colors ink cartridges with the single high-speed black cartridge.

The one exception to these rules is the solid-ink printer. They have the speed and low cost of a monochrome printer, and yet they have the highest quality color output available. Solid-ink printers are the first color printers that can handle printing color as quickly and efficiently as they handle black and white, with virtually no drawbacks either way.

Note

Most of the improvements in print quality on inkjet printers in recent years have focused on color print quality. This means that you can purchase a high-quality color inkjet printer for your office and dedicate it to color printing and relegate your older inkjet printers to text operations. The one type of printer suited to combined color and black and white operation is the solid-ink type. With a solid-ink printer, you suffer none of the drawbacks associated with either inkjet or color laser.

The cost of a color printer can range from under a hundred to many thousands of dollars, but one aspect of printing in color that many users do not anticipate is the cost of consumables. People accustomed with monochrome printing rarely contemplate the cost of the ink or toner the printer uses and the paper they print on. A single toner cartridge for a laser printer typically produces thousands of pages, and a range of paper types and qualities is available at varying prices.

Color printers, however, are usually far more expensive to run than monochrome. Depending on the color technology it uses, the printer might require special paper that is more expensive than standard printer paper. In addition, the color medium, whether ink, toner, or ribbon, is usually far more expensive than the monochrome alternative and yields fewer prints. The price of consumables per printed page depends on the coverage; a full page photograph obviously uses far more color than a page of text with a small color chart embedded in it, but color printing costs of fifty cents or more per page are common, as compared to a few pennies for monochrome printing.

An exception to the high cost rule for color printing is the solid-ink printer. These have lower consumable cost than even a monochrome laser and yet outperform all other color printer technologies, especially in speed, quality, and ease of use.

The following sections examine the various color printer technologies intended for the PC market.

Color Inkjet Printers

Inkjet printers use a fairly simple technology that is easy to adapt to color use and initially the most inexpensive. In fact, virtually every inkjet printer on the market today is capable of printing in color. The most typical arrangement is for the printer to use two cartridges: one containing black ink only and one containing the other three colors (cyan, yellow, and magenta). The advantage of this arrangement is that you have fewer individual ink containers to replace, but

the disadvantage is that when any one of the color reservoirs is empty, you have to replace the entire three-color cartridge, thus driving up the cost. Some printers (such as a few of the HP DeskJet models) also accept a second three-color cartridge in place of the black one, providing a six-color printing solution that achieves better results in photographic printing. Some mid-range and high-end color inkjet printers use a separate tank for each color, which provides for more economy in color use, especially for people who use a single color frequently.

Inkjet printers can have problems with different types of papers. The ink must dry quickly on the paper to keep from smearing. Standard inexpensive copy paper is relatively porous, which allows for quick drying, but it also causes the ink to be wicked along the paper fibers. This expands dot size, making the image less sharp and dulling the colors. Inkjets have just the opposite problem when printing transparencies or even coated papers. Because of their hard and smooth surface the image can easily smudge before it has a chance to dry. Normally for the best results, you need special paper for an inkjet printer.

Inkjet printers can be sensitive to environmental conditions. For example, if conditions are very dry and usage is low, some ink can dry in the print nozzles, clogging them and resulting in missing colors and terrible-looking print jobs. On the other hand, humid conditions can slow ink drying, which can lead to smudging, dot blooming, and feathering. Also if the paper curls due to high or low humidity, it can make contact with the print head, smudging the print.

Another problem with inkjet printers relates to the ink levels. When the ink runs low, it will cause sputtering, resulting in fuzzy text and images. Compounding this, the ink level can be difficult to accurately gauge in an ink cartridge. On some inkjet printers, pages will continue to print even though one or more inks have been exhausted. This can cause a significant amount of waste when it occurs in the middle of a large print job.

Inkjet printers vary widely in their capabilities and their prices. Very low-end models typically operate at 300–360dpi, support only letter-sized paper, print at 3 or 4ppm, and may require you to replace the black cartridge with a color cartridge. However, many models with 600–720dpi or higher resolutions and dual-cartridge support are now becoming available for around \$100. As you move up the price scale, resolutions and speeds increase, and printers might be able to use larger page sizes. One specialized breed of printer that often uses inkjet technology is designed to print poster-sized images on paper up to 36 inches wide.

Color Laser Printers

Color laser printers are a relatively new development when compared to the other technologies discussed here. The technology is the same as that of a monochrome laser printer except that there are four toners in different colors. Unlike the other types of color printers, which apply all the colors at the same time, many color lasers actually print each color on the page individually. Because the printer has only a single photoreceptor drum, the entire print engine cycle repeats four times for each page, applying the colored toners on top of each other.

This method greatly complicates the printer's paper handling. In a monochrome printer, the page passes beneath the photoreceptor drum at a speed equal to the drum's rotation so that the toner can be applied evenly onto the page. In a color printer, the page must reverse so that it can pass under the drum four times. In addition, the page must be in precisely the same position for each

pass (registration) so that the individual dots of different colors fall directly on top of one another.

Toner levels can affect the quality of output from laser printers. Just as with monochrome lasers or copiers, there is a gradual degradation of quality, or variations in print density, over the life of a toner cartridge. This becomes most noticeable as the toner runs out and is compounded in a color laser by the fact that there are four different toner cartridges used.

Humid or dry conditions can affect laser output as well. As the paper passes through the laser printer, it receives a static charge so that the oppositely charged toner can adhere to it. If the static charge on the paper is too great due to low humidity, the toner may spread or splatter when transferred to the paper. On the other hand, if the humidity is high and the paper won't hold a charge, the toner may not transfer to the page effectively, resulting in uneven print.

Color lasers can suffer from registration problems due to the fact that the same piece of paper has to pass over four different drums. If there is any misalignment, the colors will be slightly smeared or smudged. Textured paper types can pose problems. If the paper has a textured or rough surface, such as classic laid bond, toner is deposited in both the high and low spots, but the fuser rollers may not exert sufficient pressure to reach the depressions. As a result, the toner can remain a powder in those places and can be brushed off during normal handling.

To overcome the speed and registration problems of conventional color laser printers, the LED page printer mechanism (using light-emitting diodes instead of a laser) pioneered in desktop printers by Okidata is now being used by both Okidata and Lexmark in some color page-printer models. Printers using LEDs can print color pages at the same speed as monochrome pages because they can place all four colors in a single pass. Some lasers mix the toner on the drum by applying each toner in turn, after which all four colors are laid onto the paper at once. This eases the paper-handling difficulties but presents other problems when applying the toner to the drum. In either case, the result is four toner colors mixed on the page and passing through the fuser assembly at once. This technique provides results that are vastly superior to dithered inks and other media. However, color laser printers are still very expensive with PostScript-compatible models starting at \$2,000–\$3,000. Also, because the drum must rotate four times for each page, these printers are significantly slower than monochrome lasers. Although new developments in host-based color laser printers designed for Windows 9x and NT have dropped the price of some models below \$1,300, host-based printers are generally unsuitable for elaborate graphics printing.

In addition to the relatively high initial costs of color laser printers, the type and costs of consumables and accessories should also be considered before acquiring a color laser printer. Some models use solid ink “crayons” that are melted and then applied to the paper, but most models use a separate drum and toner cartridge for each primary color. Therefore, the cost-per-page will be much higher for color printing than for black.

Solid-Ink Printers

I've become somewhat jaded in this business; it takes something really astounding to get me excited. Well, excited is exactly how I felt when I discovered the secret to truly usable and functional color printing—that is, color printing that would have the speed and low cost of monochrome and yet be able to print in full color as easily as black and white, with none of the

standard color drawbacks of inkjet or color laser printers. The secret I'm referring to is solid-ink printing, developed originally by Tektronix and now owned by Xerox.

Solid-ink technology uses blocks of wax that are dropped into a loading tray and melted internally in the printer. When printing, the colored inks are sprayed onto a drum, and then transferred to the page much like a monochrome laser would work. The main difference between solid-ink and color laser is that with solid-ink only one drum is used and all the colors are applied simultaneously to the drum with a special print head. The result is printing that is fully four times faster than color laser, with printing that looks incredibly smooth and saturated, due to the natural blending of the colors as they are applied.

Not only is the solid-ink printer four times faster than a color laser when printing in color, but it is also faster when initiating the print job. A typical color laser like the HP 4500 takes approximately 36 seconds to print the first page, whether you are printing in monochrome or color, whereas the solid-ink Xerox 850 takes about 12 seconds for the first page to print. Part of this is due to the use of a high speed 200MHz PowerPC processor inside the printer, faster than most other printers on the market.

Although solid-ink is technically a dot-level technology just like laser or even inkjet, the resolution is incredibly fine (1200 dots per inch), and the natural blending of the melted ink renders beautifully saturated and vibrant colors with virtually no trace of dithering. The printing has an almost raised quality to it, similar to how some business cards are printed in raised ink. This is because the ink is actually wax, which is not just coating the paper but becomes embedded in it. The printed result is durable and impervious to water (unlike inkjet printing). Heat can be a concern, but the ink melts at a relatively high temperature of 165° F, which wouldn't be experienced under normal circumstances. Still, you might be careful about leaving print jobs in a locked car in the summer, where temperatures that high are common.

Solid-ink printing was first developed by Tektronix in 1992, and although one or two other companies played with the technology, Tektronix is the only company that remained committed to making it work. In 1998 and 1999, it completely revised its product line and came out with some revolutionary products. It received 35 patents on its latest product, the Phaser 850 printer. So revolutionary is its designs that it caught the attention of Xerox, which purchased the color printer division of Tektronix just to get the technology and patent portfolio. As it stands, Xerox is currently the only source for this type of printer.

To see how revolutionary solid-ink printing really is, you have to compare it to the other color printing technologies. In virtually every area solid-ink has them all beat. Take speed, for example. A color laser printer is four times slower than a monochrome laser for the simple reason that there are four complete laser mechanisms inside the printer, and the paper has to travel through all of them to pick up the different colors. This means that most color lasers like the HP 4500 series end up with a four page per minute (ppm) output rate. By comparison, the Xerox Phaser 850 has an astounding 14ppm output rate, in color, which is the same speed in monochrome and the same speed as a monochrome laser. True color printing at the same speed as monochrome.

How about quality? The typical color laser such as the HP 4500 series is rated at 600dpi (dots per inch). The solid-ink 850 printer is rated twice that, or 1200dpi. Then there are the quality issues

that aren't covered by raw resolution comparisons. What happens to a laser printer as the toner runs dry? The output becomes faint, of course, and with a color laser, you now have four different toner cartridges to worry about. Not so with the solid-ink printer. It uses colored blocks of ink that you can see and even drop in while the printer is printing. If any color runs out, the printer simply stops and waits for you to drop in another block. The last page printed before the ink runs out will look as good as the first page printed after the ink is replenished. There is simply no degradation in quality no matter what the status of the ink.

Unlike lasers, there are no registration problems with solid-ink. Because the color is applied to the drum in one pass, the registration is perfect every time. Inkjets have problems with different types of papers, whereas solid ink prints the same regardless of paper type. In other words you can use cheap paper without bleeding, smudging, or dull color output.

Temperature and humidity levels have little or no effect on solid ink print quality. Solid-ink prints are not effected by contact with moisture.

One of the biggest benefits of solid-ink printing is that of consumables, or rather the lack of them. A solid-ink printer can print 45,000 pages nonstop before it needs any attention. The only part that needs to be replaced at that time is a very low-cost maintenance roller, which can be replaced in less than one minute with no tools. Since you can add solid ink sticks even while the printer is running, you can print for almost two years without ever having a single print job interrupted.

By comparison, the average number of pages a color laser printer can print before it requires some form of attention (new imaging kit, transfer kit, toner cartridge, fuser, and so on) is only about 1,250 pages. That would occur every two or three weeks in a normal office environment. Not only are the consumables less costly for the solid-ink printer, but Xerox and Tektronix offer black ink for free during the life of the printer. Thus there is no penalty for printing monochrome; in fact you could say monochrome printing is subsidized.

Consider that an average office prints about 50,000 pages every two years. To print 100,000 pages (or four years worth of printing), a typical color laser will consume 100 expensive toner cartridges (\$100 each), 20 imaging kits (\$75 each), 2 transfer kits (\$150 each), and 1 fuser (\$200). To print the same number of pages on a solid-ink printer will only use 85 blocks of ink (\$50 per block, except black ink which is free for the life of the printer), and two maintenance rollers (\$130 each). This makes the total cost of consumables less than half that of a color laser, and with far less maintenance and print stoppages or problems along the way.

Not only are there very little in the way of consumables compared to a color laser or even an inkjet, but the ink blocks are 100 percent biodegradable and even edible, although I don't think they taste very good. Seriously though, there is very little wasted with solid-ink technology, and the wax ink blocks are no more harmful to the environment than crayons. Also there are no toner cartridges to throw away or send back for refilling.

Over the years I've tried inkjet and color laser printers, and neither of them were workable for me as a sole printer. I still had to maintain a laser printer for black-and-white printing. With solid-ink technology, I now have the first printer I've seen which can serve as the sole printer in an office, handling both color and black and white with the same speed and efficiency. With an initial cost

less than that of most color laser printers (about \$2,500 to start), and the low cost of the consumables, solid-ink is not only the best color printing technology I've seen, but weighing cost versus benefits, by far the most economical.

Check with Xerox at <http://www.tektronix.xerox.com> for more information on solid-ink printing and the printer models available. Now that Xerox has purchased this Tektronix-developed technology, I expect to see many more applications in the future as people discover how well it works.

Dye-Sublimation Printers

Dye sublimation, also called thermal dye transfer, is a printing technique that uses ribbons containing four colored dyes that the printer heats directly into a gas. This way, the four colors are mixed before the printer applies them to the paper. These printers can produce 256 hues for each of the four colors, which combine into a palette totaling 16.7 million different colors. This results in continuous tone (that is, undithered) images that come very close to photographic quality.

Dye-sublimation printers produce excellent output, but they suffer in almost every other way. They are slow and costly, both to buy and to run. They require a special paper type that is quite expensive, as are the ribbon cartridges they use. However, dye-sublimation technology is quite compatible with thermal wax-transfer printing; the two differ primarily in the color medium they use. Several manufacturers make dual-mode printers that can use both thermal wax transfer, which is less expensive, and dye sublimation. This enables you to use the cheaper thermal-wax mode for proofing and everyday printing, saving the dye-sublimation mode for the final product and other special uses.

One of the pioneers of this technology, Fargo Electronics, has turned its attention to card printers, but many other vendors—including Alps, Kodak Digital Science, Mitsubishi, Olympus Seiko Instruments, and others—have introduced dye-sublimation printers for uses ranging from inexpensive snapshot printing to high-end graphic arts.

Thermal Wax-Transfer Printers

Thermal wax-transfer printers use wax-based inks, similar to the Tektronix/Xerox solid-ink technology, but at a much lower resolution and quality. They apply the ink directly to the page like an inkjet, not to a drum like a laser. The process is faster than dye sublimation but is still much slower than even a color laser. The low resolution (generally 300dpi) means the dots are very coarse and colors are dithered rather than smooth. The print quality suffers as a result when compared to continuous tone output, but it is generally better than the output from inkjets.

In printers that offer both dye-sublimation and thermal wax-transfer options, the thermal wax-transfer is used for proofing, and the dye-sublimation mode is used for final results. To see the differences in print quality represented by these technologies, see the Seiko Instruments Web site.

Thermal-Fusion Printers

Some portable printers from Citizen and IBM/Lexmark use a variation of the thermal wax-transfer technology, using a thermal-transfer dot-matrix print head and a choice of a multistrike ribbon

for draft work and a one-time-use film ribbon for final copies. These thermal-fusion printers are tiny, approximating a foot-long French bread loaf, making them a good choice for travel. The latest models can also print in color.

Their extremely compact size and low travel weight is balanced by extremely slow printing speeds, relatively low resolution (360dpi tops), limited availability of ribbons, short ribbon life, and the requirement for single-sheet hand-feeding. Citizen is the main maker of these printers today, but the technology is also used by many bar-code printers from a number of vendors.

Choosing a Printer Type

With so many printers to choose from, it can be confusing to go the store or e-store to find the best one for your needs. This section will help you focus on the best choices for you and your company or family.

When you're buying a printer, you're really buying a combination of the following factors:

- Output quality
- Output speed
- Versatility
- Flexibility
- Economy
- Reliability

Always keep in mind that your printer makes an impression on those who receive the output. Make it a good impression!

Since the print quality is really the “bottom line” when it comes to printing, use the checklists that follow to help you decide on two or three models. Then, compare prices, availability of supplies, cost per page, and print quality to help you get the best models for your needs. Most printer manufacturers allow you to request print samples from their Web sites, allowing you to see actual output, even if your local stores don't have the model set up for a live demonstration.

Use the following feature checklists to help you focus on the most important features. There are three checklists: one for SOHO users, one for network users, and one for mobile users.

SOHO Users

SOHO (small office, home office) users must often use a single printer as a “jack of all trades.” The following feature checklists will help you buy a printer that comes as close as possible to “mastering” your small-office or home-office domain.

For inkjet printers, I recommend that you purchase a printer with the following features:

- At least two ink cartridges (one for black, one for color)
- A print resolution of 600dpi or above
- A speed of at least 4ppm (pages per minute) for black and 2.5ppm for color
- A parallel port
- Compatibility with your operating system

Desirable options include

- 1200dpi, 720×1440dpi, or higher print options
- Separate ink cartridges for each color
- Photo-realistic features (if you print photos)
- High-speed black ink cartridges (if it's your only printer)
- USB port option (for easy movement between PCs)

For laser printers, I recommend that you purchase a printer with the following features:

- A true print resolution of 600dpi or above
- 8ppm or higher print speeds
- PCL 5 or above (true or a good emulation)
- At least 4MB of RAM or above (installed at factory or field-upgradable)
- A parallel port

Desirable options include

- High-capacity paper trays
- Optional straight-through paper path
- USB port option (for easy movement between PCs)

Network Users

A printer that will be shared among many users needs more horsepower and more features than a printer meant for a single user. Some features from the SOHO checklist are repeated here, but the emphasis here is on helping you get a printer that's meant to be shared among all types of users.

For inkjet printers, I recommend that you purchase a printer with the following features:

- At least two ink cartridges (one for black, one for color)
- A print resolution of 720×1440dpi, 1200dpi, or above
- A speed of at least 8ppm (pages per minute) for black and 4ppm for color
- A parallel port and an Ethernet port (standard or optional)
- True PDL or escape-sequence printer control; *not* host-based

Tip

If the printer is designed for use only with Windows, it's usually not networkable.

- Can be networked
- Supports all networks and operating systems used in office

Desirable options include

- Separate ink cartridges for each color
- Photo-realistic features (if you print photos)

- High-speed black ink cartridges for extra speed
- USB port option (for easy movement between PCs)

For laser printers, I recommend that you purchase a printer with the following features:

- A true print resolution of 600dpi or above
- 12ppm or higher print speeds
- PCL 5 or above (true or a good emulation)
- Supports all networks and operating systems in your office
- At least 8MB of RAM or above (installed at factory or field-upgradable)
- A parallel port and an Ethernet port (standard or optional)
- High-capacity paper trays

Desirable options include:

- USB port option (for easy movement between PCs)
- Modular paper trays for adding extra capacity
- Envelope feeder
- Duplexing capability

Mobile Users

Mobile printer users have limited platform choices, as only thermal or small inkjet printers are available. However, a checklist can still provide valuable guidance.

- Same PDL or escape sequence control as used by office printers to make field printing similar to office printing
- Parallel interface with optional PC Card or USB for portability between systems
- Paper feed to improve reliability of printing
- Readily available ribbons or ink cartridges (check your favorite office-supply chain to see if you can get a spare at any of their locations)
- Print quality is more important than speed

Installing Printer Support

As soon as you connect a typical printer with a PDL or escape-sequence controls on-board to your PC's parallel or serial port, it is capable of receiving and processing ASCII text input. Even before you install a driver, you can issue a simple DOS command like the following:

```
dir > LPT1
```

The greater-than sign in this command redirects the directory listing to the PC's parallel port. A printer connected to that port will receive and print the listing using the printer's default page format. If the printer connected to your PC processes data a page at a time, you will have to manually eject the current page to see the printed results. This is because the echo command does not include the form feed escape sequence that causes the printer to eject the page.

You can also redirect a text file to the printer port using a command such as the following:

```
copy readme.txt > LPT1
```

These commands prove that the PC's parallel or serial port provides a fully functional interface to the printer, but to exercise any further control over the print job, you must install a printer driver. However, if you are troubleshooting a system problem that prevents you from loading the Windows printer drivers, this capability can be useful for printing documentation files or other documents.

Note

These simple tests will not work with most host-based printers. A few can perform these DOS-based tests from within a DOS session running under Windows (a "DOS box"), but most require that printer drivers be installed first. PostScript-only printers must receive PostScript commands to print. A simple printer test that does work with PostScript printers is part of the venerable Microsoft MSD utility shipped with MS-DOS and Windows 3.1 and found on the Windows 95 CD-ROM. A dual-mode printer with both PostScript and PCL modes will use the PCL mode for this print test if PCL is the default mode.

DOS Drivers

Many DOS programs use no printer drivers, relying instead on the capabilities of the printer and the ASCII characters that represent control codes (such as carriage return and line feed). Larger applications, however, such as word processors and spreadsheets, typically do include drivers for specific printers. Normally, the driver selection is part of the program's installation process.

Only a few DOS applications provide driver support for a large selection of printers. WordPerfect, for example, traditionally took pride in its comprehensive printer support, but most applications tend to include a few generic drivers that enable you to specify your printer only in the most general sense. These days, the decline of DOS has resulted in the virtual cessation of DOS application development, meaning that you will probably have a difficult time finding support for a new-model printer even in a product such as WordPerfect.

If you have a laser printer that is not specified in the applications list of drivers, you should be able to use a driver supporting the same version of the page description language that your printer uses. A LaserJet III driver, for example, will function with any of the LaserJet III variants, such as the IIId and the IIIsi, because they all use PCL 5. The same driver should also work with the LaserJet 4 and 5 lines if needed because the versions of PCL these printers use are backward compatible with PCL 5.

These more generic drivers might not support all your printer's paper trays and the other features that distinguish the various models. For example, you will not be able to print at 600dpi on your LaserJet 5 printer with a PCL 5 (not PCL 5e) driver. However, you should be able to expect reasonably good results with this type of driver support.

Caution

DOS printing support, once a given except for PostScript-only printers, is slowly becoming a missing feature, especially with low-cost laser and inkjet printers. Some models offer printing from within a "DOS box" under Windows,

but this is of no help if you need to print BIOS setup screens or if you need to print from a DOS program without Windows in the background. The lack of DOS support in new printers is a good reason to keep older inkjet or dot-matrix printers around for utility jobs.

Windows Drivers

Printer drivers in Windows differ from those in DOS in two ways:

- The printer drivers are part of the operating system, so that a Windows printer driver supports every Windows application
- You can get printer drivers for your specific model from the printer manufacturer rather than waiting on an application software developer

Windows 3.1, Windows 9x, Windows Me, Windows NT, and Windows 2000 might use different drivers to support the same printer, and the interface you use to add printer support might be different in each operating system, but the process of installing a driver is fundamentally the same:

- Select a printer manufacturer
- Select the model of printer
- Select the port (serial, parallel, network, or USB)

This process is performed through the Printers icon in the Control Panel.

Using the Printers Icon in the Control Panel

All the Windows operating systems have a Printers icon in the Control Panel. This is the central location for all driver-configuration activities:

- Local printer driver installation
- Network printer driver installation
- Printer testing
- Alternative drivers for a given printer
- Viewing and setting of printer properties
- Printer diagnostics and utilities

If you have a printer that offers a choice of PDLs, you can install a driver for each of the supported languages (typically PostScript and PCL) and select either one when you print a document. Experience will teach you that each language has its strengths and when to use a particular language. Normally, PCL is better for text-heavy documents, whereas PostScript is better for elaborate graphics, especially those created with programs such as Adobe Illustrator and CorelDRAW.

If you have a network client installed on your system, you can install drivers for the printers that you regularly access on the network. The Printers Control Panel enables you to browse the network by using your client and to select the objects representing your network printers.

You might also encounter situations in which it is convenient to “print” a document to an imaginary printer. If, for example, you have to submit a desktop publishing document for prepress

work, you can install the appropriate driver for their image setter on your PC and save the print job data to a file instead of sending it out through a parallel or serial port.

The PDL code created by a printer driver is simply ASCII text, and as such, you can store it as a normal file on your PC. All Windows and most DOS printer drivers enable you to select an output destination of FILE as an alternative to a parallel or serial port. When you actually print a document, the system prompts you for the name and location of the output file to be created.

You can then transport the print file to a system with the appropriate printer by using a disk, a modem, or any other standard medium. After the file is there, you can simply direct it out the appropriate printer port by using the COPY command shown earlier. Because the printer driver has already processed the job, you do not need to have the application that created the document or the printer driver installed on the system. All the commands are in the output file, and you simply have to get it to the printer. With Windows, you can also drag-and-drop the output file to the appropriate printer icon or right-click the file and select "Send To (printer name)" to print the document.

If you need plain-text output from a program that lacks a File, Save command but allows printed output, you should set up a text-only printer (Generic-Text only in Windows) as one of your printer choices and set its port to FILE. "Print" a report to this "printer" and you create a plain-text ASCII file you can use with a word-processing program.

Windows 9x/Me/NT/2000 Driver Installation

Windows 9x, Windows Me, Windows NT, and Windows 2000 include a wizard for installing printer drivers that walks you through the entire process. The procedure in Windows 3.1 is fundamentally the same, although the screens are somewhat different in appearance. When you click the Add Printer icon in the Printers Control Panel, the wizard first asks whether you are installing a driver for a printer connected to the local machine or to the network. You then select the manufacturer of your printer and the specific model.

The operating systems include a comprehensive selection of printer drivers and a Have Disk button that enables you to install drivers that you have obtained from the manufacturer of your printer or from other sources.

After selecting the printer type, you specify the port to which the printer is attached. The available COM and LPT ports installed on your system are listed. The FILE option allows you to save print jobs to disk files.

The wizard also asks whether you intend to use the printer with DOS applications. If you answer yes, the wizard configures your system to redirect all output sent to the LPT1 printer port to the printer driver. This is needed when you are configuring a network printer because DOS applications usually do not have support for network printing.

After you specify whether you want to make the new printer your default Windows printer, the wizard creates a new icon in the Printers control panel. This makes the printer available to all your Windows applications and provides access to the printer's Properties dialog box, which you can use to configure the driver and manipulate your print jobs.

Windows Driver Configuration

The Properties dialog box for a particular printer typically contains numerous settings apart from those for selecting the port that the printer is to use. The features and the appearance of this dialog box depend on the printer driver you have installed; however, in most cases it enables you to select items such as the size and orientation of the paper that the printer will use, the tray that the paper is loaded in, and the number of copies of each page to print.

Many printer drivers provide settings that enable you to adjust the way that the driver handles print elements such as fonts and graphics. A typical Graphics page such as that for the HP LaserJet 5P driver might contain the following parameters:

- *Resolution*. Enables you to select from the print resolutions supported by the printer. A lower resolution provides faster printing and uses less printer memory. This setting doesn't affect text quality on most recent laser printers; the text will still print at the printer's maximum resolution (600dpi on this model).
- *Dithering*. Enables you to select various types of dithering for the shades of gray or colors produced by your printer. The various dithering types provide different results depending on the nature of the image and the resolution at which you are running the printer.

Note

You might find that choosing "coarse dithering" for graphics that will be photocopied later actually produces a better quality copy than "fine dithering." This is because normal (nondigital) copiers tend to smear the dots making up the photographic image. If you're planning to photocopy your original for distribution, always make a test copy and evaluate it before you make your high-volume copy run. You might need to adjust your printer options and reprint the original to get acceptable results by varying dither, darkness, contrast, and other options.

- *Intensity*. Enables you to control how dark the graphic images in your documents should be printed.
- *Graphics mode*. Enables you to select whether the driver should send graphic images to the printer as vectors to be rasterized by the printer or the driver should rasterize the images in the computer and send the resulting bitmaps to the printer. If you're printing complex slides from a program such as Lotus Freelance Graphics to an HP LaserJet printer, you might find that the layers become "transparent" if you use the default vector graphics setting but print as intended with the bitmap setting.

Caution

If you're planning to use the printer to produce multiple copies of pages with vector graphics from presentation or draw-type software such as Freelance Graphics, Microsoft PowerPoint, CorelDRAW, or Adobe Illustrator, do a single-copy test print first to see if you have problems before running your high-volume print job.

Many printer drivers include a Fonts page that lets you control how the driver treats the TrueType fonts in the documents you print. The usual options are as follows:

- *Download TrueType fonts as outline soft fonts*. Causes the driver to send the fonts to the printer as vector outlines so that the printer can rasterize them into bitmaps of the proper size. This option generally provides the fastest performance.

- *Download TrueType fonts as bitmap soft fonts.* Causes the driver to rasterize the fonts in the computer and send the resulting bitmaps to the printer. This option is slightly slower than sending the font outlines but uses less printer memory.
- *Print TrueType as graphics.* Causes the driver to rasterize the fonts into bitmaps and send them to the printer as graphic images. This is the slowest of the three options, but it enables you to overlap text and graphics without blending them.

The Device Options provided by many printer drivers enables you to specify values for the following options:

- *Print quality.* Enables you to select the level of text quality for your documents. Lower qualities print faster but have a coarser appearance.
- *Printer memory.* Enables you to specify how much memory is installed in the printer. The setting displays the amount of memory that ships with the printer, but if you install additional memory, be sure to modify this setting. This setting is used by the Printer Memory Tracking feature (see the following option) to calculate compression and the likelihood of the print job's being completed successfully.
- *Printer memory tracking.* Enables you to control how aggressively the printer driver will use the amount of memory configured in the printer memory parameter. When it processes a print job, the driver computes the amount of printer memory needed and compares it to the amount installed in the printer. If the job requires a great deal more memory than the printer has, it will abort the job and generate an error message. When the amount of memory required is close to the amount installed, this setting determines whether the driver will attempt to send the job to the printer, at the risk of incurring an out-of-memory error, or behave conservatively by aborting the job.

Inkjet printers often feature a Main page that allows you to specify resolution, paper type (plain, photo-quality, transparency), resolution, ink (black or colors), and color adjustments. The Utility page allows you to clean the nozzles, align the nozzles, and check for clogged nozzles on many models.

Printer Sharing via a Network

Windows 9x, Windows Me, Windows NT, and Windows 2000 enable you to share local printers with other users on a Windows network. To do this, you must explicitly create a share representing the printer from the Sharing page of its Properties dialog box. On this page, you specify a NetBIOS name that will become the share name for the printer and a password if you want to limit access to certain users.

After you have created the share, the printer appears to other users on the network just like a shared drive. To access the printer, a network user must install the appropriate driver for the printer and specify the name of the share instead of a local printer port. To avoid having to type out the path, you can drag an icon representing a network printer from the Network Neighborhood and drop it onto the Add New Printer icon in the Printers Control Panel. After this, you need only select the appropriate driver and answer the default printer and printer test page questions to complete the printer installation.

Caution

Before you try to network your printer, make sure it's network compatible. Many low-cost printers today are host based and cannot be shared over a network. Check with the printer vendor for details.

Remote Drivers

Windows NT 4.0 and Windows 2000 differ from Windows 9x and Windows Me in that they can store and distribute the printer drivers for multiple operating systems. When you share a printer in Windows NT/2000, the dialog box contains an Alternate Drivers selector that enables you to choose the operating systems used by the other computers on your network.

After the wizard installs the driver for the Windows NT/2000 system, it prompts you for the appropriate media containing the drivers for the other operating systems you've selected. This way, when a client selects that Windows NT/2000 printer share, it automatically downloads the proper driver from the Windows NT/2000 system and installs it, preventing the user from having to identify the printer manufacturer and model.

Print Sharing via Switchboxes

As an alternative to networking, there are a variety of printer-sharing devices available at low cost. The easiest, cheapest way to share a single printer with two to four computers nearby is with an auto-sensing switchbox, available from cable makers such as Belkin and many others.

Printer switchboxes have an output plug where the cable to the printer is connected and two or more input plugs where the cables from the computers are connected. Computers are normally connected to the box by 25-pin straight-through cables, and the connection from the box to the printer uses a standard DB-25 to Centronics printer cable.

Manual Switchboxes

Simple switchboxes use a rotary switch to determine which computer has control of the printer. Although these units are still on the market, they're not recommended for use with laser or inkjet printers or non-printer parallel devices because these devices can be damaged by the switching process and the boxes normally lack IEEE-1284 bidirectional features.

Autosensing Switchboxes

Autosensing switchboxes are powered by either an external power pack or the data cables; they continuously switch from one port to the next until a print job is sensed. At that point, the box "locks on" to the print job until the printer has been sent the last page. For use with MS-DOS printing (which often cannot wait for the switchbox to scan the port), many of these boxes also provide the capability for the desired port to be set manually. Most recent models support bidirectional IEEE-1284 modes such as EPP and ECP. Autosensing switchboxes that support IEEE-1284 modes will work with most modern laser and inkjet printers, and they will also enable sharing of peripherals such as scanners, tape backups, and other parallel-port devices. IEEE-1284-compliant autosensing switchboxes are available from Hewlett-Packard, Belkin, and many other vendors. Many of these devices are reversible, enabling a single computer to access multiple printers from a single parallel port.

Other Options for Sharing Printers

For sharing a printer among more than four users or for long-distance printing (over 25 feet between printer and computer), there are a variety of solutions available that use a special type of telephone-style cable. Here are a few of the products available, all of which will print more slowly than the previously mentioned switchboxes because they convert short-distance parallel ports into long-distance serial communications:

Products that plug into the MIO port found on many HP LaserJet models include Excellink's JetCard for up to ten users and BayTech's LaserShare for up to eight users. Products that create a "mini-LAN" that can daisy-chain many computers together to any parallel printer (except host-based) include the following: DataDocs's Max-A-Laser, which provides for up to thirty users at distances up to 2,000 feet away. Another option is Linksys's MultiShare for up to eight printers and up to 24 computers at distances up to 1,200 feet.

Support for Other Operating Systems

If your office contains a mixture of Macintoshes and PCs, make sure that the printer offers Macintosh support. Many "personal" printers are basically host based, requiring Windows 9x/Me or NT/2000 to function. Users of the increasingly popular Linux operating system must also shop carefully, as Linux support is still primarily provided by the Linux software vendors, not by the printer makers themselves. For example, Red Hat's popular version of Linux supports PostScript printers natively but uses a PostScript-type interpreter called Ghostscript to support certain non-PostScript models. Look for the hardware compatibility list at Red Hat's Web site. Also, see *Upgrading and Repairing PCs, Linux Edition*, published by Que.

Preventative Maintenance

Printers are traditionally one of the most annoying devices to troubleshoot for computer professionals because they are prone to many mechanical problems that PCs and other networking devices are not. Variability in the quality of consumables and improper handling by users can exacerbate these problems, resulting in printers that require more attention and maintenance than other devices.

As with PCs, preventative maintenance for printers is largely based on common sense. If you keep the unit clean and treat it properly, it will last longer and produce better quality output than if you don't.

Keep the exterior of your printer clean and free of smudges by wiping it with a soft cloth dampened with water.

Laser and Inkjet Printers

For laser printers, the best preventative maintenance regimen results from purchasing a printer that uses toner cartridges with photoreceptor and developer assemblies. These components regularly come in contact with the toner, so replacing them on a regular basis ensures that these vital parts are clean and undamaged. If your printer does not use this type of cartridge, you should take extra care to clean the inside of the printer whenever you replenish the toner, following the

manufacturer's recommendations. Some printers include a special brush or other tool for this purpose.

Caution

It is particularly important to follow the manufacturer's recommendations regarding safety whenever you are working inside a laser printer. Apart from the obvious danger caused by live electrical connections, be aware that some components are very delicate and can be damaged either by rough handling (such as the developer unit and the corotrons or corona wires) or by excessive exposure to light (such as the photoreceptor). In addition, the printer's fusing mechanism is designed to heat up to 400° F or more and might remain very hot for some time after you unplug the unit. Always allow the printer to cool down for at least 15 minutes before performing any internal maintenance that brings you near the fusing rollers.

Most inkjet cartridges contain new nozzles and a new ink supply, which prevents problems caused by nozzles that have become clogged with dried ink. Like lasers, thermal inkjet printers also rely on a powerful heat source, so you should take precautions before touching the internal components.

Low-cost inkjet cleaning kits can be purchased to help keep your inkjet printer free of ink build-up. Some work with a specially textured cleaning sheet that you spray with the cleaning fluid provided with the kit and then run through the printer by printing a few words; these work with all brands. Others let you clean the print head after you remove it from the printer; these work with Canon and HP models.

To avoid inkjet problems, make sure that you turn off the printer with its own power switch, not the surge protector or power director! The printer's own power switch initiates a controlled shut-down of the printer, including capping the print heads to keep them from drying out. If you turn off the power externally (with a surge protector, for example), the print heads might dry out because they're exposed to the air, which eventually clogs them beyond user adjustment.

Minor clogging of inkjet cartridges can sometimes be cured by using the printer's diagnostics routines, accessible either through pushbuttons on the printer or through the printer's property sheets in Windows.

Dot-Matrix Printers

Dot-matrix printers are more prone to collecting dirt and dust than are any other type of printer. This is due both to the physical contact between the inked ribbon and the print head and to the use of continuous feed paper. As the printer runs, a fabric ribbon turns within its cartridge to keep a freshly inked surface in front of the print head. This lateral movement of the ribbon, combined with the continuous high-speed back-and-forth motion of the pins within the print head, tends to produce an ink-saturated lint that can clog the print heads and smudge the printed characters. Film ribbons can help reduce these problems and provide better print quality, but at the cost of a shorter ribbon life.

Continuous feed paper presents another problem. This paper has perforated borders on both edges with holes that the printer uses to pull the paper through the printer. Depending on the quality of the paper you purchase, some of the dots punched out to produce the holes might be

left in the pad of paper. As the paper passes through the printer, these dots can be left behind and can eventually interfere with the paper handling mechanism. Keep dot-matrix printers clean by removing the dots and dust with canned air or a vacuum cleaner and swabbing the print heads regularly with alcohol.

Choosing the Best Paper

Both laser and inkjet printers use cut-sheet paper exclusively, and are therefore prone to paper-handling problems such as paper jams and clumping (multiple sheets feeding simultaneously). You can minimize these problems by making sure that you use paper that is intended for your printer type. This is especially true when you are printing on unusual media such as heavy card stock, adhesive labels, or transparencies.

Printer manufacturers usually specify a range of paper weights that the printer is designed to support, and exceeding these can affect the quality of your results. Even more dangerous, using labels or transparencies in a laser printer that are not designed for laser use can be catastrophic. These media are usually not capable of withstanding the heat generated by the fusing process and might actually melt inside the printer, causing severe or irreparable damage.

It is also important to take precautions when storing your printer paper supply. Damp paper is one of the chief causes of paper jams, clumping, and bad toner coverage. Always store your paper in a cool, dry place, with the reams lying flat, and do not open a package until you are ready to use the paper. When you load paper into your printer, it's always a good idea to riffle through the pad first. This helps the individual pages to separate when the printer extracts them from the paper tray.

Common Printing Problems

You can avoid many printing problems with regular preventative maintenance procedures, but there are still likely to be occasions when you find that the output from your printer is not up to its usual standards or that the printer is not functioning at all. When you are faced with a printing problem, it can sometimes be difficult to determine whether the problem originates in your application, in the computer's printer driver, or in the printer hardware.

In many cases, you can apply standard troubleshooting methodology to printing problems. For example, if you experience the same printing problem when you generate a test page from the printer's control panel as when you print a document from your PC, you can rule out the computer, the driver, and the printer connection as the source of the problem and begin examining the printer. If you experience the same printing problem with different drivers, you can probably rule out the driver as the cause (unless the manufacturer produced several versions of the driver with the same bug).

Consistency is also an important factor when troubleshooting printer problems. If one page in ten exhibits the problem, you can generally rule out software as the cause and begin looking at the hardware, such as the connecting cable and the printer.

The following sections examine some of the most commonly seen printer problems, categorizing them according to the source of the problem. However, these categories must be taken loosely because some of the problems can have several different causes.

It's important to understand that none of the procedures described in the following sections should take the place of the maintenance and troubleshooting instructions provided with your printer. Your printer might use components and designs that differ substantially from those described in this chapter, and the manufacturer should always be the ultimate authority for hardware maintenance and problem-solving procedures.

Printer Hardware Problems

Problems with the printer usually result from the consumables, such as toner and paper. If the toner cartridge is nearly empty or if the printer's internal components become encrusted with loose toner, the quality of the print output can degrade in various ways. In the same way, paper that is damp, bent, wrinkled, or inserted into the tray improperly can cause myriad problems. You should always check these elements before assuming that printer's internal hardware is at fault:

- *Fuzzy print.* On a laser printer, characters that are suddenly fuzzy or unclear are probably the result of using paper that is slightly damp. On an inkjet printer, fuzzy or smeary characters can result when you use various types of paper not specifically intended for inkjet printing. This can also occur if there is a problem with the connection between the print cartridge and the cradle. Try reinstalling the print cartridge.
- *Variable print density.* If you find that some areas of the page are darker than others when using a laser printer, the problem is probably due to the distribution of the toner on the photoreceptor. The most common cause for this is uneven dispensation of the toner as its container empties. Removing the toner cartridge and shaking it from side to side redistributes the toner and should cause it to flow evenly. You can also use this technique to get a few more pages out of a toner cartridge after the printer has registered a "toner low" error. If your printer consistently produces pages with the same varied print density, the problem could be the printer's location. If the unit is not resting on a level surface, the toner can shift to one side of the cartridge, affecting the distribution of the toner on the page. It is also possible that your printer might have a light leak that is causing one area of the photoreceptor to be exposed to more ambient light than others. Moving the printer away from a bright light source can sometimes remedy this problem.
- *Dirty or damaged corotrons.* A laser printer's corotrons (corona wires) apply electrostatic charges to the photoreceptor and the paper. If the transfer corotron (which charges the paper) has clumps of toner or paper fragments on it, it can apply an uneven charge to the paper, and you might see faint or fuzzy white lines running vertically down your printed pages. All-black or all-white pages can be caused by a broken charger or transfer corotron (respectively). A toner cartridge that contains the photoreceptor drum typically includes the charger corotron as well, so replacing the cartridge can remedy some of these problems. You can also (gently!) clean a dirty corotron with a lint-free foam swab or other material recommended by the manufacturer. If you use a cotton swab, be sure not to leave cotton fibers behind on the wires. The transfer corotron is usually built into the printer (and not the cartridge) and will require professional servicing if it is broken. These components are made of fragile wires, so be very careful when you clean them.
- *Sharp vertical white lines.* A sharp white line extending vertically down the entire length of your laser-printed pages that does not go away when you shake the toner cartridge is probably caused by dirt or debris in the developer unit that is preventing the unit from evenly distributing the toner onto the photoreceptor. Again, if the toner cartridge includes the developer unit, replacing it is the simplest fix. If not, your printer might have a mechanism

that enables you to remove the developer roller for cleaning or even a tool designed to remove dirt from the roller while it is in place. It might also be possible to clean the roller by slipping the corner of a sheet of paper down the slots between the roller and the metal blades on either side of it.

- *Regularly spaced spots.* If your laser-printed pages have a spot or spots that are consistently left unprinted, the cause might be a scratch or other flaw in the photoreceptor drum or a buildup of toner on the fusing roller. You can often tell the difference between these two problems by the distance between the spots on the page. If the spots occur less than three inches apart (vertically), the problem is probably caused by the fusing roller. Because the photoreceptor drum has a larger diameter than the fusing roller, the spots it produces would be farther apart or perhaps only one on a page. Replacing a toner cartridge that contains the photoreceptor drum and the fuser cleaning pad (an oil-impregnated pad that presses against the fuser roller to remove excess toner) should solve either of these problems. Otherwise, you will probably have to replace the drum assembly or the fuser cleaning pad separately. Some printers require professional servicing to replace the photoreceptor drum.
- *Gray print or gray background.* As the photoreceptor drum in a laser printer wears, it begins to hold less of a charge, and less toner adheres to the drum, resulting in printing that is gray rather than black. On printers that include the drum as part of the toner cartridge, this is not usually a problem because the drum is changed frequently. Printers that use the drum for longer periods of time often have a print density control that enables you to gradually increase the amount of toner dispensed by the developer unit as the drum wears. Eventually, however, you will have to replace the drum; at that point, you must lower the print density back to its original setting, or you might find that your prints have a gray background because the developer is applying too much toner to the photoreceptor drum.
- *Loose toner.* If the pages emerging from your laser printer have toner on them that you can rub or brush off, they have not been properly fused. Usually, this means that the fuser is not reaching the temperature needed to completely melt the toner and fuse it to the page. A problem of this type nearly always requires professional service.
- *Solid vertical black line.* A vertical black line running down the entire length of several consecutive pages is a sign that your laser printer's toner cartridge might be nearly empty. Shaking the cartridge can usually eliminate the problem, but eventually you will have to replace it.
- *Frequent paper jams.* Paper handling can be a delicate part of the printer mechanism that is affected by several elements. Printer jams can result when paper is loaded incorrectly into the feed tray, when the paper is damp or wrinkled, or when you use the wrong kind of paper. Occasional jams are normal, but frequent jamming can indicate that you are using paper stock that is too heavy or textured in such a way as to be improper for laser printing. Jams can also result when the printer is not resting on a level surface.

Envelope handling is often the weak spot in paper handling, especially with older laser printers or low-cost inkjet printers. Because of their uneven thickness, they tend to produce a high percentage of jams. Even if your printer is designed to handle multiple envelopes, consider feeding them one at a time if you have problems, or use alternative addressing means such as clear labels.

- *Blank pages appear between printed pages.* Paper that is damp, wrinkled, or too tightly compressed can cause two or more sheets to run through the printer at one time. To prevent this, store your paper in a cool, dry place, don't stack the reams too high, and riffle through the stack of paper before you insert it in the feed tray. This can also be caused by different paper types or sizes loaded in the IN tray at the same time.

Note

Before you look for a paper problem, be sure to check the printer setup. Some printers, especially on networks, are set to use a blank page to separate print jobs.

- *Memory overflow/printer overrun errors.* These errors indicate that the job you sent to the printer was too complex or consisted of more data than its buffers could handle. This can be caused by the use of too many fonts, text that is too dense, or graphics that are too complex. You can resolve this problem by simplifying your document or installing more memory in the printer. You can also try adjusting the page-protection setting in your printer driver (see the previous option).

Connection Problems

- *Gibberish.* If your page printer produces page after page of seemingly random “garbage” characters, the problem is probably that the printer has failed to recognize the PDL used by the print job. For example, a PostScript print job must begin with the two characters %!. If the printer fails to receive these characters, all the remaining data in the job prints as ASCII. This kind of problem is usually the result of some sort of communications failure between the PC and the printer. Check that the cable connections are secure and the cable is not damaged. If the problem occurs consistently, it might be the result of an improperly configured port in the PC, particularly if you are using a serial port. Check the port’s parameters in the operating system. A serial port should be configured to use 8 data bits, 1 stop bit, and no parity (N-8-1).

Using the wrong printer driver will also cause gibberish printing. If you had an inkjet printer as your default and switched to a laser printer but failed to set the laser printer as the default, your print jobs would produce garbage printing unless you specifically sent jobs to the laser printer. Similarly, failing to flip a switchbox to use the intended printer will also cause this type of printing error. Thus, many of these printing problems are due to operator error. Whenever you change to a new printer, make sure you set it as the default. Also, to avoid printer-switch errors, consider adding a second parallel port for the other printer or use the new USB-compatible printers if your system is compatible with them.

- *Printer not available error.* When Windows 9x does not receive a response from a printer over the designated port, it switches the driver to offline mode, which enables you to print jobs and store them in the print spooler until the printer is available. The printer might be unavailable because the parallel or serial port is incorrectly configured, the printer cable is faulty, or the printer is turned off, offline, or malfunctioning. A malfunctioning port can be caused by an IRQ conflict (LPT1 uses IRQ 7, and COM 1 and COM 2 use IRQs 4 and 3, by default) or in the case of a serial port, incorrect start/stop/parity bit settings could be the culprit. A switchbox that is supposed to automatically scan for print jobs but has been set to manual mode or has been turned off can also cause this error.
- *Printer does not notify Windows when it is out of paper, jammed, or other problem.* This indicates a communications problem between the printer and the PC. Check the printer cable and its connections at both ends. Some manufacturers recommend that you use a cable that complies with the IEEE-1284 standard.

Note

IEEE-1284 cables don’t work in their advanced EPP/ECP modes unless your printer port is also set for an IEEE-1284 mode. Check your system documentation for details.

- *Intermittent or failed communications or a partial print job followed by gibberish.* Interruptions in the communication between the computer and the printer can cause data to be lost in transit, resulting in partial print jobs or no print output at all. Aside from a faulty cable, these problems can result from the use of additional hardware between the printer port and the printer. Switchboxes used to share a printer among several computers and peripherals that share the parallel port with the printer (such as CD-ROM drives) are particularly prone to causing problems such as this.
- *Port is busy error or printer goes offline.* These errors can occur when an ECP sends data to a printer at a rate faster than it can handle. You can remedy the problem by using the Windows 9x System Control Panel to load the standard printer port driver instead of the ECP driver.
- *Error-reporting methods.* Some models of the HP LaserJet printers (such as the LaserJet II and III) reported errors with a numerical code that was displayed on their LCD status panels. Other models use a series of blinking lights on the system to report errors. Note the error number or blinking light pattern and check the printer manual or online source to determine the problem and its resolution.

Driver Problems

The best way to determine whether a printer driver is causing a particular problem is to stop using it. If a problem printing from a Windows application disappears when you print a directory listing by issuing the `DIR > LPT1` command from the DOS prompt, you can safely say that you need to install a new printer driver. Other driver problems include the following:

- *Form feed light comes on but nothing prints.* This indicates that the printer has less than a full page of data in its buffer and that the computer has failed to send a form feed command to eject the page. This is a common occurrence when you print from a DOS prompt or application without the benefit of a printer driver or use the Print Screen key from DOS or within your BIOS setup screens, but it can also be the result of a malfunctioning driver. Some drivers (particularly PostScript drivers) provide an option to send an extra form feed at the end of every print job. Otherwise, you must eject the page manually from the printer's control panel.
- *Incorrect fonts printing.* Virtually all laser printers have a selection of fonts built into the printer, and by default, most drivers use these fonts in place of similar TrueType or PostScript Type 1 fonts installed on the computer. Sometimes, there can be noticeable differences between the two fonts, however, and the printed text might not look exactly like that on the screen. Slight size discrepancies between the fonts can also cause the page breaks in the printed output to differ from those on the screen.

Note

Because different printers will use TrueType or Type 1 fonts differently, you should select the printer your document will be printed with before you save the document. After you select the printer, you should scroll through the document and check for problems due to page breaks being shifted, margins changing, or other problems.

You should also perform this procedure before you fax your document using a fax modem. Because fax resolution is a maximum of 200dpi in most cases, this lower resolution can cause major layout changes, even with scalable fonts such as TrueType or PostScript Type 1.

Application Problems

- *Margins out of range error.* Most laser printers have a border around all four sides of the page of approximately one-third of an inch where the toner cannot reach. If you configure an application to use margins smaller than this border, some drivers can generate this error message, whereas others simply truncate the output to fit the maximum printable page size. If your application or driver does not generate an error message and does not give you an opportunity to enter a correct margin setting, be sure to check your printer manual to find the possible margin settings before printing.

Note

Some applications offer a “print-to-fit” option that automatically adjusts the document to fit on the page in case you’ve made a margin-setting mistake. These options work by changing the font size or by readjusting line and page breaks. This option can be useful, but preview it before you use it blindly.

Network Printing Problems

- *Can’t print to a networked printer.* Make sure you have rights to the printer; you must log on to the network to be able to use any networked resource. If your printer is a peer resource, you might need to provide a password. If the printer is on a Linux, Novell NetWare, UNIX, or Windows NT/2000 network, contact the network administrator to have the printer added to your list of permissions.

Make sure the printer is designed to be networked; if nobody but the user connected directly to the printer can use it, but the network settings are correct, the printer may not be suitable for network use. Check this feature before you buy (see the checklists found earlier in this chapter).

You must map an LPT or COM port to the print queue to print from an MS-DOS printer; you can use the UNC (Universal Naming Convention) print queue name to print from a Windows application.

- *Simple jobs print, but complex jobs don’t.* Adjust the timings in the printer properties sheet for the network printer.
- *Printer prints gibberish for some users.* The wrong printer driver may be used by some network users; install the correct driver.

Scanners

Scanners are among the most popular peripherals to be used along with a printer, and they often plug into the same parallel or USB port used by the printer.

Scanners provide you with a way to convert documents and photographs of many different types into computer-readable form. Similar to the scanning element on a copier, a scanner works by transferring digital signals representing the document to the computer for processing.

Regardless of the final use for the scanned document, all scans are received by the computer as a digital image.

Scanners differ in how the signals are created, how the scanner is interfaced with the computer, and what types of documents can be scanned. After the document is scanned, a scanning utility program provided with the scanner sends the scan to application software. This software determines whether the scan will be saved as an image or converted into computer-readable text.

Note

Although you'll find useful and updated coverage of scanners here, you'll find more information in *Upgrading and Repairing PCs, Eleventh Edition*, included in its entirety on the CD accompanying this book. The PDF version of the book is printable.

Older Scanner Types

The oldest type of scanners were the now-obsolete hand scanners, which typically used a dedicated interface card. Some of the final models interfaced through the parallel port. Hand scanners were useful for scanning books that were too fragile to be placed on a flatbed scanner, but their small scanning area made working with large originals difficult.

The hand scanner was replaced for single-sheet scanning by sheet-fed scanners, which typically used the parallel port for interfacing. Sheet-fed scanners pulled the paper past a fixed scanning head similar to those used in fax machines, and subject to similar limitations in scanning quality. Sheet-fed scanners have also become largely obsolete as standalone units, although many of the lower-cost "all-in-one" units that combine a printer and fax use the fax input tray as a sheet-fed scanner.

Flatbed Scanners

Take the toner, drum, and paper feed off a copier and add a computer interface, and you have the basic understanding of a flatbed scanner, the current favorite among after-the-fact imaging technologies.

As with other types of scanners, reflected light is used to start the imaging process, but flatbed scanners require a more precise design than hand or sheet-fed scanners because the light that reflects off the document has a long way to go afterward (and even before because scanning colored images requires the light to go through red, green, and blue filters first). See Figure 22.8.

The light that bounces off the document is reflected through a series of mirrors to a CCD (Charge Coupled Device), a series of light-sensing diodes that convert the light into electricity. The electricity is sent to an analog to digital converter (ADC) that converts the electricity into digital pixels that can represent black-and-white or gray tones or color (if the original was scanned in color). The digital information is sent to the computer, where your application determines its future as text, graphics, or a bad scan that must be redone.

Figure 22.8 The path from the light source to the A/D converter is shown here.

Advantages of Flatbed Scanners

- Flexible media handling.** Even the simplest flatbed scanners, like flatbed copiers, can handle documents of varying sizes from small scraps of paper and wallet-sized photos to letter-sized documents as well as books. More sophisticated scanners with automatic document feeders can even handle legal-sized 8.5"×14" documents. Add a transparency adapter, which shines light through the item to be scanned, and your scanner can also handle negatives, slides, and filmstrips of varying sizes.

There are several different ways of handling transparency media. The least expensive way is an adapter that will reflect light from the normal scanner mechanism behind and through the media. This unit, which can handle single 35mm slides only, is intended for casual use. More serious users will opt for a true transparency adapter, which is a device that replaces the normal scanner cover and contains its own light source and mirror mechanism. The scanner driver is used to select this adapter as the scanning source, and the normal light source inside the main scanner body is turned off. The most sophisticated variation found in very high-priced scanners is a media drawer that slides open and enables transparencies to be slid into the body of the scanner. Of these three, only the media drawer technology provides for true high-resolution scanning of small 35mm slides and negatives.

- High resolution made even higher through interpolation.** Unlike simpler types of scanners, flatbed scanners actually have two resolutions: optical and interpolated. Optical resolution refers to the actual resolution of the scanning optics—the hardware. To achieve higher resolution, flatbed scanners also offer a second resolution in which the scanner's software driver fills in fine details lost when detailed line art or text is scanned. This second method is called *interpolation* and usually increases the maximum resolution of the scanner by a factor of at least 4×. Thus, a scanner with a 600dpi optical resolution has an interpolated resolution of at least 2,400dpi. Because the interpolated resolution is software, not hardware-based, poorly written scanner drivers can cause you to have poor results when using these higher resolutions. However, most scanners feature excellent interpolated modes that can produce much better results when scanning line art or text for OCR use. Although these modes can also be used for photographs, this is seldom needed because of the resolution limitations inherent in photographs. Interpolated resolutions should not be used to scan 35mm transparencies, either.

Drawbacks of Flatbed Scanners

- *Size and bulk.* Because flatbed scanners are designed to handle letter-sized documents, they take up a fairly large amount of desk space, although some newer models are hardly larger than the 8.5"×11" letter size paper they handle as a maximum size.
- *Reflective media limitations.* The least expensive flatbed scanners have no provision for transparency adapters, but most mid-range to high-end models have optional adapters for 35mm and larger negatives and slides. The scanning quality is very high when scanning 4"×5" and larger negatives (I've scanned hundreds of 1920-vintage glass negatives for a university archiving project). However, because of the limits of optical resolution, they're not the best choice for small negatives and slides.

Interfacing the Flatbed Scanner

Three interface methods are used on recent and current-model flatbed scanners: parallel-port, SCSI, and USB.

Parallel (LPT) Port Interfacing

Parallel-port scanners are primarily limited to low-end and mid-range models. This interface type often takes advantage of the higher data-transfer rates of the IEEE-1284 compatible port settings, such as EPP and ECP, and always takes advantage of bidirectional or PS/2-style printer ports. Because virtually all computers have a parallel port, parallel-port scanners are universal scanners capable of working virtually everywhere.

Parallel-port scanners have some significant disadvantages, though. First, it can be difficult to juggle any combination of devices beyond a scanner and a printer. With Zip, LS-120, CD-R/CD-RW, tape backup, and other types of removable-media drives often fighting for the parallel port, the order in which devices are connected to the computer can be critical. Should the Zip drive or the scanner be connected first? The printer must be the last item in the daisy-chain because printers lack the pass-through ports used by the other devices. Conflicts between daisy-chained devices are common. Sometimes they can be resolved through changing printer port modes. For example, if one device you use requires EPP mode, and another uses ECP mode, see if your printer port configuration supports EPP+ECP. If you cannot get both devices to work on the same printer port, add a second LPT port to separate your scanner and printer from other devices, or use USB-based devices if you have Windows 98, Windows 2000, or Windows Me with the appropriate device-driver support.

A second disadvantage is scanning speed. Even if your scanner can use the fastest ECP or ECP/EPP port modes, the parallel port can't lay a glove on the faster SCSI or USB ports. Use parallel-port scanners for light-duty operation or when other types of expansion aren't feasible.

SCSI Interfacing

As you saw in Chapter 8, "The SCSI Interface," SCSI interfacing is extremely flexible, providing for daisy-chains of up to seven SCSI devices of varying types and even more with advanced SCSI interface cards.

In tests, a typical scanner equipped with both SCSI and USB ports scanned an 8"×10" color image in about half the time using the SCSI port as compared to when the USB port was used.

SCSI is the best choice for users who need speed and flexibility and who already have a SCSI interface or don't mind the extra cost of the card (some scanners come with an appropriate interface card).

USB Interfacing

The Universal Serial Bus is the latest widely available port and will replace serial and parallel ports sometime in the next few years. For users needing to mix the “no-brainer” installation typical of parallel-port devices with the flexibility of SCSI device handling, USB is the way to go for hobbyist use on the latest machines with Windows 98, which is the first version of Windows sold at retail to include USB drivers. USB is covered in more detail in Chapter 16, “Serial, Parallel, and Other I/O Interfaces.”

Other Types of Scanners

Slide scanners use a motorized film holder that pulls a 35mm slide or filmstrip holder past a scanning mechanism. Even though the moving parts in the scanner are limited to the film holder, the high optical resolution of these scanners (1,900–2,700dpi are typical), the resulting precision of the motors, and the relatively small market for transparency film all make slide scanners relatively expensive; most models are SCSI based.

Photo scanners combine high-resolution slide and filmstrip scanning with limited print scanning. These models usually fit into an empty drive bay on a computer.

Drum scanners are expensive but offer the best possible scanning quality and resolution; they are used strictly by graphics arts professionals.

Getting the Most from Your Scanner's Hardware Configuration

1. *Use the fastest interface your scanner offers.*

If your scanner offers either SCSI and USB or SCSI and parallel, it's worth the extra time and expense (both minimal with Windows 9x) to buy and install a SCSI interface card (some scanners come with the appropriate SCSI card). SCSI is the fastest of the three major interfaces, and speed is a critical factor in scanning, especially with large originals and high scanning resolutions. If you're already using a SCSI card for any other device, you should be able to attach your scanner to it if it's an Adaptec ASPI-compliant SCSI card and scanner.

2. *Set your LPT port for best performance.*

Generally, bidirectional, EPP, or ECP/EPP modes are recommended for scanners that use parallel ports. (Check your documentation for details.) As you saw with other parallel-port devices, using the fastest possible settings that are compatible with all LPT devices you use is the best route to follow.

3. *Get SCSI right.*

Although SCSI interfacing is the fastest interface for scanners and many other peripherals, it offers several challenges.

If your scanner will be added to a daisy-chain of existing SCSI devices, you might need to purchase a different cable from the one that came with your scanner.

If you'll be using a scanner bundled with a SCSI card and cable, the cable you receive will work fine, but you must make sure that your scanner's terminator is turned on or connected to end the SCSI bus at the scanner. If in the future you add another SCSI device to your system by connecting it to the scanner, turn off the scanner's terminator and turn on or install the new device's terminator.

Scanner Troubleshooting

Scanner Fails to Scan

If the scanner's on a parallel port, make sure you've loaded the correct DOS-based parallel-port driver as well as the scanner driver for Windows. Epson scanners use EPSN.SYS in the computer's CONFIG.SYS file, for example. These device drivers normally require configuration options to indicate the correct LPT port address.

Also, make sure the parallel port is set correctly. At a minimum, parallel-port scanners require the bidirectional or PS/2-style port setting. Some might work with the later IEEE-1284 EPP or ECP modes, but others don't.

If the scanner's SCSI-based, make sure the scanner's device ID isn't in use by other SCSI devices. If your SCSI interface card is made by Adaptec, for example, you can use the included SCSI Interrogator to make sure your scanner and other SCSI-based devices are available.

Make sure that terminators are set correctly for SCSI devices; the last device in the daisy-chain needs to be terminated.

If you've just updated a Windows 95 system to Windows 98, an important TWAIN driver file might have been replaced. Use the Microsoft Windows 98 Version Conflict Manager (VCM) to check for a changed file called TWAIN.DLL, and replace the one installed during the Windows 98 upgrade with the one you were using (that worked!).

Can't Detect Scanner (SCSI or Parallel)

Scanners must already be turned on when the system starts to be detected. In some cases with a SCSI-based device, you can open the Device Manager (Control Panel, System, Properties Sheet) for Windows 9x and hit the Refresh button after resetting or turning on the scanner. If this fails or if the scanner's a parallel-port model, you must turn on the scanner and restart the computer to get the scanner to be recognized.

Can't Use "Acquire" from Software to Start Scanning

To see if the scanner or the application is at fault, use the scanner's own driver to scan directly (it's normally added to the Windows 9x/NT/2000 menu). If it scans correctly, you might have a problem with TWAIN registration in your application's File, Import/Acquire option. Check your application's documentation for help; the fix might require reinstalling your scanner drivers.

Graphic Looks Clear on Screen, but Prints Poorly

- *Colors don't match.* You must use a color-management tool (either one included with your scanner or one that must be purchased separately), and you must color-calibrate your scanner and your monitor. See the documentation for your photo-editing program or scanner for compatible color-management tools.
- *Print is fuzzy, lacks definition.* You might have scanned the photograph at 72dpi instead of 200dpi or higher (depending on the printer). Because inkjet and laser printers have many more dots per inch than displays do, a display-optimized scan will become very small and still lack sharpness when printed on a printer with a higher resolution.

OCR Text Is Garbled

- *Check the quality of your document.* Photocopies of documents scanned after handwritten notes and highlighters were used on the original will be very difficult for even the most accurate page-recognition program to decipher.
- *Scan at a minimum of 300dpi or higher if your scanner permits it.* Compare the results at 300dpi to those at 600dpi or even higher; standardize on the resolution that provides the best results. The higher resolutions might take a bit more time, but quality is king! You can't recognize data that doesn't exist.
- *Check the straightness of your document.* Deskew the scan, or reinsert the original and rescan it.
- *The fonts in the document might be excessively stylized—such as script, black letter Gothic, and others.* If you have a hard time telling an *A* from a *D*, for example, it's equally difficult for a page-recognition program to decipher it. If you plan to scan documents using the same hard-to-recognize fonts frequently, consider taking the time to “train” your page-recognition program to understand the new alphabet, numbers, and symbols.
- *Try manually zoning the document (drawing boxes around what you want scanned).* Check the expected data type in each zone. The program might be mistaking a graphics box for a text area or a table for ordinary text.

CHAPTER 23

Portable PCs

Evolution of the Portable Computer

Portable computers, like their desktop counterparts, have evolved a great deal since the days when the word *portable* could refer to a desktop-sized case with a handle on it. Today, portable systems can rival the performance of their desktop counterparts in nearly every way. Many systems are now being marketed as “desktop replacements,” which companies are providing to traveling employees as their primary systems. This chapter examines the types of portable computers available and the technologies designed specifically for use in mobile systems.

Portables started out as suitcase-sized systems that differed from desktops mainly in that all the components, including the monitor, were installed into a single case. Compaq was among the first to market portable computers like these in the 1980s, and although their size, weight, and appearance were almost laughable when compared to today’s portables, they were cutting-edge technology for the time. The components themselves were not very different from those in standard computers. Most portable systems are now approximately the size of the notebook they are often named for and are built using the clamshell design that has become an industry standard, with nearly every component developed specifically for use in mobile systems.

All my professional life I have been on the road teaching PC hardware and software. Since I am almost never home or at a single desk, I have had to rely on portable systems, usually as my primary, if not only, system. In fact I have used portable systems even before there were PCs. I had some experience with the original Osborne portable, as well as several different Kaypro systems. These were sewing machine–sized portables that ran CP/M, the most popular operating system before DOS existed.

My first DOS portable was the original Compaq sewing machine–sized portable, and from there I graduated to an IBM Portable PC (also sewing machine–sized) and then to a succession of briefcase-sized portables. I had to use these larger AC-powered systems in lieu of laptop or notebook systems because I needed a system with desktop power, performance, and storage. In 1995, laptop and notebook systems reached parity with desktop systems in power and storage, and I was able to graduate to laptop/notebook systems, which I have been using ever since.

Every version of this book, starting with my first self-published manuscripts in 1985, has been written on a portable system of one kind or another. With the processing power of modern notebook systems moving even closer to desktop systems, I look forward to carrying even smaller and lighter systems in the future.

Portable computers have settled into a number of distinct roles that now determine the size and capabilities of the systems available. Traveling users have specific requirements of portable computers, and the added weight and expense incurred by additional features make it less likely for a user to carry a system more powerful than is needed.

Portable System Designs

Obviously, portable systems are designed to be smaller and lighter than desktops, and much of the development work that has been done on desktop components has certainly contributed to this end. The 2 1/2-inch hard drives typically used in portables today are a direct extension of the size reductions that have occurred in all hard drives over the past few years. However, two other

issues have created a need for the development of new technologies specifically for portable systems; those issues are power and heat.

Environmental concerns are leading to the development of more efficient power-management technologies, but, obviously, operating a computer from a battery imposes system limitations that designers of desktop systems never had to consider before the advent of portable systems. What's more, the demand for additional features such as CD-ROM drives, larger displays, and ever faster processors has increased the power drain on the typical system enormously. The problem of conserving power and increasing the system's battery life is typically addressed in three ways:

- *Low-power components.* Nearly all the components in today's portable systems are specifically designed to use less power than their desktop counterparts.
- *Increased battery efficiency.* Newer battery technologies such as lithium ion or lithium polymer are making batteries and power supplies more consistent and reliable and allowing for longer battery life on a single charge.
- *Power management.* Operating systems and utilities that turn off specific system components, such as disk drives, when they are not in use can greatly increase battery life.

Perhaps a more serious problem than battery life in portable systems is heat. The moving parts in a computer, such as disk drives, generate heat through friction, which must somehow be dissipated. In desktop systems, this is accomplished by using fans to continuously ventilate the empty spaces inside the system. Portable systems must be designed to run fan-free most of the time, using innovative systems for moving and dissipating heat.

The worst culprit, as far as heat is concerned, is the system processor. When they were first released, the amount of heat generated by Intel's 486 and Pentium processors was a problem even in desktop systems. Heat sinks and tiny fans mounted on top of the CPU became standard components in most systems. Modern Pentium III and Celeron systems benefit from newer processor technology featuring lower voltages, smaller die sizes, integrated L2 cache, and in general, lower power consumption than their predecessors.

Because many portable systems are now being designed as replacements for desktops, users are not willing to compromise on processing power. Even the newest and fastest processors designed for desktop systems, such as the Pentium III, are quickly adapted for use in mobile systems. However, for reasons of power consumption, noise, and space, fans in portable computers must be much smaller or omitted entirely, and there is very little empty space within the case for ventilation.

To address this problem, Intel and AMD have created special methods for packaging mobile processors that are designed to keep heat output to a minimum. Mobile processors also reduce heat through use of extra-low voltage designs (dual voltage in some cases) and integrating the Level 2 cache directly on the processor die. Other components are also designed to withstand the heat within a portable computer, which is usually greater than that of a desktop.

Form Factors

There are three basic form factors that describe most of the portable computers on the market today: laptops, notebooks, and subnotebooks. The definitions of the three types are fluid,

however, with the options available on some systems causing particular models to ride the cusp of two categories. The categories are based primarily on size and weight, but these factors have a natural relationship to the capabilities of the system, because a larger case obviously can fit more into it. The three form factors are described in the following sections. Note that these designations are somewhat vague, and the marketing departments in most companies like to come up with their own terms for what they think a particular system might conform to. So don't be surprised if you see a system I might refer to as a laptop be called a notebook, or vice versa, by the manufacturer.

Laptops

As the original name coined for the clamshell-type portable computer, the laptop is the largest of the three basic form factors. Typically, a laptop system weighs seven pounds or more, and is approximately 9×12×2 inches in size, although the larger screens now arriving on the market are causing all portable system sizes to increase. Originally the smallest possible size for a computer, laptops today have become the high-end machines, offering features and performance that are comparable to a desktop system.

Indeed, many laptops are being positioned in the market either as desktop replacements or as multimedia systems suitable for delivering presentations on the road. Because of their greater weight, laptops are typically used by salespeople and other travelers who require the features they provide. However, many high-performance laptops are now being issued to users as their sole computer, even if they only travel from the office to the home. Large active-matrix displays, 32MB to 256MB of RAM, and hard drives of up to 20GB or more in size are all but ubiquitous, with virtually all systems now carrying fast CD-ROM or DVD drives, onboard speakers, and connectivity options that enable the use of external display, storage, and sound systems.

To use them as a desktop replacement, you can equip many laptops with a docking station (or a less expensive port replicator) that functions as the user's "home base," enabling connection to a network and the use of a full-size monitor and keyboard. For someone who travels frequently, this arrangement often works better than separate desktop and portable systems, on which data must continually be kept in sync. Naturally, you pay a premium for all this functionality. Cutting-edge laptop systems can now cost as much as \$2,500–4,500 or more, at least twice the price of a comparable desktop.

Notebooks

A notebook system is designed to be somewhat smaller than a laptop in nearly every way: size, weight, features, and price. Note that the dividing line between what we might call a notebook or laptop system is somewhat fuzzy. You'll find that these categorizations are somewhat flexible. Weighing five to seven pounds, notebooks typically have smaller and less capable displays and lack the high-end multimedia functions of laptops, but they need not be stripped-down machines. Many notebooks have hard drive and memory configurations comparable to laptops, and virtually all are equipped with CD-ROM drives and sound capabilities.

Designed to function as an adjunct to a desktop system rather than a replacement, a notebook can actually be used as a primary desktop replacement for all but the most power-hungry users. Notebooks typically have a wide array of options, as they are targeted at a wider audience, from the power user who can't quite afford (or who doesn't want the size and weight of) the top-of-the-line laptop to the bargain hunter who requires only basic services. Prices can range from under \$1,000 to more than \$2,500.

Subnotebooks

Subnotebooks are substantially smaller than both notebooks and laptops and are intended for users who must enter and work with data on the road, as well as connect to the office network. Weighing four to five pounds, and often less than an inch thick, the subnotebook is intended for the traveler who feels overburdened by the larger machines and doesn't need their high-end capabilities.

Usually, the first component omitted in a subnotebook design is the internal floppy drive, although some include external units. You also will not find CD-ROM drives and other bulky hardware components built-in; although, some machines, such as IBM's ThinkPad 570, use a detachable module (or "slice") that fits under the main system to carry CD-ROM or DVD drives and floppy drives. However, many subnotebooks do include large, high-quality displays, plenty of hard drive space, and a full-size keyboard (by portable standards).

As is common in the electronics world, devices become more inexpensive as they get smaller, but only up to a certain point at which small size becomes a commodity and prices begin to go up. Some subnotebooks are intended (and priced) for the high-end market, such as for the executive who uses the system for little else but email and scheduling, but wants a lightweight, elegant, and impressive-looking system. Subnotebooks range in price from under \$2,000 to around \$4,000, depending on features.

Palmtop (Handheld Mini-Notebooks)

There is also a category of systems that are so incredibly small, they fit in the palm of your hand. I am not referring to the PDAs (Personal Digital Assistants) or the non-PC type systems that run Windows CE, but to systems that although tiny, are fully functional PCs that run the same operating systems and applications as your normal desktop systems. Portable PC systems are no longer constrained by the standard keyboard design and spacing. They normally offer a standard layout of keys, but with the keys spaced much more closely together than with a standard keyboard. As such, this class of system is very difficult to use for extensive typing, but for simple field work, email or Internet access, or anything that doesn't require a lot of data entry, they are incredibly useful.

Palmtop computers are typified by the Libretto series from Toshiba, which weigh about two pounds, have screens of eight inches or less in size, and offer a tiny keyboard with an integral TrackPoint device. These systems don't offer the faster or more power-hungry processors but are fully functional PCs that run normal Windows and normal applications. This type of system is ideal as a secondary system for somebody who travels and demands the smallest and lightest, yet fully functional PC.

Upgrading and Repairing Portables

The portable systems manufactured today are less upgradable or repairable in general than desktop systems, mainly due to the lack of standard form factors for cases, motherboards, keyboards, displays, and even batteries. Even so, in some ways a portable can be easier to upgrade than a desktop because portable systems typically use modular components with snap-in connectors that eliminate the need for ribbon cables, mounting rails, and separate electrical connections. Thus, common upgrades like adding memory and swapping out a hard drive (on models with modular drive bays) can usually be accomplished in seconds.

The problem with replacing components in portables is that the hardware tends to be much less generic than it is in desktops. The exceptions are for PC cards (which are interchangeable by definition), memory, and in some cases, hard drives. Purchasing a component that is not specifically intended for use in your exact system model can be risky.

In some cases, these compatibility problems are a matter of simple logistics. Portable system manufacturers jam a great deal of machinery into a very small case, and sometimes a new device just will not fit in the space left by the old one. This is particularly true of devices that must be accessible from the outside of the case, such as CD-ROM and floppy drives. Keyboards and monitors, the most easily replaceable of desktop components, are so completely integrated into the case of a portable system that they may not be practically removed at all.

In other cases, your upgrade path may be deliberately limited by the options available in the system BIOS. For example, manufacturers might limit the hard drive types supported by the system to force you to buy a replacement drive from them (at an inflated price), and not a third party. This is something you should check when shopping for a portable system by asking whether the BIOS is upgradable and finding out how much the vendor charges for replacement components.

◀◀ See "Upgrading the BIOS," p. 390.

Most of the time, components for portable systems are sold by referencing the system model number, even when third parties are involved. If you look through a catalog for desktop memory, for example, you see parts listed generically by attributes such as chip speed, form factor, and parity or non-parity. The memory listings for portable systems, on the other hand, will very likely consist of a series of systems manufacturers' names and model numbers, plus the amount of memory in the module.

There are always exceptions to the rule, of course. However, purchasing compatible components that fit together properly is certainly more of a challenge than it is for a desktop system. Table 23.1 explains which portable PC components can be upgraded.

Note

Generally speaking, purchasing a preassembled portable system from a reputable manufacturer is strongly recommended, as is purchasing only replacement components that are advertised as being specifically designed for your system.

Table 23.1 Upgradable Portable System Components

Component	Upgradable	Sources	Notes
CPU	No ¹	n/a	Adoption of newer Intel CPU/chipset packaging allows designers to more easily incorporate new CPUs into existing system designs, but this is not intended for upgrades.
Memory	Yes	OEM vendor and third parties	Modules are not interchangeable among many models; only one or two upgrade sockets in most systems.
Hard disk	Varies	OEM vendor and third parties	For systems that lack a modular bay, upgrade requires partial disassembly of system; older systems may not have BIOS support for largest drives; several drive form factors (thicknesses) may limit choices for some systems.
Video adapter/chipset	No	n/a	Get fastest video circuitry with 4MB or more memory if true-color display needed; some systems offer MPEG2 hardware decoder upgrades for DVD video.
Video display	No	n/a	Get highest resolution; active-matrix if available.
Removable-media drives	Varies	n/a	For systems that lack modular bays, use PC Card or CardBus-interface adapter for highest performance peripherals (CD-RW, tape backup, SCSI devices, and so on); lower-performance devices can use USB connection (LS-120, Zip, Jaz, CD-ROM, and so on).

1 Note that a few companies will upgrade the processor in your portable. When you send the system to them, they will desolder or remove the original processor and solder or plug in a replacement. Most of the time these upgrades are limited in nature and costly to perform, and the result might include overheating or battery life problems in the future. For the costs involved and the limited benefits, I don't consider processor upgrades to be a viable option for portable systems, except in rare or unique circumstances.

Most portable systems, especially the smaller laptop or notebook designs, are difficult to disassemble. They have many more screws than desktop systems, and these screws are often hidden under stickers or covers. The case covers often feature thin plastic parts that interlock and can be tricky to separate without damage. Unlike desktops, once you've taken one portable apart, they are not all alike, so it really helps to have specific documentation on disassembly from your manufacturer.

Figure 23.1 shows the components that make up a typical laptop or notebook system, such as the IBM ThinkPad 770.

Normally no special tools are required to disassemble a portable, but there are usually lots of screws, often hidden behind self-stick plastic covers, that will need to be carefully removed. The exact location of these screws vary from system to system, as does the best order to remove components. The best advice I can give you is to get the manufacturer-specific service manual for

your system. One reason I like the IBM ThinkPad series so much is that IBM makes the service/repair and technical reference manuals available free on its Web site. These documents include complete disassembly and reassembly instructions and a complete parts list including detailed exploded diagrams and part numbers.

Figure 23.1 The components found in a typical laptop or notebook system are shown here. *Illustration courtesy of IBM Corporation.*

Toshiba also has detailed service and technical reference manuals, although you have to purchase them through a dealer. With systems from other manufacturers, you'll have to check to see if such documentation is available. I personally avoid any systems where I can't get this type of information from the manufacturer. I make it a point to get the service and technical reference manuals for any portable system I own. Obtaining these manuals makes future repairs and upgrades much easier.

Portable System Hardware

From a technical standpoint, some of the components used in portable systems are similar to those in desktop computers, whereas others are completely different. The following sections examine the various subsystems found in portable computers and how they differ from their desktop counterparts.

Displays

Perhaps the most obvious difference between a portable system and a desktop is the display screen. Gone is the box with an emitter bombarding a concave glass tube with electrons. In its place is a flat screen, which is less than half an inch thick. This is called an LCD, or liquid crystal display. Virtually all the screens in portable systems today are color, although monochrome displays were at one point the industry standard, just as in standard monitors.

An LCD consists of two sheets of a flexible, polarizing material with a layer of liquid crystal solution between them. If you press gently on an LCD screen while it is lit, you can see how it gives slightly, displacing the liquid inside. When an electric current is passed through the liquid, the crystals align and become semi-permeable to light.

◀◀ See "LCD Displays," p. 851.

The display is usually the single most expensive component in a portable system, often costing the manufacturer \$1,000 or more. In fact, if the system is out of warranty, it is sometimes more economical to replace the entire computer rather than have a broken display replaced. In the first laptops with color screens, the display was a poor replacement for a standard VGA monitor. Today's portable screens are much improved, with some high-end displays even rivaling the performance of a good monitor and providing excellent performance, suitable even for graphic-intensive applications such as bitmap editing and videoconferencing. In fact, there are even LCD displays now being manufactured for use with non-portable systems.

The LCD display in a portable system is designed to operate at a specific resolution. This is because the size of the pixels on an LCD panel cannot be changed. On a desktop system, the signal output from the video adapter can change the resolution on the monitor, thus changing the number of pixels created on the screen. Obviously, as you switch from a resolution of 640×480 to 800×600, the pixels must be smaller to fit into the same space. Systems are currently available with the following resolutions:

- VGA 640×480
- SVGA 800×600
- XGA 1,024×768

- SXGA 1,280×1,024
- SXGA+ 1,400×1,050

Besides the issue of resolution, there is the issue of size. Be careful when selecting notebooks or laptops with the XGA, SXGA, or SXGA+ displays, because the higher resolution will often result in smaller text and icons than the typical desktop user is accustomed to. The difference between LCD and normal analog displays is that the relative resolution of an LCD is fixed; that is, it normally cannot be scaled. On a monitor, each pixel (picture element) is not tied to the individual phosphor dots, whereas on an LCD, pixels are tied to the individual LCD transistor display elements. For example, if you change from 1,024×768 to 800×600 on a standard monitor, the image still fills the screen because each pixel is now larger. On the other hand, when you do that on a portable LCD screen, the image becomes smaller, with a dark band of unused space surrounding the image in the center. An icon displayed in either resolution will be the same size on an LCD, which is not the case on a normal monitor.

To gauge the size of displayed items on an LCD, it is common to express the resolution of the screen in pixels per inch, which is a fixed value for a given screen. Table 23.2 shows the relative pixels per inch and other statistics for typical color screens available on portable systems over the years.

Table 23.2 LCD Display Dimensions and Pixel Sizes

Display	Dimension	Pixels	Aspect Ratio	Length (in)	Pixels per Inch
8.4" VGA	across	640	1.33	6.72	95
	down	480		5.04	
	diagonal	800		8.40	
9.5" VGA	across	640	1.33	7.60	84
	down	480		5.70	
	diagonal	800		9.50	
10.4" VGA	across	640	1.33	8.32	77
	down	480		6.24	
	diagonal	800		10.40	
10.4" SVGA	across	800	1.33	8.32	96
	down	600		6.24	
	diagonal	1000		10.40	
11.3" SVGA	across	800	1.33	9.04	88
	down	600		6.78	
	diagonal	1000		11.30	
12.1" SVGA	across	800	1.33	9.68	83
	down	600		7.26	
	diagonal	1000		12.10	
12.1" XGA	across	1024	1.33	9.68	106
	down	768		7.26	
	diagonal	1280		12.10	
13.3" XGA	across	1024	1.33	10.64	96
	down	768		7.98	
	diagonal	1280		13.30	

Display	Dimension	Pixels	Aspect Ratio	Length (in)	Pixels per Inch
13.7" SXGA	across	1280	1.25	10.70	120
	down	1024		8.56	
	diagonal	1639		13.70	
14.1" XGA	across	1024	1.33	11.28	91
	down	768		8.46	
	diagonal	1280		14.10	
15.0" XGA	across	1024	1.33	12.00	85
	down	768		9.00	
	diagonal	1280		15.00	
15.0" SXGA+	across	1400	1.33	12.00	117
	down	1050		9.00	
	diagonal	1750		15.00	
15.4" SXGA	across	1280	1.25	12.03	106
	down	1024		9.62	
	diagonal	1639		15.40	

From this table you can see that most LCD display resolutions are under 100 pixels per inch, while some of the newer high-resolution displays are higher than that. Normally anything under 100 pixels per inch is considered fairly loose, meaning that individual icons, text, and other display items will be large enough for most people to easily see. Regardless of the actual resolution, any two displays having the same number of pixels per inch will display text, icons, and other elements on the screen at the same sizing. For example, both the 12.1-inch XGA display and the 15.4-inch SXGA display have the same pixel size (106 per inch), which means if an object is 106 pixels wide, it will be an inch wide on either display. If you have the SXGA display and change settings to display only XGA resolution, you'd see a 12.1-inch active display area centered inside the 15.4-inch screen.

After you go over 100 pixels per inch, the icons, text, and other items on the display become smaller and, for some, possibly difficult to see. In the more extreme cases you may have to change display settings to use large fonts to make onscreen text easier to read. I currently use both the 13.7-inch SXGA and 15.0-inch SXGA+, which are the highest resolution displays available in laptop systems today, and which have 120 and 117 pixels per inch respectively. I consider 120 pixels per inch the maximum that you can run Windows without absolutely requiring adjustments in font sizes, icon sizes and spacing, and so on, but this is something that depends on your vision, especially close up. If you are considering a system with more than 100 pixels per inch in the display, make sure you preview it first to be sure that the level of screen density is acceptable. The amount of desktop visible and number of open windows you can have make these high-resolution displays very appealing for desktop replacement systems.

Even with their tinier text and icons, the LCD screens are much sharper and clearer than an analog desktop monitor, so even though they are smaller, they are often more readable with less eye strain.

An LCD panel can be thought of as a grid ruled off to a specified resolution, with transistors controlling the color displayed by each individual pixel. The arrangement of the transistors defines

the two major types of LCD displays used in portable systems today: dual scan and active matrix. While dual-scan displays ruled the notebook/laptop market for a long time, recent price drops in active-matrix displays have made them the display of choice for all except the most price-conscious shopper. Many manufacturers are now only making active-matrix systems, because the costs have come down and the technology is superior.

Even though the prices for these displays have come down, they are still one of the most expensive parts of a portable system. They are also fragile. If you drop your laptop or notebook, you will likely fracture the display, which means it must be replaced. Often the replacements are close to the same cost as purchasing a new system, and accidents such as dropping are not covered under the standard warranty. Another common way people damage their screens is to close the system with a pen, pencil, or other item on or above the keyboard. Make sure this area is clear before closing the system.

Dual-Scan (Passive-Matrix) Displays

The dual-scan display, sometimes called a passive-matrix display, has an array of transistors running down the X and Y axes of two sides of the screen. The number of transistors determines the screen's resolution. For example, a dual-scan display with 640 transistors along the X axis and 480 along the Y creates a grid like that shown in Figure 23.2. Each pixel on the screen is controlled by the two transistors representing its coordinates on the X and Y axes.

Figure 23.2 Dual scan LCD displays use a combination of two transistors on intersecting axes to control the color of each pixel.

If a transistor in a dual-scan display should fail, a whole line of pixels is disabled, causing a black line across the screen (either horizontally or vertically). There is no solution for this problem other than to replace the display or just live with it. The term *dual scan* comes from the fact that the processor redraws half of the screen at a time, which speeds up the refresh process somewhat.

Dual-scan displays are generally inferior to active-matrix screens. Dual-scan displays tend to be dimmer, because the pixels work by modifying the properties of reflected light (either room light

or, more likely, a white light source behind the screen), rather than generating their own. Dual-scan panels are also prone to ghost images and are difficult to view from an angle, making it hard for two or more people to view the same screen.

However, newer passive-matrix technologies such as color super-twist nematic (CSTN), double-layer super-twist nematic (DSTN), and especially high-performance addressing (HPA) screens have come a long way in making passive-matrix displays a viable, lower-cost alternative to active-matrix technology. These newer displays offer better response rates and contrast—problems that plagued many of the earlier display types—but they are still not as sharp or as fast as an active-matrix screen.

◀◀ See “LCD Displays,” p. 851.

Of course, passive-matrix displays are also far less expensive than active-matrix screens. The drawbacks of a passive-matrix display are most noticeable during video-intensive applications, such as presentations, full-color graphics, video, fast-moving games, or under bright lighting conditions, such as in a window seat on an airplane, outdoors, or in offices with a lot of window lighting. For computing tasks, such as word processing and email, that consist largely of reading words onscreen, the passive-matrix display is quite serviceable, even for long periods of time.

The standard size for a dual-scan display has been 10 1/2 inches (measured diagonally), running at 640×480, but most newer systems have 12.1-inch or 13.3-inch displays that run at 800×600 or 1024×768 resolution. If you are familiar with the dual-scan display of an older portable, you will find that today's models are greatly improved.

One major advantage that dual-scan displays still possess is the cost of replacement in case of breakage (a major concern for notebook-equipped travelers). Breakage insurance tends to be far less expensive for dual-scan displays than for active-matrix. The cost of breakage insurance for both types of displays should be considered along with other price factors when choosing a system.

Active-Matrix Displays

An active-matrix display differs from a dual scan in that it contains three transistors for every pixel onscreen (color displays), rather than just at the edges. The transistors are arranged on a grid of conductive material, with each connected to a horizontal and a vertical member (see Figure 23.3). Selected voltages are applied by electrodes at the perimeter of the grid to address each pixel individually.

Most active-matrix displays use a thin film transistor (TFT) array. TFT is a method for packaging one (monochrome) to three (RGB color) transistors per pixel within a flexible material that is the same size and shape as the display, so the transistors for each pixel lie directly behind the liquid crystal cells they control.

Two different TFT manufacturing processes account for most of the active-matrix displays on the market today: hydrogenated amorphous silicon (a-Si) and low-temperature polysilicon (p-Si). These processes differ primarily in their cost. At first, most TFT displays were manufactured using the a-Si process because it required lower temperatures (less than 400° Celsius) than the p-Si process of the time. Now, lower temperature p-Si manufacturing processes are making this method an economically viable alternative to a-Si.

Figure 23.3 Active-matrix LCD displays contain one or more transistors for each pixel on the screen. The pixels generate their own light for a brighter display.

Although a TFT display has a great many transistors—4,410,000 for a color 1400×1050 display—each pixel does not have its own separate signal connection. Instead, voltages are applied through connections for each row and column, much like the transistors in a passive-matrix display.

Because every pixel is individually powered, each one generates its own light of the appropriate color, creating a display that is much brighter and more vivid than a dual-scan panel. The viewing angle is also greater, allowing multiple viewers to gather around the screen, and refreshes are faster and crisper, without the fuzziness of the dual scans, even in the case of games or full-motion video.

On the downside, it should be no surprise that, with more transistors an active-matrix display requires a lot more power than a dual scan. It drains batteries faster and costs a great deal more, as well.

With all these transistors, it is not uncommon for failures to occur, resulting in displays with one or more “dead pixels,” due to malfunctioning transistors. Actually we are talking about subpixels, the individual RGB triad transistor elements that make up each pixel. Subpixels can fail in either the off or on state, with failure in the on-state more common. In particular those that fail when on are very noticeable on a dark background as bright red, green, or blue dots. Most manufacturers have standards for the number of defective pixels that are allowed on their displays. It is considered acceptable to have a few, although they can be annoying. Most companies have policies allowing up to 21 dead or illuminated subpixels per display, but in practice I’ve never seen even close to that amount on a given display. It is normal to see perhaps one to five, and in many cases I’ve seen perfect displays. If you feel the number or placement of dead pixels is unworkable in your specific situation, contact your manufacturer for a possible replacement.

Because all the transistors of a TFT display are integrated into a single component, there is no way to remedy a dead pixel except by replacing the entire transistor array. Because this is one of the most expensive components in a portable system, many portable computer manufacturers refuse to accept returns of systems for less than a set number of bad pixels (this amount varies by

vendor). The location or clustering of the bad pixels can also affect this policy. For example, if there are several bad pixels together in the middle of the display, the manufacturer is more likely to offer a replacement than if they are scattered around the edge. This is another part of the vendor's purchasing policy that you should check before ordering a system with an active-matrix display.

The 13.3-inch (diagonal) active-matrix screen has become a standard on many portable systems, running at a resolution of 1024×768. High-end systems now include TFT screens as large as 15 inches or more at up to 1400×1050 resolution. Higher resolutions and sizes are possible, but I question whether anything larger than a 15-inch display will be workable for a portable system, and increasing the resolution without increasing the size makes text and icons difficult to see. Many portable systems now also include AGP bus video adapters with up to 16MB of RAM, providing extra speed, even at 16- or 24-bit color depths. A good TFT display and integrated AGP adapter rival the quality and performance of a quality monitor and video adapter in a desktop system. In fact, a 15-inch TFT display (which, unlike most conventional monitors, describes the actual diagonal size of the image) generally has a better picture quality and usability than a similarly sized CRT-type display.

Note

Another flatscreen technology, called the gas-plasma display, has been used in large display screens and a few portables. Plasma displays provide a CRT-quality picture on a thin flat screen using two glass panes filled with a neon/xenon gas mixture. Unfortunately, the displays require far more power than LCDs and have never become a practical alternative for the portable computer market.

Screen Resolution

The screen resolution of a portable system's display can be an important factor in your purchasing decision. If you are accustomed to working on desktop systems running at 1024×768 pixels or more, you will find a 800×600 laptop screen to be very restrictive. Remember that an LCD screen's resolution is determined as much by the screen hardware as by the drivers and the amount of video memory installed in the system.

◀◀ See "Monitor Resolution," p. 858.

Some portables can use a virtual screen arrangement to provide a larger display on a smaller screen. The larger display is maintained in video memory while the actual screen displays only the portion that fits into the window provided by the native LCD resolution (see Figure 23.4). When you move the cursor to the edge of the screen, the image pans, moving the smaller window around within the larger virtual display. The effect is difficult to get used to, rather like a pan-and-scan videotape of a widescreen movie. The most serious problem with this arrangement is that some manufacturers have advertised it as a higher resolution display, without being more clear about its actual nature.

Color depth is affected by the amount of video memory in the system, just as in a desktop system. To operate any LCD screen in 16- or 24-bit color mode, you must have sufficient video memory available. Portables typically have the video adapter hardware permanently installed on the motherboard, leaving little hope for a video memory upgrade, so make sure you get a system

that can handle your video needs. Also check to be sure that the LCD natively supports the color depth you will require.

Figure 23.4 A virtual screen lets you use a small display to view a portion of a larger screen.

Processors

As with desktop systems, the majority of portables use Intel multiprocessors, and the creation of chips designed specifically for portable systems is a major part of the company's development effort. Intel has a complete line of processors optimized for mobile or portable use. Intel has focused on mobile processors since the 386SL and has dramatically expanded mobile processor technology and features with the Pentium, the Pentium II/III, and the Celeron. As with most portable system components, the main concerns with the mobile processors are reducing their size, power requirements, and heat generation.

Virtually all new portable systems sold today contain a mobile version of either a Pentium, a Pentium with MMX technology, a Pentium II/III, or a Celeron. (There were no mobile versions of the Pentium Pro.) The mobile versions of these processors have features and architecture that are similar to full-size models; they differ mainly in their packaging and power consumption. The processor's packaging defines the type of casing used to enclose and protect the internal circuitry of the chip, as well as the type of connector that provides the processor's interface with the motherboard.

Mobile Pentium

The main idea for mobile processors is to shrink them as small as possible, which then lets them run at lower voltages; this saves power. The 200MHz and 233MHz mobile Pentium processors with MMX technology (code-named Tillamook) were the first products manufactured using Intel's advanced 0.25 micron process technology now used for the Pentium II/III and Celeron, as well. Since then, Intel added 300MHz, 266MHz, and 166MHz mobile Pentium MMX processors also made on the 0.25 micron process. Mobile processors in general provide notebook manufacturers with a unique opportunity to offer users better battery life along with features and functionality that are on par with desktop systems.

The 0.25 micron manufacturing process and Intel's voltage reduction technology decrease the core voltage from 2.45 volts to 1.8 volts (2.0 volts for the 266MHz version) and the I/O interface from 3.3 volts to 2.5 volts, relative to previous generation processors. Intel's new 0.25 micron manufacturing process increases chip speed up to 60 percent, while reducing power consumption (up to 53 percent) when compared to 166MHz mobile Pentium processors with MMX technology on the 0.35 micron process. This reduction in voltages allows for higher speeds with less battery power use and less heat production. Typical power consumption can be reduced from 7.7 watts for 166MHz mobile Pentium processors with MMX technology on the 0.35 process to 3.9 watts for the 233MHz processor. These improvements represent nearly a 50 percent decrease in power consumption.

While Intel has largely replaced its mobile Pentium processors with mobile Pentium II/III and Celeron processors, the power and heat savings pioneered in the mobile Pentium line live on in improved form in these newer processors for portable systems.

- ◀◀ See "Pentium Processors," p. 153.
- ◀◀ See "Pentium-MMX Processors," p. 160.
- ◀◀ See "Pentium II Processors," p. 175.
- ◀◀ See "Celeron," p. 187.

Intel also manufactured regular (non-MMX) Pentium chips at speeds of 75-, 100-, 120-, 133-, and 150MHz for use in low-end portable systems. These chips also use voltage reduction technology (VRT), which means that they draw the standard 3.3v from the motherboard, but internally they operate on only 2.9v (3.1v for the 150MHz model). Although not as dramatic a reduction as that evidenced in the 0.25 micron process chips, VRT still reduces the overall power consumption and heat production of these processors. These processors are no longer being manufactured but will appear in older notebook computers you may have or encounter.

Mobile Pentium II and III

In April 1998 Intel announced the first mobile Pentium II processors. Running at 233MHz and 266MHz, these processors are also manufactured using the 0.25 micron process. With a core voltage of 1.7v and an I/O buffer voltage of 1.8v, they run at even lower voltage levels than their Pentium MMX counterparts. Although at 8.6 watts, a 266MHz Pentium II consumes more power overall than a Pentium MMX running at the same speed, you must take into account that the Pentium II includes an integrated L2 cache, while the Pentium MMX, at 4.5 watts, does not.

To reduce power consumption and heat buildup while preserving speed, Intel redesigned the mobile Pentium II in late 1998 to use a different method for accessing L2 cache. While the original mobile Pentium II used a 512KB L2 cache running at half CPU speed, just like the desktop Pentium II processor, the revised design changed to an integrated on-die L2 cache of just 256KB, but running at the same speed as the CPU. By manufacturing this cache directly on the processor die, it runs at the same speed as the processor core and uses less power than slower external cache.

- ◀◀ See "Pentium II Processors," p. 175.
- ◀◀ See "Pentium III," 191.

Table 23.3 lists the speed, manufacturing process, and voltage specifications for the mobile Pentium, Pentium/MMX, and Pentium II processors currently manufactured by Intel.

Table 23.3 Intel Mobile Processor Specifications

Processor Voltage	Core Speed	Bus Speed	Mfg. Process	Core Voltage	I/O Buffer
Pentium	75MHz	50MHz	0.35 micron	2.9V	3.3V
Pentium	100MHz	66MHz	0.35 micron	2.9V	3.3V
Pentium	120MHz	60MHz	0.35 micron	2.9V	3.3V
Pentium	133MHz	66MHz	0.35 micron	2.9V	3.3V
Pentium	150MHz	60MHz	0.35 micron	3.1V	3.3V
Pentium MMX	120MHz	60MHz	0.35 micron	2.45V	3.3V
Pentium MMX	133MHz	66MHz	0.35 micron	2.45V	3.3V
Pentium MMX	150MHz	60MHz	0.35 micron	2.45V	3.3V
Pentium MMX	166MHz	66MHz	0.35 micron	2.45V	3.3V
Pentium MMX	166MHz	66MHz	0.25 micron	1.8V	2.5V
Pentium MMX	200MHz	66MHz	0.25 micron	1.8V	2.5V
Pentium MMX	233MHz	66MHz	0.25 micron	1.8V	2.5V
Pentium MMX	266MHz	66MHz	0.25 micron	2.0V	2.5V
Pentium MMX	300MHz	66MHz	0.25 micron	2.0V	2.5V
Pentium II	233MHz	66MHz	0.25 micron	1.7V	1.8V
Pentium II	266MHz	66MHz	0.25 micron	1.7V	1.8V
Pentium II	300MHz	66MHz	0.25 micron	1.6V	1.8V
Pentium II	333MHz	66MHz	0.25 micron	1.6V	1.8V
Pentium II	366MHz	66MHz	0.25 micron	1.6V	1.8V
Pentium II	400MHz	66MHz	0.25 micron	1.6V	1.8V
Celeron	266MHz-LV	66MHz	0.25 micron	1.5V	1.8V
Celeron	266MHz	66MHz	0.25 micron	1.6V	1.8V
Celeron	300MHz	66MHz	0.25 micron	1.6V	1.8V
Celeron	333MHz	66MHz	0.25 micron	1.6V	1.8V
Celeron	366MHz	66MHz	0.25 micron	1.6V	1.8V
Celeron	400MHz	66MHz	0.25 micron	1.6V	1.8V
Celeron	433MHz	66MHz	0.25 micron	1.9V	1.8V
Celeron	466MHz	66MHz	0.25 micron	1.9V	1.8V
Celeron	400MHz-LV	100MHz	0.18 micron	1.35V	1.5V
Celeron	450MHz	100MHz	0.18 micron	1.6V	1.5V
Celeron	500MHz-LV	100MHz	0.18 micron	1.35V	1.5V
Celeron	500MHz	100MHz	0.18 micron	1.6V	1.5V
Celeron	550MHz	100MHz	0.18 micron	1.6V	1.5V
Celeron	600MHz	100MHz	0.18 micron	1.6V	1.5V
Celeron	650MHz	100MHz	0.18 micron	1.6V	1.5V

Processor Voltage	Core Speed	Bus Speed	Mfg. Process	Core Voltage	I/O Buffer
Pentium III	400MHz	100MHz	0.18 micron	1.35V	1.5V
Pentium III	450MHz	100MHz	0.18 micron	1.6V	1.5V
Pentium III	500MHz	100MHz	0.18 micron	1.6V	1.5V
Pentium III	600MHz-LV	100MHz	0.18 micron	1.35/1.1V ¹	1.5V
Pentium III	600MHz	100MHz	0.18 micron	1.6/1.35V ¹	1.5V
Pentium III	650MHz	100MHz	0.18 micron	1.6/1.35V ¹	1.5V
Pentium III	700MHz	100MHz	0.18 micron	1.6/1.35V ¹	1.5V
Pentium III	750MHz	100MHz	0.18 micron	1.6/1.35V ¹	1.5V

¹ Uses Intel Speedstep technology, optionally switching to lower speed and voltage to conserve battery life.
LV = Low Voltage

SpeedStep and PowerNow! Technology

Mobile Pentium III, K6-2+, and K6-3+ processors all feature new technology to allow for longer battery life in mobile operation. Intel calls this technology SpeedStep (originally codenamed Geyserville), whereas AMD calls it PowerNow! This technology allows the processors to optionally reduce both speed and voltage when running on batteries. Prior processors could reduce speed, but by also reducing voltage, power consumption is significantly reduced, as is heat production.

This technology is designed to work when the notebook is running on battery power. When the notebook computer is connected to the AC outlet, CPU speed and voltage are at their maximums. When powered by a battery, the processor drops to a lower frequency (by changing ratios, the bus frequency remains constant) and voltage, thus conserving battery life while still maintaining a relatively high level of performance. In most cases the actual power consumption drops by half, which means about double the battery life as compared to full power, while only reducing speed a small amount. For example, a 750MHz Pentium III will consume up to 24.6 watts at full power (750MHz and 1.6V), while in SpeedStep mode the power consumption drops to only 14.4 watts (600MHz and 1.35V). This means that while power consumption drops by over 41%, the speed only drops by about 20%.

If you don't want any performance drop when running under battery power there is a manual override as well.

When the system is powered up, the processor will start in the lower of its two speeds; in other words it will start in the Battery Optimized mode. BIOS or operating system instructions can rapidly switch the processor from mode to mode.

The requirements for this technology to work are

- A processor that supports the SpeedStep or PowerNow! technology
- A supporting motherboard (chipset, BIOS, and voltage regulator)
- An operating system and driver support
- An operating system that supports SpeedStep/PowerNow! technology (Win95/98/Me, WinNT/2000)
- SpeedStep/PowerNow! drivers

Contact your portable system manufacturer to see if your system supports SpeedStep or PowerNow! Technology.

Most of the mobile processors include a thermal diode built-in which can be used to monitor CPU temperature. The notebook systems use this to control fan operation. Utilities are available which can use this sensor to display the processor temperature information onscreen.

Intel Mobile Pentium Processor Steppings

As with Intel's desktop processor, the chips of the mobile processor line undergo continual development, and are modified in the form of steppings that incorporate corrections and refinements into the hardware manufacturing process. Tables 23.4 and 23.5 list the steppings for the mobile Pentium and Pentium/MMX processor lines, respectively.

Table 23.4 Mobile Pentium Processor Versions and Steppings

Type	Family	Model	Stepping	Mfg. Stepping	Speed	Spec. Number	Comments
0	5	2	1	B1	75-50	Q0601	TCP

ES = Engineering Sample. These chips were not sold through normal channels, but were designed for development and testing purposes.

STP = The cB1 stepping is logically equivalent to the C2 stepping, but on a different manufacturing process. The mcB1 step is logically equivalent to the cB1 step (except it does not support DP, APIC, or FRC). The mcB1, mA1, mA4, and mcC0 steps also use Intel's VRT (voltage reduction technology) and are available in the TCP or SPGA package, primarily to support mobile applications. The mxA3 is logically equivalent to the xA3 stepping (except it does not support DP or APIC).

TCP = Tape Carrier Package

PPGA = Plastic PGA

VRT = Voltage Reduction Technology

2.285v = This is a mobile Pentium processor with MMX technology with a core operating voltage of 2.285v–2.665v.

1.8v = This is a mobile Pentium processor with MMX technology with a core operating voltage of 1.665v–1.935v and an I/O operating voltage of 2.375v–2.625v.

2.2v = This is a mobile Pentium processor with MMX technology with a core operating voltage of 2.10v–2.34v.

2.0v = This is a mobile Pentium processor with MMX technology with a core operating voltage of 1.850v–2.150v and an I/O operating voltage of 2.375v–2.625v.

Table 23.6 lists the steppings for mobile Pentium II processors in the mobile module, mobile mini-cartridge, and other forms.

Table 23.6 Mobile Pentium II Processor Steppings

Family	Model	Core Stepping	L2 Cache Size (KB)	L2 Cache Speed	S-Spec	Core/Bus	Notes
6	5	mdAO	512	1/2 core	SL2KH	233/66	MC, 1.7v
6	5	mdAO	512	1/2 core	SL2KJ	266/66	MC, 1.7v
6	5	mmdAO	512	1/2 core	PMD233	233/66	MMO, 1.7v

6	5	mdBO	512	1/2 core	SL2RS	300/66	MC, 1.6v1
6	5	mdBO	512	1/2 core	SL2RR	266/66	MC, 1.6v1
6	5	mdBO	512	1/2 core	SL2RQ	233/66	MC, 1.6v1
6	5	mdxAO	256	core	SL32M	266/66	MC, 1.6v1
6	5	mdxAO	256	core	SL32N	300/66	MC, 1.6v1
6	5	mdxAO	256	core	SL32P	333/66	MC, 1.6v1
6	5	mdxAO	256	core	SL36Z	366/66	MC, 1.6v1
6	5	mdbAO	256	core	SL32Q	266/66	BG, 1.6v2
6	5	mdbAO	256	core	SL32R	300/66	BG, 1.6v2
6	5	mdbAO	256	core	SL32S	333/66	BG, 1.6v2
6	5	mdbAO	256	core	SL3AG	366/66	BG, 1.6v2
6	5	mdbAO	256	core	SL3DR	266/66	BG, 1.5v
6	5	mdbAO	256	core	SL3HH	266/66	PG, 1.6v2
6	5	mdbAO	256	core	SL3HJ	300/66	PG, 1.6v2
6	5	mdbAO	256	core	SL3HK	333/66	PG, 1.6v2
6	5	mdbAO	256	core	SL3HL	366/66	PG, 1.6v2

1.7v = Core processor voltage is 1.7v for these mobile Pentium processors.

1.6v1 = Core processor voltage is 1.6v +/- 120mV for these processors.

1.6v2 = Core processor voltage is 1.6v +/- 135mV for these processors.

1.5v = Core processor voltage is 1.6v +/- 135mV for this processor.

MC = Mobile Pentium II processor mounted in a mini-cartridge.

MMO = Mobile Pentium II processor mounted in a mobile module including the 440BX North Bridge.

BG = Mobile Pentium II processor in BGA packaging for low-profile surface mounting.

PG = Mobile Pentium II processor in a (upsilon symbol—υ) PGA1 package.

◀◀ See "Pentium Processor Models and Steppings," p. 164.

Mobile Pentium III Processors and Steppings

The mobile Pentium III has also been available in a number of models and steppings which can be distinguished by their specification number and other details (see Table 23.7).

Table 23.7 Mobile Pentium III Processor Models and Revisions

Speed (MHz)	Speed Step (MHz)	S-spec	Stepping	CPUID	L2 Cache	Power (W)	Speed Step (W)	Voltage	Form Factor
400	-	SL3DU	BA2	0681	256K	10.1	-	1.35V	BGA2

650	500	SL43X	BBO	0683	256K	21.5	12.2	1.6/ 1.35V	BGA2
650	500	SL3TQ	PA2	0681	256K	21.5	12.2	1.6/ 1.35V	PGA2
650	500	SL3PL	PA2	0681	256K	21.5	12.2	1.6/ 1.35V	PGA2
650	500	SL442	PBO	0683	256K	21.5	12.2	1.6/ 1.35V	PGA2
650	500	PML65 00200 1AA	MA2	0681	256K	17.8	12.2	1.6/ 1.35V	MMC-2

Speed (MHz)	Speed Step (MHz)	S-spec	Stepping	CPUID	L2 Cache	Power (W)	Speed Step (W)	Voltage	Form Factor
700	550	SL4DL	PBO	0683	256K	23.0	13.4	1.6/ 1.35V	PGA2
700	550	SL3Z8	PBO	0683	256K	23.0	13.4	1.6/ 1.35V	PGA2
700	550	PMM70 00210 1AA	MBO	0683	256K	19.1	13.4	1.6 /1.35V	MMC-2
750	600	SL4DM	MBO	0683	256K	24.6	14.4	1.6/ 1.35V	PGA2
750	600	SL44T	MBO	0683	256K	24.6	14.4	1.6/ 1.35V	PGA2
750	600	SL4AS	MBO	0683	256K	24.6	14.4	1.6/ 1.35V	BGA2
750	600	PMM75 00210 1AB	MBO	0683	256K	24.6	14.4	1.6/ 1.35V	MMC-2

PGA2 = 495-pin Micro-PGA2 (Pin Grid Array 2) form factor

BGA2 = 495-pin BGA2 (Ball Grid Array 2) form factor

MMC-2 = Mobile Module Connector-2 form factor

SpeedStep = Technology which optionally runs the processor at a lower speed and voltage in a battery optimized mode

Mobile Celeron Processors and Steppings

Table 23.8 lists the steppings for mobile Celeron processors.

Table 23.8 Mobile Celeron Processor Steppings

Family	Model	Core Stepping	L2 Cache (KB)	S-Spec	Speed Core/Bus	Notes
6	6	mcbA0	128	SL23Y	266/66	B,1
6	6	mcbA0	128	SL3AH	300/66	B,1
6	6	mcbA0	128	SL3C8	333/66	B,1
6	6	mcbA0	128	SL3DQ	266/66	B,2
6	6	mcbA0	128	SL3GQ	400/66	B,1
6	6	mcpA0	128	SL3HM	266/66	P,1
6	6	mcpA0	128	SL3HN	300/66	P,1
6	6	mcpA0	128	SL3HP	333/66	P,1
6	6	mcpA0	128	SL3HQ	366/66	P,1
6	6	mcpA0	128	SL3GR	400/66	P,1

B = In a BGA package

P = In a (upsilon symbol—v) PGA package

1 = Runs at a core voltage of 1.6v

2 = Runs at a core voltage of 1.5v

AMD K6-Series Mobile Processors

AMD's K6 series of processors have become very popular among cost-conscious personal and corporate computer buyers, and they have dominated the under-\$1,000 computer market over the last year. Starting in the fall of 1998, AMD began to develop this Socket 7-compatible series of processors for mobile use.

- ◀◀ See "AMD-K6 Series," p. 203.
- ◀◀ See "Socket 7 (and Super7)," p. 103.

All mobile versions of the AMD K6 family share some common characteristics, including the use of the compact .25 micron process technology, low-voltage operation, MMX technology, and a choice of either ceramic pin grid array (CPGA) or the more-compact ceramic ball grid array (CBGA) packaging. Mobile K6 processors, like their desktop siblings, also have a large 64KB L1 memory cache. AMD offers the Mobile K6 processors shown in Table 23.9.

Table 23.9 Mobile AMD K6 Processors

CPU Model	Core Voltage	Clock Speeds	Notes
Mobile K6	2.1v	233, 266	66
Mobile K6	2.2v	300	66
Mobile K6-2	1.8v	266, 300, 333, 350, 366, 380	66, 3DN
Mobile K6-III	2.2v	350, 366, 380	100, 256KL2, 3DN

66 = Has a 66MHz bus speed

100 = Has a 100MHz bus speed

256KL2 = Contains a 256KB integrated L2 cache running at full processor speed and supports L3 cache on the motherboard

3DN = Supports 3Dnow! multimedia enhancements

More recently AMD has introduced newer versions of the mobile K6 called the K6-2+ and K6-3+. These new processors are both made on a 0.18 micron technology process allowing for reduced die size and voltage. They both incorporate on-die L2 cache running at full processor speed, and PowerNow! technology, which is AMD's version of Intel's SpeedStep technology. This allows for lower speed and voltage operation while on battery power to conserve battery life. The only difference between the K6-2+ and K6-3+ is the size of their on-die L2 caches. They both incorporate 64KB of L1 on-die, the K6-2+ adds a further 128KB of on-die L2 cache, while the L2 size is increased to 256KB in the K6-3+.

Mobile Processor Packaging

The heat generated by Pentium processors has been a concern since the first chips were released. In desktop systems, the heat problem is addressed, to a great extent, by computer case manufacturers. The use of multiple cooling fans and better internal layout designs can keep air flowing through the system to cool the processor, which is usually equipped with its own fan and heat sink.

For developers of portable systems, however, not as much can be accomplished with the case arrangement. So it was up to the chip manufacturers to address the problem in the packaging of the chip. At the same time, users became increasingly unwilling to compromise on the clock speed of the processors in portable systems. Running a Pentium at 133MHz or 166MHz requires more power and generates even more heat than the 75MHz Pentiums that were originally designed for mobile use.

Tape Carrier Packaging

An early solution to the size and heat problems for Pentium processors is the tape carrier package (TCP), a method of packaging processors for use in portable systems that reduces the size, the power consumed, and the heat generated by the chip. A Pentium mounted onto a motherboard using TCP is much smaller and lighter than the standard SPGA (staggered pin grid array) Pentiums used in desktop systems. The 49mm square of the SPGA is reduced to 29mm in the TCP processor, the thickness to approximately 1mm, and the weight from 55 grams to under 1 gram.

Instead of metal pins inserted into a socket on the motherboard, a TCP processor is essentially a raw die encased in an oversized piece of polyamide film. The film is similar to photographic film. The die is attached to the film using a process called tape automated bonding (TAB), the same process used to connect electrical connections to LCD panels. The film, called the tape, is laminated with copper foil that is etched to form the leads that will connect the processor to the motherboard (see Figure 23.5). This is similar to the way electrical connections are photographically etched onto a printed circuit board.

Figure 23.5 A processor that is mounted using the tape carrier package is attached to a piece of copper-laminated film that replaces the pins used in standard desktop processors.

After the leads are formed, they are plated with gold to allow bonding to a gold bump on the silicon die and to guard against corrosion. Next, they are bonded to the processor chip itself, and then the whole package is coated with a protective polyamide siloxane resin and mounted on a filmstrip reel for machine assembly. To get a feel for the small size of this processor, look at Figure 23.6, where it is shown next to a standard-size push-pin for comparison.

After testing, the processor ships to the motherboard manufacturer in this form. The reels of TCP chips are loaded into special machines that stamp-solder them directly to the portable system's motherboard. As such, the installation is permanent; a TCP processor can never be removed from the board for repair or upgrade. Because there is no heat sink or physical container directly attached to the processor, the motherboard itself becomes the conduit to a heat sink mounted underneath it, thus using the portable system's chassis to pull heat away. Some faster portable systems include thermostatically controlled fans to further aid in heat removal.

Mounting the TCP to the system circuit board requires specific tooling available from all major board assembly equipment vendors. A special tool cuts the tape containing the processor to the proper size and folds the ends containing the leads into a modified gull-wing shape that contacts the circuit board, leaving the processor suspended just above the board (see Figure 23.7). Another tool dispenses a thermally conductive paste to the circuit board prior to placement of the tape containing the processor. This is done so that the heat can be dissipated through a sink on the underside of the motherboard while it is kept away from the soldered connections.

Figure 23.6 Pentium MMX processor in TCP Mobile Package. *Photograph used by permission of Intel Corporation.*

Finally, a hot bar soldering tool connects the leads on the tape to the circuit board. The pinouts for the mobile Pentium TCP are shown in Figure 23.8. The completed TCP assembly forms an efficient thermal contact directly from the die to the motherboard, allowing the processor to run within its temperature limits even in such a raw state. By eliminating the package and essentially bonding the die directly to the motherboard, a significant amount of size and weight are saved.

Figure 23.7 The tape keeps the processor’s connections to the motherboard away from the chip and allows the underside of the processor to be thermally bonded to the motherboard.

Note

Some manufacturers of portable systems use standard desktop PGA processors, sometimes accompanied by fans. Apart from a greatly diminished battery life, systems such as these can sometimes be too hot to touch comfortably. For this reason, it is a good idea to determine the exact model processor used in a system that you intend to purchase, and not just the speed.

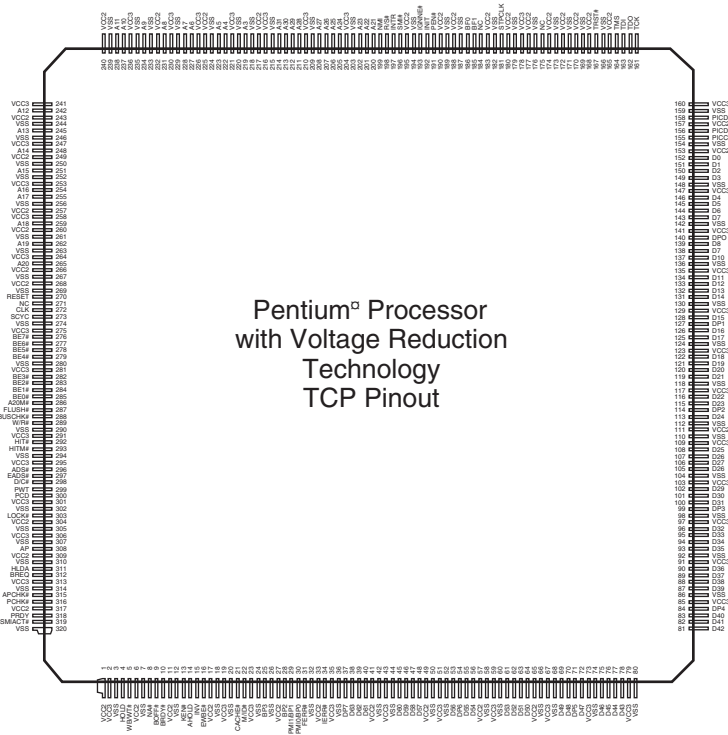

Figure 23.8 Intel mobile Pentium tape carrier package pinout.

Mobile Module

Portable system manufacturers can purchase Pentium processors in raw TCP form and mount the processors to their motherboards themselves. Intel has also introduced another form of processor packaging called the mobile module, or MMO (see Figure 23.9).

Figure 23.9 Mobile Pentium processors in mobile module or raw tape carrier package form. Photograph used by permission of Intel Corporation.

The mobile module consists of a Pentium or Pentium II processor in its TCP form, mounted on a small daughterboard along with the power supply for the processor's unique voltage requirements, the system's Level 2 cache memory, and the North Bridge part of the motherboard chipset. This is the core logic that connects the processor to standard system buses containing the South Bridge part of the chipset, as shown in the block diagram in Figure 23.10. North Bridge and South Bridge describe what has come to be an accepted method for dividing the functionality of the chipset into halves that are mounted on separate modules. In a typical portable system design, the manufacturer purchases the mobile module (complete with the North Bridge) from Intel, and uses a motherboard designed by another company that contains the South Bridge.

A newer version of the MMO is called the MMC, which stands for Mobile Module Connector and is available in MMC-1 and MMC-2 versions. The Celeron and Pentium II were available in MMC-1 and MMC-2 versions while the Pentium III was available in the MMC-2 version only.

In many ways, the MMO/MMC is similar to the Pentium II Single Edge Cartridge (SEC) design, and in the future will allow the cache memory to run at higher speeds on a separate bus from the rest of the system.

- ◀◀ See "Intel Chipsets," p. 257.
- ◀◀ See "Single Edge Contact (SEC) and Single Edge Processor (SEP) Packaging," p. 93.

The module interfaces electrically to its host system via a 3.3v PCI bus, a 3.3v memory bus, and Intel chipset control signals bridging the half of the chipset on the module to the other half of the chipset on the system motherboard. The Intel mobile module also incorporates a single thermal connection that carries all the module's thermal output to the mobile PC's main cooling mechanisms.

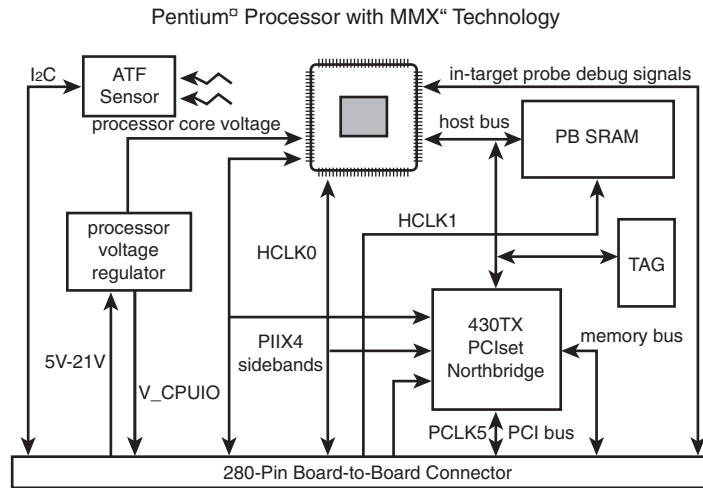

Figure 23.10 Intel Pentium mobile module block diagram.

The MMO is mounted with screws and alignment guides to secure the module against the typical shock and vibration associated with mobile PC usage. The MMO (shown in Figure 23.11) is 4 inches (101.6mm) long by 2.5 inches (63.5mm) wide by 0.315 inch (8mm) high (0.39 inch or 10mm high at connector).

Figure 23.11 Intel Pentium MMX mobile module, including the processor, chipset, and L2 cache. Photograph used by permission of Intel Corporation.

The mobile module greatly simplifies the process of installing a Pentium or Pentium II processor into a portable system, permits manufacturers to build more standardization into their portable

computer designs, and eliminates the need for manufacturers to invest in the special tools needed to mount TCP processors on circuit boards themselves. The module also provides a viable processor upgrade path that was unavailable with a TCP processor permanently soldered to the motherboard.

IBM has adopted the MMO/MMC in the latest ThinkPad systems, which should allow it to come out with new designs more quickly because the MMO/MMC part of the system will remain an industry standard. The size of the MMO/MMC precludes its use in some very thin notebooks, so IBM and others still use the raw TCP processor version for many portable designs as well.

Mini-Cartridge

The mobile versions of the Pentium II processor are available in the mobile module package, with the North Bridge portion of the Intel 440BX AGP chipset. However, Intel has also introduced another new package for the Pentium II called the mini-cartridge. The mini-cartridge is designed especially for use in ultralight portable computers in which the height or bulk of the mobile module would interfere with the system design. It contains only the processor core and 512KB of L2 cache memory in a stainless steel case that exposes the connector and the processor die.

◀◀ See "Intel 440BX," p. 282.

The mini-cartridge is approximately 51mm×47mm in size and 4.5mm in height. Overall, the package is about one-fourth the weight, one-sixth the size, and consumes two-thirds of the power of a desktop Pentium II processor using the Single Edge Connector (SEC). To connect to the socket on the motherboard, the mini-cartridge has a 240-pin connector at one end of the bottom side, with the pins arranged in an 8×30 ball grid array (BGA), as shown in Figure 23.12.

BGA packaging uses solder balls on the bottom of the device, which means that after it is soldered in, there are no visible pins. The unique features of BGA packaging makes it one of the smallest physical packages, and the soldered-in design is thermally more stable than most others; it also allows better heat transfer from the device to the board.

Figure 23.12 Bottom side of the Pentium II mini-cartridge package.

◀◀ To learn more about BGA packaging, see "Pentium II Processors" p. 175.

The BGA packaging is also used in some versions of AMD's mobile K6 family.

BGA and PGA

The newest packaging for mobile processors is called micro-BGA (Ball Grid Array) or PGA (Pin Grid Array). The PGA is basically just a BGA chip mounted on an interposer card with pins that plug into a slot. Normally the BGA versions are permanently soldered in; the PGA versions are socketed. The BGA form factor is currently the smallest, thinnest, and lightest packaging for mobile processors. Both Intel and AMD are using BGA and PGA form factors for their newest mobile processors.

Chipsets

As in the desktop market, Intel has come to dominate the mobile chipset industry by creating products that support the advanced features of each new processor it releases. The recent mobile Pentium II processor releases were accompanied by the introduction of the mobile 440BX AGPset, which provides support for the accelerated graphics port, 100MHz memory and system buses, and processor power-management capabilities designed to extend battery life.

A similar chipset, but optimized for the mobile Celeron processors and their 66MHz system bus, is the 440ZX-66M AGPset.

Intel's other current chipsets intended for mobile systems are the 430TX PCIset for the Pentium/MMX and the 430MX PCIset for the Pentium.

◀◀ See "P5 (586) Fifth-Generation Processors," p. 153.

◀◀ See "Intel P6 (686) Sixth-Generation Processors," p. 167.

Intel's most recent chipset innovation, however, is intended to accommodate the mobile module package for the Pentium MMX and Pentium II/III processors. In this design, the chipset's two halves, called the North Bridge and South Bridge, are located on the mobile module and the system motherboard, respectively.

In the 440BX AGPset, for example, the host bridge system controller consists of two VLSI devices. The first of these, the 443BX host bridge (the North Bridge) is part of the mobile module. The other device is the PIIX4 PCI/ISA bridge, which the system manufacturer must incorporate into the motherboard design for the portable computer. This forms the South Bridge. The mobile module connects to the motherboard through a 3.3v PCI bus, a 3.3v memory bus, and some 443BX host bridge control signals. It is these signals that combine the North Bridge and the South Bridge into a single functional chipset.

The new 440MX chipset, designed for mobile Celeron systems, brings chipset integration to a new level, because it combines both North Bridge and South Bridge functions into a single chip. In addition to reducing the chip count at the chipset level, the 440MX provides audio and modem support at a performance level comparable to PCI-based hardware modems and sound cards, with just slightly higher CPU utilization rates.

Clearly, innovations like the mobile module accentuate the association between a computer's processor and its motherboard chipset. Now that the development cycles for new processors tend to be measured in months, not years, it is rapidly becoming a foregone conclusion that to get the most out of the latest Intel processor, you have to use an Intel chipset as well. As when shopping

for a desktop system, you should be aware of what chipset is used in the portable computer you plan to buy and whether it fully supports the capabilities of the processor and the system's other components.

Memory

Adding memory is one of the most common upgrades performed on computers, and portables are no exception. However, most portable systems are exceptional in the design of their memory chips. Unlike desktop systems, in which there are only a few basic types of slots for additional RAM, there are literally dozens of different memory chip configurations that have been designed to shoehorn RAM upgrades into the tightly packed cases of portable systems.

Most portables use a type of DIMM called a Small Outline DIMM (SO-DIMM), which is physically smaller but similar electrically to the standard DIMMs used in desktop systems. SO-DIMMs are normally available in EDO (Extended Data Out) or SDRAM (Synchronous DRAM) form, with various speeds and voltages available. The latest portables are starting to use SO-RIMMs (Small Outline Rambus Inline Memory Modules) similar to the RIMMs used in desktop systems, but again physically smaller. Some systems in the past used proprietary memory cartridges that look like PC cards, but which plug into a dedicated IC (integrated circuit) memory socket, but this isn't common anymore. In any case, appearance is not a reliable measure of compatibility; make sure the memory you are purchasing will work with your system or that you can get a refund or replacement if it doesn't. It is strongly recommended that you install only memory modules that have been designed for your system, in the configurations specified by the manufacturer.

◀◀ See "SIMMs and DIMMs," p. 455.

This recommendation does not necessarily limit you to purchasing memory upgrades only from the manufacturer. Many companies now manufacture memory upgrade modules for dozens of different portable systems, by reverse-engineering the original vendor's products. This adds a measure of competition to the market, usually making third-party modules much cheaper than those of a manufacturer that is far more interested in selling new computers for several thousand dollars rather than memory chips for a few hundred.

Note

Some companies have developed memory modules that exceed the original specifications of the system manufacturer, allowing you to install more memory than you could with the maker's own modules. Some manufacturers, such as IBM, have certification programs to signify their approval of these products. Otherwise, there is an element of risk involved in extending the system's capabilities in this way.

Inside the memory modules, the components are not very different from those of desktop systems. Portables use the same types of DRAM and SRAM as desktops, including memory technologies such as EDO (Enhanced Data Out), SDRAM (Synchronous DRAM), or RDRAM (Rambus DRAM). At one time, portable systems tended not to have memory caches because the SRAM chips typically used for this purpose generate a lot of heat. Advances in thermal management have now made this less of an issue, however, and you should expect a high-end system to include SRAM cache memory.

The best philosophy to take when adding RAM to a notebook or laptop computer is “fill ‘er up!” Because of the proprietary (non-reusable) nature of portable memory modules, and because adding memory will speed up operations and extend battery life (due to less use of the hard drive for virtual memory swapping), it’s wise to bring a notebook up to 64MB or RAM or higher, depending on the chipset and processor. I don’t recommend installing more than 64MB in Pentium systems, because the chipsets do not support caching for any memory over 64MB. Pentium II/III or Celeron systems can cache 512MB or 4GB, so in those systems you can install as much memory as you can afford. Keep in mind that more memory means more power consumption and shorter battery life, so exceeding your needs by a wide margin won’t help performance but will drain the battery faster. Since most notebook/laptop computers only have a single RAM connector, you need to keep that in mind when you upgrade, because any future upgrades will not add to what you already have, but replace it instead.

Hard Disk Drives

Hard disk drive technology is also largely unchanged in portable systems, except for the size of the disks and their packaging. Enhanced IDE drives are all but universal in portable computers. Internal hard drives typically use 2 1/2-inch platters and are available in varying heights or thicknesses.

As with memory modules, systems manufacturers have different ways of mounting hard drives in the system, which can cause upgrade compatibility problems. Some systems use a caddy to hold the drive and make the electrical and data connections to the system. This makes the physical part of an upgrade as easy as inserting a new drive into the caddy, and then mounting it in the system. You can either purchase the drive with the caddy already installed, you can get a bare drive and swap it into your existing caddy, or you can get a bare drive and a new caddy. Usually it is much less expensive to get the bare drive, whether you also add the caddy or not, than it is to get one with the caddy preinstalled.

In many portables, replacing a hard drive is much simpler than in a desktop system. Quite a few manufacturers now design their portable systems with external bays that let you easily swap out hard drives without opening the case, as long as the drives are preinstalled in the appropriate caddies. Multiple users can share a single machine by snapping in their own hard drives, or you can use the same technique to load different operating systems on the same computer.

The most important aspect of hard-drive upgrades that you must be aware of is the drive support provided by the system’s BIOS. The BIOS in some systems, and particularly older ones, may offer limited hard drive size options. This is particularly true if your system was manufactured before 1995, when EIDE hard drives came into standard use. BIOSes made before this time support a maximum drive size of 528MB. In some cases, flash BIOS upgrades, which provide support for additional drives, might be available for your system.

◀◀ See “Motherboard BIOS,” p. 375.

After BIOS support, you need to be concerned about the physical mounting. Whether you are going to use your existing caddy or get a new one (if required) you have to be concerned about the height of the drive. 2.5-inch drives have been manufactured in various thicknesses over the

years, and many notebook or laptop systems are restricted as to how thick a drive they will support. The common thicknesses that have been sold are

- 8.4mm
- 9.5mm
- 12.5mm
- 12.7mm
- 17.0mm

The popular ones are the 9.5 through 12.7mm, although there are still some of the thicker 17mm drives being used. If your notebook currently has a 9.5mm high unit, you may not be able to install a taller 12.5, 12.7, or 17mm unit in its place. Normally you can always install a shorter drive in place of a taller one.

Many manufacturers have adapted the compact 2 1/2-inch hard drives on the market for after-market use in older notebooks, many of which have drives under 2GB in size. The kits usually start at about 3GB and can be as large as 32GB in size. Normally, you'll pay about two to three times per megabyte what you would for a desktop hard drive.

To make your upgrade of these systems as easy as possible, make sure you buy a data-transfer kit with the drive. These kits should come with a high-speed PC card (PCMCIA) connector for the new drive and data-transfer/drive preparation software to automate the switchover. Some of these kits can then be used to make the old hard drive a portable model that you can use through a connection via the PC card slot.

Another option for extending hard-drive space is PC card hard drives. These are devices that fit into a type III PC card slot and can provide as much as 520MB of disk space in a remarkably tiny package (usually with a remarkably high price). You can also connect external drives to a portable PC, using a PC card SCSI host adapter or specialized parallel port drive interface. This frees you from the size limitations imposed by the system's case, and you can use any size SCSI drive you want, without concern for BIOS limitations.

Removable Media

Apart from hard disk drives, portable systems are now being equipped with other types of storage media that can provide access to larger amounts of data. CD-ROM drives are now available in many laptop and notebook systems, while a few include removable cartridge drives, such as Iomega's Zip drive. This has been made possible by the enhanced IDE specifications that let other types of devices share the same interface as the hard drive.

Another important issue is that of the floppy drive. Smaller systems (those under five pounds) often omit the floppy drive to save space, sometimes including an external unit. Some other systems enable you to substitute a second hard drive or battery for the floppy drive. For certain types of users, the lack of a floppy drive may or may not be an acceptable inconvenience. Many users of portables, especially those that frequently connect to networks, have little use for a floppy drive. This is now true even for the installation of applications, as virtually all software now ships on CD-ROMs.

One of the features that is becoming increasingly common in notebook systems is swappable drive bays that you can use to hold any one of several types of components. This arrangement lets you customize the configuration of your system to suit your immediate needs. For example, when traveling you might remove the floppy drive and replace it with an extra battery, or install a second hard drive when your storage needs increase. Notebook vendors and magazine reviews may refer to the number of spindles when discussing the number of drives a notebook can have installed simultaneously. For example, a computer that can use a floppy drive, CD-ROM, and hard drive simultaneously is a three-spindle system. If a system has two spindles, the most common configuration is a hard drive along with a bay that you can swap a floppy drive, CD-ROM drive, battery, or second hard drive in and out of. When evaluating your notebook needs and hardware, be sure to determine which devices included with a model can be used simultaneously and which require removing another device. If lightweight travel is a concern, determine which parts you don't need for travel that can be swapped out. Swappable bays should come with a cover or faceplate for the open bay to prevent dirt and foreign objects from entering when the bay is empty. If they don't include a blank cover, perhaps one is sold or available as an option.

If you aren't satisfied with the removable media drives your current notebook offers, the PC card slot is again your gateway to virtually unlimited choices. All the popular desktop choices, such as Zip, Jaz, LS-120 SuperDrive, CD-R, and CD-RW can be attached via either a dedicated PC card version of the drive or by using a SCSI PC card with a SCSI version of the drive.

While parallel-port drives are also popular, you'll normally suffer a big speed drop for large file transfers, especially if you don't use the high-speed EPP/ECP IEEE-1284 LPT port modes. Instead of the parallel port you should consider using your USB ports, if your notebook/laptop computer is so equipped. There are special cables that work with some of the file transfer programs that allow direct USB to USB connections between different systems, even though that is not officially supported by the USB Forum.

PC Cards (PCMCIA)

In an effort to give notebook computers the kind of expandability that users have grown used to in desktop systems, the Personal Computer Memory Card International Association (PCMCIA) has established several standards for credit card size expansion boards that fit into a small slot on laptops and notebooks. The development of the PC card interface is one of the few successful feats of hardware standardization in a market full of proprietary designs.

The PC card standards, which were developed by a consortium of more than 300 manufacturers (including IBM, Toshiba, and Apple), have been touted as being a revolutionary advancement in mobile computing. PC card laptop and notebook slots enable you to add memory expansion cards, fax/modems, SCSI adapters, network interface adapters, and many other types of devices to your system. If your computer has PC card slots that conform to the standard developed by the PCMCIA, you can insert any type of PC card (built to the same standard) into your machine and expect it to be recognized and usable.

The promise of PC card technology is enormous. There are not only PC card memory expansion cards, tiny hard drives, and wireless modems available, but also ISDN adapters, MPEG decoders, network interface adapters, sound cards, CD-ROM controllers, and even GPS systems, which use

global positioning satellites to help you find your way by locating your exact position on Earth. Besides having use in nautical and aircraft environments, many newer automobiles include in-dash GPS systems that not only pinpoint your exact location, but give you directions to anywhere you'd like to go. If your car is not equipped with a factory-installed GPS system, you can use a notebook or laptop with a GPS receiver and mapping software to provide the same function.

Originally designed as a standard interface for memory cards, the PCMCIA document defines both the PC card hardware and the software support architecture used to run it. The PC cards defined in version 1 of the standard, called Type I, are credit-card size (3.4×2.1 inches) and 3.3mm thick. The standard has since been revised to support cards with many other functions. The third version, called PC Card Specification - February 1995, defines three types of cards, with the only physical difference being their thickness. This was done to support the hardware for different card functions.

Most of the PC cards on the market today, such as modems and network interface adapters, are 5mm-thick Type II devices. Type III cards are 10.5mm thick and are typically used for PC card hard drives. All the card types are backward compatible; you can insert a Type I card into a Type II or III slot. The standard PC card slot configuration for portable computers is two Type II slots, with one on top of the other. This way, you can also insert a single Type III card, taking up both slots but using only one of the connectors.

Note

There was also a Type IV PC card, thicker still than the Type III, which was designed for higher-capacity hard drives. This card type is not recognized by the PCMCIA, however, and is not included in the standard document. There is, therefore, no guarantee of compatibility between Type IV slots and devices, and they should generally be avoided.

The latest version of the standard, published in March 1997, includes many features designed to increase the speed and efficiency of the interface, such as

- DMA (direct memory access) support.
- 3.3v operation.
- Support for APM (Advanced Power Management).
- Plug-and-Play support.
- The PC card ATA standard, which lets manufacturers use the AT Attachment protocols to implement PC card hard disk drives.
- Support for multiple functions on a single card (such as a modem and a network adapter).
- The Zoomed Video (ZV) interface, a direct video bus connection between the PC card adapter and the system's VGA controller, allowing high-speed video displays for videoconferencing applications and MPEG decoders.
- A thermal ratings system that can be used to warn users of excessive heat conditions.
- CardBus, a 32-bit interface that runs at 33MHz and provides 32-bit data paths to the computer's I/O and memory systems, as well as a new shielded connector that prevents CardBus devices from being inserted into slots that do not support the latest version of the

standard. This is a vast improvement over the 8- or 16-bit bus width and 8MHz speed of the original PC card-16 interface. If you connect your portable computer to a 100Mbps network, CardBus can provide the high-speed interface that, in a desktop system, would be provided by PCI.

- ◀◀ See "DMA Channels," p. 348.
- ◀◀ See "Plug-and-Play BIOS," p. 424.
- ◀◀ See "ATA IDE," p. 521.

The PC card usually has a sturdy metal case, and is sealed except for the interface to the PCMCIA adapter in the computer at one end, which consists of 68 tiny pinholes. The other end of the card may contain a connector for a cable leading to a telephone line, a network, or some other external device.

The pinouts for the PC card interface are shown in Table 23.10.

PC Card Software Support

PC cards are by definition *hot-swappable*, meaning that with the proper software support you can remove a card from a slot and replace it with a different one without having to reboot the system. If your PC card devices and your operating system conform to the Plug-and-Play standard, inserting a new card into the slot causes the appropriate drivers for the device to be loaded and configured automatically.

To make this possible, two separate software layers are needed on the computer that provide the interface between the PCMCIA adapter (that controls the card slots) and the applications that use the services of the PC card devices (see Figure 23.13). These two layers are called Socket Services and Card Services. A third module, called an enabler, actually configures the settings of the PC cards.

Figure 23.13 The Card and Socket Services enable an operating system to recognize the PC card inserted into a slot and configure the appropriate system hardware resources for the device.

Socket Services

The PCMCIA adapter that provides the interface between the card slots and the rest of the computer is one of the only parts of the PCMCIA architecture that is not standardized. There are many different adapters available to portable systems manufacturers and, as a result, an application or operating system cannot address the slot hardware directly, as it can a parallel or serial port.

Instead, there is a software layer called Socket Services that is designed to address a specific make of PCMCIA adapter hardware. The Socket Services software layer isolates the proprietary aspects of the adapter from all the software operating above it. The communications between the driver and the adapter may be unique, but the other interface, between the Socket Services driver and the Card Services software, is defined by the PCMCIA standard.

Socket Services can take the form of a device driver, a TSR program run from the DOS prompt (or the AUTOEXEC.BAT file), or a service running on an operating system such as Windows 9x or Windows NT. It is possible for a computer to have PC card slots with different adapters, as in the case of a docking station that provides extra slots in addition to those in the portable computer itself. In this case, the computer can run multiple Socket Services drivers, which all communicate with the same Card Services program.

Card Services

The Card Services software communicates with Socket Services and is responsible for assigning the appropriate hardware resources to PC cards. PC cards are no different from other types of bus expansion cards, in that they require access to specific hardware resources to communicate with the computer's processor and memory subsystems. If you have ever inserted an ISA network interface card into a desktop system, you know that you must specify a hardware interrupt, and maybe an I/O port or memory address, for the card to operate.

A PC card network adapter requires the same hardware resources, but you don't manually configure the device using jumpers or a software utility as you would an ISA card. The problem is also complicated by the fact that the PCMCIA standard requires that the computer be capable of assigning hardware resources to different devices as they are inserted into a slot. Card Services addresses this problem by maintaining a collection of various hardware resources that it allots to devices as needed and reclaims as the devices are removed.

If, for example, you have a system with two PC card slots, the Card Services software might be configured to use two hardware interrupts, two I/O ports, and two memory addresses, regardless of whether any cards are in the slots at boot time. No other devices in the computer can use those interrupts. When cards are inserted, Card Services assigns configuration values for the settings requested by the devices, ensuring that the settings allotted to each card are unique.

Card Services is not the equivalent of Plug and Play, although the two may seem similar. In fact, in Windows 9x, Card Services obtains the hardware resources it assigns to PC cards using Plug and Play. For other operating systems, the resources may be allotted to the Card Services program using a text file or command-line switches. In a non-Plug-and-Play system, you must configure the hardware resources assigned to Card Services with the same care that you would configure an

ISA board. Although Card Services won't allow two PC cards to be assigned the same interrupt, there is nothing in the PCMCIA architecture to prevent conflicts between the resources assigned to Card Services and those of other devices in the system.

You can have multiple Socket Services drivers loaded on one system, but there can be only one Card Services program. Socket Services must always be loaded before Card Services.

Enablers

One of the oldest rules of PC configuration is that the software configuration must match that of the hardware. For example, if you configure a network interface card to use interrupt 10, you must also configure the network driver to use the same interrupt, so it can address the device. Today, this can be confusing because most hardware is configured not by physically manipulating jumpers or DIP switches but by running a hardware configuration utility.

In spite of their other capabilities, neither Socket Services nor Card Services is capable of actually configuring the hardware settings of PC cards. This job is left to a software module called an enabler. The enabler receives the configuration settings assigned by Card Services and actually communicates with the PC card hardware itself to set the appropriate values.

Like Socket Services, the enabler must be designed to address the specific PC card that is present in the slot. In most cases, a PCMCIA software implementation includes a generic enabler—that is, one that can address many different types of PC cards. This, in most cases, lets you insert a completely new card into a slot and have it be recognized and configured by the software.

The problem with a generic enabler, and with the PCMCIA software architecture in general, is it requires a significant amount of memory to run. Because it must support many different cards, a generic enabler can require 50KB of RAM or more, plus another 50KB for the Card and Socket Services. For systems running DOS (with or without Windows 3.1), this is a great deal of conventional memory just to activate one or two devices. Once installed and configured, the PC card devices may also require additional memory for network, SCSI, or other device drivers.

Note

Windows 9x or Windows 2000 are the preferred operating systems for running PC card devices. The combination of their advanced memory management, Plug-and-Play capabilities, and the integration of the Card and Socket Services into the operating system makes the process of installing a PC card (usually) as easy as inserting it into the slot.

With Windows NT 4.0, for example, you have to shut down the system and reboot to change the PC card in a slot. What's more, it can be difficult to find Windows NT drivers for many of the PC cards on the market.

When memory is scarce, there can be an alternative to the generic enabler. A specific enabler is designed to address only a single specific PC card, and uses much less memory for that reason. Some PC cards ship with specific enablers that you can use in place of a generic enabler. However, it is also possible to use a specific enabler when you have a PC card that is not recognized by your generic enabler. You can load the specific enabler to address the unrecognized card, along with the generic enabler to address any other cards that you may use. This practice, of course, increases the memory requirements of the software.

Finally, you can avoid the overhead of generic enablers and the Card and Socket Services entirely by using what is known as a point enabler. A *point enabler* is a software module that is included with some PC cards that addresses the hardware directly, eliminating the need for Card and Socket Services. As a result, the point enabler removes the capability to hot swap PC cards and have the system automatically recognize and configure them. If, however, you intend to use the same PC cards all the time and have no need for hot swapping, point enablers can save you a tremendous amount of memory.

Keyboards

Unlike desktop systems, portables have keyboards that are integrated into the one-piece unit. This makes them difficult to repair or replace. The keyboard should also be an important element of your system purchasing decision, because manufacturers are forced to modify the standard 101-key desktop keyboard layout to fit in a smaller case.

The numeric keypad is always the first to go in a portable system's keyboard. Usually, its functionality is embedded into the alphanumeric keyboard and activated by a Function key combination. The Function (or Fn) key is an additional control key used on many systems to activate special features such as the use of an alternative display or keyboard.

Most portable systems today have keyboards that approach the size and usability of desktop models. This is a vast improvement over some older designs in which the keys were reduced to a point at which you could not comfortably touch-type with both hands. Standard conventions such as the "inverted T" cursor keys also were modified, causing extreme user displeasure.

Some systems still have half-sized function keys, but one of the by-products of the larger screens found in many of today's portable systems is more room for the keyboard. Thus, many manufacturers are taking advantage of the extra space.

If you plan to perform a lot of numeric data entry with your portable computer, look for numeric keypads that plug into your system and override the embedded keypad on the right side of your keyboard, or use a standard 101-key keyboard if you're at your desk.

Standard keyboards are covered in depth in Chapter 17, "Input Devices."

Pointing Devices

As with the layout and feel of the keyboard, pointing devices are a matter of performance and personal taste. Most portable systems have pointing devices that conform to one of the three following types:

- *Trackball*. A small ball (usually about 1/2-inch) partially embedded in the keyboard below the spacebar, which is rolled by the user. While serviceable and accurate, trackballs have become unpopular, primarily due to their tendency to gather dust and dirt in the well that holds the ball, causing degraded performance.
- *TrackPoint*. Developed by IBM and adopted by many other manufacturers (especially Toshiba), the TrackPoint is a small (about 1/4-inch) rubberized button located between the G, H, and B keys of the keyboard. It looks like a pencil eraser and can be nudged in any direction to move the cursor around the screen. The TrackPoint doesn't actually move,

instead it uses a pressure transducer to sense pressure and direction, allowing full control over the pointer. The TrackPoint is convenient because you can manipulate it without taking your hands off the keyboard. On some earlier models, the rubber cover tended to wear off after heavy use. Newer versions are made of sturdier materials with a grippy surface similar to a cat's tongue.

The TrackPoint is generally considered the best pointing device for portable systems—certainly for those who touch type. It is the most efficient, accurate, consistent, easiest to use (for most people), and by far the most reliable. If you use a portable system extensively and are a touch-typist, I'd highly recommend selecting systems with a TrackPoint. Personally I won't even consider a laptop or notebook system without one.

Note

For more information on the TrackPoint, see Chapter 17.

- *Trackpad.* The trackpad or touchpad is an electromagnetically sensitive pad, usually about 1×2 inches, that responds to the movement of a finger across its surface. Mouse clicks can be simulated by tapping the pad. Trackpads have great potential but tend to be overly sensitive to accidental touches, causing undesired cursor movements and especially unwanted mouse clicks. Trackpads are also notoriously imprecise and sensitive to humidity and moist fingers, resulting in unpredictable performance.

Some systems allow users a choice by providing both a TrackPoint and a trackpad; however, some only allow one or the other to operate, whereas others allow both to be active at the same time.

Note

If you want to use an external mouse with your portable, don't assume that the internal pointing device can be used simultaneously with the external device. Some systems have a BIOS setup option which allows you to activate both internal and external devices simultaneously, or use either one or the other. Regardless of whether you use a PS/2 mouse or a serial mouse, it may be necessary on some systems to go into the portable's BIOS Setup program and disable the trackpad to avoid accidental cursor movement.

Another important part of the pointer arrangement is the location of the primary and secondary buttons. Some systems locate the buttons in peculiar configurations that require unnatural contortions to perform a click-and-drag operation. Pointing devices are definitely a feature of a portable system that you should test drive before you make a purchase. As an alternative, remember that nearly all portables have a serial port or PS/2 port that you can use to attach an external mouse to the system, when your workspace permits.

Batteries

Battery life is one of the biggest complaints users have about portable systems. Although a great deal has been done to improve the power-management capabilities of today's portable computers, the hardware configuration of a fully equipped portable system dissipates 90 percent more power than it did three years ago, and that trend is still continuing. The efficiency of a computer's power use may also have doubled in the last two years, but battery technology has not improved at anything approaching the same rate, leaving the battery life of a typical portable system approximately the same as it was before.

The goal sought by many mobile users has been the same for many years: a full-featured portable system that can run on a single battery for the entire duration of a transcontinental U.S. airplane flight. Some airlines are now providing 12V automotive type power connectors under the seat for use with automotive power adapters; in this case, battery life on a plane is no longer an issue. For those who are relegated to using batteries, you will still typically have to carry two or more battery packs for a six-hour flight. While mobile power technologies are improving, so are the demands of today's systems. However, while typical battery life has remained in the two- to four-hour range for most reputable manufacturers, the new notebooks have the advantage of having larger hard drives, bigger and brighter screens, more RAM, faster processors, integrated speakers, and CD-ROM drives. Based on the increasing popularity of these notebook systems, the buying consumer has clearly voiced that a more powerful notebook with continuing average battery life is more important and useful than a system that would run for 6–10 hours but sacrifice features they have grown used to using.

For users who simply must have a system that can run for 6–10 hours, check for airlines that are adding at-seat power connections designed for notebook computers.

An interesting fact that many don't seem to know is that there are three different batteries in most portable systems. One is the main battery used to power the system; the next is a rechargeable standby battery which powers the RAM to maintain data when in suspend mode or when changing main batteries; and the third is the CMOS RAM/clock battery. Of these three batteries only the CMOS/clock battery requires replacement (every two to five years depending on the design) as the others are rechargeable. The standby battery in particular normally lasts the life of the system and recharges automatically anytime the system is powered on. Refer to Figure 23.1 for the locations of these batteries in a typical system.

Battery Types

The battery technology also plays a major role in the portable power issue, of course. Most portable systems today use one of four battery types for their main power batteries:

- *Nickel Cadmium (NiCad)*. As the oldest of the four technologies, nickel cadmium batteries are rarely used in portable systems today, because of their shorter life and sensitivity to improper charging and discharging. The life of the battery's charge can be shortened by as much as 40 percent if the battery is not fully discharged before recharging, or if it is overcharged. Permanent damage to the cell can be prevented by periodically discharging it to one volt or less. Despite this "memory" effect, however, NiCad batteries hold a charge well when not in use, losing 10 percent of their capacity in the first 24 hours and approximately 10 percent per month after that, and they can be recharged 1,500 times or more.
- *Nickel Metal-Hydrate (NiMH)*. More expensive than NiCads, NiMH batteries have approximately a 30 percent longer life than NiCads, are less sensitive to the memory effect caused by improper charging and discharging, and do not use the environmentally dangerous substances found in NiCads. They have a recommended discharge current that is lower than that of a NiCad battery (one-fifth to one-half of the rated capacity) and a self-discharge rate that is 1 1/2 times to twice that of a NiCad, and they can be recharged as many as 500 times. NiMH batteries also require nearly twice as long to recharge as NiCads. While they are still used in many portable systems, NiMH batteries are now found mostly in computers at the lower end of the price range.

- **Lithium-Ion (Li-ion).** As the current industry standard, Li-ion batteries are longer-lived than either NiCad or NiMH technologies, cannot be overcharged, and hold a charge well when not in use. Batteries that use lithium—one of the lightest of all metals, with the greatest electrochemical potential, and providing the largest energy content—have been manufactured since the 1970s. However, lithium is also an unstable substance, and some battery explosions resulted in a large number of battery recalls in the early 1990s. Subsequent models were manufactured using lithium ions from chemicals such as lithium-cobalt dioxide (LiCoO₂). Despite a slightly lower energy density, Li-ion batteries are much safer than the lithium designs. Various types of Li-ion batteries use different active materials for their negative electrodes; coke versions and two graphite versions have slightly different voltage characteristics. Li-ion batteries can also support the heavy-duty power requirements of today's high-end systems, and modern versions can be recharged up to 1,000 times or more. They also recharge faster than most of the other types. Unlike NiCad and NiMH batteries, which can be used in the same system without modification to the circuitry, Li-ion batteries can only be used in systems specifically designed for them. Inserting a Li-ion battery into a system designed for a NiCad or NiMH can result in a fire. Although the most expensive of the four technologies, Li-ion batteries have come to be used in all but the very low end of the portable system market.
- **Lithium-Ion Polymer.** This is a fourth battery type that has been in development for several years, but which only recently appeared on the market. Lithium-ion polymer batteries are manufactured using a lithium ion and cobalt oxide cell with a proprietary polymer electrolyte and can be formed into flat sheets as small as 1mm thick and of almost any size. Thus, a thin battery panel can be fitted into a portable computer behind the LCD panel. Lithium-ion polymer batteries provide an energy density that is four times better than a NiCad and a charge life that is 40 percent longer than a Li-ion battery, at one-fifth the weight. This battery technology provides up to 500 charges and is immune to the memory effect that can prevent NiCad and NiMH batteries from recharging fully. After they are manufactured in sufficient quantities, lithium-ion polymer batteries could replace the bulky battery packs used today in portable systems.

Note

All the battery types in use today function best when they are completely discharged before being recharged. In fact, batteries that have gone unused for several months should be conditioned by putting them through three full discharge/recharge cycles. You can do this by leaving the system on until it automatically suspends or shuts down; there are also battery-conditioning utilities that can manage this process for you. One indication that you need to discharge cycle your batteries is if charging stops before the charge indicator reaches 100 percent. Cycling the battery a few times will normally correct this situation and allow for proper charge indication. Lithium-ion batteries are affected the least by incomplete discharging and have a higher discharge cut-off point (2.5–3v versus 1v for NiCads), but the effect on the life of future charges is still noticeable.

Unfortunately, buying a portable computer with a more efficient battery does not necessarily mean that you will realize a longer charge life. Power consumption depends on the components installed in the system, the power-management capabilities provided by the system software, and the size of the battery itself. Some manufacturers, for example, when moving from NiMH to Li-ion batteries, see this as an opportunity to save some space inside the computer. They decide that because they are using a more efficient power storage technology, they can make the battery smaller and still deliver the same performance.

Battery technology trails behind nearly all the other subsystems found in a portable computer, as far as the development of new innovations is concerned. Because of the continuing trend of adding more features and components to mobile computers, their power consumption has risen enormously in recent years, and power systems have barely been capable of keeping up. On a high-end laptop system, a battery life of three hours is very good, even with all the system's power-management features activated.

One other way that manufacturers are addressing the battery life problem is by designing systems that are capable of carrying two batteries. The inclusion of multipurpose bays within the system's case enables users to replace the floppy or CD-ROM drive with a second battery pack, effectively doubling the computer's charge life.

Power Management

There are various components in a computer that do not need to run continuously while the system is turned on. Mobile systems often conserve battery power by shutting down these components based on the activities of the user. If, for example, you open a text file in an editor and the entire file is read into memory, there is no need for the hard drive to spin while you are working on the file.

After a certain period of inactivity, a power-management system can park the hard drive heads and stop the platters from spinning until you save the file to disk or issue any other command that requires drive access. Other components, such as floppy and CD-ROM drives and PC cards, can also be powered down when not in use, resulting in a significant reduction of the power needed to run the system.

Most portables also have systemic power saver modes that suspend the operation of the entire system when it is not in use. The names assigned to these modes can differ, but there are usually two system states that differ in that one continues to power the system's RAM while the other does not. Typically, a "suspend" mode shuts down virtually the entire system after a preset period of inactivity except for the memory. This requires only a small amount of power and allows the system to be reawakened in a few seconds, rather than having to go through the complete boot process. When in this standby mode, the memory will be maintained by the main battery, or the standby battery if the main battery is dead or you are changing the main battery. The standby battery will normally power the RAM for a few minutes to a few hours or more in some models. For this reason it is important to save any work before suspending the system.

Portable systems usually have a "hibernate" mode, as well, which writes the current contents of the system's memory to a special file on the hard disk, and then shuts down the system, erasing memory as well. The hibernate mode does not require any power from either the main or standby batteries, so a system can theoretically hibernate indefinitely. When the computer is reactivated (powered up), it reads the contents of the hibernation file back into memory, restoring the system to exactly the condition it was in when hibernation started, and work can continue. The reactivation process takes a bit longer than a normal resume from suspend mode, but the system conserves more power by shutting down the memory array.

Note

The memory swap file used for hibernate mode may, in some machines, be located in a special partition on the hard drive dedicated to this purpose. If you inadvertently destroy this partition, you may need a special utility from the system manufacturer to re-create the file. Newer operating systems like Windows Me and 2000 create their own hibernation files.

In most cases, these functions are defined by the APM (Advanced Power Management) standard, a document developed jointly by Intel and Microsoft that defines an interface between an operating system power-management policy driver and the hardware-specific software that addresses devices with power-management capabilities. This interface is usually implemented in the system BIOS.

◀◀ See "Advanced Power Management," p. 1189.

However, as power-management techniques continue to develop, it becomes increasingly difficult for the BIOS to maintain the complex information states needed to implement more advanced functions. There is, therefore, another standard that has been developed by Intel, Microsoft, and Toshiba called ACPI (the Advanced Configuration and Power Interface), which is designed to implement power-management functions in the operating system. Microsoft Windows 98, Me, and 2000 automatically use ACPI if ACPI functions are found in the system BIOS when these operating systems are first installed. The need to update system BIOSes for ACPI support is one reason many computer vendors have recommended performing a BIOS update before installing Windows 98, Me, or 2000.

◀◀ See "Power Management Menu," p. 418.

Placing power management under the control of the OS allows for a greater interaction with applications. For example, a program can indicate to the operating system which of its activities are crucial, forcing an immediate activation of the hard drive, and which can be delayed until the next time that the drive is activated for some other reason.

Peripherals

There are a great many add-on devices available for use with portable systems that provide functions that cannot practically or economically be included inside the system itself. Many of the most common uses for portable systems may require additional hardware, either because of the computer's location or the requirements of the function. The following sections discuss some of the most common peripherals used with portable systems.

External Displays

High-end laptop systems are often used to host presentations to audiences that can range in size from the boardroom to the auditorium. For all but the smallest groups of viewers, some means of enlarging the computer display is needed. Most portable systems are equipped with a standard VGA jack that allows the connection of an external monitor.

Systems typically allow the user to choose whether the display should be sent to the internal, the external, or both displays, as controlled by a keystroke combination or the system BIOS.

Depending on the capabilities of the video display adapter in the computer, you may be able to use a greater display resolution on an external monitor than you would on the LCD panel.

For environments where the display of a standard monitor is not large enough, there are several alternatives, as discussed in the following sections.

◀◀ See "LCD Displays," p. 851.

Overhead LCD Display Panels

An LCD display panel is something like the LCD screen in your computer except that there is no back on it, making the display transparent. The display technologies and screen resolution options are the same as those for the LCD displays in portable systems, although most of the products on the market use active-matrix displays.

You use an LCD panel by placing it on an ordinary overhead projector, causing the image on the panel to be projected onto a screen (or wall). Because they are not intended solely for use with portable systems, these devices typically include a pass-through cable arrangement, allowing a connection to a standard external monitor, as well as the panel.

While they are serviceable for training and internal use, overhead display panels do not usually deliver the depth and vibrancy of color that can add to the excitement of a sales presentation. The quality of the image also depends on the brightness of the lamp used to display it. While the panel itself is fairly small and lightweight, overhead projectors frequently are not. Overhead projectors with sufficient power to produce a bright display through an LCD panel are very expensive and sometimes difficult to rent. If a projector is already available at the presentation site, the LCD panel is a convenient way of enlarging your display. If, however, you are in a position where you must travel to a remote location and supply the overhead projector yourself, you are probably better off with a self-contained LCD projector.

Overhead display panels are not cheap. You will probably have to pay more for one than you paid for your computer. However, on a few models of the IBM ThinkPad, you can remove the top cover that serves as the back of the display and use the computer's own LCD screen as an overhead panel.

LCD Projectors

An LCD projector is a self-contained unit that is a combination of a transparent display panel and a projector. The unit connects to the video output connector on the system, just like a regular monitor, and frequently includes speakers that connect with a separate cable as well. Not all LCD projectors are portable; some are intended for permanent installations. The portable models vary in weight, display technologies, and the brightness of the lamp, which is measured in lumens.

A 10-pound unit delivering 500 ANSI lumens is usually satisfactory for a conference room environment; a larger room normally requires a projector delivering at least 750 ANSI lumens or more. More powerful projectors of up to 2000 lumens or higher are available; normally the brighter ones weigh more as well. LCD projectors tend to deliver images that are far superior to those of overhead panels, and they offer a one-piece solution to the image-enlargement problem.

However, you have to pay for the convenience. Prices of LCD projectors can range from under \$1,000 to well over \$10,000, but if your business relies on your presentations, the cost may be justified.

For best results, match the resolution of your projector to the native resolution of your notebook computer. If your notebook computer has a 1024×768 resolution screen, make sure your projector offers this same resolution without tricks like scaling or compression. Having the projector and your built-in screen match will permit most systems to use simultaneous display, a great benefit for presenters.

TV-Out

One of the simplest display solutions is a feature that is being incorporated into many of the high-end laptop systems on the market today. It allows you to connect the computer to a standard television set. Called TV-out, various systems provide support for either the North American NTSC television standard, the European PAL standard, or both. Once connected, a software program lets you calibrate the picture on the TV screen.

TV-out is becoming a popular feature on high-end video adapters for desktop systems as well as portables. There are also some manufacturers that are producing external boxes that plug into any computer's VGA port and a television set to provide an external TV display solution. The products convert the digital VGA signal to an analog output that typically can be set to use the NTSC or PAL standard.

Obviously, TV-out is an extremely convenient solution, as it provides an image size that is limited only by the type of television available, costs virtually nothing, and adds no extra weight to the presenter's load (unless you have to bring the TV yourself). You can also connect your computer to a VCR and record your presentation on standard videotape. However, the display resolution of a television set does not approach that of a computer monitor, and the picture quality suffers as a result. This is particularly noticeable when displaying images that contain a lot of text, such as presentation slides and Web pages. It is recommended that you test the output carefully with various size television screens before using TV-out in a presentation environment.

Use simple sans-serif fonts such as Arial or Helvetica in presentations and limit the amount of text on any given screen to achieve best results with TV-out devices.

Docking Stations

Now that many portable systems are being sold as replacements for standard desktop computers, docking stations are becoming increasingly popular. A *docking station* is a desktop unit to which you attach (or dock) your portable system when you are at your home or office. At the very least, a docking station provides an AC power connection, a full-size keyboard, a standard desktop mouse, a complete set of input and output ports, and a VGA jack for a standard external monitor.

Once docked, the keyboard and display in the portable system are deactivated, but the other components—particularly the processor, memory, and hard drive—remain active. You are essentially running the same computer but using a standard full-size desktop interface. Docking stations can also contain a wide array of other features, such as a network interface adapter, external

speakers, additional hard disk or CD-ROM drives, additional PC card slots, and a spare battery charger.

An operating system such as Windows 9x, Me, or 2000 can maintain multiple hardware profiles for a single machine. A *hardware profile* is a collection of configuration settings for the devices accessible to the system. To use a docking station, you create one profile for the portable system in its undocked state and another that adds support for the additional hardware available while docked.

The use of a docking station eliminates much of the tedium involved in maintaining separate desktop and portable systems. With two machines, you must install your applications twice and continually keep the data between the two systems synchronized. This is traditionally done using a network connection or the venerable null modem cable (a crossover cable used to transfer files between systems by connecting their parallel or serial ports). With a docking station and a suitably equipped portable, you can achieve the best of both worlds.

Docking stations are highly proprietary items that are designed for use with specific computer models. Prices vary widely depending on the additional hardware provided, but because a docking station lacks a CPU, memory, and a display, the cost is usually not excessive.

For systems that lack the docking station option or for those which seem too expensive, consider the less expensive port replicator. While it lacks drive bays and may not feature a network interface card, even the simplest ones offer connectors for video, printer, serial, and keyboard/mouse, which enables you to use more comfortable devices. Because a port replicator is simpler, you may not even need to use the multiple hardware profiles of Windows 9x.

One economic concern for both docking stations and port replicators is that any given model will work with just a few computer models at most. If you plan to change computers frequently and are also looking to increase the number of printer and serial ports you have, consider the Universal Port Replicators available from Mobility Electronics. These units feature serial, parallel, PS/2 mouse, and PS/2 keyboard connectors, as well as a PC card slot. Mobility also offers model-specific port replicators for most popular notebook computer models.

Connectivity

One of the primary uses for portable computers is to keep in touch with the home office while traveling by using a modem. Because of this, many hotels and airports are starting to provide telephone jacks for use with modems, but there are still many places where finding a place to plug into a phone line can be difficult. There are products on the market, however, which can help you overcome these problems, even if you are traveling overseas.

Line Testers

Many hotels use digital PBXs for their telephone systems, which typically carry more current than standard analog lines. This power is needed to operate additional features on the telephone, such as message lights and LCD displays. This additional current can permanently damage your modem without warning, and unfortunately, the jacks used by these systems are the same standard RJ-11 connectors used by traditional telephones.

To avoid this problem, you can purchase a line-testing device for about \$50 that plugs into a wall jack and measures the amount of current on the circuit. It then informs you whether it is safe to plug in your modem.

Acoustic Couplers

On those occasions when you cannot plug your modem into the phone jack, or when there is no jack available (such as at a pay phone), the last resort is an acoustic coupler. The acoustic coupler is an ancient telecommunications device that predates the system of modular jacks used to connect telephones today. To connect to a telephone line, the coupler plugs into your modem's RJ-11 jack at one end and clamps to a telephone handset at the other end. A speaker at the mouthpiece and a microphone at the earpiece allow the audible signals generated by the modem and the phone system to interact.

The acoustic coupler may be an annoying bit of extra baggage to have to carry with you, but it is the one foolproof method for connecting to any telephone line without having to worry about international standards, line current, or wiring.

Cellular Modems

If you want to get online with no wires, one of the easiest and least expensive ways is via a cellular modem and your existing cell phone. Most business people today carry a portable cell phone, which in most cases can now be used for online communications with your laptop. The only missing items are a cellular modem compatible with your particular brand of phone and the cable that goes from the modem to the phone.

Most laptops include built-in modems these days, but unfortunately most of them are not cellular capable, in which case you'll need to purchase a PC card-based cellular capable modem to use. 3Com and others make modems that work with most of the popular cell phones on the market using AMPS or GSM service. For example I use a Nokia 6100 series phone, which is supported by the 3Com CXM756 (56K Data/Fax/Cell) modem. To use this, I needed a cable, which 3Com also sells.

After installing the modem and driver and plugging in the cable between the modem and phone, dialing out then works just as previously. You can dial your ISP using whatever numbers it provides for normal modem access; the only caveat is that connections through the cell phone run at up to 9600bps maximum, and in some cases less than that due to interference. The modem puts the cell phone into analog mode for communications, even if the phone is a digital type. There are no additional ISP or other service charges necessary, and you use your normal dialup software to log on.

Using the proper modem and cable, you can turn your ordinary cell phone into a direct wireless email and Internet connection.

The Traveler's Survival Kit

For successful computing on the road, have these with you at all times:

- Your operating system installation files (on CD-ROM or on your hard drive)
- A 56Kbps modem and 10BaseT or dual-speed Ethernet card (can be combo)

- Replacement “dongle” connectors for the modem and network card(s)
- Portable surge protector with RJ11 phone-line protection
- RJ11 Line couplers that allow you to extend your modem and network card “dongles” with standard RJ11 and RJ45 cables
- RJ11 line splitter or 2-into-1 connector
- “Modem Saver” RJ11 line tester to check for dangerous high-voltage PBX systems
- Lightweight extension cord (like that you’d use to plug in your Christmas tree lights) for powering your notebook computer, if it uses ungrounded polarized line cord
- 2-to-3-prong outlet adapter
- 12V power adapter or 12V to 120V car adapter for automotive or aircraft operation and recharging
- Spare battery
- List of local dialup numbers for your national ISP (America Online, CompuServe, CompuServe 2000, and so on)
- Spare media for your diskette, Zip, or LS-120 drive
- Tech-support Web sites and phone numbers

Portable Security

There is a growing concern for security and safety with portables, as their small size and weight makes them easy targets for thieves. A prime target is the traveler at the airport; in that environment you should always make sure you keep tight control over your computer or it can easily be stolen.

A common scam involves two people at the X-ray scanner. They both stand in front of you in line; one goes through and the other waits until you put your system on the conveyer belt before holding up the line fumbling with change and other items in his pocket. This serves to detain you while the companion grabs your notebook and runs. By the time you get through, your system is gone. Moral of the story: don’t set your computer on the conveyer belt until there is nobody between you and the metal detector portal.

There are various alarms sold that can shriek if your system is stolen, but these are a fairly extreme solution.

System manufacturers offer protection for their systems in several ways. One is to offer a latch on the system to which a security lock cable can be bolted. This is ideal if you are working with your system on a desk and want to lock it to the desk. Companies such as Kensington Microware sell steel cables with a key lock that goes through the latch in the system case, and which can then be wrapped around a secure object. The latch in the case is made as a part of the frame and not the flimsy plastic exterior casing.

A second method for protection involves passwords. Most notebook systems offer several levels of password protection, but the most secure are the Administrator password and the Hard-disk password. Both of those, if lost, cannot be reset or deleted, so losing them will render the motherboard or hard disk useless. Be careful if you set these passwords that you don’t forget them! Of course the idea is that if thieves steal your portable, they won’t be able to access any of the data on it, even if they move the hard disk to another machine.

IBM and other manufacturers also often include a Personalization Editor, which allows you to place information such as your name, address, phone number, company information, and even logo directly into the BIOS such that they will appear when the system is started. This will easily identify the proper owners of the system if it falls into the wrong hands. It can also be useful for identifying individual computers in a company where everybody is issued the same system.

CHAPTER 24

Building or Upgrading Systems

System Components

In these days of commodity parts and component pricing, building your own system from scratch is no longer the daunting process it once was. Every component necessary to build a PC system is available off the shelf at competitive pricing. In many cases, the system you build can use the same or even better components than the top name-brand systems.

There are, however, some cautions to heed. The main thing to note is that you rarely save money when building your own system; purchasing a complete system from a mail-order vendor or mass merchandiser is almost always less expensive. The reason for this is simple: Most system vendors who build systems to order use many, if not all the same components you can use when building your own system. The difference is that they buy these components in quantity and receive a much larger discount than you can by purchasing only one of a particular item.

In addition, there is only one shipping and handling charge when you purchase a complete system instead of the multiple shipping charges when you purchase separate components. In fact, the shipping, handling, and phone charges from ordering all the separate parts needed to build a PC often add up to \$100 or more. This cost rises if you encounter problems with any of the components and have to make additional calls or send improper or malfunctioning parts back for replacement. Many companies charge restocking fees if you purchase something and then determine you don't need it or can't use it.

Then there is the included software. Although I can sometimes come close in price to a commercial system when building my own from scratch, the software really clinches it for the commercial system. A new copy of Windows (98 or Me) runs \$100 or more, and most commercial systems also include Microsoft Office or other applications as well. I'd value the software included with most systems at from \$250 to \$500 depending on what you get.

It is clear that the reasons for building a system from scratch often have less to do with saving money and more to do with the experience you gain and the results you achieve. In the end, you have a custom system that contains the exact components and features you have selected. Most of the time when you buy a preconfigured system, you have to compromise in some way. For example, you may get the video adapter you want, but you would prefer a different make or model of motherboard. By building your own system, you can select the exact components you want and build the ultimate system for your needs. The experience is also very rewarding. You know exactly how your system is constructed and configured because you have done it yourself. This makes future support and installation of additional accessories much easier.

Another benefit of building your own system is that you are guaranteed a non-proprietary system that will be easily upgradable in the future. Of course if you have been reading the book up to this point, you already know everything you need to ensure any preassembled systems you purchase would be non-proprietary and, therefore, upgradable and repairable in the future.

It may be possible to save some money using components from your current system when building your new system. You might have recently upgraded your hard drive and memory in an attempt to extend the life of your current computer. In most cases, you can take those components with you to the new system if you plan appropriately. For example, if you used 72-pin SIMMs in your old system, you can buy a new motherboard that supports both 72-pin SIMMs

and 168-pin DIMMs. Unfortunately, most of these boards won't allow mixing SIMMs and DIMMs, meaning you can either use your old memory or get new DIMM memory, but not use both in the same board. Most boards that use the newer RIMM modules won't accept any of your existing memory.

So if you are interested in a rewarding experience, want a customized and fully upgradable system that is not exactly the same as that offered by any vendor, are able to take on all system repair and troubleshooting tasks, want to save some money by reusing some of the components from your current system, and are not in a hurry, building your own PC might be the way to go. On the other hand, if you are interested in getting a PC with the most value for the best price, you want one-stop support for in-warranty repairs and technical problems, and you need an operational system quickly, building your own system should definitely be avoided.

This chapter details the components needed to assemble your own system, explains the assembly procedures, and lists some recommendations for components and their sources.

The components used in building a typical PC are

- Case and power supply
- Motherboard
- Processor with heat sink
- Memory
- Floppy drive
- Hard disk drive
- CD-ROM/DVD drive
- Keyboard
- Pointing device (mouse)
- Video card and display
- Sound card and speakers
- Modem or LAN card (Internet/email access)
- Cooling fans and heat sinks
- Cables
- Hardware (nuts, bolts, screws, and brackets)
- Operating system software (on CD-ROM)

Each of these components is discussed in the following sections.

Case and Power Supply

The case and power supply are usually sold as a unit, although some vendors do sell them separately. There are a multitude of designs to choose from, usually dependent on the motherboard form factor you want to use, the number of drive bays available, and whether the system is desk-top or floor mounted. There are cases with extra fans for cooling (recommended), air filters on the air inlets to keep down the dust, removable side panels, or motherboard trays; cases that require no tools for assembly, rack-mounted versions, and more. For most custom-built systems,

an ATX mid-tower case and power supply is the recommended choice. Cases designed for the older Baby-AT motherboard form factor are still available, but the ATX architecture offers considerable improvements. The size and shape of the case, power supply, and even the motherboard are called the *form factor*. The most popular case form factors are

- Full-tower
- Mini-tower
- Desktop
- Low-profile (also called Slimline)

Cases that take ATX boards are found mostly in the full-tower, mini-tower, and desktop form factors. When deciding what type of case to purchase, you should consider where you will place your computer. Will it be on a desk? Or is it more feasible to put the system on the floor and just have the monitor, keyboard, and mouse on the desk? The amount of space you have available for the computer can affect other purchasing decisions, such as the length of the monitor, keyboard, and mouse cables.

Of the choices listed, it is recommended that you avoid the low-profile systems. Designed primarily for use in business environments, these Slimline systems have a smaller footprint, meaning that they take up less space on your desk than the typical desktop computer and are usually not designed with expansion in mind. These cases require a special type of motherboard called a Low Profile or LPX board. The low-profile version of the ATX form factor is called the NLX. LPX and NLX motherboards often have virtually everything built in, including video, sound, and even network adapters.

LPX and NLX motherboards do not have any normal adapter slots. Instead, all the expansion slots are mounted on an adapter board called a riser card, which plugs into a special slot on the motherboard. Standard PCI or ISA adapter cards then plug sideways into the riser card (parallel to the motherboard), making expansion difficult and somewhat limited. In addition, the small size of the case makes it difficult to work inside the machine. Some designs force you to remove some components to gain access to others, making system maintenance inconvenient.

Many of the case designs other than the Low Profile (or Slimline) take a standard sized motherboard called a Baby-AT type. This designation refers to the form factor or shape of the motherboard, which is to say that it mimics the original IBM AT but is slightly smaller. Actually, the Baby-AT form factor is kind of a cross between the IBM XT and AT motherboard sizes.

◀◀ See "Motherboard Form Factors," p. 222.

Most newer cases accept ATX-style boards, which have become the standard for Celeron- and Pentium II/III-based systems. If you are interested in the most flexible type of case and power supply that will support the widest variety of future upgrades, I recommend sticking with the ATX-style cases and power supplies.

Whether you choose a desktop or one of the tower cases is really a matter of personal preference and system location. Most people feel that the tower systems are roomier and easier to work on, and the full-sized tower cases have lots of bays for different storage devices. Tower cases typically have enough bays to hold floppy drives, multiple hard disk drives, CD-ROM drives, tape drives,

and anything else you might want to install. However, some of the desktop cases can have as much room as the towers, particularly the mini- or mid-tower models. In fact, a tower case is sometimes considered to be a desktop case turned sideways or vice versa. Some cases are convertible—that is, they can be used in either a desktop or tower orientation.

As to the power supply, the most important consideration is how many devices you plan to install in the system and how much power they require. Chapter 21, “Power Supply and Chassis/Case,” describes the process for calculating the power required by your system hardware and selecting an appropriate power supply for your needs.

◀◀ See “Power-Use Calculations,” p. 1183.

When you build your own system, you should always keep upgradability in mind. A properly designed custom PC should last you far longer than an off-the-shelf model because you can more easily add and substitute new components. When choosing a case and power supply, leave yourself some room for expansion, on the assumption that you will eventually need another hard drive or that some new device will appear on the market that you won’t be able to live without.

Motherboard

Several compatible form factors are used for motherboards. The form factor refers to the physical dimensions and size of the board and dictates what type of case the board will fit into. The types of compatible industry-standard motherboard form factors generally available for system builders are as follows:

Obsolete form factors

- Baby-AT
- Full-size AT
- LPX (semi-proprietary)

Modern form factors

- ATX
- Micro-ATX
- Flex-ATX
- NLX
- WTX

All others

- Proprietary designs (Compaq, Packard Bell, Hewlett-Packard, notebook/portable systems, and so on)

ATX motherboards are recommended for most people building their own systems today. ATX is an open architecture that improves on the older Baby-AT design in many ways that affect other components of the computer, such as the case and the power supply. An ATX motherboard has the same basic dimensions as a Baby-AT; however, it is rotated 90° in the case from the standard

Baby-AT orientation. This places the expansion slots parallel to the short side of the board, allowing more space for other components without interfering with expansion boards.

Components that produce large amounts of heat, such as the CPU and memory, are located next to the power supply for better cooling and easier access to the processor and memory sockets.

The ATX-style power supply features a redesigned, single-keyed (foolproof!) connector that cannot be plugged in backward or off-center. Plugging power supply connectors backward or off-center by a pin is easy to do in the Baby-AT design and the result is catastrophic: The motherboard will be destroyed the moment the power is turned on. This is impossible with the shrouded and keyed ATX power connector. This power supply provides the motherboard with the 3.3v current used by many of the newer CPUs and other components. ATX power supplies are also designed to support the advanced power-management features now found in system BIOS and operating systems.

The micro-ATX form factor is a further development of the ATX design, intended for use in lower-cost systems. The micro-ATX architecture is backward compatible with ATX and specifies a motherboard that is physically smaller, as the name implies. These smaller motherboards can be installed in standard ATX cases or in smaller cases specifically designed for the micro-ATX boards.

If you plan to build a full-sized desktop or tower system, the ATX motherboard is definitely the way to go. Virtually all motherboard manufacturers have committed to the new ATX design in the long run, as the ATX motherboard designs are cheaper, easier to access, and more reliable.

Other form factors used in motherboards today are the LPX and NLX form factors. These form factors require the use of a low-profile case and are normally not recommended when building your own system. This is because of the number of different variations on case and riser-card designs, the limited expandability imposed by the motherboard and case architecture, and the difficulty of working in such a small space.

There can be some differences among systems with LPX motherboards, so it is possible to find interchangeability problems among different motherboards and cases. The NLX form factor is another open standard developed by Intel, with features comparable to the ATX but defining a Slimline-style case and motherboard arrangement. Systems based on the NLX standard should not experience the compatibility problems of LPX-based systems, but the inherent problems of the Low-Profile design remain. These types of form factors are popular with corporate clients and novice consumers because of the systems' small footprint and the "everything-on-the-motherboard" design.

Note

For more information on all the motherboard form factors, see Chapter 4, "Motherboards and Buses." There are detailed descriptions and diagrams showing the various types.

In addition to the form factor, you should consider several other features when selecting a motherboard. The following sections examine each feature.

Processor

In some cases, your motherboard comes with the processor already installed. Most of the name-brand motherboard manufacturers like to install the processor and warranty the board and processor as a unit. This is not always the case, especially with slot-type processors, as they are easier to ship with the processor removed. Most companies that sell motherboards like to sell you the processor at the same time and will give you some type of a discount when you buy both. Even so, it is possible to purchase the motherboard and processor separately if you want.

The motherboards you consider should have one of the following processor sockets or slots:

- *Socket 370 (also called PGA370)*. Supports the socketed versions of the Intel Pentium III and Celeron processor.
- *Slot 1 (also called SC-242)*. Supports the slot versions of the Intel Pentium III, Celeron, and Pentium II processors.
- *Slot 2 (also called SC-330)*. Supports the Intel Pentium III and Pentium II Xeon processors.
- *Socket 7 (also called Super7 beyond 66MHz)*. Supports the Intel Pentium, Pentium MMX, AMD K5, K6, K6-2, K6-3, Cyrix 6x86, 6x86MX, and MII processors.
- *Slot A*. Supports the AMD Athlon processors.
- *Socket A*. Supports the AMD Duron processor and PGA package Athlon processors.

Because the motherboard you choose will dictate or limit your choice in processor, normally you would choose your processor first. These days the choice in processors runs the gamut from the AMD K6 series and Intel Celeron on the low end to the AMD Athlon and Intel Pentium III for the midrange and the Pentium III Xeon on the high end. For more information on these and all other processors, see Chapter 3, “Microprocessors Types and Specifications.”

◀◀ See “Processor Sockets and Slots,” p. 96.

◀◀ See “Intel P6 (686) Sixth-Generation Processors,” p. 167, and “Other Sixth-Generation Processors,” p. 202.

Depending on the type of motherboard you select, there may be jumpers on the motherboard to set. There might also be jumpers to control the voltage supplied to the processor. Normally Socket 7 or Super7 boards have jumpers for motherboard bus speed, CPU multiplier, and CPU voltage settings. If you purchase this type of board, make sure you get these settings correct or the system won’t run properly. In a worst-case situation you might damage the processor with too high a voltage setting, for example.

Socket 370, Slot 1, Slot 2, Socket A, and Slot A boards handle all these settings automatically, so there is little danger of incorrect settings. Even so, several boards have overrides for the automatic settings, which can be useful for those intending on hotrodding or overclocking their processors. Most of these boards use the BIOS Setup to control these overrides, meaning there are no jumpers or switches that need to be set.

Chipsets

Aside from the processor, the main component on a motherboard is called the *chipset*. This is normally a set of one to five chips that contains the main motherboard circuits. These chipsets replace the 150 or more distinct components that were used in the original IBM AT systems and allow a motherboard designer to easily create a functional system from just a few parts. The chipset contains all the motherboard circuitry except the processor and memory in most systems.

Since the chipset really *is* the motherboard, the chipset used in a given motherboard has a profound effect on the performance of the board. It dictates all the performance parameters and limitations of the board, such as memory size and speed, processor types and speeds, supported buses and their speeds, and more. If you plan to incorporate newer technologies such as the Accelerated Graphics Port (AGP) or the Universal Serial Bus (USB) into your system, you must be sure that your motherboard has a chipset that supports these features.

Because chipsets are constantly being introduced and improved over time, I cannot list all of them and their functions; however, you will find a detailed description of many of them in Chapter 4. There are several popular high-performance chipsets on the market today. The best of these offer support for SDRAM (Synchronous DRAM) or RDRAM (Rambus DRAM) memory, PCI and AGP buses, Advanced Configuration and Power Interface (ACPI), and Ultra-DMA ATA (IDE) support.

Intel is by far the most popular manufacturer of chipsets in the world, which is not surprising as the development of new chipsets parallels the introduction of new processors. There are other chipset manufacturers, but as Intel releases new processor models at an ever-increasing rate, it becomes more difficult for other developers to keep up. In many cases you can use the Intel-compatible processors manufactured by other companies, such as AMD and Cyrix, with motherboards containing Intel chipsets.

◀◀ See "Chipsets," p. 255.

◀◀ See "Knowing What to Look For (Selection Criteria)," p. 365.

Clearly, the selection of a chipset must be based largely on the processor you choose and the additional components you intend to install in the computer.

However, no matter what chipset you look for, I recommend checking for the following supported features:

- 100/133MHz or faster CPU bus support
- SDRAM or RDRAM (main memory) support
- ECC (Error Correcting Code) memory support
- ACPI (Advanced Configuration and Power Interface) energy-saving functions
- AGP 4x
- Dual Ultra-ATA/33 or Ultra-ATA/66 ATA interfaces
- USB support

Most of the better chipsets on the market today should have these features and more. If you are intent on building the ultimate PC (at least by this week's standards), you will also want to consider the fastest processors available. Chipsets designed for these processors should include support for the latest technologies, such as the 133MHz system bus (called the FSB or Front Side Bus) and the accelerated graphics port (AGP) 4x mode. Be sure not to waste your investment on the most capable processor by using a chipset that doesn't fully exploit its capabilities.

Most motherboards manufactured today include both the ISA and PCI expansion buses, although the ISA bus is being eliminated from many newer motherboards. When you are designing your system, carefully consider the number and type of expansion cards that you intend to install. Then, make sure that the motherboard you select has the correct number of slots and that they are of the correct bus type for your peripherals (ISA, PCI, and AGP). Because many newer boards don't have ISA slots, it might be time to get rid of any ISA boards you have and replace them with more capable PCI versions.

When you buy a motherboard, I highly recommend you contact the chipset manufacturer and obtain the documentation (usually called the data book) for your particular chipset. This will explain how the memory and cache controllers, as well as many other devices in the system, operate. This documentation should also describe the Advanced Chipset Setup functions in your system's Setup program. With this information, you may be able to fine-tune the motherboard configuration by altering the chipset features. Because chipsets are frequently discontinued and replaced with newer models, don't wait too long to get the chipset documentation, as most manufacturers make it available only for chips currently in production.

Note

One interesting fact about chipsets is that in the volume that the motherboard manufacturers purchase them, the chipsets usually cost about \$40 each. If you have an older motherboard that needs repair, you normally cannot purchase the chipset because they are usually not stocked by the manufacturer after they are discontinued. Not to mention that most chipsets feature surface mounting with ball grid array (BGA) packages that are extremely difficult to remove manually and replace. The low-cost chipset is one of the reasons why motherboards have become disposable items that are rarely, if ever, repaired.

BIOS

Another important feature on the motherboard is the BIOS (basic input/output system). This is also called the ROM BIOS because the code is stored in a read-only memory (ROM) chip. There are several things to look for here. One is that the BIOS is supplied by one of the major BIOS manufacturers such as AMI (American Megatrends International), Phoenix, Award, or Microid Research. Also, make sure that the BIOS is contained in a special type of reprogrammable chip called a Flash ROM or EEPROM (Electrically Erasable Programmable Read Only Memory). This will allow you to download BIOS updates from the manufacturer and, using a program they supply, easily update the code in your BIOS. If you do not have the Flash ROM or EEPROM type, you will have to physically replace the chip if an update is required.

◀◀ See "Upgrading the BIOS," p. 390.

Virtually all motherboards built in the last few years will include a BIOS with support for the Plug-and-Play (PnP) specification. This will make installing new cards, especially PnP cards, much easier. PnP automates the installation and uses special software built into the BIOS and the operating system (such as Windows 95/98 and Windows 2000) to automatically configure adapter cards and resolve adapter resource conflicts.

Note

See "See Plug-and-Play BIOS," in Chapter 5, "BIOS." Also, an exhaustive listing of PnP device IDs can be found in the Technical Reference section of the CD included with this book.

Memory

Older systems had L2 cache memory on the motherboard, but for almost all newer systems this cache is now a part of the processor. Socket 7 or Super7 motherboards do still include cache on-board, and it is normally soldered in and non-removable or upgradable.

◀◀ See "Cache Memory: SRAM," p. 436.

Most Super7 motherboards support at least 1–2MB of cache memory.

For Pentium Pro/II/III and Celeron systems, no additional L2 memory is needed because the processors have the cache memory integrated into the processor package. The Athlon also has the L2 cache in the CPU, although some Athlon motherboards also have additional cache on-board, which they call L3.

Main memory is normally installed in the form of SIMMs (Single Inline Memory Modules), DIMMs (Dual Inline Memory Modules), or RIMMs (Rambus Inline Memory Modules). Three different physical types of main memory modules are used in PC systems today, with several variations of each. The three main types are as follows:

- 72-pin SIMMs (EDO RAM)
- 168-pin DIMMs (SDRAM)
- 184-pin RIMMs (RDRAM)

The 168-pin SDRAM DIMMs are by far the most common type of memory module used today; however, just a few years ago, most systems came with 72-pin EDO SIMMs. Most systems use the DIMMs because they are 64 bits wide and can be used as a single bank on a Pentium or higher-class processors that have a 64-bit external data bus. Some of the newest and fastest systems use the RDRAM RIMMs, which offer the greatest performance of the available memory types.

Double Data Rate (DDR) SDRAM memory is a new design of standard SDRAM in which data is transferred twice as fast. DDR support is found in the newest server chipsets from Intel and others.

◀◀ See "Physical RAM Memory," p. 454.

◀◀ See "DDR SDRAM," p. 452.

A 64-bit Pentium class system requires two 72-pin SIMMs (32 bits wide each) or a single 168-pin DIMM (64 bits wide) to make a single bank.

Memory modules can include an extra bit for each eight for parity checking or ECC use. Make sure your chipset (and motherboard) supports ECC before purchasing the more expensive ECC modules.

◀◀ See "Parity and ECC," p. 477.

Another thing to watch out for is the type of metal on the memory module contacts. They are available with either tin- or gold-plated contacts. Although it might seem that gold-plated contacts are better (they are), you should not use them in all systems. You should instead always match the type of plating on the module contacts to what is also used on the socket contacts. In other words, if the motherboard SIMM, DIMM, or RIMM sockets have tin-plated contacts, you must use modules with tin-plated contacts. Most motherboards with SIMM sockets used tin-plated ones requiring tin-plated SIMMs, whereas most DIMM and RIMM sockets are gold-plated, requiring gold-plated DIMMs and RIMMs.

If you mix dissimilar metals (tin with gold), corrosion on the tin side is rapidly accelerated, and tiny electrical currents are generated. The combination of the corrosion and tiny currents causes havoc, and all types of memory problems and errors may occur. In some systems, I have observed that everything seems fine for about a year, during which the corrosion develops. After that, random memory errors result. Removing and cleaning the memory module and socket contacts postpones the problem for another year, and then the problems return again. How would you like this problem if you have 100 or more systems to support? Of course, you can avoid these problems if you insist on using SIMMs with contacts whose metal matches the metal found in the sockets in which they will be installed.

◀◀ See "Gold Versus Tin," p. 473.

For more information on PC memory of all types, see Chapter 6, "Memory."

I/O Ports

Most motherboards today have built-in I/O ports. If these ports are not built in, they will have to be supplied via a plug-in expansion board that, unfortunately, wastes an expansion slot. The following ports should be included in any new system you assemble:

- Keyboard connector (mini-DIN type)
- Mouse port (mini-DIN type)
- One or two serial ports (16550A buffered UART type)
- Parallel port (EPP/ECP type)
- Dual USB ports
- Optional display connector (integrated video)
- Optional audio/game connectors (MIDI/joystick, speaker, and microphone)
- Two local bus enhanced IDE ports (primary and secondary)
- Floppy controller

Many motherboards feature the optional integrated video and sound interfaces.

All the integrated ports are supported either directly by the motherboard chipset or by an additional Super I/O chip and additional interface components. Adding the optional video and sound interfaces directly to the motherboard saves both money and the use of an expansion slot, especially important in the less expensive systems sold today.

If these devices are not present on the motherboard, various Super I/O or multi-I/O boards that implement all these ports are available. Again, most of the newer versions of these boards use a single-chip implementation because it is cheaper and more reliable.

◀◀ See “Super I/O Chips,” p. 300.

It has become an increasingly popular practice in recent years (especially in Slimline-style systems) to integrate other standard computer functions into the motherboard design, such as video, sound, and even network adapters. The advantages of this practice include freeing up expansion slots that would normally be occupied by separate adapter cards and saving money. The price difference between a motherboard with integrated video and sound and one without would be far less than the cost of good-quality sound and video cards.

The drawback, of course, is that you have little or no choice about the features or quality of the integrated adapters. Integrated components like these are nearly always of serviceable quality, but they certainly do not push the performance envelope of higher end expansion cards. Most people who decide to build a system themselves do so because they want optimum performance from every component, which you do not get from integrated video and sound.

Buying a motherboard with integrated adapters, however, does not preclude you from adding expansion devices of the same type. You can usually install a video or sound card into a system with an integrated sound adapter without major problems, except that the additional cost of the integrated component is wasted. You may also encounter difficulties with the automated hardware detection routines in operating systems, such as Windows 9x detecting the wrong adapter in your system, but you can remedy this by manually identifying the expansion card to the OS.

Note that if your motherboard has integrated devices such as video and sound, you must normally go into the BIOS Setup to disable these devices if you want to add a card-based replacement device. Check your BIOS Setup menus for an Enable/Disable setting for any integrated devices.

A trend with some newer low-cost systems is the complete elimination of the Super I/O chip and all the integrated ports contained within. These are called legacy-free PCs and lack any serial ports, parallel ports, and standard keyboard and mouse connections. All external expansion must be done via the USB ports. This means your keyboard, mouse, printer, external modem, and so on must be of the USB type.

Floppy Disk and Removable Drives

Since the advent of the CD-ROM, the floppy disk drive has largely been relegated to a minor role as an alternative system boot device. Usually, today's systems are equipped with a 1.44MB 3 1/2-inch drive, but 2.88MB drives and 120MB SuperDisk drives are also available. All boards today have full support for the LS-120 (SuperDisk) drives, which is a floppy drive that can read and write not only the standard 720KB and 1.44MB formats, but a high-capacity 120MB format as well, because, unlike Zip drives, they are fully BIOS supportable and therefore bootable. They are a true non-proprietary industry standard, and they are much more reliable than Zip drives. I recommend the SuperDisk drives over Zip unless you must exchange data with other systems that already have Zip drives.

There is another advantage of the SuperDisk drive over Zip. Since the SuperDisk drive functions as a standard floppy as well as a 120MB floppy, you don't need a standard floppy along with a SuperDisk drive. If you use a Zip drive, you will need to install a conventional floppy for backward compatibility, system configuration, and system maintenance issues. Note that many newer motherboards only support a single floppy drive, not two like in most previous boards.

For additional removable storage, I recommend a CD-RW (CD-Rewritable) drive. These are now relatively inexpensive and the media is low priced as well. A CD-RW drive can also write on even more inexpensive CD-R media. This allows an easy way to back up or archive up to 700MB of data (74-minute CDs hold 650MB, whereas 80-minute CDs hold 700MB).

Hard Disk Drive

Your system also needs at least one hard disk drive. In most cases, a drive with a minimum capacity of 10GB is recommended, although in some cases you can get away with less for a low-end configuration. High-end systems should have drives of 20GB or higher. One of the cardinal rules of computer shopping is that you can never have too much storage. Buy as much as you can afford, and you'll almost certainly end up filling it anyway.

Tip

If you are an Internet user, one informal method of estimating how much disk space you will need is to go by the speed of your Internet connection. If you have a high-speed link such as that provided by an ISDN connection, a cable modem, or a LAN, you will find that the ease of downloading large amounts of data fills disk drives amazingly quickly. I would recommend at least a 20GB hard drive in these cases, and a removable storage system with a large capacity, such as a CD-RW drive, is also a good idea.

The most popular hard drive interface for desktop systems is ATA (IDE), though SCSI is preferable for use with multitasking OSs. ATA generally offers greater performance for single-drive installations, but SCSI is better for use with two or more drives or with multitasking operating systems such as Windows 95/98/Me and NT/2000. This is because of the greater intelligence in the SCSI interface, which removes some of the I/O processing burden from the system's CPU. This is especially important if you are using Windows NT or Windows 2000 in a server role, where it is supporting multiple users and much heavier file access.

Note

In most cases, a system's ATA adapter is integrated into the motherboard. With SCSI, this is much less common. Although it is sometimes possible to purchase a motherboard with an integrated SCSI adapter, you are more likely to have to purchase a separate SCSI host adapter and install it into one of your system's expansion slots. It is recommended that you select a SCSI adapter that uses the fastest expansion bus that your system supports, which in most cases today is PCI. Good-quality SCSI host adapters are considerably more complex than are ATA/IDE adapters and are therefore more expensive. Be sure to consider this additional expense and the need for an additional slot when deciding on a hard drive interface for your system.

SCSI adapters and hard disk drives cost considerably more than their ATA counterparts, but they offer greater expandability (up to seven or even 15 devices per SCSI card, depending on the SCSI type) and better performance when several different processes are accessing the same devices. If you are building a relatively simple standalone system containing one or two hard disk drives and a CD-ROM, ATA is probably more than sufficient for your needs. However, if you plan on adding other peripherals such as tape drives, cartridge drives, and scanners, or if you plan to share your drives with other users over a network, SCSI might be a worthwhile investment.

Tip

For removable storage devices that require a consistent stream of data to function properly, such as CD-RW and tape drives, SCSI is strongly recommended. ATA devices do not handle multiple tasks nearly as well as SCSI and can result in buffer underruns, slower data transfer rates, and less efficient storage capacity when used with these types of devices.

◀◀ See "How to Reliably Make CD-Rs," p. 778.

◀◀ See "SCSI Versus IDE," p. 576.

There are several brands of high-quality hard disk drives to choose from, and most of them offer similar performance within their price and capacity categories. In fact, you may notice that the capacities and specifications of the various ATA and SCSI drives offered by certain manufacturers are remarkably similar. This is because a single drive assembly is manufactured for use with both interfaces. The same ATA drive, for example, with the addition of a SCSI interface chip on the logic board, becomes a SCSI drive, often at a substantially higher price.

CD/DVD-ROM Drive

A CD or DVD-ROM drive should be considered a mandatory item in any PC you construct these days. This is because virtually all software is now being distributed on CD-ROM, and many newer titles are on DVD. DVD drives can read CD-ROMs as well as DVD-ROMs, so they are more flexible. Systems can now even boot from CD-ROM drives as long as the system BIOS provides the proper support.

DVD-ROM is a high-density data storage format that uses a CD-sized disc to store a great deal more data than a CD-ROM—from 4.7 to 17GB, depending on the format. These drives can read standard CD-ROMs and audio CDs, as well as the higher-capacity DVD data and video discs.

◀◀ See “DVD (Digital Versatile Disc),” p. 786.

There are several types of CD-ROM or DVD drives to consider these days, but I generally recommend a minimum of a 32x CD-ROM or a 4x DVD-ROM drive connected using the integrated ATA interface found on all modern motherboards. This results in the best possible performance with the minimum amount of hassle. If you plan on using SCSI for your hard drives, however, you might want to select an SCSI CD- or DVD-ROM drive; you’ll improve your multitasking performance.

You might also consider purchasing a rewritable CD-ROM drive, generally known as a CD-RW drive. If you do, I recommend you get this in addition to your existing CD-ROM or DVD-ROM drive—that way you can easily copy existing CDs. This is also a good idea because the recordable drives are usually much slower than the ROM-only versions.

CD-R/RW

Burning your own CDs can be a convenient and relatively inexpensive data storage method. Drives advertised as CD-RW handle both CD-RW (rewritable) and CD-R (record once) media. Note that many older CD-ROM drives cannot read CD-RW media, whereas virtually all drives can read CD-R discs. Drives that conform to the multiread specification will be able to read both CD-R and RW discs with no problems. Initially read problems arose because the reflection rate of the disc is only 25–35 percent that of a standard CD.

Keyboard and Pointing Device (Mouse)

Obviously, your system needs a keyboard and some type of pointing device, such as a mouse. Different people prefer different types of keyboards, and the “feel” of one type can vary considerably from other types. If possible, I suggest you try a variety of keyboards until you find the type that suits you best. I prefer a stiff action with tactile feedback myself, but others prefer a lighter, quieter touch.

Because two types of keyboard connectors are found in systems today, make sure that the keyboard you purchase matches the connector on your motherboard. Most Baby-AT boards use the larger five-pin DIN connector, and most ATX boards use the six-pin, mini-DIN connector; however, the trend now seems to be changing to the mini-DIN connector for all boards. On some motherboards, you have an option of choosing either connector when you purchase the board. If you end up with a keyboard and motherboard that do not match, there are several companies that sell adapters to mate either type of keyboard to either type of motherboard connector. You can also purchase extension cables for both keyboards and mice that enable you to comfortably

place a tower system under a desk or table while the keyboard and mouse remain on the work surface.

- ◀◀ See “Keyboards,” p. 952.
- ◀◀ See “Keyboard Technology,” p. 957.

The same selection concept also applies to mice or other pointing devices; there are a number of different choices that suit different individuals. Try several before deciding on the type you want. If your motherboard includes a built-in mouse port, make sure you get a mouse designed for that interface. This mouse is often called a PS/2 type mouse because the IBM PS/2 systems introduced this type of mouse port. Many systems use a serial mouse connected to a serial port, but a motherboard-integrated mouse port is preferable because it leaves both serial ports free for other devices.

Note that it is possible to purchase keyboards and mice that plug into the USB connector, but I normally don't recommend these unless your system lacks the standard mini-DIN keyboard and mouse ports.

Tip

You might be tempted to skimp on your keyboard and mouse in order to save a few dollars. Don't! You do all your interacting with your new PC through these devices, and cheap ones make their presence known every time you use your system. I insist on high-quality mechanical switch type keyboards on all my systems.

- ◀◀ See “USB Keyboards and Mice,” p. 968.

Video Card and Display

You need a video adapter and a monitor or display to complete your system. There are numerous choices in this area, but the most important piece of advice I have to give is to choose a good monitor. The display is your main interface to the system and can be the cause of many hours of either pain or pleasure, depending on what monitor you choose.

I usually recommend a minimum of a 17-inch display these days. Anything smaller cannot acceptably display a 1,024×768 pixel resolution. If you opt for a 15-inch or smaller display, you might find that the maximum tolerable resolution is 800×600. This may be confusing because many 15-inch monitors are capable of displaying 1,024×768 resolution or even higher, but the characters and features are so small onscreen at that resolution that excessive eyestrain and headaches are often the result. If you spend a lot of time in front of your system and want to work in the higher screen resolutions, a 17-inch display should be considered mandatory. If you can afford it, I recommend a 19-inch display; they work even better at the higher resolutions and have come down in price somewhat from previous years.

Your video card and monitor should be compatible in terms of refresh rate. The minimum refresh rate for a solid, nonflickering display is 70–72Hz—the higher the better. If your new video card can display 16 million colors at a resolution of 1,024×768 and a refresh rate of 76Hz, but your monitor's maximum refresh rate at 1,024×768 is 56Hz, you can't use the video card to its maximum potential. Configuring a video adapter to deliver signals that the monitor cannot support is one of the few software configuration processes that can physically damage the system hardware. Pushing a monitor beyond its capabilities can cause it irreparable harm.

Video adapters in recent years have become standardized on the accelerated graphics port (AGP) interface, although many older systems used PCI-based video cards. You may need to use a PCI video card if you are adding a secondary video adapter to your system to run a second monitor. Windows 98, Me, and 2000 support this feature and it can be very useful for some applications.

If you are into gaming, you will want one of the high-performance 3D video cards on the market. Modern games are very video-intensive, so be sure to check with the game software companies as to what cards they would recommend. It is possible to use separate cards for 2D and 3D graphics (by linking the cards), but I recommend getting a single 2D/3D combination card; they are much easier to set up and generally work better.

◀◀ See "Accelerated Graphics Port (AGP)," p. 338.

◀◀ See "3D Graphics Accelerators," p. 900.

Sound Card and Speakers

You need a sound card and a set of external speakers for any system that you want to be multi-media capable. Although the sound card should be compatible with the Creative Labs Sound Blaster cards, which set the early standards for DOS audio, it is increasingly important to purchase a sound card that is compatible with Windows-based sound APIs, such as DirectX and A3D. Getting a sound card with upgradable memory (the same SIMMs you use for your main memory) enables you to download additional sound samples. For best performance, I recommend you get a PCI-based sound card instead of an older ISA bus design. There can be some problems with support for older DOS-based games with some of the new cards, but most of these issues have been addressed by special drivers for the newer cards.

Speakers designed for use with PCs range from tiny, underpowered devices to large audiophile systems. Many of the top manufacturers of stereo speakers are now producing speaker systems for PCs. Let your budget be your guide.

USB Peripherals

The Universal Serial Bus (USB) promises to render the standard I/O ports on the PC obsolete. Essentially, USB brings PnP support to external peripherals by enabling you to plug up to 127 devices into a single port supporting data transfer rates up to 12Mbps. Typically, you plug in a

USB hub to a port integrated into the motherboard, and then plug other devices into that. Virtually all current motherboards support USB, and there are numerous external USB devices to connect.

◀◀ See “USB and 1394 (i.Link) FireWire—Serial and Parallel Port Replacements,” p. 940.

There are virtually no limits to the types of devices available for USB. Modems, keyboards, mice, CD-ROM drives, speakers, joysticks, tape and floppy drives, scanners, cameras, and printers are just some of the devices available. However, before you start buying all USB peripherals for your new system, be aware that there can be performance problems with a lot of devices on a single bus, and sometimes compatibility problems as well.

Accessories

Apart from the major components, you need a number of other accessories to complete your system. These are the small parts that can make the assembly process a pleasure or a chore. If you are purchasing your system components from mail-order sources, you should make a complete list of all the parts you need, right down to the last cable and screw, and be sure you have everything before you begin the assembly process. It is excruciating to have to wait several days with a half-assembled system for the delivery of a forgotten part.

Heat Sinks/Cooling Fans

Most of today's faster processors produce a lot of heat, and this heat has to be dissipated or your system will operate intermittently or even fail completely. Heat sinks are available in two main types: passive and active.

Passive heat sinks are simply finned chunks of metal (usually aluminum) that are clipped or glued to the top of the processor. They act as a radiator and, in effect, give the processor more surface area to dissipate the heat. I normally recommend this passive-design type of heat sink because there are no mechanical parts to fail; however, an active heat sink does cool better for a given size. Often you will have no control over which heat sink you use because it comes already attached to the processor. If you have to attach it yourself, you should use a thermal transfer grease or sticky tape to fill any air gaps between the heat sink and the processor. This allows for maximum heat transfer and the best efficiency.

An active heat sink includes a fan. These can offer greater cooling capacity than the passive types, and some processors are sold with the fan already attached. If you rely on a CPU fan to cool your processor, be sure to buy a high-quality one that runs from the computer's internal power. I've seen some battery-operated fans, and even some lower-quality system-powered ones, fail without warning; this can result in damage to the processor from excessive heat.

Note

The newer ATX form factor motherboards and chassis are designed to improve system cooling. These systems move the processor and memory near the power supply for better cooling. They often feature secondary case-mounted cooling fans for extra insurance. Note that many processors today come with the heat sink integrated as a part of the unit, often an active type with a high-quality ball bearing cooling fan built-in.

Another consideration for cooling is with the case. The fan in the power supply and optionally one on the CPU heat sink are often not enough for a modern high-performance system. I recommend you get a case that includes at least one additional cooling fan. This will normally be mounted in the front of the chassis, taking air in from the front and directing it over the motherboard. Some cases include extra fans near the drive bays for cooling the drives as well.

If you are upgrading an existing system, there are several companies that make fan assemblies that insert into a drive bay for additional cooling. They take the place of a 5 1/4-inch drive and take air in through the front bezel, directing it back into the case. There are even fan assemblies mounted on cards, which blow air out the rear of the case. Keep in mind that it is best to keep the interior of the PC below 100° F; anything over 110° will dramatically reduce component life and lead to stability problems.

Cables

PC systems need a number of different cables to hook up everything. These can include power cables or adapters, disk drive cables, internal or external CD-ROM cables, and many others. Most of the time, the motherboard will include the cables for any of the internal ports such as floppy or hard drives; other external devices you purchase will come with included cables, but in some cases, they aren't supplied. The Vendor List, on the CD, contains contact information for several cable and small parts suppliers that can get you the cables or other parts you need to complete your system.

Another advantage of the ATX motherboard form factor is that these boards feature externally accessible I/O connectors directly mounted to the rear of the board. This eliminates the "rat's nest" of cables found in the common Baby-AT form factor systems and also makes the ATX system a little cheaper and more reliable.

If you build your system using all OEM (what the industry calls "white box") components, be aware that these sometimes don't include the accessories such as cables and additional documentation that you would get with a normal boxed-retail version of the same component.

Hardware

You will need screws, standoffs, mounting rails, and other miscellaneous hardware to assemble your system. Most of these parts are included with the case or your other system components. This is especially true of any card or disk drive brackets or screws. When you purchase a component such as a hard drive, some vendors offer you the option of purchasing the bare drive or a kit containing the required cables and mounting hardware for the device. Most of the time bare drives don't include any additional hardware, but you might not need it anyway if the mounting hardware comes with your case. Even so, spending the few additional dollars for the complete drive kit is rarely a waste of money. Even if you're left with some extra bits and pieces after assembling your system, they will probably come in handy someday.

In situations where you need other hardware not included with your system components, you can consult the Vendor List for suppliers of small parts and hardware needed to get your system operational.

Hardware and Software Resources

When you are planning to build a system, it is important to consider how all your selected components will work together and how the software you run must support them. It is not enough to be sure that you have sufficient slots on the motherboard for all your expansion cards and enough bays in the case for all your drives. You must also consider the resources required for all the components.

For example, not only should you be certain that you have enough hardware interrupts (IRQs) to support all your components, you should also know which IRQs are supported by each device. Otherwise, you might find yourself stuck with hardware that you can't install, even though you have interrupts free. Essentially, you should completely configure the system before you begin ordering any parts. Planning a system to this level of detail can be a lot of work, which is one reason why the vast majority of PCs are prebuilt.

Another consideration is the operating system and other software you will need. Prebuilt systems nearly always arrive with the operating system installed, but when you build your own, you must be prepared with a copy of your selected operating system, including a system disk so that you can boot the system the first time. Since nearly any operating system in use today is distributed on CD-ROM, you'll have to get your computer to recognize the CD-ROM drive before you can install an operating system. To make this process simpler, you might want to create a bootable CD.

◀◀ See "Making a Bootable CD-ROM for Emergencies," p. 804.

The operating system that you select for your new computer is another important decision. You must be certain that the OS supports all the hardware you've selected, which can occasionally be a difficult task. If, for example, you intend to use USB devices, you must run, at the very least, Windows 95 OSR 2.1 (95B), which consists of the operating system plus an additional USB support module. To obtain the Windows 95 OSR 2 release, you must purchase it with a new system or, alternatively, a new motherboard or hard drive. Fortunately, USB support is fully integrated into the Windows 98 retail product.

Windows 98, 98SE (Second Edition), Millennium Edition (Me), Windows NT 4.0, and Windows 2000 come on bootable CD-ROMs if you get what is called the OEM version of the operating system. The so-called retail or upgrade editions are often restricted, aren't bootable, and may also search for preexisting files or operating systems before they will load. Since Microsoft doesn't allow OEM versions of its operating systems to be sold separately, make sure you get an OEM edition of whatever operating system you will be running with your motherboard or hard disk. The terms of the Microsoft dealer (or system builder) agreement allows dealers to sell the OS only with a PC, and the terms of the agreement state that a motherboard or hard disk qualify as enough of a PC to allow an operating system bundle. No matter what, make sure you get the original OEM version on CD-ROM.

If you don't have the OEM version of your OS, or the system you are assembling does not support booting from CD (called El Torito support after the Phoenix-created standard), you will need to create a boot floppy with CD-ROM drivers. Windows 98 and Windows 2000 include a diskette

with a set of universal CD-ROM drivers that will work for most systems; for Windows 95 and older operating systems, you will need to either borrow a Windows 98 startup disk or create your own bootable floppy with the right drivers.

I'll cover this in more detail when we get to the OS load section of the building process.

Drivers for specific hardware components might also be a problem. It is a good idea to gather all the latest driver revisions for your hardware, as well as BIOS flashes, firmware updates, and other software components and have them available when you begin the assembly process. Floppy disks are preferable for this, because your CD-ROM drive and connectivity hardware may not yet be operative.

System Assembly and Disassembly

Actually assembling the system is easy after you have lined up all the components! In fact, you will find the parts procurement phase the most lengthy and trying of the entire experience. Completing the system is basically a matter of screwing everything together, plugging in all the cables and connectors, and configuring everything to operate properly together.

In short order, you will find out whether your system operates as you had planned or whether there are some incompatibilities between some of the components. Be careful and pay attention to how you install all your components. It is rare that a newly assembled system operates perfectly the first time, even for people who are somewhat experienced. It is very easy to forget a jumper, switch, or cable connection that later causes problems in system operation. Most people's first reaction when there are problems is to blame defective hardware, but that is usually not the source. Usually, the problem can be traced to some missed step or error made in the assembly process.

Above all, the most crucial rule of assembling your own system is to save every piece of documentation and software that comes with every component in your system. This material can be indispensable in troubleshooting problems you encounter during the assembly process or later. You should also retain all the packing materials used to ship mail order components to you until you are certain that they will not have to be returned.

Assembly Preparation

The process of physically assembling a PC requires only a few basic tools: a 1/4-inch nut driver or Phillips-head screwdriver for the external screws that hold the cover in place and a 3/16-inch nut driver or Phillips-head screwdriver for all the other screws. Needle-nose pliers can also help in removing motherboard standoffs, jumpers, and stubborn cable connectors. Because of marketplace standardization, only a couple different types and sizes of screws (with a few exceptions) are used to hold a system together. Also, the physical arrangement of the major components is similar even among different manufacturers. Figure 24.1 shows the components that go into a typical system, and Figure 24.2 shows the system with those components assembled. Note that the components shown here are for a standard PC. You might want to add a sound card (for higher-quality sound) or a modem. Your final component list might vary.

Figure 24.1 Components used in building a typical PC. *Case and power supply courtesy of PC Power & Cooling, Inc. Motherboard and processor courtesy of Intel Corporation. Other components supplied by Micro X-Press (www.microx-press.com) and Creative Labs, Inc.*

Other tools you'll need are software related. You'll need the master operating system CD-ROM, and if your particular CD-ROM version isn't bootable, or your system is older and doesn't support booting from CD, you'll also need an operating system startup floppy disk with CD-ROM drivers installed. This way, your system will recognize the CD-ROM drive and allow you to install the operating system from it. Newer operating systems often come on bootable CDs, but normally only the OEM (and not retail) versions of the OS are configured that way.

Figure 24.2 The completed system using all components shown in Figure 24.1. *Case and power supply courtesy of PC Power & Cooling, Inc. Motherboard and processor courtesy of Intel Corporation. Other components supplied by Micro X-Press (www.microx-press.com).*

The Windows 98, Millennium Edition, and 2000 startup floppies include generic ATAPI and SCSI CD-ROM drivers on them, allowing virtually all CD-ROMs to be recognized after booting from them. If you are installing Windows 95 or some other operating system that does not include a startup disk with CD-ROM drivers already installed, you can either use a Win98 or 2000 startup disk, or take your existing startup disk and install the CD-ROM drivers that came with your drive. That procedure is covered later in this chapter.

The following sections cover the assembly and disassembly procedure:

- Case or cover assembly
- Power supply
- Adapter boards
- Motherboard
- Disk drives

Later, you will learn how to install and remove these components for several different types of systems. With regard to assembly and disassembly, it is best to consider each system by the type of case that it uses. All systems that have AT-type cases, for example, are assembled and disassembled in much the same manner. Tower cases are basically AT-type cases turned sideways, so the same basic instructions apply. Most Slimline and XT-style cases are similar; these systems are assembled and disassembled in much the same way.

The following section lists assembly and disassembly instructions for several case types.

ESD Protection

One issue you must be aware of is ESD (electrostatic discharge) protection. The other is recording the configuration of the system, with regard to the physical aspects of the system (such as jumper or switch settings and cable orientations) and to the logical configuration of the system (especially in terms of elements such as CMOS settings).

When you are working on the internal components of a computer, you need to take the necessary precautions to prevent accidental static discharges to the components. At any time, your body can hold a large static voltage charge that can easily damage components of your system. Before I ever put my hands into an open system, I first touch a grounded portion of the chassis, such as the power supply case. This action serves to equalize the electrical charges that the device and your body may be carrying. Be sure the power supply is unplugged during all phases of the assembly process. Some will claim that you should leave the system plugged in to provide an earth ground through the power cord and outlet, but that is unnecessary.

By touching the chassis or using a wrist strap connecting you and the chassis, all electrical charges will be equalized. It is not important to be earth grounded; the only thing that is important is that you and the components you are working on carry the same relative charge. If you leave the system plugged in, you open yourself up to other problems such as accidentally turning it on or leaving it on when installing a board or device, which can damage the motherboard or other devices.

Caution

Also note that ATX power supplies used in many systems today deliver a +5v current to the motherboard continuously—that is, whenever they are plugged in. Bottom line: Make sure any system you are working on is completely unplugged from the wall outlet.

High-end workbenches at repair facilities have the entire bench grounded, so it's not as big of a problem; however, you need something to be a good ground source to prevent a current from building up in you.

A more sophisticated way to equalize the charges between you and any of the system components is to use an ESD protection kit. These kits consist of a wrist strap and mat, with ground wires for attachment to the system chassis. When you are going to work on a system, you place the mat next to or partially below the system unit. Next, you clip the ground wire to both the mat and the system's chassis, tying the grounds together. You then put on the wrist strap and attach that wire to a ground. Because the mat and system chassis are already wired together, you can attach the wrist-strap wire to the system chassis or to the mat. If you are using a wrist strap

without a mat, clip the wrist-strap wire to the system chassis. When clipping these wires to the chassis, be sure to use an area that is free of paint so a good ground contact can be achieved. This setup ensures that any electrical charges are carried equally by you and any of the components in the system, preventing the sudden flow of static electricity that can damage the circuits.

As you install or remove disk drives, adapter cards, and especially delicate items such as the entire motherboard, SIMMs, or processors, you should place these components on the static mat. Sometimes people put the system unit on top of the mat, but the unit should be alongside the mat so you have room to lay out all the components as you work with them. If you are going to remove the motherboard from a system, be sure that you leave enough room for it on the mat.

If you do not have such a mat, place the removed circuits and devices on a clean desk or table. Always pick up a loose adapter card by the metal bracket used to secure the card to the system. This bracket is tied into the ground circuitry of the card, so by touching the bracket first, you prevent a discharge from damaging the components of the card. If the circuit board has no metal bracket (a motherboard, for example), handle the board carefully by the edges, and try not to touch any of the connectors or components. If you don't have proper ESD equipment such as a wrist strap or mat, be sure to periodically touch the chassis while working inside the system to equalize any charge you might have built up.

Caution

Some people recommend placing loose circuit boards and chips on sheets of aluminum foil. I absolutely *do not recommend* this procedure because it can actually result in an explosion! Many motherboards, adapter cards, and other circuit boards today have built-in lithium or NiCad batteries. These batteries react violently when they are shorted out, which is exactly what you would be doing by placing such a board on a piece of aluminum foil. The batteries will quickly overheat and possibly explode like a large firecracker (with dangerous shrapnel). Because you will not always be able to tell whether a board has a battery built into it somewhere, the safest practice is to never place any board on any conductive metal surface.

Recording Physical Configuration

While you are assembling a system, it is a good idea to record all the physical settings and configurations of each component, including jumper and switch settings, cable orientations and placement, ground-wire locations, and even adapter board placement. Keep a notebook handy for recording these items, and write down all the settings.

It is especially important to record all the jumper and switch settings on every card that you install in the system, as well as those on the motherboard. If you accidentally disturb these jumpers or switches, you will know how they were originally set. This knowledge is very important if you do not have all the documentation for the system handy. Even if you do, undocumented jumpers and switches often do not appear in the manuals but must be set a certain way for the item to function. Also, record all cable orientations. Most name-brand systems use cables and connectors that are keyed so that they cannot be plugged in backward, but some generic PCs do not have this added feature. In addition, it is possible to mix up hard disk and floppy cables. You should mark or record what each cable was plugged into and its proper orientation. Ribbon cables usually have an odd-colored (red, green, blue, or black) wire at one end that indicates pin 1. There may also be a mark on the connector such as a triangle or even the number 1.

The devices the cables are plugged into are also marked in some way to indicate the orientation of pin 1. Often, there will be a dot next to the pin 1 side of the connector, or there might be a 1 or other mark.

Although cable orientation and placement seem to be very simple, we rarely get through the entire course of my PC troubleshooting seminars without at least one group of people having cable-connection problems. Fortunately, in most cases (except power cables), plugging any of the ribbon cables inside the system backward rarely causes any permanent damage.

Power and battery connections are exceptions; plugging them in backward in most cases will cause damage. In fact, plugging the motherboard power connectors in backward or in the wrong plug location will put 12v where only 5v should be—a situation that can cause components of the board to violently explode. I know of several people who have facial scars caused by shrapnel from exploding components caused by improper power supply connections! As a precaution, I always turn my face away from the system when I power it on for the first time. If you are using an ATX board and power supply, there is little chance of this happening because of the superior type of power connector used.

Plugging in the CMOS battery backward can damage the CMOS chip, which usually is soldered into the motherboard; in such a case, the motherboard must be replaced.

Finally, it is a good idea to record miscellaneous items such as the placement of any ground wires, adapter cards, and anything else that you might have difficulty remembering later. Some configurations and setups might be particular about the slots in which the adapter cards are located; it usually is a good idea to put everything back exactly the way it was originally.

Motherboard Installation

When you are installing your system's motherboard, unpack the motherboard and check to make sure you have everything that should be included. If you purchase a new board, normally you get at least the motherboard, some I/O cables, and a manual. If you ordered the motherboard with a processor or memory, it will normally be installed on the board for you but may also be included separately. Some board kits will include an anti-static wrist strap to help prevent damage due to static electricity when installing the board.

Prepare the New Motherboard

Before your new motherboard is installed, you should install the processor and memory. This will normally be much easier to do before the board is installed in the chassis. Some motherboards have jumpers that control both the CPU speed and the voltage supplied to it. If these are set incorrectly, the system might not operate at all, might operate erratically, or might possibly even damage the CPU. If you have any questions about the proper settings, contact the vendor who sold you the board before making any jumper changes.

◀◀ See "CPU Operating Voltages," p. 114.

Most processors today run hot enough to require some form of heat sink to dissipate heat from the processor. To install the processor and heat sink, use the following procedures:

1. Take the new motherboard out of the anti-static bag it was supplied in, and set it on the bag or the anti-static mat, if you have one.

2. Install the processor. There are two procedures, one for socketed processors, the other for slot-based processors. Follow the appropriate instructions for the type you are installing.
- *For socketed processors, the procedure is as follows:* Find pin 1 on the processor; it is usually denoted by a corner of the chip that is marked by a dot or a bevel. Next, find the corresponding pin 1 of the ZIF socket for the CPU on the motherboard; it is also usually marked on the board, or there may be a bevel in one corner of the socket. Insert the CPU into the ZIF socket by lifting the release lever until it is vertical. Then align the pins on the processor with the holes in the socket and drop it down into place. If the processor does not go all the way into the socket, check for possible interference or pin-alignment problems, but make sure it is fully seated and there is no gap between the bottom of the processor and the socket. If the processor does not seem to want to drop in all the way, remove it to check for proper alignment and any possibly bent pins. If necessary, use small needle-nose pliers or a hemostat to carefully straighten any pins. Don't bend them too much or they will break off. When the processor is fully seated in the socket, push the locking lever on the socket down until it latches to secure the processor.
 - *For slot-based processors, the procedure is different.* You will need the processor, the universal retention mechanism brackets with included fasteners, and the heat sink supports. Most slot-based processors already come with either an active or a passive heat sink already installed. Start by positioning the two universal retention mechanism brackets on either side of the processor slot so that the holes in the brackets line up with the holes in the motherboard (see Figure 24.3). Push the included fasteners through the mounting holes in the retention bracket and the motherboard until you feel them snap into place. Insert the fastener retainer pins through the holes in the fastener to lock them into place. Then slide the processor/heat sink down between the brackets until it is firmly seated in the slot. The latches on the top sides of the processor will lock into place when the processor is fully seated. Install the heat sink supports into the holes provided in the motherboard and processor.

Figure 24.3 Universal Retention Mechanism for slot-based processors. *Illustration used by permission of Intel Corporation.*

If the CPU does not already have a heat sink attached to it, attach it now. Most heat sinks will clip either directly to the CPU or to the socket with one or more retainer clips (see Figure 24.4). Be careful when attaching the clip to the socket; you don't want it to scrape against the motherboard, which might damage circuit traces or components. In most cases, it is a good idea to put a dab of heat sink thermal transfer compound (normally a white-colored grease) on the CPU before installing the heat sink. This prevents any air gaps and allows the heat sink to work more efficiently. If the CPU has an active heat sink (with a fan), plug the fan power connector into one of the fan connectors supplied on the motherboard (see Figure 24.5). Optionally some heat sinks use a disk drive power connector for fan power.

Figure 24.4 Installing a slot-based (Single Edge Contact Cartridge or SECC) processor. *Motherboard and processor courtesy of Intel Corporation.*

Figure 24.5 Attaching the heat sink fan power connector. *Motherboard and processor courtesy of Intel Corporation.*

3. Refer to the motherboard manufacturer's manual to set the jumpers, if any, to match the CPU you are going to install. Look for the diagram of the motherboard to find the jumper location, and look for the tables for the right settings for your CPU. If the CPU was supplied already installed on the motherboard, the jumpers should already be correctly set for you, but it is still a good idea to check them.

Install Memory Modules

In order to function, the motherboard must have memory installed on it. Modern motherboards use either DIMMs or RIMMs. Depending on the module type, it will have a specific method of sliding into and clipping to the sockets. Normally, you install modules in the lowest-numbered sockets or banks first. Note that some boards will require modules to be installed in pairs or even four at a time. Consult the motherboard documentation for more information on which sockets to use first and in what order and how to install the specific modules the board uses.

◀◀ See "Memory Banks," p. 471.

Memory modules are normally keyed to the sockets by a notch on the side or on the bottom, so they can go in only one way. Figure 24.6 shows how to install a DIMM or RIMM. More detailed instructions for installing DIMMs, RIMMs, and SIMMs can be found in Chapter 6.

Figure 24.6 Installing the memory modules. *Motherboard courtesy of Intel Corporation.*

Caution

Be careful not to damage the connector. If you damage the motherboard memory connector, you could be facing an expensive repair. Never force the module; it should come out easily. If it doesn't, you are doing something wrong.

Mount the New Motherboard in the Case

The motherboard attaches to the case with one or more screws and often several plastic standoffs. If you are using a new case, you might have to attach one or more metal spacers or plastic standoffs in the proper holes before you can install the motherboard. Use the following procedure to install the new motherboard in the case:

1. Find the holes in the new motherboard for the metal spacers and plastic standoffs. You should use metal spacers wherever there is a ring of solder around the hole. Use plastic standoffs where there is no ring of solder (see Figure 24.7). Screw any metal spacers into the new case in the proper positions to align with the screw holes in the motherboard.

Figure 24.7 Make sure the standoffs align with the holes in the motherboard. *Motherboard courtesy of Intel Corporation.*

2. Most motherboards today attach directly to the chassis or to a removable motherboard tray with screws that thread into brass standoffs attached to the chassis or tray. Figure 24.8 shows three different types of standoffs, including two brass types and one plastic. One screws directly to the chassis or tray, whereas the others attach to the motherboard and then slide into notches in the case or tray.

Figure 24.8 Different types of motherboard standoffs, used to support the board when installed in the chassis or motherboard tray.

If the board uses the type of standoff that fits into slots in the chassis or tray, rather than screwing directly in, insert the standoffs directly into the new motherboard from underneath until they snap into place (see Figure 24.9). Or attach them to the board with a screw if necessary. Figure 24.10 shows a typical ATX-style motherboard with arrows indicating the typical location of the screw holes for mounting the motherboard to the case (see your motherboard manual for the exact location of these screw holes).

Figure 24.9 Insert standoffs into their mounting slots.

After you have inserted the standoffs and lined up the standoffs with the screw holes on the motherboard, carefully attach the screws to secure the motherboard to the motherboard tray or case (depending on your chassis design). See Figure 24.11.

Figure 24.10 Mounting screw holes in a typical ATX motherboard. The arrows mark the screw holes for mounting the motherboard to the case.

Figure 24.11 Attaching the motherboard to the motherboard tray. *Motherboard courtesy of Intel Corporation.*

3. Install the I/O shield (if used) into the chassis by snapping it into place (see Figure 24.12).

Figure 24.12 Snapping the I/O shield into place in the chassis. *Case courtesy of PC Power & Cooling, Inc.*

4. Install the new motherboard into the case or motherboard tray. Either screw it directly to the standoffs or slide the standoffs already attached to the board by sliding the entire board into position. Make sure you align the I/O shield with the case or the ports on the back of the board with the I/O shield already in the case. Often you will have to set the board into the case and slide it sideways to engage the standoffs into the slots in the case. When the board is in the proper position, the screw holes in the board should be aligned with all the metal spacers or screw holes in the case. Figure 24.13 shows a motherboard attached to a motherboard tray being installed in the chassis.

Some cases and boards, particularly ATX types, don't use any plastic spacers. Instead they use up to seven screws into metal standoffs that are installed in the case (refer back to Figure 24.10). These are somewhat easier to install because the board drops into place and doesn't require that it be slid to the side to engage any standoffs.

5. Take the screws and any plastic washers that were supplied with the new motherboard and screw the board into the case (see Figure 24.14).

Figure 24.13 Installing the motherboard and tray into the chassis. *Case courtesy of PC Power & Cooling, Inc. Motherboard courtesy of Intel Corporation.*

Figure 24.14 Installing the screws that hold the motherboard tray to the chassis. *Case courtesy of PC Power & Cooling, Inc.*

Connect the Power Supply

The power supply is very easy to install, and normally attaches to the chassis with four screws. Figures 24.15 and 24.16 show installing the power supply into the chassis and tightening the screws.

Figure 24.15 Installing the power supply into the chassis. *Case and power supply courtesy of PC Power & Cooling, Inc.*

Figure 24.16 Installing the screws to retain the power supply. *Case and power supply courtesy of PC Power & Cooling, Inc.*

ATX-style motherboards have a single power connector that can go on only one way and an optional secondary connector that is also keyed (see Figure 24.17). Baby-AT and other-style board designs usually have two separate six-wire power connectors from the power supply to the board, which might not be keyed and therefore may be interchangeable (see Figure 24.18). Even though it might be possible to insert them several ways, only one way is correct! These power leads are usually labeled P8 and P9 in most systems. The order in which you connect them to the board is crucial; if you install them backward, you can damage the motherboard when you power it up. Many systems use a CPU cooling fan, which should also be connected. To attach the power connectors from the power supply to the motherboard, do the following:

1. If the system uses a single ATX-style power connector, plug it in; it can go on only one way. If two separate six-wire connectors are used, the two black ground wires on the ends of the connectors must meet in the middle. Align the power connectors such that the black ground wires are adjacent to each other and plug in the connectors. Consult the documentation with your board to make sure the power supply connection is correct. Incorrectly connecting the power connectors can destroy the motherboard.

2. Plug in the power lead for the CPU fan if one is used. The fan will either connect to the power supply via a disk drive power connector or connect directly to a fan power connector on the motherboard.

Figure 24.18 Attaching Baby-AT motherboard power connector.

◀◀ See "Power Supply Connectors," p. 1168.

Connect I/O and Other Cables to the Motherboard

There are several connections that must be made between a motherboard and the case. These include LEDs for the hard disk and power, an internal speaker connection, a reset button, a

power button, and a de-turbo button on some systems. Most modern motherboards also have several built-in I/O ports that have to be connected. This would include dual IDE host adapters, a floppy controller, dual serial ports, and a parallel port. Some boards will also include additional items such as built-in video, sound, or SCSI adapters.

If the board is an ATX type, the connectors for all the external I/O ports are already built into the rear of the board. If you are using a Baby-AT type board, you might have to install cables and brackets to run the serial, parallel, and other external I/O ports to the rear of the case. If your motherboard has onboard I/O, use the following procedures to connect the cables:

1. Connect the floppy cable between the floppy drives and the 34-pin floppy controller connector on the motherboard.
2. Connect the IDE cables between the hard disk, IDE CD-ROM, and the 40-pin primary and secondary IDE connectors on the motherboard (see Figure 24.19). Normally, you will use the primary IDE channel connector for hard disks only and the secondary IDE channel connector to attach an IDE CD-ROM or other device, such as a tape drive.

Figure 24.19 ATA/IDE drive connectors. *Motherboard courtesy of Intel Corporation.*

3. On non-ATX boards, a 25-pin female cable port bracket is normally used for the parallel port. There are usually two serial ports: a 9-pin and either another 9-pin or a 25-pin male connector port. Align pin 1 on the serial and parallel port cables with pin 1 on the motherboard connector and plug them in.
4. If the ports don't have card slot-type brackets or if you need all your expansion slots, there may be port knockouts on the back of the case that you can use instead. Find ones that fit the ports and push them out, removing the metal piece covering the hole. Unscrew the hex nuts on each side of the port connector and position the connector in the hole. Install the hex nuts back in through the case to hold the port connector in place.
5. Most newer motherboards also include a built-in mouse port. If the connector for this port is not built into the back of the motherboard (usually next to the keyboard connector), you will probably have a card bracket type connector to install. In that case, plug the cable into the motherboard mouse connector and then attach the external mouse connector bracket to the case.
6. Attach the front-panel switch, LED, and internal speaker wires from the case front panel to the motherboard. If they are not marked on the board, check where each one is on the diagram in the motherboard manual. Figure 24.20 shows the front-panel connectors.

Figure 24.20 Motherboard front-panel connectors (speaker, power switch, LEDs, and so on).
Motherboard courtesy of Intel Corporation.

Install the Drives

At this point you want to install your hard drive, floppy drive, CD-ROM or DVD drive, and optionally your CD-RW drive. This is covered in detail in Chapter 14, “Physical Drive Installation and Configuration.”

The basic process for mounting CD, hard drives and floppy drives is as follows:

1. Remove the drive bay plates (if needed). Simply bend or knock the plate out of the way.
2. To install a CD drive, simply slide the drive into a the chassis as shown in Figure 24.21. Note that it is easier to connect the IDE cable to the rear of the drive and make jumper selections before mounting the drive. See Chapter 7, “The IDE Interface,” and Chapter 14, for more about IDE jumpers and drive installation.

Figure 24.21 Slide the CD drive into the bay. *Chassis courtesy of PC Power & Cooling, Inc. CD drive supplied by Micro X-Press.*

3. After the drive is in the bay, line up the drive mounting screw holes on the drive with the holes in the case chassis. Secure the drive with four screws (use the ones that came with your case or the drive you are installing). See Figure 24.22.

Figure 24.22 Secure the drive to the chassis using four screws. *Chassis courtesy of PC Power & Cooling, Inc. CD drive supplied by Micro X-Press.*

4. Connect the other end of the IDE cable to your motherboard's IDE connector or to the back of another IDE device if you are chaining drives.
5. To install floppy and hard drives, remove the drive cage (if your case has a removable drive cage). Slide your drives into the drive cage and secure them with screws that came with your case or with the drive you are installing (see Figure 24.23). As with the CD drive, it's easier to connect the floppy and IDE cables to the rear of the drives and make any jumper selections prior to placing the drives or the drive cage into the chassis.

Figure 24.23 Use four screws to secure each drive to the drive cage. *Chassis courtesy of PC Power & Cooling, Inc. Hard drive supplied by Micro X-Press.*

Note

If your chassis does not include a removable drive cage, you'll simply have to mount the drives in the chassis. This is a little more difficult since there's not much working room inside a PC.

6. Slide the drive cage back into the PC and secure it to the chassis using the screws provided with your case (see Figure 24.24).
7. Connect the drive cables to the appropriate locations on your motherboard. See Chapters 7 and 14 for more about jumper setting and cable connections for hard drives and floppy drives.

3-1/2 inch drive cage

Figure 24.24 Use four screws to secure each drive to the drive cage. *Chassis courtesy of PC Power & Cooling, Inc. Hard drive supplied by Micro X-Press.*

Install Bus Expansion Cards

Most systems use expansion cards for video, network interface, sound, and SCSI adapters. These cards are plugged into the bus slots present on the motherboard (see Figure 24.25). To install these cards, follow these steps:

1. Insert each card by holding it carefully by the edges, making sure not to touch the chips and circuitry. Put the bottom-edge finger connector into a slot that fits. Firmly press down on the top of the card, exerting even pressure, until it snaps into place.
2. Secure each card bracket with a screw (see Figure 24.26).
3. Attach any internal cables you may have removed earlier from the cards.

Figure 24.25 Inserting the video adapter into a slot. *Video card courtesy of Creative Labs, Inc. Motherboard courtesy of Intel Corporation.*

Figure 24.26 Installing the screw to retain the card. *Video card courtesy of Creative Labs, Inc. Motherboard courtesy of Intel Corporation.*

Replace the Cover and Connect External Cables

Now the system should be nearly assembled. All that remains is installing the cover assembly and connecting any external devices that are cabled to the system. I usually don't like to install the case cover screws until I have tested the system and I am sure everything is working properly. Often, I will find that a cable has been connected improperly, or some jumper setting is not correct, requiring that I remove the cover to repair the problem. Use the following procedure to complete the assembly:

1. Slide the cover onto the case.
2. Before powering up the system, connect any external cables. Most of the connectors are D-shaped and go in only one way.
3. Plug the 15-pin monitor cable into the video card female connector.
4. Attach the phone cord to the modem, if any.
5. Plug the round keyboard cable into the keyboard connector, and plug the mouse into the mouse port or serial port (if you are using a serial mouse).
6. If you have any other external cabling, such as joystick or audio jacks to a sound card, attach them now.

Run the Motherboard BIOS Setup Program (CMOS Setup)

Now that everything is connected, you can power up the system and run the BIOS Setup program. This will enable you to configure the motherboard to access the installed devices and set the system date and time. The system will also test itself to determine whether there are any problems:

1. Power on the monitor first, and then the system unit. Observe the operation via the screen and listen for any beeps from the system speaker.
2. The system should automatically go through a power-on self test (POST) consisting of video BIOS checking, RAM test, and usually an installed component report. If there is a fatal error during the POST, you may not see anything onscreen and the system might beep several times, indicating a specific problem. Check the motherboard or BIOS documentation to determine what the beep codes mean.
3. If there are no fatal errors, you should see the POST display onscreen. Depending on the type of motherboard BIOS such as Phoenix, AMI, Award, or others, you need to press a key or series of keys to interrupt the normal boot sequence and get to the Setup program screens that allow you to enter important system information. Normally, the system will indicate via the onscreen display which key to press to activate the BIOS setup program during the POST, but if not, check the motherboard manual for the key(s) to press to enter the BIOS setup. Common keys used to enter BIOS Setup are F1, F2, F10, Esc, Ins, or Del.
4. After the Setup program is running, use the Setup program menus to enter the current date and time, your hard drive settings, floppy drive types, video cards, keyboard settings, and so on. Most newer motherboard BIOSes can autodetect the hard drive, so you should not have to manually enter any parameters for it.
5. Entering the hard drive information is the most critical when building a new system. Most modern BIOSes feature an autodetect or auto-type setting for the drive; I recommend you choose that if it is available. This will cause the BIOS to read the parameters directly from the drive, which eliminates a chance for errors, especially if the builder is less experienced.

These parameters include CHS (Cylinder Head Sector) specifications and transfer speed and translation settings. Most systems will also let you set a *user-definable type*, which means that the cylinder, head, and sector counts for this type were entered manually and are not constant. If you set a user-definable type (not normally recommended unless you don't have "auto" as a choice), it is especially important to write down the exact settings you use because this information might be very difficult to figure out if it is ever lost.

Modern ATA drives will also have additional configuration items that you should record. These include the translation mode and transfer speed setting. With drives larger than 528MB, it is important to record the translation mode, which will be expressed differently in different BIOS versions. Look for settings such as CHS, ECHS (Extended CHS), Large (which equals ECHS), or LBA (Logical Block Addressing). Normally you would set LBA or Large for any drive over 528MB. Whatever you set, it should be recorded as it can cause problems to change this setting after the drive has been formatted.

6. After you have checked over all the settings in the BIOS Setup, follow the instructions on the screen or in the motherboard manual to save the settings and exit the Setup menu.

◀◀ See "Running or Accessing the CMOS Setup Program," p. 402.

Troubleshooting New Installations

At this point, the system should reset and attempt to boot normally from either a floppy disk or hard disk. With the operating system startup disk in drive A:, the system should boot and either reach an installation menu or an A: prompt. If there are any problems, here are some basic items to check:

- If the system won't power up at all, check the power cord. If the cord is plugged into a power strip, make sure the strip is switched on. There is usually a power switch on the front of the case, but some power supplies have a switch on the back as well.
- Check to see if the power switch is connected properly inside the case. There is a connection from the switch to the motherboard, check both ends to see that they are connected properly.
- Check the main power connector from the supply to the board. Make sure the connectors are seated fully and if the board is a Baby-AT type, make sure they are plugged in with the correct orientation and sequence.
- If the system appears to be running but you don't see anything on the display, check the monitor to ensure that it is plugged in, turned on, and properly connected to the video card. Make sure the monitor cord is securely plugged into the card.
- Check the video card to be sure it is fully seated in the motherboard slot. Remove and reseat the video card, and possibly try a different slot if it is a PCI card.
- If the system beeps more than once, the BIOS is reporting a fatal error of some kind. See the BIOS Error code listings in Chapter 5 and on the CD accompanying this book for more information on what these codes mean, as they depend on the type and version of BIOS you have. Also consult your motherboard documentation—look in the BIOS section for a table of beep codes.
- If the LED on your floppy drive, hard drive, or CD/DVD-ROM drive stays on continuously, the data cable is probably installed backward or is off by some pins. Check to see that the stripe on the cable is properly oriented toward pin 1 on both the drive and board connector ends. Also check the drive jumpers for proper master/slave relationships.

When you are sure the system is up and running successfully, power it off and screw the chassis cover securely to the case. Now your new system should be ready for the operating system installation.

Installing the Operating System

If you are starting with a new drive, you will need to install the operating system. If you are using a non-Windows operating system, follow the documentation for the installation procedures. Here I will cover installing Windows 9x on an IDE hard drive.

Partitioning the Drive

From the A:> prompt, with the startup disk inserted in the floppy drive, type the following command:

```
FDISK
```

This command is used to partition your drive. Follow the menus to create either a single partition for the entire drive or to create multiple partitions. Normally the first partition must also be made active, which means it will be bootable. I recommend you answer Yes to the prompt “Do you wish to enable large disk support (Y/N)?” This will allow Windows 95B or later (including Windows 98) to install using the FAT32 file system. Then you can continue accepting default entries for all the prompts to partition the drive as a single bootable partition that covers the entire drive.

Next, exit FDISK; this will cause the system to restart.

Note

If you'd rather not use FDISK to partition your drive, you can use PartitionMagic to easily create drive partitions.

Note

Using FDISK is covered extensively in Chapter 14.

Format the Drive

After rebooting on the startup floppy, you then need to format each partition you created. The first partition has to be formatted with the operating system startup files using the `FORMAT` command as follows:

```
FORMAT C: /S
```

All other partitions would be formatted without the `/S` (system) parameter. The `/S` parameter tells the system to make the disk bootable. After the `FORMAT` command completes on all the drives, you should reboot again from the startup floppy. Now you are ready to install Windows.

Note

Drive formatting is covered extensively in Chapter 10, “Hard Disk Storage.” See Chapter 14 for more details on installing and setting up a hard drive.

Loading the CD-ROM Driver

Before you can install Windows, you will have to make sure your startup disk is properly configured to support the CD/DVD drive in your system. This requires that real mode (DOS-based) drivers be installed on the disk that is compatible with your drive. The easiest solution is to use a Windows 98 startup disk, because it is already prepared with the proper drivers for 99 percent of all systems on the market. Even if you are installing Windows 95, you can still use the Windows 98 startup disk to start the process.

If you are using a Windows 95 startup disk and you don't have the CD-ROM drivers on it, you should look for a CD-ROM driver disk that normally comes with your drive. It should have a driver installation batch file on it, which if run will copy the drivers to your startup disk and create the appropriate CONFIG.SYS and AUTOEXEC.BAT files to enable CD-ROM support. If the driver is called CDRM.SYS, that file, along with the following line (or something similar) should be added to the CONFIG.SYS file on your Windows 95 startup disk:

```
device=CDROM.SYS /D:oemcd001
```

This causes the CDRM.SYS driver to be loaded and assigns it an in-memory driver designation of oemcd001. Any designation can be used here, but it should be eight characters or fewer and it will have to match a similar designation in the next step.

Next you must also load the Microsoft CD-ROM extensions driver in your AUTOEXEC.BAT file. This driver is called MSCDEX.EXE and is already included on the Windows 95 startup disk. If you used the designation I listed in the previous step, add the following line to the AUTOEXEC.BAT file on the Windows 95 startup disk:

```
LH MSCDEX.EXE /D:oemcd001
```

This loads the MSCDEX.EXE driver (in upper memory via the LH or LoadHigh command if possible) and looks to attach to the CD-ROM driver loaded earlier via the driver designation oemcd001 in this case.

After these statements are added to the CONFIG.SYS and AUTOEXEC.BAT files, you should reboot on the startup floppy and now you should be able to access your CD-ROM drive. It will appear one drive letter after your last drive partition. If your hard disk partitions are C: and D:, the CD-ROM drive will be E:.

Note that these procedures require that you find your CD-ROM driver, and copy it onto the startup disk. If you can't find the driver or have a SCSI hard disk (which uses different types of drivers), I recommend you borrow a copy of a Windows 98 startup disk. The Win98 startup disks already include a series of drivers that will work with virtually any CD-ROM drive on the market, even SCSI versions. You can boot from a Win98 startup disk and install any other operating system you want, including Win95.

After you have successfully created a startup disk with the CD-ROM drivers (or have the Win98 startup disk), install the Windows CD-ROM in your CD/DVD drive. After booting from the startup floppy, change to the CD/DVD drive letter, and at that prompt run the SETUP command. This starts the Windows installation program. From here you can follow the prompts to install Windows as you see fit. This procedure can be somewhat lengthy, so be prepared to spend

some time. You will not only be installing Windows, but also the drivers for any hardware detected during the installation process.

As a tip, I recommend copying the Windows files to your hard disk and actually running the installation from the hard disk and not the CD. This will be helpful in the future should you want to reinstall or install any additional parts of Windows, as it will then work directly from the hard disk and you won't be asked to insert the CD.

To do this, first check the CD for the directory containing the *.CAB files and copy them to the hard disk. For example, using Windows 98 it would go something like this:

```
copy E:\WIN98\*. * C:\WIN98 /S
```

This copies all the files from the WIN98 directory on the CD-ROM (E: drive in this example) to the hard disk and places them in a directory called WIN98. Then you can remove the CD (it is no longer needed) and run the installation directly from the hard disk by entering the following commands:

```
C:  
CD\  
C:\WIN98\SETUP
```

These commands change you to drive C:, place you in the root directory, and then run the Windows SETUP program to start the installation. From there the menu-driven Windows installation routines will guide you.

Note

If you'd like to create a bootable CD containing your Windows installation files, see Chapter 13, "Optical Storage." For more information about installing CD/DVD drives, see Chapter 14.

After Windows is installed, you can install any additional drivers or application programs you like. At this point, your system should be fully operational.

Disassembly/Upgrading Preparation

After you've built your system, you probably will have to open it up again sometime to perform a repair or upgrade. Before you power off the system for the last time and begin to open the case, you should learn and record several things about your computer. Often, when working on a system, you intentionally or accidentally wipe out the CMOS setup information. Most systems use a special battery-powered CMOS clock and data chip that is used to store the system's configuration information. If the battery is disconnected, or if certain pins are accidentally shorted, you can discharge the CMOS memory and lose the setup. The CMOS memory in most systems is used to store simple things such as how many and what type of floppy drives are connected, how much memory is in the system, and the date and time.

A critical piece of information is the hard disk-type settings. Although you or the system can easily determine the other settings the next time you power on the system, the hard disk-type information may be another story. Most modern BIOS software can read the type information directly from most IDE and all SCSI drives. With older BIOS software, however, you have to explicitly tell

the system the parameters of the attached hard disk. This means that you need to know the current settings for cylinders, heads, and sectors per track.

If you reconfigure a system and do not set the same drive translation as was used originally with that drive, all the data may be inaccessible. Most modern BIOSes have an Autodetect feature that automatically reads the drive's capabilities and sets the CMOS settings appropriately. Even so, there have been some problems with the BIOS not reading the drive settings properly or where someone had overridden the settings in the previous installation. With translation, you have to match the setting to what the drive was formatted under previously if you want to read the data properly.

The speed setting is a little more straightforward. Older IDE drives can run up a speed of 8.3MB/sec, which is PIO (Programmed I/O) mode 2. Newer EIDE drives can run PIO Mode 3 (11.1MB/sec), PIO Mode 4 (16.6MB/sec), or several DMA modes including Ultra DMA33 or Ultra DMA66. Most BIOSes today allow you to set the mode specifically, or you can use the Autodetect feature to automatically set the speed. For more information on the settings for hard disk drives, refer to Chapters 7 and 10.

If you do not enter the correct hard disk type information in the CMOS Setup program, you will not be able to access the data on the hard disk. I know of several people who lost some or all their data because they did not enter the correct type information when they reconfigured their systems. If this information is incorrect, the usual results are a missing operating system error message when the systems starts and the inability to access the C: drive.

Some people think that it's possible to figure out the parameters by looking up the particular hard disk in a table. (I have included a table of popular hard disk drive parameters in the Technical Reference on the CD-ROM. This table has proved to be useful to me time and time again.) Unfortunately, this method works only if the person who set up the system originally entered the correct parameters. I have encountered a large number of systems in which the hard disk parameters were not entered correctly; the only way to regain access to the data is to determine, and then use, the same incorrect parameters that were used originally. As you can see, no matter what, you should record the hard disk information from your setup program.

Most systems have the setup program built right into the ROM BIOS software. These built-in Setup programs are activated by a hotkey sequence such as Ctrl+Alt+Esc or Ctrl+Alt+S. Other ROMs prompt you for the setup program every time the system boots, such as with the popular AMI BIOS. With the AMI, you simply press the Delete key when the prompt appears onscreen during a reboot.

The major vendors have standardized on these following keystrokes to enter the BIOS Setup:

- *AMI BIOS*. Press Del during POST.
- *Phoenix BIOS*. Press F2 during POST.
- *Award BIOS*. Press Del or Ctrl+Alt+Esc during POST.
- *Microid Research BIOS*. Press Esc during POST.

If your system will not respond to one of these common keystroke settings, you might have to contact the manufacturer or read the system documentation to find the correct keystrokes to enter setup.

Some unique ones I have encountered are as follows:

- *IBM Aptiva/Valuepoint*. F1 during POST.
- *Older Phoenix BIOS*. Boot to a safe mode DOS command prompt, and then press Ctrl+Alt+Esc, or Ctrl+Alt+S.
- *Compaq*. F10 during POST.

◀◀ See “Running or Accessing the CMOS Setup Program,” p.402.

After you're in the BIOS Setup main screen, you'll usually find a main menu allowing access to other menus and submenus offering different sections or screens. When you get the setup program running, record all the settings. The easiest way to do this is to print it. If a printer is connected, press Shift+Print Screen; a copy of the screen display will be sent to the printer. Some setup programs have several pages of information, so you should record the information on each page.

Many setup programs allow for specialized control of the particular chipset used in the motherboard. These complicated settings can take up to several screens of information—all should be recorded. Most systems will return these settings to a BIOS default if the CMOS battery is removed, and you will lose any customized settings you might have changed. See Chapter 5 for more information on the BIOS settings.

CHAPTER 25

PC Diagnostics, Testing, and Maintenance

PC Diagnostics

No matter how well built your PC is, and how well written its software, something is eventually going to go wrong, and you might not always have a support system available to resolve the problem. Diagnostic software, the kind that comes with your computer, as well as that available from third parties, can be vitally important to you any time your computer malfunctions or you begin the process of upgrading a system component or adding a new device. This chapter examines the types of software that are available, and particularly those that you might already own because they are included with common operating system and hardware products.

You might also find that your system problems are caused by a hardware malfunction and that you have to open up the computer case to perform repairs. This chapter also examines the tools and testers used to upgrade and repair PCs—both the basic items that every user should own and some of the more advanced devices.

Of course, the best way to deal with a problem is to prevent it from happening in the first place. The preventive maintenance sections of this chapter describe the procedures that you should perform on a regular basis to keep your system in good working order.

This chapter describes three levels of diagnostic software (POST, system, and advanced) included with your computer or available from your computer manufacturer. The chapter describes how you can get the most from this software. It also details IBM's audio codes and error codes, which are similar to the error codes used by most computer manufacturers, and examines aftermarket diagnostics and public-domain diagnostic software.

Diagnostics Software

Several types of diagnostic software are available for PCs. Some diagnostic functions are integrated into the PC hardware or into peripheral devices such as expansion cards, whereas others take the form of operating system utilities or separate software products. This software, some of which is included with the system when purchased, assists users in identifying many problems that can occur with a computer's components. In many cases, these programs can do most of the work in determining which PC component is defective or malfunctioning. The types of diagnostic software are as follows:

- *POST.* The power on self test operates whenever any PC is powered up (switched on).
- *Manufacturer supplied diagnostics software.* Many of the larger manufacturers—especially high-end, name-brand manufacturers such as IBM, Compaq, Hewlett-Packard, Dell, and others—make special diagnostics software that is expressly designed for their systems. This manufacturer-specific software normally consists of a suite of tests that thoroughly examines the system. In some cases, you can download these diagnostics from the manufacturer's online services, or you might have to purchase them. Many vendors such as Gateway include a limited version of one of the aftermarket packages that has been customized for use with their systems. In some older IBM and Compaq systems, the diagnostic software is installed on a special partition on the hard drive and can be accessed during startup. This was a convenient way for those system manufacturers to make sure that you always had diagnostics available.

- *Peripheral diagnostics software.* Many hardware devices ship with specialized diagnostics software designed to test their particular functions. Adaptec SCSI host adapters, for example, include diagnostic functions in the card's BIOS that you can access with a keystroke (Ctrl+A) at boot time. Sound cards normally include a diagnostic program on a disk along with the driver that tests and verifies all the card's functions. Network adapters usually include a diagnostic specific to that adapter, on a disk normally with the drivers. Other devices or adapters might also provide a diagnostic program or disk, usually included with the drivers for the device.
- *Operating system diagnostics software.* Operating systems such as Windows 9x and Windows NT/2000 include a variety of diagnostic software designed to identify and monitor the performance of various components in the computer.
- *Aftermarket diagnostics software.* A number of manufacturers make general-purpose diagnostics software for PCs. This type of software is often bundled with other system maintenance and repair utilities to form a general PC software toolkit.

The Power On Self Test (POST)

When IBM first began shipping the original PC in 1981, it included safety features that had never been seen in a personal computer. These features were the POST and parity-checked memory. Although parity-checked memory is being phased out on many systems, every PC still executes a POST when you turn it on. The following sections provide more detail on the POST, a series of program routines buried in the motherboard ROM-BIOS chip that tests all the main system components at power-on time. This series of routines is partially responsible for the delay when you turn on your PC; the computer executes the POST before loading the operating system.

What Is Tested?

Whenever you start up your computer, it automatically performs a series of tests that checks the primary components in your system, such as the CPU, ROM, motherboard support circuitry, memory, and major peripherals such as the expansion chassis. These tests are brief and are designed to catch hard (not intermittent) errors. The POST procedures are not very thorough compared with available disk-based diagnostics. The POST process provides error or warning messages whenever it encounters a faulty component.

Although the diagnostics performed by the system POST are not very thorough, they are the first line of defense, especially when it comes to detecting severe motherboard problems. If the POST encounters a problem severe enough to keep the system from operating properly, it halts the system boot process and generates an error message that often identifies the cause of the problem. These POST-detected problems are sometimes called fatal errors because they prevent the system from booting. The POST tests normally provide three types of output messages: audio codes, onscreen text messages, and hexadecimal numeric codes that are sent to an I/O port address.

POST Audio Error Codes

POST audio error codes take the form of a series of beeps that identify the faulty component. When your computer is functioning normally, you should usually hear one short beep when the

system starts up at the completion of the POST, although some systems (such as Compaq's) do not do this. If a problem is detected, a different number of beeps sound, sometimes in a combination of short and long tones. These BIOS-dependent codes can vary among different BIOS manufacturers and even among different BIOS from the same manufacturer. It is best if you consult your motherboard manufacturer for the codes specific to your board and BIOS. If that fails, the BIOS manufacturer might have this information.

Note

Tables showing the most current and common BIOS error codes are included in the Technical Reference section on the CD. Consider printing out the codes for your BIOS and keeping them in a safe location.

POST Visual Error Codes

On most PCs, the POST also displays the results of its system memory test on the monitor. The last number displayed is the amount of memory that tested successfully. For example, a system might display the following message:

32768 KB OK

The number displayed by the memory test should agree with the total amount of memory installed on the system motherboard. Some older systems display a slightly lower total because they deduct part or all of the 384KB of UMA (Upper Memory Area) from the count. On old systems that use expanded memory cards, the memory on the card is not tested by the POST and does not count in the numbers reported. Also, this memory test is performed before any system software loads, so many memory managers or device drivers you might have installed do not affect the results of the test. If the POST memory test stops short of the expected total, the number displayed can indicate how far into the system memory array a memory error lies. This number can help you to identify the exact module that is at fault and can be a valuable troubleshooting aid in itself.

If an error is detected during the POST procedures, an error message might be displayed onscreen. These messages usually are in the form of a numeric code several digits long—for example, 1790-Disk 0 Error. You should check the documentation for your motherboard or system BIOS for information about these errors. The major BIOS manufacturers also maintain Web sites where this information should be available.

Note

I've also included BIOS error messages for AMI Award, Phoenix, Microid Research (MR BIOS), and IBM on the CD, in the Technical Reference section. You should print the codes for your BIOS and keep them in a safe place in case you need them.

I/O Port POST Codes

A lesser-known feature of the POST is that at the beginning of each POST, the BIOS sends test codes to a special I/O port address. These POST codes can be read only by a special adapter card plugged in to one of the system slots. These cards originally were designed to be used by system

manufacturers for burn-in testing of the motherboard, to prevent the need for a video display adapter and display. Several companies now make these cards available to technicians. Micro 2000, JDR Microdevices, Data Depot, Ultra-X, and Trinitech are just a few manufacturers that market these POST cards.

When you plug one of these POST cards into a slot, during the POST you see two-digit hexadecimal numbers flash on the card's display. If the system stops unexpectedly or hangs, you can identify the test in progress during the hang from the two-digit code. This step usually identifies the malfunctioning component.

Most of the system BIOSes on the market output the POST codes to I/O port address 80h.

Most POST cards plug in to the 8-bit connector that is a part of the ISA or EISA bus. Because most systems, even those with PCI slots, still have ISA connectors, those cards are adequate. In the future, however, there will be PCs with no ISA slots at all, and an ISA POST card won't work. Micro2000 has a card called the Post-Probe, which has both ISA and PCI connectors on the same board. The Post-Probe also includes a MicroChannel (MCA) bus adapter, making it one of the most flexible POST cards available. Data Depot also offers slot adapters that enable its existing ISA bus cards to work in MCA bus systems. I recommend looking for POST cards that are designed to work in PCI slots. These will certainly become more prevalent as more PCI-only systems (no ISA slots) come on the market. Another ISA/PCI card is the POSTPlus from ForeFront Direct.

Note

A listing of POST I/O port error codes for various BIOSes (including AMI Award, Phoenix, Microid Research, and IBM) can be found in the Technical Reference section of the CD. Also, see Chapter 5, "BIOS," to learn more about working with your BIOS. Remember to consult your motherboard documentation for codes specific to your BIOS version. Also the documentation included with the various POST cards covers most older as well as newer BIOS versions.

Hardware Diagnostics

Many types of diagnostic software are used with specific hardware products. This software can be integrated into the hardware, included with the hardware purchase, or sold as a separate product. The following sections examine several different types of hardware-specific diagnostics.

Note

IBM included specialized diagnostic software for its older PS/2 systems. For more information on this software, see the sixth edition of *Upgrading and Repairing PCs* on the CD-ROM included with this book.

SCSI Diagnostics

Unlike the IDE drive support that is built into the system BIOS of virtually every PC, SCSI is an add-on technology, and most SCSI host adapters contain their own BIOS that enables you to boot the system from a SCSI hard drive. In some cases, the SCSI BIOS also contains configuration software for the adapter's various features, and diagnostics software as well.

The most popular manufacturer of SCSI host adapters is Adaptec, and most of its host adapters contain these features. An Adaptec SCSI adapter normally includes a BIOS that can be enabled or disabled. When the BIOS is activated, you see a message on the monitor as the system boots, identifying the model of the adapter and the revision number of the BIOS. The message also instructs you to press Ctrl+A to access what Adaptec calls its SCSISelect utility.

The SCSISelect utility identifies the Adaptec host adapters installed in the system and, if there is more than one, enables you to choose the adapter you want to work with by selecting its port address. After you do this, you are presented with a menu of the functions built into the adapter's BIOS. Every adapter BIOS contains a configuration program and a SCSI Disk Utilities feature that scans the SCSI bus, identifying the devices connected to it. For each hard disk drive connected to the bus, you can perform a low-level disk format or scan the disk for defects, remapping any bad blocks that are found.

For SCSI adapters that use DMA (Direct Memory Access), there is also a Host Adapter Diagnostics feature that tests the communication between the adapter and the main system memory array by performing a series of DMA transfers. If this test should fail, you are instructed how to configure the adapter to use a lower DMA transfer rate.

Network Interface Diagnostics

As with SCSI adapters, many network interface adapters are equipped with their own diagnostics, designed to test their own specialized functions. The EZSTART program included with all SMC network interface cards, for example, contains two adapter test modes. The Basic mode performs the following internal tests on the SMC8000 adapter:

- Bus Interface Controller test
- LAN Address ROM test
- Network Interface Controller test
- RAM test
- ROM test
- Interrupt Generation
- Loopback test

The Two Node test sequence requires that you have another node installed on the same network with an SMC adapter. By running the EZSTART software on both computers, you can configure one adapter as the Responder and the other as the Initiator. The Initiator transmits test messages to the Responder that echoes the same messages back again. If the adapters and the network are functioning properly, the messages should return to the Initiator system in exactly the same form as they were transmitted.

Other network adapters have similar testing capabilities, although the names of the tests might not be exactly the same. The software for the 3Com 3C509B adapter, for example, performs the following tests:

- Register Access test
- EEPROM Vital Data test

- EEPROM Configurable Data test
- FIFO Loopback test
- Interrupt test
- Ethernet Core Loopback test
- Encoder/Decoder Loopback test
- Echo Exchange test (requires two adapters on the same network)

Both the SMC and 3Com diagnostics programs are integrated into the software you use to configure the hardware resources used by the adapters and their other features. The software is not integrated into the hardware; it takes the form of a separate program that ships with the devices and that you can also download free of charge from the manufacturers' respective Web sites.

General-Purpose Diagnostics Programs

A large number of third-party diagnostics programs are available for PC systems. Specific programs are available also to test memory, floppy drives, hard disks, video adapters, and most other areas of the system. Although some of these utility packages should be considered essential in any toolkit, many fall short of the level needed by professional-level troubleshooters.

Tip

Before trying a commercial diagnostic program to solve your problem, look in your operating system. Most operating systems today provide at least some of the diagnostic functions that diagnostic programs do. You might be able to save some time and money.

Unfortunately, there is no clear leader in the area of diagnostic software. Each program has unique advantages. As a result, no program is universally better than another. When deciding which diagnostic programs, if any, to include in your arsenal, look for the features that you need.

Note

The CD included with this book contains a breakdown of some of the PC diagnostics software available today. See the Technical Reference section of the CD.

Operating System Diagnostics

In many cases, it might not be necessary to purchase third-party diagnostic software because your operating system has all the diagnostic tools you need. Windows 95, 98, Millennium, NT, and 2000 include a large selection of programs that enable you to view, monitor, and troubleshoot the hardware in your system.

Note

The CD included with this book contains a breakdown of some of the operating system–diagnostics software available today. See the Technical Reference section of the CD.

DOS Versions and Utilities

In more than a decade and a half of development, a great many DOS versions have been released. IBM and Microsoft released version 1.0 of the operating system in 1981, but by version 3.x, Microsoft also began releasing its own DOS, using the same version numbers as IBM in most cases. Early versions of DOS were frequently designed for the hardware configurations of specific machines. At one time, IBM, Compaq, and other original equipment manufacturers would each have their own versions of DOS (created by IBM or Microsoft), designed to support only their hardware. You could not, in many cases, boot an IBM computer using a Compaq DOS boot disk and still gain full functionality.

Over the years, DOS has added a number of commands to the repertoire, many of which can be useful when troubleshooting a system. In dealing with different versions, it has always been difficult to remember whether a particular version included a certain command. Table 25.1 is a list of external MS-DOS command programs, MS-DOS versions they were included with, and the file extension used.

The Hardware Boot Process

The term *boot* comes from the word bootstrap and describes the method by which the PC becomes operational. Just as you pull on a large boot by the small strap attached to the back, a PC loads a large operating system by first loading a small program that can then pull the operating system into memory. The chain of events begins with the application of power, and finally results in a fully functional computer system with software loaded and running. Each event is triggered by the event before it and initiates the event after it.

Tracing the system boot process might help you find the location of a problem if you examine the error messages that the system displays when the problem occurs. If you see an error message that is displayed only by a particular program, you can be sure the program in question was at least loaded and partially running. Combine this information with the knowledge of the boot sequence, and you can at least tell how far along the system's startup procedure has progressed before the problem occurred. You usually want to look at whatever files or disk areas were being accessed during the failure in the boot process. Error messages displayed during the boot process

and those displayed during normal system operation can be hard to decipher. However, the first step in decoding an error message is to know where the message came from—what program actually generated or displayed it. The following programs are capable of displaying error messages during the boot process:

OS Independent:

- Motherboard ROM BIOS
- Adapter card ROM BIOS extensions
- Master (partition) boot record
- Volume boot record

OS Dependent:

- System files (IO.SYS/IBMBIO.COM and MSDOS.SYS/IBMDOS.COM)
- Device drivers (loaded through CONFIG.SYS or the Win 9x Registry SYSTEM.DAT)
- Shell program (COMMAND.COM in DOS)
- Programs run by AUTOEXEC.BAT, the Windows Startup group, and the Registry
- Windows (WIN.COM)

The first portion of the startup sequence is operating system independent, which means these steps are the same for all PCs no matter what operating system you have installed. The latter portion of the boot sequence is operating system dependent, which means those steps can vary depending on which operating system is installed or being loaded. The following section examines the operating system-independent startup sequence and provides a detailed account of many of the error messages that might occur during this process.

The Boot Process: Operating System Independent

If you have a problem with your system during startup and you can determine where in this sequence of events your system has stalled, you know what events have occurred and you probably can eliminate each of them as a cause of the problem. The following steps occur in a typical system startup regardless of which operating system you may be loading:

1. You switch on electrical power to the system.
2. The power supply performs a self-test (known as the POST—power on self test). When all voltages and current levels are acceptable, the supply indicates that the power is stable and sends the Power_Good signal to the motherboard. The time from switch-on to Power_Good is normally between .1 and .5 seconds.
3. The microprocessor timer chip receives the Power_Good signal, which causes it to stop generating a reset signal to the microprocessor.

◀◀ See “The Power_Good Signal,” p. 1176.

4. The microprocessor begins executing the ROM BIOS code, starting at memory address FFFF:0000. Because this location is only 16 bytes from the very end of the available ROM space, it contains a JMP (jump) instruction to the actual ROM BIOS starting address.

◀◀ See “Motherboard BIOS,” p. 375.

5. The ROM BIOS performs a test of the central hardware to verify basic system functionality. Any errors that occur are indicated by audio “beep” codes because the video system has not yet been initialized. If the BIOS is Plug and Play (PnP), the following steps are executed; if not, skip to step 10.
6. The Plug-and-Play BIOS checks non-volatile random access memory (RAM) for input/output (I/O) port addresses, interrupt request lines (IRQs), direct memory access (DMA) channels, and other settings needed to configure PnP devices on the computer.
7. All Plug-and-Play devices found by the Plug-and-Play BIOS are disabled.
8. A map of used and unused resources is created.
9. The Plug-and-Play devices are configured and re-enabled, one at a time. If your computer does not have a Plug-and-Play BIOS, PnP devices are initialized using their default settings. These devices may be reconfigured dynamically when Windows 9x starts. At that point, the Windows 9x Configuration Manager queries the Plug-and-Play BIOS for device information, and then queries each Plug and Play device for its configuration.
10. The BIOS performs a video ROM scan of memory locations C000:0000 through C780:0000, looking for video adapter ROM BIOS programs contained on a video adapter found either on a card plugged into a slot or integrated into the motherboard. If the scan locates a video ROM BIOS, it is tested by a checksum procedure. If the video BIOS passes the checksum test, the ROM is executed; the video ROM code initializes the video adapter and a cursor appears onscreen. If the checksum test fails, the following message appears:

```
C000 ROM Error
```
11. If the BIOS finds no video adapter ROM, it uses the motherboard ROM video drivers to initialize the video display hardware, and a cursor appears onscreen.
12. The motherboard ROM BIOS scans memory locations C800:0000 through DF80:0000 in 2KB increments for any other ROMs located on any other adapter cards (such as SCSI adapters). If any ROMs are found, they are checksum-tested and executed. These adapter ROMs can alter existing BIOS routines and establish new ones.
13. Failure of a checksum test for any of these ROM modules causes this message to appear:

```
XXXX ROM Error
```

where the address XXXX indicates the segment address of the failed ROM module.
14. The ROM BIOS checks the word value at memory location 0000:0472 to see whether this start is a cold start or a warm start. A word value of 1234h in this location is a flag that indicates a warm start, which causes the BIOS to skip the memory test portion of the POST. Any other word value in this location indicates a cold start and the BIOS performs the full POST procedure. Some system BIOSes let you control various aspects of the POST procedure, making it possible to skip the memory test, for example, which can be lengthy on a system with a lot of RAM.
15. If this is a cold start, the full POST executes; if this is a warm start, a mini-POST executes, minus the RAM test. Any errors found during the POST are reported by a combination of audio and displayed error messages. Successful completion of the POST is indicated by a single beep.
16. The ROM BIOS searches for a boot record at cylinder 0, head 0, sector 1 (the very first sector) on the default boot drive. At one time, the default boot drive was always the first floppy disk, or A: drive. However, the BIOSes on today’s systems often enable you to select

the default boot device and the order that the BIOS will look for other devices to boot from if needed, using a floppy disk, hard disk, or even a CD-ROM drive in any order you choose. This sector is loaded into memory at 0000:7C00 and tested.

If a disk is in the drive but the sector cannot be read, or if no disk is present, the BIOS continues with step 19.

Tip

If you do want to boot from a CD-ROM, make sure the CD-ROM drive is specified first in the boot devices menu in your BIOS setup. To ensure that you can boot from an emergency disk, set your floppy drive as the second device in the boot order. A hard disk containing your operating system should be the third drive in the boot order. This allows you to always be ready for an emergency. So long as you do not boot with a CD or floppy loaded, the BIOS will bypass both the CD and floppy disk drives and boot from the hard drive.

Note that not all operating system CDs are bootable. The Windows 95 CD is not bootable; however, starting with Windows 98, Microsoft made the operating system CD bootable, but only for OEM (Original Equipment Manufacturer) versions. The retail Windows CDs were not bootable. Windows NT 4.0 and later, including Windows 2000, are shipped on bootable CDs. See Chapter 13, "Optical Storage," for information on how to make a bootable CD.

- 17.** If booting from a floppy disk and the first byte of the volume boot record is less than 06h, or if the first byte is greater than or equal to 06h and the first nine words contain the same data pattern, this error message appears and the system stops:

602-Diskette Boot Record Error

- 18.** If the volume boot record cannot find or load the system files, or if a problem was encountered loading them, one of the following messages appears:

Non-System disk or disk error
Replace and strike any key when ready

Non-System disk or disk error
Replace and press any key when ready

Invalid system disk_
Replace the disk, and then press any key

Disk Boot failure

Disk I/O Error

All these messages originate in the volume boot record (VBR) and relate to VBR or system file problems.

- 19.** If no boot record can be read from drive A: (such as when there is no disk in the drive), the BIOS then looks for a master boot record (MBR) at cylinder 0, head 0, sector 1 (the very first sector) of the first hard disk. If this sector is found, it is loaded into memory address 0000:7C00 and tested for a signature.

- 20.** If the last two (signature) bytes of the MBR are not equal to 55AAh, software interrupt 18h (Int 18h) is invoked on most systems.

This causes the BIOS to display an error message that can vary for different BIOS manufacturers, but which is often something like one of the following messages, depending on which BIOS you have:

IBM BIOS

```
The IBM Personal Computer Basic_  
Version C1.10 Copyright IBM Corp 1981  
62940 Bytes free_  
Ok_
```

Or, some newer IBM computers display a graphic depicting the front of a floppy drive, a 3 1/2-inch diskette, and arrows prompting you to put a disk in the drive and press the F1 key to proceed.

AMI BIOS

```
NO ROM BASIC - SYSTEM HALTED
```

Compaq BIOS

```
Non-System disk or disk error  
replace and strike any key when ready
```

Award BIOS

```
DISK BOOT FAILURE, INSERT SYSTEM DISK AND PRESS ENTER
```

Phoenix BIOS

```
No boot device available -  
strike F1 to retry boot, F2 for setup utility
```

or

```
No boot sector on fixed disk -  
strike F1 to retry boot, F2 for setup utility
```

Although the messages vary from BIOS to BIOS, the cause for each relates to specific bytes in the MBR, which is the first sector of a hard disk at the physical location cylinder 0, head 0, sector 1.

The problem involves a disk that has either never been partitioned or has had the Master Boot Sector corrupted. During the boot process, the BIOS checks the last two bytes in the MBR (first sector of the drive) for a signature value of 55AAh. If the last two bytes are not 55AAh, an Interrupt 18h is invoked, which calls the subroutine that displays one of the error messages just shown, which basically instruct the user to insert a bootable floppy to proceed.

The MBR (including the signature bytes) is written to the hard disk by the DOS FDISK program. Immediately after a hard disk is low-level formatted, all the sectors are initialized with a pattern of bytes, and the first sector does not contain the 55AAh signature. In other words, these ROM error messages are exactly what you see if you attempt to boot from a hard disk that has been low-level formatted, but has not yet been partitioned.

- 21.** The MBR program searches its partition table for an entry with a system indicator byte designating an extended partition. If the program finds such an entry, it loads the extended partition boot sector at the location indicated. The extended partition boot sector also has a table that is searched for another extended partition indicating logical drives. If another extended partition entry is found, that extended partition boot sector is loaded from the location indicated. The search continues until either no more logical drives are indicated or the maximum number of 24 total logical drives (including C:) has been reached.

22. The MBR searches its built-in partition table entries for a boot indicator byte marking an active partition entry.
23. If none of the partitions are marked active (bootable), the BIOS displays a disk error message.
24. If any boot indicator byte in the MBR partition table is invalid or if more than one indicates an active partition, the following message is displayed, and the system stops:
Invalid partition table
25. If an active partition is found in the MBR, the partition boot record from the active partition is loaded and tested.
26. If the partition boot record cannot be read successfully from the active partition within five retries because of read errors, this message appears and the system stops:
Error loading operating system
27. The hard disk's partition boot record is tested for a signature. If it does not contain a valid signature of 55AAh as the last two bytes in the sector, this message appears and the system stops:
Missing operating system
28. The volume boot record is executed as a program. This program looks for and loads the operating system kernel or system files. If the volume boot record cannot find or load the system files, or if a problem was encountered loading them, one of the following messages appears:
Non-System disk or disk error
Replace and strike any key when ready

Non-System disk or disk error
Replace and press any key when ready

Invalid system disk_
Replace the disk, and then press any key

Disk Boot failure

Disk I/O Error

All these messages originate in the volume boot record (VBR) and relate to VBR or system file problems.

From this point forward what happens depends on which operating system you have. The operating system-dependent boot procedures are discussed in the next several sections.

The DOS Boot Process

1. The initial system file (called IO.SYS or IBMBIO.COM) is executed.
2. The initialization code in IO.SYS/IBMBIO.COM copies itself into the highest region of contiguous DOS memory and transfers control to the copy. The initialization code copy then relocates MSDOS.SYS over the portion of IO.SYS in low memory that contains the initialization code, because the initialization code no longer needs to be in that location. Windows 9x's IO.SYS combines the functions of DOS's IO.SYS and MSDOS.SYS.
3. The initialization code executes MSDOS.SYS (or IBMDOS.COM), which initializes the base device drivers, determines equipment status, resets the disk system, resets and initializes attached devices, and sets the system default parameters.

4. The full DOS file system is active, and control is returned to the IO.SYS initialization code.
5. The IO.SYS initialization code reads the CONFIG.SYS file multiple times. In Windows 9x, IO.SYS also looks for the SYSTEM.DAT Registry file.
6. When loading CONFIG.SYS, the DEVICE statements are first processed in the order in which they appear. Any device driver files named in those DEVICE statements are loaded and executed. Then any INSTALL statements are processed in the order in which they appear; the programs named are loaded and executed. The SHELL statement is processed and loads the specified command processor with the specified parameters. If the CONFIG.SYS file contains no SHELL statement, the default \COMMAND.COM processor is loaded with default parameters. Loading the command processor overwrites the initialization code in memory (because the job of the initialization code is finished).

In Windows 9x, the system looks in the Registry's Hkey_Local_Machine\System\CurrentControlSet key to load the device drivers and other parameters specified there before executing the CONFIG.SYS file. The COMMAND.COM program is loaded at this time only if an AUTOEXEC.BAT file exists, so it can process the commands contained within it. The Windows 9x boot menu also provides a safe mode option. This option bypasses the loading of the drivers for the specific hardware in the system and instead loads a set of generic drivers designed to get the system up and running with only minimal functionality. This enables the computer to boot the Windows GUI in situations where a malfunctioning driver or device would otherwise prevent access to the system.

During the final reads of CONFIG.SYS, all the remaining statements are read and processed in a predetermined order. Thus, the order of appearance for statements other than DEVICE, INSTALL, and SHELL in CONFIG.SYS is of no significance.

7. If AUTOEXEC.BAT is present, COMMAND.COM loads and runs AUTOEXEC.BAT. After the commands in AUTOEXEC.BAT have been executed, the DOS prompt appears (unless the AUTOEXEC.BAT calls an application program or shell of some kind, in which case the user might operate the system without ever seeing a DOS prompt).
8. If no AUTOEXEC.BAT file is present, COMMAND.COM executes the internal DATE and TIME commands, displays a copyright message, and displays the DOS prompt.

In Windows 9x, IO.SYS automatically loads HIMEM.SYS, IFSHLP.SYS, and SETVER.EXE. Finally, it loads WIN.COM and Windows 9x is officially started. For more information on how Windows 9x loads, see the section, "The Windows 9x/Me Boot Process," later in this chapter.

Some minor variations from this scenario are possible, such as those introduced by other ROM programs in the various adapters that might be plugged into an expansion slot. Also, depending on the exact ROM BIOS programs involved, some of the error messages and sequences might vary. Generally, however, a computer follows this chain of events while "coming to life."

You can modify the system startup procedures by altering the CONFIG.SYS and AUTOEXEC.BAT files or the Windows 9x Registry or Startup folder. These files control the configuration of DOS or Windows 9x and allow special startup programs to be executed every time the system starts.

The Windows 9x/Me Boot Process

Knowing exactly how Windows 9x and Millennium Edition (Me) load and start can be helpful when troubleshooting startup problems. The Windows 9x boot process can be broken into three phases:

- The IO.SYS file is loaded and run.
- Real mode configuration takes place.
- The WIN.COM file is loaded and run.

Phase 1—Loading and Running the IO.SYS File

1. The initialization code initializes the base device drivers, determines equipment status, resets the disk system, resets and initializes attached devices, and sets the system default parameters.
2. The file system is activated, and control is returned to the IO.SYS initialization code.
3. The Starting Windows message is displayed for *<n>* seconds, or until you press a Windows function key. The amount of time the message is displayed is determined by the `BootDelay=<n>` line in the MSDOS.SYS file; the default is 2 seconds.
4. The IO.SYS initialization code reads the MSDOS.SYS configuration file. If you have multiple hardware profiles, you receive the following message and must choose a hardware configuration to use:

```
Windows cannot determine what configuration your computer is in.
```

5. The LOGO.SYS file is loaded and displays a startup image on the screen.
6. If the DRVSPACE.INI or DBLSPACE.INI files exist, they are loaded into memory. IO.SYS also automatically loads HIMEM.SYS, IFSHLP.SYS, and SETVER.EXE.
7. The IO.SYS file checks the system Registry files (SYSTEM.DAT and USER.DAT) for valid data.
8. IO.SYS opens the SYSTEM.DAT file. If the SYSTEM.DAT file is not found, the SYSTEM.DA0 file is used for start up. If Windows 9x starts successfully, the SYSTEM.DA0 file is copied to the SYSTEM.DAT file.
9. The DBLBUFF.SYS file is loaded if the `DoubleBuffer=1` is in the MSDOS.SYS file or if double buffering is enabled under the following Registry key:

```
HKLM\System\CurrentControlSet\Control\WinBoot\DoubleBuffer
```

Note

Windows 9x Setup automatically enables double buffering if it detects that it is required.

10. If you have multiple hardware profiles, the hardware profile you chose is loaded from the Registry.
11. In Windows 9x/Me, the system looks in the Registry's `Hkey_Local_Machine\System\CurrentControlSet` key to load the device drivers and other parameters specified there before executing the CONFIG.SYS file.

Phase 2—Real Mode Configuration

Some older hardware devices and programs require that drivers or files be loaded in real mode (16-bit mode) for them to work properly. To ensure backward compatibility, Windows 9x processes the CONFIG.SYS and AUTOEXEC.BAT files if they exist.

1. The CONFIG.SYS file is read if it exists, and the statements within are processed, including the loading of drivers into memory. If the CONFIG.SYS file does not exist, the IO.SYS file loads the following required drivers:

IFSHLP.SYS
 HIMEM.SYS
 SETVER.EXE

IO.SYS obtains the location of these files from the WinBootDir= line of the MSDOS.SYS file, and must be on the hard disk.

2. Windows reserves all global upper memory blocks (UMBs) for the Windows 9x operating system use or for expanded memory support (EMS).
3. The AUTOEXEC.BAT file is processed if present, and any terminate-and-stay resident (TSR) programs listed within are loaded into memory.

Phase 3—Loading and Running the WIN.COM File

1. WIN.COM is loaded and run.
2. WIN.COM file accesses the VMM32.VXD file. If there is enough available RAM, the VMM32.VXD file loads into memory; otherwise, it is accessed from the hard disk (resulting in a slower startup time).
3. The real-mode virtual device driver loader checks for duplicate virtual device drivers (VxDs) in the WINDOWS\SYSTEM\VMM32 folder and the VMM32.VXD file. If a VxD exists in both the WINDOWS\SYSTEM\VMM32 folder and the VMM32.VXD file, the duplicate VxD is “marked” in the VMM32.VXD file so that it is not loaded.
4. VxDs that are not already loaded by the VMM32.VXD file are loaded from the [386 Enh] section of the WINDOWS\SYSTEM.INI file.

Required VxDs

Some VxDs are required for Windows to run properly. These required VxDs are loaded automatically and do not require a Registry entry. The following VxDs are required by Windows 9x:

*BIOSLIAT	*CONFIGMG	*DYNAPAGE
*DOSMGR	*EBIOS	*IFSMGR
*INT13	*IOS	*PAGESWAP
*SHELL	*V86MMGR	*VCD
*VCACHE	*VCOMM	*VCOND
*VDD	*VDMAD	*VFAT
*VKD	*VMCPD	*VPICD
*VTD	*VTDAPI	*VWIN32
*VXDldr		

5. The real-mode virtual device driver loader checks that all required VxDs loaded successfully. If not, it attempts to load the drivers again.
6. Once the real-mode virtual device driver loading is logged, driver initialization occurs. If any VxDs require real-mode initialization, they begin their process in real mode.
7. VMM32 switches the computer’s processor from real mode to protected mode.
8. A three-phase VxD initialization process occurs in which the drivers are loaded according to their InitDevice instead of the order in which they are loaded into memory.

9. After all the VxDs are loaded, the KRNL32.DLL, GDI.EXE, USER.EXE, and EXPLORER.EXE (the default Windows 9x GUI shell) files are loaded.
10. If a network is specified, load the network environment and multiuser profiles. The user is prompted to log on to the network that is installed. Windows 9x/Me allows multiple users to save their custom desktop settings. When a user logs on to Windows, his or her desktop settings are loaded from the Registry. If the user does not log on, the desktop configuration uses a default desktop.
11. Programs in the StartUp group and the RunOnce Registry key are run during the last phase of the startup process. After each program in the RunOnce Registry key is started, the program is removed from the key.

Windows NT and Windows 2000 Startup

When you start a Windows NT or Windows 2000 system, the boot process is identical to that of a DOS or Windows 9.x/Me system, up until the time when the system reads the partition boot record from the active partition. Instead of the IO.SYS and MSDOS.SYS files, Windows NT and 2000 use an OS loader program called NTLDR that begins the hardware detection process and enables you to select the operating system to load. If, for example, you have installed Windows NT or Windows 2000 on a system already running another OS, you have the option of booting either operating system. The boot options are stored in a file called BOOT.INI.

Once you elect to load Windows NT or Windows 2000, a file called NTDETECT.COM loads and detects the hardware in the computer. Then, the Windows NT Kernel (NTOSKRNL.EXE) and the hardware abstraction layer (HAL.DLL) are loaded into memory. The kernel is responsible for initializing most of the operating system, including the device drivers, the Windows NT subsystems and services, and the memory paging file. It isn't until you press the Ctrl+Alt+Delete key combination and log on to the system that the startup process is considered to be complete.

PC Maintenance Tools

To troubleshoot and repair PC systems properly, you need a few basic tools. If you intend to troubleshoot and repair PCs professionally, there are many more specialized tools you will want to purchase. These advanced tools enable you to more accurately diagnose problems and make jobs easier and faster. The basic tools that should be in every troubleshooter's toolbox are

- Simple hand tools for basic disassembly and reassembly procedures, including a flat blade and Phillips screwdrivers (both medium and small sizes), tweezers, an IC extraction tool, and a parts grabber or hemostat. Most of these items are included in \$10–20 starter toolkits found at most computer stores.
- Diagnostics software and hardware for testing components in a system.
- A multimeter that provides accurate measurements of voltage and resistance, as well as a continuity checker for testing cables and switches.
- Chemicals, such as contact cleaners, component freeze sprays, and compressed air for cleaning the system.
- Foam swabs, or lint-free cotton swabs if foam isn't available.
- Small nylon wire ties for “dressing” or organizing wires.

Some environments might also have the resources to purchase the following devices, although they're not required for most work:

- Memory-testing machines, used to evaluate the operation of SIMMs (single inline memory modules), DIMMs (dual inline memory modules), DIP (dual inline pin) chips, and other memory modules
- Serial and parallel loopback (or wrap) plugs to test serial and parallel ports
- A network cable scanner (if you work with networked PCs)
- A serial breakout box (if you use systems that operate over serial cables, such as UNIX dumb terminals)

In addition, an experienced troubleshooter will probably want to have soldering and desoldering tools to fix bad serial cables. These tools are discussed in more detail in the following sections.

Hand Tools

When you work with PC systems, the tools required for nearly all service operations are simple and inexpensive. You can carry most of the required tools in a small pouch. Even a top-of-the-line “master mechanics” set fits inside a briefcase-sized container. The cost of these toolkits ranges from about \$20 for a small service kit to \$500 for one of the briefcase-sized deluxe kits. Compare these costs with what might be necessary for an automotive technician. An automotive service technician would have to spend \$5,000 to \$10,000 or more for a complete set of tools. Not only are PC tools much less expensive, but I can tell you from experience that you don't get nearly as dirty working on computers as you do working on cars.

In this section, you learn about the tools required to assemble a kit that is capable of performing basic, board-level service on PC systems. One of the best ways to start such a set of tools is to purchase a small kit sold especially for servicing PCs.

The following list shows the basic tools that you can find in one of the small PC toolkits that sell for about \$20:

- 3/16-inch nut driver
- 1/4-inch nut driver
- Small Phillips screwdriver
- Small flat-blade screwdriver
- Medium Phillips screwdriver
- Medium flat-blade screwdriver
- Chip extractor
- Chip inserter
- Tweezers
- Claw-type parts grabber
- T10 and T15 Torx drivers

Note

Some tools aren't recommended because they are of limited use. However, they normally come with these types of kits.

You use nut drivers to remove the hexagonal-headed screws that secure the system-unit covers, adapter boards, disk drives, and power supplies in most systems. The nut drivers work much better than conventional screwdrivers.

Because some manufacturers have substituted slotted or Phillips-head screws for the more standard hexagonal-head screws, standard screwdrivers can be used for those systems.

Caution

When working in a cramped environment such as the inside of a computer case, screwdrivers with magnetic tips can be a real convenience, especially for retrieving that screw you dropped into the case. However, although I have used these types of screwdrivers many times with no problems, you must be aware of the damage that a magnetic field can cause to memory chips and magnetic storage devices such as hard drives and floppy disks. Laying the screwdriver down on or near a floppy or working too close to a hard drive can damage the data on the disk.

Chip-extraction and insertion tools are rarely needed these days because memory chips are mounted on SIMMs or DIMMs and processors use ZIF (zero insertion force) sockets or other user-friendly connectors. The ZIF socket has a lever that, when raised, releases the grip on the pins of the chip, allowing you to easily lift it out with your fingers.

However, if you work with older systems, you must use a chip extractor (see Figure 25.1) to install or remove memory chips (or other smaller chips) without bending any pins on the chip. Usually, you pry out larger chips, such as microprocessors or ROMs, with the small screwdriver. Larger processors require a chip extractor if they are mounted in the older LIF (low insertion force) socket. These chips have so many pins on them that a large amount of force is required to remove them, despite the fact that they call the socket "low insertion force." If you use a screwdriver on a large physical size chip such as a 486, you risk cracking the case of the chip and permanently damaging it. The chip extractor tool for removing these chips has a very wide end with tines that fit between the pins on the chip to distribute the force evenly along the chip's underside. This will minimize the likelihood of breakage. Most of these types of extraction tools must be purchased specially for the chip you're trying to remove.

Tip

The older-style chip extractor shown on the left in Figure 25.1 does have another use as a keycap extractor. In fact for this role it works quite well. By placing the tool over a keycap on a keyboard and squeezing the tool so the hooks grab under the keycap on opposite sides, you can cleanly and effectively remove the keycap from the keyboard without damage. This works much better than trying to pry the caps off with a screwdriver, which often results in damaging them or sending them flying across the room.

Figure 25.1 The chip extractor (left) would be used to remove an individual RAM or ROM chip from a socket but it would not be useful for a larger processor chip. Use an extractor such as the one on the right for extracting socketed processors—if the processor does not use a ZIF socket.

The tweezers and parts grabber can be used to hold any small screws or jumper blocks that are difficult to hold in your hand. The parts grabber (see Figure 25.2) is especially useful when you drop a small part into the interior of a system; usually, you can remove the part without completely disassembling the system.

Figure 25.2 The parts grabber has three small metal prongs that can be extended to grab a part.

Finally, the Torx driver is a star-shaped driver that matches the special screws found in most Compaq systems and in many other systems as well (see Figure 25.3). You can also purchase tamperproof Torx drivers that can remove Torx screws with the tamper-resistant pin in the center of the screw. A tamperproof Torx driver has a hole drilled in it to allow clearance for the pin.

Figure 25.3 A Torx driver and bit.

Although this basic set is useful, you should supplement it with some other small hand tools, such as

- Needle-nose pliers
- Vise or clamp
- Hemostat
- File
- Wire cutter or wire stripper
- Small flashlight

Pliers are useful for straightening pins on chips, applying or removing jumpers, crimping cables, or grabbing small parts.

Hemostats are especially useful for grabbing small components, such as jumpers.

The wire cutter or stripper, obviously, is useful for making or repairing cables or wiring. For example, you'd need these (along with a crimping tool) to make 10BaseT Ethernet cables using UTP cable and RJ45 connectors (see Chapter 19, "Local Area Networking").

You can use a vise to install connectors on cables, to crimp cables to the shape you want, and to hold parts during delicate operations. In addition to the vise, Radio Shack sells a nifty "extra hands" device that has two movable arms with alligator clips on the end. This type of device is very useful for making cables or for other delicate operations where an extra set of hands to hold something might be useful.

You can use the file to smooth rough metal edges on cases and chassis and to trim the faceplates on disk drives for a perfect fit.

You might often need a flashlight to illuminate system interiors, especially when the system is cramped and the room lighting is not good, or when you are working on a system underneath a user's desk. I consider this tool to be essential.

Another consideration for your toolkit is an ESD (electrostatic discharge) protection kit. This kit consists of a wrist strap with a ground wire and a specially conductive mat with its own ground wire. Using a kit like this when working on a system will help ensure that you never accidentally

damage any of the components with a static discharge. You can also get just the wrist strap or the anti-static mat separately. A wrist strap is shown in Figure 25.4.

Note

You can work without an ESD protection kit, if you're disciplined and careful about working on systems. If you don't have an ESD kit available, you should discharge yourself by touching some metallic part of the case while the computer is still plugged in to the AC power source, and then unplug the computer. Many systems today continue to feed power to the motherboard through the soft off connection whenever the computer is plugged in, even when the power switch is turned off. It can be very dangerous to work inside a PC that is still connected to a power source.

Figure 25.4 A typical ESD wrist strap clipped to a non-painted surface in the case chassis.

The ESD kits, as well as all the other tools and much more, are available from a variety of tool vendors. Specialized Products Company and Jensen Tools are two of the most popular vendors of computer and electronic tools and of service equipment. Their catalogs show an extensive selection of very high-quality tools. (These companies and several others are listed in the Vendor List, on the CD.) With a simple set of hand tools, you will be equipped for nearly every PC repair or installation situation. The total cost of these tools should be less than \$150, which is not much considering the capabilities they give you.

A Word About Hardware

This section discusses some problems that you might encounter with the hardware (screws, nuts, bolts, and so on) used in assembling a system.

Types of Hardware

One of the biggest aggravations that you encounter in dealing with various systems is the different hardware types and designs that hold the units together.

For example, most systems use screws that fit 1/4-inch or 3/16-inch hexagonal nut drivers. IBM used these screws in all its original PC, XT, and AT systems, and most other system manufacturers use this standard hardware as well. Some manufacturers use different hardware, however.

Compaq, for example, uses Torx screws extensively in many of its systems. A Torx screw has a star-shaped hole driven by the correct-size Torx driver. These drivers carry size designations such as T-8, T-9, T-10, T-15, T-20, T-25, T-30, and T-40.

A variation on the Torx screw is the tamperproof Torx screw found in power supplies and other assemblies. These screws are identical to the regular Torx screws, except that a pin sticks up from the middle of the star-shape hole in the screw. This pin prevents the standard Torx driver from entering the hole to grip the screw; a special tamperproof driver with a corresponding hole for the pin is required. An alternative is to use a small chisel to knock out the pin in the screw. Usually, a device that is sealed with these types of screws is considered to be a replaceable unit that rarely, if ever, needs to be opened.

Many manufacturers also use the more standard slotted-head and Phillips-head screws. Using tools on these screws is relatively easy, but tools do not grip these fasteners as well as hexagonal head or Torx screws do, and the heads can be stripped more easily than the other types. Extremely cheap versions tend to lose bits of metal as they're turned with a driver, and the metal bits can fall onto the motherboard. Stay away from cheap fasteners whenever possible; the headaches of dealing with stripped screws aren't worth it.

Some system manufacturers now use cases that snap together or use thumb screws. These are usually advertised as "no-tool" cases because you literally do not need any tools to take off the cover and access the major assemblies.

A company called Curtis sells special nylon plastic thumb screws that fit most normal cases and can be used to replace the existing screws to make opening the case a no-tool proposition. However, you should still always use metal screws to install internal components such as adapter cards, disk drives, power supplies, and the motherboard because the metal screws provide a ground point for these devices.

English Versus Metric

Another area of aggravation with hardware is the fact that there are two types of thread systems: English and metric. IBM used mostly English-threaded fasteners in its original line of systems, but many other manufacturers used metric-threaded fasteners.

The difference between the two becomes especially apparent with disk drives. American-manufactured drives typically use English fasteners, whereas drives made in Japan or Taiwan usually use metric. Whenever you replace a floppy drive in an older PC, you encounter this problem. Try to buy the correct screws and any other hardware, such as brackets, with the drive because they might be difficult to find as separate items. Many drive manufacturers offer retail drive kits that include all the required mounting components. The OEM's drive manual lists the correct data about a specific drive's hole locations and thread size.

Hard disks can use either English or metric fasteners; check your particular drive to see which type it uses. Most drives today use metric hardware.

Caution

Some screws in a system can be length-critical, especially screws that are used to retain hard disk drives. You can destroy some hard disks by using a mounting screw that's too long; the screw can puncture or dent the sealed disk chamber when you install the drive and fully tighten the screw. When you install a new drive in a system, always make a trial fit of the hardware to see how far the screws can be inserted into the drive before they interfere with its internal components. When you're in doubt, the drive manufacturer's OEM documentation will tell you precisely what screws are required and how long they should be.

Soldering and Desoldering Tools

In certain situations—such as repairing a broken wire, making cables, reattaching a component to a circuit board, removing and installing chips that are not in a socket, or adding jumper wires or pins to a board—you must use a soldering iron to make the repair.

Although virtually all repairs these days are done by simply replacing the entire failed board and many PC technicians never touch a soldering iron, you might find one useful in some situations. The most common case would be where there is physical damage to a system, such as when someone rips the keyboard connector off of a motherboard by pulling on the cable improperly. Simple soldering skills can save the motherboard in this case.

Most motherboards these days include I/O components such as serial and parallel ports. Many of these ports are fuse-protected on the board; however, the fuse is usually a small soldered-in component. These fuses are designed to protect the motherboard circuits from being damaged by an external source. If a short circuit or static charge from an external device blows these fuses, the motherboard can be saved if you can replace them.

To perform minor repairs such as these, you need a low-wattage soldering iron—usually about 25 watts. More than 30 watts generates too much heat and can damage the components on the board. Even with a low-wattage unit, you must limit the amount of heat to which you subject the board and its components. You can do this with quick and efficient use of the soldering iron and with the use of heat-sinking devices clipped to the leads of the device being soldered. A heat sink is a small metal clip-on device designed to absorb excessive heat before it reaches the component that the heat sink is protecting. In some cases, you can use a pair of hemostats as an effective heat sink when you solder a component.

To remove components that are soldered into place on a printed circuit board, you can use a soldering iron with a solder sucker. This device normally takes the form of a small tube with an air chamber and a plunger-and-spring arrangement. (I do not recommend the squeeze-bulb type of solder sucker.) The unit is “cocked” when you press the spring-loaded plunger into the air chamber. When you want to remove a device from a board, you use the soldering iron from the underside of the board, and heat the point at which one of the component leads joins the circuit board until the solder melts. As soon as melting occurs, move the solder-sucker nozzle into position, and press the actuator. When the plunger retracts, it creates a momentary suction that draws the liquid solder away from the connection and leaves the component lead dry in the hole.

Always do the heating and suctioning from the underside of a board, not from the component side. Repeat this action for every component lead joined to the circuit board. When you master this technique, you can remove a small component in a minute or two with only a small likelihood of damage to the board or other components. Larger chips that have many pins can be more difficult to remove and resolder without damaging other components or the circuit board.

Tip

These procedures are intended for “through-hole” devices only. These are components whose pins extend all the way through holes in the board to the underside. Surface-mount devices are removed with a completely different procedure, using much more expensive tools. Working on surface-mounted components is beyond the capabilities of all but the most well-equipped shops.

If you intend to add soldering and desoldering skills to your arsenal of abilities, you should practice. Take a useless circuit board and practice removing various components from the board; then, reinstall the components. Try to remove the components from the board by using the least amount of heat possible. Also, perform the solder-melting operations as quickly as possible, limiting the time that the iron is applied to the joint. Before you install any components, clean out the holes through which the leads must project and mount the component in place. Then, apply the solder from the underside of the board, using as little heat and solder as possible.

Attempt to produce joints as clean as the joints that the board manufacturer produced by machine. Soldered joints that do not look clean can keep the component from making a good connection with the rest of the circuit. This “cold-solder joint” is normally created because you have not used enough heat. Remember that you should not practice your new soldering skills on the motherboard of a system that you are attempting to repair! Don’t attempt to work on real boards until you are sure of your skills. I always keep a few junk boards around for soldering practice and experimentation.

Tip

When first learning to solder, you might be tempted to set the iron on the solder and leave it there until the solder melts. If the solder doesn’t melt immediately when you apply the iron to it, you’re not transferring the heat from the iron to the solder efficiently. This means that either the iron is dirty or there is debris between it and the solder. To clean the iron, take a wet sponge and drag it across the tip of the iron.

If after cleaning the iron there’s still some resistance, try to scratch the solder with the iron when it’s hot. Generally, this removes any barriers to heat flow and instantly melts the solder.

No matter how good you get at soldering and desoldering, some jobs are best left to professionals. Components that are surface-mounted to a circuit board, for example, require special tools for soldering and desoldering, as do other components that have high pin densities.

Test Equipment

In some cases, you must use specialized devices to test a system board or component. This test equipment is not expensive or difficult to use, but it can add much to your troubleshooting abilities.

Electrical Testing Equipment

I consider a voltmeter to be required gear for proper system testing. A multimeter can serve many purposes, including checking for voltage signals at different points in a system, testing the output of the power supply, and checking for continuity in a circuit or cable. An outlet tester is an invaluable accessory that can check the electrical outlet for proper wiring. This capability is useful if you believe that the problem lies outside the computer system.

Loopback Connectors (Wrap Plugs)

For diagnosing serial- and parallel-port problems, you need loopback connectors (also called wrap plugs), which are used to circulate, or wrap, signals (see Figure 25.5). The plugs enable the serial or parallel port to send data to itself for diagnostic purposes.

Figure 25.5 Typical wrap plugs including 25-pin and 9-pin serial and 25-pin parallel versions

Different types of loopback connectors are available. To accommodate all the ports you might encounter, you need one for the 25-pin serial port, one for the 9-pin serial port, and one for the 25-pin parallel port. Many companies, including IBM, sell the plugs separately, but be aware that you also need diagnostic software that can use them. Some diagnostic software products, such as Micro 2000's Micro-Scope, include loopback connectors with the product.

IBM sells a special combination plug that includes all three connector types in one compact unit. The device costs approximately \$30 from IBM. If you're handy, you can even make your own wrap plugs for testing. I include wiring diagrams for the three types of wrap plugs in Chapter 16, "Serial, Parallel, and Other I/O Interfaces." In that chapter, you also will find a detailed discussion of serial and parallel ports.

Besides simple loopback connectors, you might also want to have a breakout box for your toolkit. A breakout box is a DB25 connector device that enables you to make custom temporary cables or even to monitor signals on a cable. For most PC troubleshooting uses, a "mini" breakout box works well and is inexpensive.

Meters

Some troubleshooting procedures require that you measure voltage and resistance. You take these measurements by using a handheld Digital Multi-Meter (DMM). The meter can be an analog device (using an actual meter) or a digital-readout device. The DMM has a pair of wires called test leads or probes. The test leads make the connections so that you can take readings. Depending on the meter's setting, the probes measure electrical resistance, direct-current (DC) voltage, or alternating-current (AC) voltage.

Usually, each system-unit measurement setting has several ranges of operation. DC voltage, for example, usually can be read in several scales, to a maximum of 200 millivolts (mv), 2v, 20v, 200v, and 1,000v. Because computers use both +5v and +12v for various operations, you should use the 20v maximum scale for making your measurements. Making these measurements on the 200mv or 2v scale could “peg the meter” and possibly damage it because the voltage would be much higher than expected. Using the 200v or 1,000v scale works, but the readings at 5v and 12v are so small in proportion to the maximum that accuracy is low.

If you are taking a measurement and are unsure of the actual voltage, start at the highest scale and work your way down. Most of the better meters have autoranging capability—the meter automatically selects the best range for any measurement. This type of meter is much easier to operate. You simply set the meter to the type of reading you want, such as DC volts, and attach the probes to the signal source. The meter selects the correct voltage range and displays the value. Because of their design, these types of meters always have a digital display rather than a meter needle.

Caution

Whenever using a multimeter to test any voltage that could potentially be 110v or above, always use one hand to do the testing, not two. Either clip one lead to one of the sources and probe with the other or hold both leads in one hand.

If you hold a lead in each hand and accidentally slip, you can very easily become a circuit, allowing power to conduct or flow through you. When power flows from arm to arm, the path of the current is directly across the heart. Hearts tend to quit working when subjected to high voltages. They're funny that way.

I prefer the small digital meters; you can buy them for only slightly more than the analog style, and they're extremely accurate and much safer for digital circuits. Some of these meters are not much bigger than a cassette tape; they fit in a shirt pocket. Radio Shack sells a good unit (made for Radio Shack by Beckman) in the \$25 price range; the meter is a half-inch thick, weighs 3 1/2 ounces, and is digital and autoranging, as well. This type of meter works well for most, if not all, PC troubleshooting and test uses.

Caution

You should be aware that many analog meters can be dangerous to digital circuits. These meters use a 9v battery to power the meter for resistance measurements. If you use this type of meter to measure resistance on some digital circuits, you can damage the electronics because you essentially are injecting 9v into the circuit. The digital meters universally run on 3–5v or less.

Logic Probes and Logic Pulsers

A logic probe (see Figure 25.6) can be useful for diagnosing problems in digital circuits. In a digital circuit, a signal is represented as either high (+5v) or low (0v). Because these signals are present for only a short time (measured in millionths of a second) or oscillate (switch on and off) rapidly, a simple voltmeter is useless. A logic probe is designed to display these signal conditions easily.

Figure 25.6 A typical logic probe.

Logic probes are especially useful for troubleshooting a dead system. By using the probe, you can determine whether the basic clock circuitry is operating and whether other signals necessary for system operation are present. In some cases, a probe can help you cross-check the signals at each pin on an integrated circuit chip. You can compare the signals present at each pin with the signals that a known-good chip of the same type would show—a comparison that is helpful in isolating a failed component. Logic probes can also be useful for troubleshooting some disk drive problems by enabling you to test the signals present on the interface cable or drive-logic board.

A companion tool to the probe is the logic pulser. A pulser is designed to test circuit reaction by delivering a logical high (+5v) pulse into a circuit, usually lasting from 1 1/2 to 10 millionths of a second. Compare the reaction with that of a known-functional circuit. This type of device normally is used much less frequently than a logic probe, but in some cases, it can be helpful for testing a circuit.

Outlet Testers

Outlet testers are very useful test tools. These simple, inexpensive devices, sold in hardware stores, test electrical outlets. You simply plug in the device, and three LEDs light in various combinations, indicating whether the outlet is wired correctly.

Although you might think that badly wired outlets would be a rare problem, I have seen a large number of installations in which the outlets were wired incorrectly. Most of the time, the problem is in the ground wire. An improperly wired outlet can result in unstable system operation, such as random parity checks and lockups. With an improper ground circuit, currents can begin flowing on the electrical ground circuits in the system. Because the system uses the voltage on the ground circuits as a comparative signal to determine whether bits are 0 or 1, a floating ground can cause data errors in the system.

Once, while running one of my PC troubleshooting seminars, I used a system that I literally could not approach without locking it up. Whenever I walked past the system, the electrostatic field generated by my body interfered with the system, and the PC locked up, displaying a parity-check error message. The problem was that the hotel at which I was giving the seminar was very old and had no grounded outlets in the room. The only way I could prevent the system from locking up was to run the class in my stocking feet because my leather-soled shoes were generating the static charge.

Other symptoms of bad ground wiring in electrical outlets are continual electrical shocks when you touch the case or chassis of the system. These shocks indicate that voltages are flowing where they should not be. This problem can also be caused by bad or improper grounds within the system. By using the simple outlet tester, you can quickly determine whether the outlet is at fault.

If you just walk up to a system and receive an initial shock, it's probably only static electricity. Touch the chassis again without moving your feet. If you receive another shock, there is something very wrong. In this case, the ground wire actually has voltage applied to it. You should have a professional electrician check the outlet immediately.

If you don't like being a human rat in an electrical experiment, you can test the outlets with your multimeter. First, remember to hold both leads in one hand. Test from one blade hole to another. This should read between 110v and 125v depending on the electrical service in the area. Then check from each blade to the ground (the round hole). One blade hole, the smaller one, should show a voltage almost identical to the one that you got from the blade hole-to-blade hole test. The larger blade hole when measured to ground should show less than 0.5v.

Because ground and neutral are supposed to be tied together at the electrical panel, a large difference in these readings indicates that they are not tied together. However, small differences can be accounted for by current from other outlets down the line flowing on the neutral, when there isn't any on the ground.

If you don't get the results you expect, call an electrician to test the outlets for you. More weird computer problems are caused by improper grounding and other power problems than people like to believe.

Memory Testers

I now consider a memory test machine an all-but-mandatory piece of equipment for anyone serious about performing PC troubleshooting and repair as a profession. The tester is a small device designed to evaluate SIMMs, DIMMs, RIMMs, and other types of memory modules, including individual chips such as those used as cache memory. These testers can be somewhat expensive, costing upward of \$1,000 to \$2,500 or more, but these machines are the only truly accurate way to test memory.

Without one of these testers, you are reduced to testing memory by running a diagnostic program on the PC and testing the memory as it is installed. This can be very problematic, as the memory diagnostic program can only do two things to the memory: write and read. A SIMM/DIMM/RIMM tester can do many things that a memory diagnostic running in a PC cannot do, such as

- Identify the type of memory
- Identify the memory speed
- Identify whether the memory has parity or is using bogus parity emulation
- Vary the refresh timing and access speed timing
- Locate single bit failures
- Detect power- and noise-related failures
- Detect solder opens and shorts
- Isolate timing-related failures
- Detect data retention errors

No conventional memory diagnostic software can do these things because it has to rely on the fixed access parameters set up by the memory controller hardware in the motherboard chipset. This prevents the software from being able to alter the timing and methods used to access the memory. You might have memory that fails in one system and works in another when the chips are actually bad. This type of intermittent problem is almost impossible to detect with diagnostic software.

The bottom line is that there is no way that you can test memory with true accuracy while it is installed in a PC; a memory tester is required for comprehensive and accurate testing. The price of a memory tester can be justified very easily in a shop environment where a lot of PCs are tested, because many software and hardware upgrades today require the addition of new memory. With the large increases in the amount of memory in today's systems and stricter timing requirements of newer motherboard designs, it has become even more important to be able to identify or rule out memory as a cause of system failure. One company manufacturing memory testers I recommend is Tanisys Technologies. Its Darkhorse Systems line of memory testers can handle virtually every type of memory on the market. See the Vendor List on the CD for more information. Also see Chapter 6, "Memory," for more information on memory in general.

Special Tools for the Enthusiast

All the tools described so far are commonly used by most technicians. However there are a few additional tools that a true PC enthusiast may want to have.

Electric Screwdriver

Perhaps the most useful tool I use is an electric screwdriver. It allows me to disassemble and reassemble a PC in record time and makes the job not only faster but easier as well. I like the type with a clutch that you can use to set how tight it will make the screws before slipping; such a clutch makes it even faster to use. If you use the driver frequently, it makes sense to use the type with replaceable rechargeable batteries, so when one battery dies you can quickly replace it with a fresh one.

Caution

Note that using an electric screwdriver when installing a motherboard can be dangerous, since it is very easy for the bit to slip off the screw and damage the board. A telltale series of swirling scratches near the screw holes on the board can be the result, for which most manufacturers will rightfully deny a warranty claim. Be especially careful if your motherboard is retained with Phillips head screws, as they are extremely easy for the bit to slip out of. Normally I only recommend using Torx head or hex head screws to retain the motherboard, as they are far more resistant to having the bit slip out and cause damage.

With the electric screwdriver I recommend getting a complete set of English and metric nut driver tips as well as various sizes of Torx, flat head, and Phillips head screwdriver tips.

Tamperproof Torx Bits

Many devices such as power supplies and monitors are held together with tamperproof Torx screws. These are just like the standard Torx screws except they have a pin in the center that prevents a standard Torx driver from being inserted. To disassemble items held together with tamperproof Torx screws, I use a special set of tamperproof drivers. These are available from any good electronics tool supplier.

Caution

Note that devices sealed with these types of screws generally have high voltages or other dangers waiting inside, so being able to bypass these screws doesn't mean it's always a good idea. Make sure you know what you are doing before disassembling devices such as monitors or power supplies.

Temperature Probe

It is often useful to determine the interior temperature of a PC to diagnose whether heat-related issues are causing problems. This requires some way of measuring the temperature inside the PC, as well as the ambient temperature outside the system. The simplest and best tool for the job I've found is the digital thermometers that are sold at most auto parts stores for automobile use. They are designed to read the temperature inside and outside the car and normally come with an internal sensor as well as one at the end of a length of wire.

With this type of probe, you can run the wired sensor inside the case (if it is metal, make sure that it does not directly touch the motherboard or other exposed circuits where it might cause a short) with the wires slipped through a crack in the case or out one of the drive bays. Then with the system running you can take the internal temperature as well as read the room's ambient temperature. Normally the maximum limit for internal temperature should be 110° F (43° C) or

less. If your system is running near or above that temperature, problems may be expected. You can also position the probe in the system to be near any heat producing devices such as the processor, video card, and so on to see the effect of the device. Probing the temperature with a device like this will allow you to determine whether additional cooling is necessary (that is, adding more cooling fans to the case) and will allow you to check whether the added fans are helping.

Large Claw-type Parts Grabber

One of the more useful tools in my toolbox is a large claw-type parts grabber normally sold in stores that carry automotive tools. Having one of these around has saved many hours of frustration digging back into a system or behind a desk for a loose or dropped screw.

These grabbers are very similar to the small claw-type grabber included with most PC toolkits except they are much larger, normally two feet or so in length. They can be very useful if you drop a screw down inside a tower case, or even on the floor under or behind a desk or cabinet. Although magnetic parts grabbers are also available, I normally recommend the claw-type, as using a powerful magnet near a computer can cause problems with any disk storage media you have about, or even the hard disk or CRT.

Preventive Maintenance

Preventive maintenance is the key to obtaining years of trouble-free service from your computer system. A properly administered preventive maintenance program pays for itself by reducing problem behavior, data loss, and component failure and by ensuring a long life for your system. In several cases, I have “repaired” an ailing system with nothing more than a preventive maintenance session. Preventive maintenance can also increase your system’s resale value because it will look and run better.

Developing a preventive maintenance program is important to everyone who uses or manages personal computer systems. There are two types of preventive maintenance procedures: active and passive.

An active preventive maintenance program includes procedures that promote a longer, trouble-free life for your PC. This type of preventive maintenance primarily involves the periodic cleaning of the system and its components. The following sections describe several active preventive maintenance procedures, including cleaning and lubricating all major components, reseating chips and connectors, and reformatting hard disks.

Passive preventive maintenance includes steps you can take to protect a system from the environment, such as using power-protection devices; ensuring a clean, temperature-controlled environment; and preventing excessive vibration. In other words, passive preventive maintenance means treating your system well.

Active Preventive Maintenance Procedures

How often you should perform active preventive maintenance procedures depends on the system’s environment and the quality of the system’s components. If your system is in a dirty environment, such as a machine shop floor or a gas station service area, you might need to clean

your system every three months or less. For normal office environments, cleaning a system every one to two years is usually fine. However, if you open your system after one year and find dust bunnies inside, you should probably shorten the cleaning interval.

Other hard disk preventive maintenance procedures include making periodic backups of your data and critical areas such as boot sectors, file allocation tables (FATs), and directory structures on the disk. Also, defragment hard disks periodically to maintain disk efficiency and speed.

System Backups

One of the most important preventive maintenance procedures is the performance of regular system backups. A sad reality in the computer repair and servicing world is that hardware can always be repaired or replaced, but data cannot. Many hard disk troubleshooting and service procedures, for example, require that you repartition or reformat the disk, which overwrites all existing data.

The hard disk drive capacity in a typical PC has grown far beyond the point at which floppy disks are a viable backup solution. Backup solutions that employ floppy disk drives, such as the DOS backup software, are insufficient and too costly for hard disk backups in today's systems. It would take 2,867 1.44MB floppy disks, for example, to back up the 4GB hard disk in my portable system! That would cost more than \$1,000 in disks, not to mention the time involved.

The traditional alternative to floppies is magnetic tape. A DAT (digital audio tape) or Travan tape system can store 4–8GB or more on a single tape costing less than \$30. The increasing popularity of removable cartridge (such as Iomega Zip and Jaz drives) and writable CD-ROM drives presents even more alternatives.

Although a tape drive can cost up to \$500 or more, the media costs are really far more significant than the cost of the drive. If you do responsible backups, you should have at least three sets of media for each system you are backing up. You should use each media set on a rotating basis, and store one of them offsite at all times, in case of fire or theft. You should also introduce new media to the rotation after approximately a year to prevent excessive wear. If you are backing up multiple systems, these media costs can add up quickly.

You should also factor in the cost of your time. If a backup requires manual intervention to change the media during the job, I don't recommend it. A backup system should be capable of fitting a complete backup on a single tape so that you can schedule the job to run unattended. If someone has to hang around to switch tapes every so often, backups become a real chore and are more likely to be overlooked. Also, every time a media change occurs, there is a substantial increase in the likelihood of errors and problems that you might not see until you attempt to perform a restore operation. Backups are far more important than most people realize, and spending a little more on a quality piece of hardware such as a Travan or DAT drive will pay off in the long run with greater reliability, lower media costs, higher performance, and unattended backups that contain the entire system file structure.

With the increasing popularity of removable bulk storage media such as cartridge drives, including Iomega's Zip and Jaz drives, and rewritable CD-ROMs (CD-RWs), many people are using these devices to perform system backups. In most cases, however, although these drives are excellent

for storing backup copies of selected data, they are impractical solutions for regular system backups. This can be due both to the capacity of the media in relation to today's hard disk drives and to the cost of the media.

Although the media for a CD-RW drive are quite inexpensive, it would take several discs to back up a multi-gigabyte hard drive, adding a measure of inconvenience to the backup process that makes it far less likely to be performed on a regular basis. Even the Iomega Jaz drive that can store up to 2GB on a single cartridge can require several media changes to complete a single system backup. Add this to the fact that the Jaz cartridges can cost \$150 or more each, and you have a backup solution that is both inconvenient and expensive.

Tip

No matter what backup solution you use, the entire exercise is pointless if you cannot restore your data from the storage medium. You should test your backup system by performing random file restores at regular intervals to ensure the viability of your data.

Cleaning a System

One of the most important operations in a good preventive maintenance program is regular and thorough cleaning of the system. Dust buildup on the internal components can lead to several problems. One is that the dust acts as a thermal insulator, which prevents proper system cooling. Excessive heat shortens the life of system components and adds to the thermal stress problem caused by greater temperature changes between the system's power-on and power-off states. Additionally, the dust can contain conductive elements that can cause partial short circuits in a system. Other elements in dust and dirt can accelerate corrosion of electrical contacts, resulting in improper connections. In all, the regular removal of any layer of dust and debris from within a computer system benefits that system in the long run.

Most non-ATX and some ATX PCs use a forced-air cooling system that provides even cooling inside the case. A fan is mounted in, on, or near the power supply and pushes air outside. This depressurizes the interior of the system relative to the outside environment. The lower pressure inside the system causes outside air to be drawn in through openings in the system chassis and cover. This draw-through, or depressurization, is the most efficient cooling system that can be designed without an air filter. Air filters typically are not used with depressurization systems because there is no easy way to limit the air intake to a single port that can be covered by a filter.

Some industrial computers and ATX (as well as NLX) systems use a forced-air system that uses the fan to pressurize, rather than to depressurize, the case. This system forces air to exhaust from any holes in the chassis and case or cover. The key to the pressurization system is that all air intake for the system is at a single location—the fan. You can therefore filter the air flowing into the system by integrating a filter assembly into the fan housing. The filter must be cleaned or changed periodically, however, to prevent it from becoming clogged with dust.

Because the interior of the case is pressurized relative to the outside air, airborne contaminants are not drawn into the system even though it might not be completely sealed. Any air entering the system must pass through the fan and filter housing, which removes the contaminants. Pressurization cooling systems were originally designed for use in industrial computer models

intended for extremely harsh environments. However, with the growing popularity of the ATX and NLX architectures, pressurization systems are more common.

A recent trend in ATX case and power supply design, however, has reverted to the negative-pressure design. Some claim that using the fan in the power supply to cool the CPU directly is not effective because the air is preheated by the power supply, especially if it is heavily loaded. Another important reason is that the single biggest advantage of the positive-pressure system, the capability to filter the incoming air, is either not included in the system design or not maintained properly.

Most of the PCs now in use are depressurization systems. Mounting any sort of air filter on these types of systems is impossible because air enters the system from too many sources. With any cooling system in which incoming air is not filtered, dust and other chemical matter in the environment is drawn in and builds up inside the computer. This buildup can cause severe problems if left unchecked.

Tip

Cigarette smoke contains chemicals that can conduct electricity and cause corrosion of computer parts. The smoke residue can infiltrate the entire system, causing corrosion and contamination of electrical contacts and sensitive components such as floppy drive read/write heads and optical drive lens assemblies. You should avoid smoking near computer equipment and encourage your company to develop and enforce a similar policy.

Floppy disk drives are particularly vulnerable to the effects of dirt and dust. A floppy drive is essentially a large “hole” in the system case through which air continuously flows. Therefore, these drives accumulate a large amount of dust and chemical buildup within a short time. Hard disk drives do not present quite the same problem. Because the head disk assembly (HDA) in a hard disk is a sealed unit with a single barometric vent, no dust or dirt can enter without passing through the barometric vent filter. This filter ensures that contaminating dust or particles cannot enter the interior of the HDA. Thus, cleaning a hard disk requires blowing off the dust and dirt from outside the drive. No internal cleaning is required.

Disassembly and Cleaning Tools

To properly clean the system and all the boards inside requires certain supplies and tools. In addition to the tools required to disassemble the unit, you should have these items:

- Contact cleaning solution
- Canned air
- A small brush
- Lint-free foam cleaning swabs
- Anti-static wrist-grounding strap

You also might want to acquire these optional items:

- Foam tape
- Low-volatile room-temperature vulcanizing (RTV) sealer
- Silicone-type lubricant
- Computer vacuum cleaner

These simple cleaning tools and chemical solutions enable you to perform most common preventive maintenance tasks.

Chemicals

Chemicals can be used to help clean, troubleshoot, and even repair a system. You can use several different types of cleaning solutions with computers and electronic assemblies. Most fall into the following categories:

- Standard cleaners
- Contact cleaner/lubricants
- Dusters

Tip

The makeup of many of the chemicals used for cleaning electronic components has been changing because many of the chemicals originally used are now considered environmentally unsafe. They have been attributed to damaging the earth's ozone layer. Chlorine atoms from chlorofluorocarbons (CFCs) and chlorinated solvents attach themselves to ozone molecules and destroy them. Many of these chemicals are now strictly regulated by federal and international agencies in an effort to preserve the ozone layer. Most of the companies that produce chemicals used for system cleaning and maintenance have had to introduce environmentally safe replacements. The only drawback is that many of these safer chemicals cost more and usually do not work as well as those they replace.

Standard Cleaners

For the most basic function—cleaning components, electrical connectors, and contacts—one of the most useful chemicals is 1,1,1 trichloroethane. This substance is a very effective cleaner that was at one time used to clean electrical contacts and components because it does not damage most plastics and board materials. In fact, trichloroethane could be very useful for cleaning stains on the system case and keyboard as well. Unfortunately, trichloroethane is now being regulated as a chlorinated solvent, along with CFCs (chlorofluorocarbons) such as Freon, but electronic chemical-supply companies are offering several replacements.

Alternative cleaning solutions are available in a variety of types and configurations. You can use pure isopropyl alcohol, acetone, Freon, trichloroethane, or a variety of other chemicals. Most board manufacturers and service shops are now leaning toward alcohol, acetone, or other chemicals that do not cause ozone depletion and comply with government regulations and environmental safety.

Recently, new biodegradable cleaners described as “citrus-based cleaners” have become popular in the industry, and in many cases are more effective and more economical for circuit board and contact cleaning. These cleaners are commonly known as d-limonene or citrus terpenes and are derived from orange peels, which gives it a strong (but pleasant) citric odor. Another type of terpene is called α -pinene, and is derived from pine trees. You must exercise care when using these cleaners, however, because they can cause swelling of some plastics, especially silicone rubber and PVC.

You should be sure that your cleaning solution is designed to clean computers or electronic assemblies. In most cases, this means that the solution should be chemically pure and free from contaminants or other unwanted substances. You should not, for example, use drugstore rubbing alcohol for cleaning electronic parts or contacts because it is not pure and could contain water or perfumes. The material must be moisture-free and residue-free. The solutions should be in liquid form, not a spray. Sprays can be wasteful, and you almost never spray the solution directly on components. Instead, wet a foam or chamois swab used for wiping the component. These electronic-component cleaning solutions are available at any good electronics parts store.

Contact Cleaner/Lubricants

These chemicals are similar to the standard cleaners but include a lubricating component. The lubricant eases the force required when plugging and unplugging cables and connectors, reducing strain on the devices. The lubricant coating also acts as a conductive protectant that insulates the contacts from corrosion. These chemicals can greatly prolong the life of a system by preventing intermittent contacts in the future.

A unique type of contact enhancer and lubricant called Stabilant 22 is currently on the market. This chemical, which you apply to electrical contacts, greatly enhances the connection and lubricates the contact point; it is much more effective than conventional contact cleaners or lubricants.

Stabilant 22 is a liquid-polymer semiconductor; it behaves like liquid metal and conducts electricity in the presence of an electric current. The substance also fills the air gaps between the mating surfaces of two items that are in contact, making the surface area of the contact larger and also keeping out oxygen and other contaminants that can corrode the contact point.

This chemical is available in several forms. Stabilant 22 is the concentrated version, whereas Stabilant 22a is a version diluted with isopropanol in a 4:1 ratio. An even more diluted 8:1-ratio version is sold in many high-end stereo and audio shops under the name Tweek. Just 15ml of Stabilant 22a sells for about \$40; a liter of the concentrate costs about \$4,000!

As you can plainly see, Stabilant 22 is fairly expensive, but little is required in an application, and nothing else has been found to be as effective in preserving electrical contacts. (NASA uses the chemical on spacecraft electronics.) An application of Stabilant can provide protection for up to 16 years, according to its manufacturer, D.W. Electrochemicals. You will find the company's address and phone number in the Vendor List on the CD.

Stabilant is especially effective on I/O slot connectors, adapter-card edge and pin connectors, disk drive connectors, power-supply connectors, and virtually any connector in the PC. In addition to enhancing the contact and preventing corrosion, an application of Stabilant lubricates the contacts, making insertion and removal of the connector easier.

Dusters

Compressed gas often is used as an aid in system cleaning. You use the compressed gas as a blower to remove dust and debris from a system or component. Originally, these dusters used

CFCs (chlorofluorocarbons) such as Freon, whereas modern dusters now use either HFCs (hydrofluorocarbons such as difluoroethane) or carbon dioxide, neither of which is known to damage the ozone layer. Be careful when you use these devices because some of them can generate a static charge when the compressed gas leaves the nozzle of the can. Be sure that you are using the kind approved for cleaning or dusting off computer equipment, and consider wearing a static grounding strap as a precaution. The type of compressed-air cans used for cleaning camera equipment can sometimes differ from the type used for cleaning static-sensitive computer components.

When using these compressed air products, make sure you hold the can upright so that only gas is ejected from the nozzle. If you tip the can, the raw propellant will come out as a cold liquid, which not only is wasteful but can damage or discolor plastics. You should only use compressed gas on equipment that is powered off, to minimize any chance of damage through short circuits.

Closely related to compressed-air products are chemical-freeze sprays. These sprays are used to quickly cool down a suspected failing component, which often temporarily restores it to normal operation. These substances are not used to repair a device, but to confirm that you have found a failed device. Often, a component's failure is heat-related and cooling it temporarily restores it to normal operation. If the circuit begins operating normally, the device you are cooling is the suspect device.

Vacuum Cleaners

Some people prefer to use a vacuum cleaner instead of canned gas dusters for cleaning a system. Canned gas is usually better for cleaning in small areas. A vacuum cleaner is more useful when you are cleaning a system loaded with dust and dirt. You can use the vacuum cleaner to suck out the dust and debris instead of simply blowing it around on the other components, which sometimes happens with canned air. For on-site servicing (when you are going to the location of the equipment instead of the equipment coming to you), canned air is easier to carry in a toolkit than a small vacuum cleaner. There are also tiny vacuum cleaners available for system cleaning. These small units are easy to carry and can serve as an alternative to compressed air cans.

There are special vacuum cleaners specifically designed for use on and around electronic components. They are designed to minimize electrostatic discharge (ESD) while in use. If you are using a regular vacuum cleaner and not one specifically designed with ESD protection, you should take precautions such as wearing a grounding wrist strap. Also, if the cleaner has a metal nozzle, be careful not to touch it to the circuit boards or components you are cleaning.

Brushes and Swabs

You can use a small makeup, photographic, or paint brush to carefully loosen the accumulated dirt and dust inside a PC before spraying it with canned air or using the vacuum cleaner. Be careful about generating static electricity, however. In most cases, you should not use a brush directly on circuit boards, but only on the case interior and other parts such as fan blades, air vents, and keyboards. Wear a grounded wrist strap if you are brushing on or near any circuit boards, and brush slowly and lightly to prevent static discharges from occurring.

Use cleaning swabs to wipe off electrical contacts and connectors, disk drive heads, and other sensitive areas. The swabs should be made of foam or synthetic chamois material that does not

leave lint or dust residue. Unfortunately, proper foam or chamois cleaning swabs are more expensive than typical cotton swabs. Do not use cotton swabs because they leave cotton fibers on everything they touch. Cotton fibers are conductive in some situations and can remain on drive heads, which can scratch disks. Foam or chamois swabs can be purchased at most electronics supply stores.

Caution

One item to avoid is an eraser for cleaning contacts. Many people (including me) have recommended using a soft pencil-type eraser for cleaning circuit-board contacts. Testing has proven this to be bad advice for several reasons. One reason is that any such abrasive wiping on electrical contacts generates friction and an ESD. This ESD can be damaging to boards and components, especially the newer low-voltage devices. These devices are especially static sensitive, and cleaning the contacts without a proper liquid solution is not recommended. Also, the eraser will wear off the gold coating on many contacts, exposing the tin contact underneath, which will rapidly corrode when exposed to air.

Some companies sell premoistened contact cleaning pads that are soaked in a proper contact cleaner and lubricant. These pads are safe to wipe on conductor and contacts with no likelihood of ESD damage or abrasion of the gold plating.

Silicone Lubricants

You can use a silicone lubricant such as WD-40 to lubricate the door mechanisms on floppy disk drives and any other part of the system that might require clean, non-oily lubrication. Other items that you can lubricate are the disk drive-head slider rails and even printer-head slider rails, to provide smoother operation.

Using silicone instead of conventional oils is important because silicone does not gum up and collect dust and other debris. Always use the silicone sparingly. Do not spray it anywhere near the equipment because it tends to migrate and will end up where it doesn't belong (such as on drive heads). Instead, apply a small amount to a toothpick or foam swab and dab the silicone lubricant on the components where needed. You can use a lint-free cleaning stick soaked in silicone to lubricate the metal print-head rails in a printer.

Obtaining Required Tools and Accessories

You can obtain most of the cleaning chemicals and tools discussed in this chapter from an electronics supply house, or even your local Radio Shack. A company called Chemtronics specializes in chemicals for the computer and electronics industry. These and other companies that supply tools, chemicals, and other computer and electronic cleaning supplies are listed in the Vendor List on the CD. With all these items on hand, you should be equipped for most preventive maintenance operations.

Disassembling and Cleaning Procedures

To properly clean your system, you must at least partially disassemble it. Some people go as far as to remove the motherboard. Removing the motherboard results in the best possible access to other areas of the system; but in the interest of saving time, you probably need to disassemble the system only to the point at which the motherboard is completely visible.

To do this, remove all the system's plug-in adapter cards and the disk drives. Complete system disassembly and reassembly procedures are listed in Chapter 24, "Building or Upgrading Systems." Although you can clean the heads of a floppy drive with a cleaning disk without opening the system unit's cover, you probably will want to do more thorough cleaning. In addition to the drive heads, you should clean and lubricate the door mechanism and clean any logic boards and connectors on the drive. This procedure usually requires removing the drive.

Next, do the same thing with the hard disk drives: Clean the logic boards and connectors, and lubricate the grounding strap. To do this, you must remove the hard disk assembly. As a precaution, be sure your data is backed up first.

Reseating Socketed Chips

Another primary preventive maintenance function is to undo the effects of chip creep. As your system heats and cools, it expands and contracts, and the physical expansion and contraction can cause components that are plugged in to sockets to gradually work their way out of those sockets. This process is called chip creep. To correct its effects, you must find all socketed components in the system and make sure that they are properly reseated.

In most of today's systems, the memory chips are installed in socketed SIMMs or DIMMs. SIMM/DIMM devices are retained securely in their sockets by a positive latching mechanism and cannot creep out. The Memory SIPP (single inline pin package) devices (SIMMs with pins rather than contacts) used in older systems are not retained by a latching mechanism, however, and therefore can creep out of their sockets. Standard socketed memory chips are prime candidates for chip creep. Most other logic components are soldered in. On an older system, you might also find the ROM chips, a math coprocessor, and even the main system processor in sockets. Newer systems place the CPU in a ZIF socket, which has a lever that releases the grip of the socket on the chip. In most cases, there is very little creep with a ZIF socket. In most current systems, the memory (in SIMMs or DIMMs) and the processor are the only components that you will find in sockets; all others are soldered in.

Exceptions, however, might exist. A socketed component in one system might not be socketed in another—even if both are from the same manufacturer. Sometimes this difference results from a parts-availability problem when the boards are manufactured. Rather than halt the assembly line when a part is not available, the manufacturer adds a socket instead of the component. When the component becomes available, it is plugged in and the board is finished.

To make sure that all components are fully seated in their sockets, place your hand on the underside of the board and then apply downward pressure with the thumb of your other hand (from the top) on the chip to be seated. For larger chips, seat the chip carefully in the socket, and press separately on each end of the chip with your thumb to be sure that the chip is fully seated. (The processor and math coprocessor chips can usually be seated in this manner.) In most cases, you should hear a crunching sound as the chip makes its way back into the socket. Because of the great force that is sometimes required to reseat the chips, this operation is difficult if you do not remove the board.

For motherboards, forcibly seating chips can be dangerous if you do not directly support the board from the underside with your hand. Too much pressure on the board can cause it to bow

or bend in the chassis, and the pressure can crack it before the chip is fully seated. The plastic standoffs that hold the board up off the metal chassis are spaced too far apart to properly support the board under this kind of stress. Try this operation only if you can remove and support the board adequately from underneath.

You might be surprised to know that, even if you fully seat a chip, it might need reseating again within a year. The creep usually is noticeable within a year or less.

Cleaning Boards

After reseating any socketed devices that might have crept out of their sockets, the next step is to clean the boards and all connectors in the system. For this step, use the cleaning solutions and the lint-free swabs mentioned earlier.

First, clean the dust and debris off the board and then clean any connectors on the board. To clean the boards, it is usually best to use a vacuum cleaner designed for electronic assemblies and circuit boards or a duster can of compressed gas. The dusters are especially effective at blasting any dust and dirt off the boards.

Also, blow any dust out of the power supply, especially around the fan intake and exhaust areas. You do not need to disassemble the power supply to do this; simply use a duster can and blast the compressed air into the supply through the fan exhaust port. This will blow the dust out of the supply and clean off the fan blades and grill, which will help with system airflow.

Caution

Be careful with ESD, which can cause damage when you are cleaning electronic components. Take extra precautions in the dead of winter or in extremely dry, high-static environments. You can apply anti-static sprays and treatments to the work area to reduce the likelihood of ESD damage.

An anti-static wrist-grounding strap is recommended (see Figure 25.4 earlier in this chapter). This should be connected to a ground on the card or board you are wiping. This strap ensures that no electrical discharge occurs between you and the board. An alternative method is to keep a finger or thumb on the ground of the motherboard or card as you wipe it off.

Cleaning Connectors and Contacts

Cleaning the connectors and contacts in a system promotes reliable connections between devices. On a motherboard, you will want to clean the slot connectors, power supply connectors, keyboard and mouse connectors, and speaker connector. For most plug-in cards, you will want to clean the edge connectors that plug in to slots on the motherboard and any other connectors, such as external ones mounted on the card bracket.

Submerge the lint-free swabs in the liquid cleaning solution. If you are using the spray, hold the swab away from the system and spray a small amount on the foam end until the solution starts to drip. Then, use the soaked foam swab to wipe the connectors on the boards. Presoaked wipes are the easiest to use. Simply wipe them along the contacts to remove any accumulated dirt and leave a protective coating behind.

On the motherboard, pay special attention to the slot connectors. Be liberal with the liquid; resoak the foam swab repeatedly, and vigorously clean the connectors. Don't worry whether some of the liquid drips on the surface of the motherboard. These solutions are entirely safe for the whole board and will not damage the components.

Use the solution to wash the dirt off the gold contacts in the slot connectors, and then clean any other connectors on the board. Clean the keyboard and mouse connectors, the grounding positions where screws ground the board to the system chassis, power-supply connectors, speaker connectors, and the battery connectors.

If you are cleaning a plug-in board, pay special attention to the edge connector that mates with the slot connector on the motherboard. When people handle plug-in cards, they often touch the gold contacts on these connectors. Touching the gold contacts coats them with oils and debris, which prevents proper contact with the slot connector when the board is installed. Make sure these gold contacts are free of all finger oils and residue. It is a good idea to use one of the contact cleaners that has a conductive lubricant, which makes it easier to push the adapter into the slot and also protects the contacts from corrosion.

You will also want to use the swab and solution to clean the ends of ribbon cables or other types of cables or connectors in a system. Clean the floppy drive cables and connectors, the hard disk cables and connectors, and any others you find. Don't forget to clean the edge connectors that are on the disk drive logic boards, as well as the power connectors to the drives.

Cleaning the Keyboard and Mouse

Keyboards and mice are notorious for picking up dirt and garbage. If you have ever opened up an older keyboard, you often will be amazed at the junk you will find in there.

To prevent problems, it is a good idea to periodically clean the keyboard with a vacuum cleaner. An alternative method is to turn the keyboard upside down and shoot it with a can of compressed air. This will blow out the dirt and debris that has accumulated inside the keyboard and possibly prevent future problems with sticking keys or dirty keyswitches.

If a particular key is stuck or making intermittent contact, you can soak or spray that switch with contact cleaner. The best way to do this is to first remove the keycap and then spray the cleaner into the switch. This usually does not require complete disassembly of the keyboard. Periodic vacuuming or compressed gas cleaning will prevent more serious problems with sticking keys and keyswitches.

Most mice are easy to clean. In most cases, there is a twist-off locking retainer that keeps the mouse ball retained in the body of the mouse. By removing the retainer, the ball will drop out. After removing the ball, you should clean it with one of the electronic cleaners. I would recommend a pure cleaner instead of a contact cleaner with lubricant because you do not want any lubricant on the mouse ball. Then you should wipe off the rollers in the body of the mouse with the cleaner and some swabs.

Periodic cleaning of a mouse in this manner will eliminate or prevent skipping or erratic movement. I also recommend a mouse pad for most ball-type mice because the pad will prevent the mouse ball from picking up debris from your desk.

Other pointing devices requiring little or no maintenance are the IBM-designed TrackPoint and similar systems introduced by other manufacturers, such as the Glidepoint by Alps. These devices are totally sealed and use pressure transducers to control pointer movement. Because they are sealed, cleaning need only be performed externally and is as simple as wiping the device off with a mild cleaning solution to remove oils and other deposits that have accumulated from handling them.

Hard Disk Maintenance

Certain preventive maintenance procedures protect your data and ensure that your hard disk works efficiently. Some of these procedures actually minimize wear and tear on your drive, which will prolong its life. Additionally, a high level of data protection can be implemented by performing some simple commands periodically. These commands provide methods for backing up (and possibly later restoring) critical areas of the hard disk that, if damaged, would disable access to all your files.

Defragmenting Files

Over time, as you delete and save files to a hard disk, the files become fragmented. This means that they are split into many noncontiguous areas on the disk. One of the best ways to protect both your hard disk and the data on it is to periodically defragment the files on the disk. This serves two purposes. One is that by ensuring that all the files are stored in contiguous sectors on the disk, head movement and drive wear and tear will be minimized. This has the added benefit of improving the speed at which the drive retrieves files by reducing the head thrashing that occurs every time it accesses a fragmented file.

The second major benefit, and in my estimation the more important of the two, is that in the case of a disaster where the FATs and root directory are severely damaged, the data on the drive can usually be recovered easily if the files are contiguous. On the other hand, if the files are split up in many pieces across the drive, it is virtually impossible to figure out which pieces belong to which files without an intact FAT and directory system. For the purposes of data integrity and protection, I recommend defragmenting your hard disk drives on a monthly basis.

There are three main functions in most defragmentation programs:

- File defragmentation
- File packing (free space consolidation)
- File sorting

Defragmentation is the basic function, but most other programs also add file packing. Packing the files is optional on some programs because it usually takes additional time to perform. This function packs the files at the beginning of the disk so that all free space is consolidated at the end of the disk. This feature minimizes future file fragmentation by eliminating any empty holes on the disk. Because all free space is consolidated into one large area, any new files written to the disk will be able to be written in a contiguous manner with no fragmentation.

The last function, file sorting (sometimes called disk optimizing), is not usually necessary and is performed as an option by many defragmenting programs. This function adds a tremendous

amount of time to the operation, and has little or no effect on the speed at which information is accessed. It can be somewhat beneficial for disaster recovery purposes because you will have an idea of which files came before or after other files if a disaster occurs. Not all defragmenting programs offer file sorting, and the extra time it takes is probably not worth any benefits you will receive. Other programs can sort the order that files are listed in directories, which is a quick and easy operation compared to sorting the file ordering the disk.

Windows 9x and Millennium include a disk defragmentation program with the operating system that you can use on both the FAT16 and FAT32 file systems that the OS supports. For DOS and Windows systems, you must purchase a third-party defragmentation program. Norton Utilities includes a disk defragmenter, as do many other utility packages. If you elect to use a third-party product on a Windows 9x system, be certain that it supports the file system you use on your drives. Running a FAT16 defragmentation program on a FAT32 drive can cause severe problems.

Before you defragment your disks, it is a good idea to run a disk repair program such as Windows 9x's ScanDisk or Norton Disk Doctor, even if you are not experiencing any problems. This ensures that your drives are in good working order before you begin the defragmentation process.

Windows 98/Millennium Maintenance Wizard

Windows 98 and Millennium include a Task Scheduler program that enables you to schedule programs for automatic execution at specified times. The Maintenance Wizard walks you through the steps of scheduling regular disk defragmentations, disk error scans, and deletions of unnecessary files. You can schedule these processes to execute during nonworking hours, so regular system activities are not disturbed.

Virus Checking

Viruses are a danger to any system, and it's a good idea to make scans with an antivirus program a regular part of your preventive maintenance program. Although both Microsoft and IBM provide antivirus software in MS- and PC-DOS, respectively, if you run Windows 9x or Windows NT, you must obtain a third-party program to scan your system. There are many aftermarket utility packages available that scan for and remove viruses. No matter which of these programs you use, you should perform a scan for virus programs periodically, especially before making hard disk backups. This helps ensure that you catch any potential virus problem before it spreads and becomes a major catastrophe. In addition, it is important to select an antivirus product from a vendor that provides regular updates to the program's virus signatures. The signatures determine which viruses the software can detect and cure, and because there are new viruses constantly being introduced, these updates are essential.

Passive Preventive Maintenance Procedures

Passive preventive maintenance involves taking care of the system by providing the best possible environment—both physical and electrical—for the system. Physical concerns are conditions such as ambient temperature, thermal stress from power cycling, dust and smoke contamination, and disturbances such as shock and vibration. Electrical concerns are items such as ESD, power-line noise, and radio-frequency interference. Each of these environmental concerns is discussed in the following sections.

Examining the Operating Environment

Oddly enough, one of the most overlooked aspects of microcomputer preventive maintenance is protecting the hardware—and the sizable financial investment it represents—from environmental abuse. Computers are relatively forgiving, and they are generally safe in an environment that is comfortable for people. Computers, however, are often treated with no more respect than desktop calculators. The result of this type of abuse is many system failures.

Before you set up a new PC, prepare a proper location for it that is free of airborne contaminants such as smoke or other pollution. Do not place your system in front of a window; the computer should not be exposed to direct sunlight or temperature variations. The environmental temperature should be as constant as possible. Power should be provided through properly grounded outlets and should be stable and free from electrical noise and interference. Keep your system away from radio transmitters or other sources of radio frequency energy.

Heating and Cooling

Thermal expansion and contraction from ambient temperature changes places stress on a computer system. Therefore, keeping the temperature in your office or room relatively constant is important to the successful operation of your computer system.

Temperature variations can lead to serious problems. You might encounter excessive chip creep, for example. If extreme variations occur over a short period, signal traces on circuit boards can crack and separate, solder joints can break, and contacts in the system can undergo accelerated corrosion. Solid-state components such as chips can be damaged also, and a host of other problems can develop.

Temperature variations can play havoc with hard disk drives. Writing to a disk at different ambient temperatures can, on some drives, cause data to be written at different locations relative to the track centers. This can cause read and write problems at a later time.

To ensure that your system operates in the correct ambient temperature, you must first determine your system's specified functional range. Most manufacturers provide data about the correct operating temperature range for their systems. Two temperature specifications might be available, one indicating allowable temperatures during operation and another indicating allowable temperatures under non-operating conditions. IBM, for example, indicates the following temperature ranges as acceptable for most of its systems:

System on: 60–90° Fahrenheit

System off: 50–110° Fahrenheit

For the safety of the disk and the data it contains, avoid rapid changes in ambient temperatures. If rapid temperature changes occur—for example, when a new drive is shipped to a location during the winter and then brought indoors—let the drive acclimate to room temperature before turning it on. In extreme cases, condensation can form on the platters inside the drive HDA, which is disastrous for the drive if you turn it on before the condensation has a chance to evaporate. Most drive manufacturers specify a timetable to use as a guide in acclimating a drive to room temperature before operating it. You usually must wait several hours to a day before a drive is ready to use after it has been shipped or stored in a cold environment. Manufacturers normally

advise that you leave the drive in its packing until it is acclimated. Removing the drive from a shipping carton when extremely cold increases the likelihood of condensation forming as the drive warms up.

Most office environments provide a stable temperature in which to operate a computer system, but some do not. Be sure to give some consideration to the placement of your equipment.

Power Cycling (On/Off)

As you have just learned, the temperature variations that a system encounters greatly stress the system's physical components. The largest temperature variations a system encounters, however, are those that occur during the warm-up period right after you turn on the computer. Powering on a cold system subjects it to the greatest possible internal temperature variations. If you want a system to have the longest and most trouble-free life possible, you should limit the temperature variations in its environment. You can limit the extreme temperature cycling in two simple ways during a cold startup: Leave the system off all the time or leave it on all the time. Of these two possibilities, of course, you will probably want to choose the latter option. Leaving the power on is the best way I know to promote system reliability. If your only concern is system longevity, the simple recommendation would be to keep the system unit powered on (or off!) continuously. In the real world, however, there are more variables to consider, such as the cost of electricity, the potential fire hazard of unattended running equipment, and other concerns, as well.

If you think about the way light bulbs typically fail, you can begin to understand how thermal cycling can be dangerous. Light bulbs burn out most often when you first turn them on because the filament must endure incredible thermal stress as it changes temperature, in less than one second, from ambient to several thousands of degrees. A bulb that remains on continuously lasts longer than one that is turned on and off repeatedly.

The place where problems are most likely to occur immediately at power-on is in the power supply. The startup current draw for the system during the first few seconds of operation is very high compared to the normal operating-current draw. Because the current must come from the power supply, the supply has an extremely demanding load to carry for the first few seconds of operation, especially if several disk drives must be started. Motors have an extremely high power-on current draw. This demand often overloads a marginal circuit or component in the supply and causes it to burn or break with a "snap." I have seen several power supplies die the instant a system was powered up. To enable your equipment to have the longest possible life, try to keep the temperature of solid-state components relatively constant, and limit the number of startups on the power supply. The only way I know to do this is to leave the system on.

Although it sounds like I am telling you to leave all your computer equipment on 24 hours a day, seven days a week, I no longer recommend this type of operation. A couple of concerns have tempered my urge to leave everything running continuously. One is that an unattended system that is powered on represents a fire hazard. I have seen monitors catch fire after internally shorting and systems whose cooling fans have frozen, causing the power supply and the entire system to overheat. I do not leave any system running in an unattended building. Another problem is wasted electrical power. Many companies have adopted austerity programs that involve turning off lights and other items when not in use. The power consumption of some of today's

high-powered systems and accessories is not trivial. Also, an unattended operating system is more of a security risk than one that is powered off and locked.

Realities—such as the fire hazard of unattended systems running during night or weekend hours, security problems, and power-consumption issues—might prevent you from leaving your system on all the time. Therefore, you must compromise. Power on the system only one time daily. Don't power the system on and off several times every day. This good advice is often ignored, especially when several users share systems. Each user powers on the system to perform work on the PC and then powers off the system. These systems tend to have many more problems with component failures.

If you are in a building with a programmable thermostat, you have another reason to be concerned about temperatures and disk drives. Some buildings have thermostats programmed to turn off the heat overnight or over the weekend. These thermostats are programmed also to quickly raise the temperature just before business hours every day. In Chicago, for example, outside temperatures in the winter can dip to -20° (excluding the wind-chill factor). An office building's interior temperature can drop as low as 50° during the weekend. When you arrive Monday morning, the heat has been on for only an hour or so, but the hard disk platters might not yet have reached even 60° when you turn on the system. During the first 20 minutes of operation, the disk platters rapidly rise in temperature to 120° or more. If you have an inexpensive stepper motor hard disk and begin writing to the disk at these low temperatures, you are setting yourself up for trouble.

Tip

If you do not leave a system on continuously, at least give it 15 minutes or more to warm up after a cold start before writing to the hard disk. This practice does wonders for the reliability of the data on your disk.

If you do leave your system on for long periods of time, make sure that the screen is blank or displays a random image if the system is not in use. The phosphor on the picture tube can burn if a stationary image is left onscreen continuously. Higher-persistence phosphor monochrome screens are most susceptible, and the color displays with low-persistence phosphors are the least susceptible. Most of the monitors used with today's PCs will not show the effect of a screen burn. If you ever have seen a monochrome display with the image of some program permanently burned in—even with the display off—you know what I mean. Look at the monitors that display flight information at the airport; they usually show some of the effects of phosphor burn.

Most modern displays that have power-saving features can automatically enter a standby mode on command by the system. If your system has these power-saving functions, enable them, as they will help to reduce energy costs and preserve the monitor.

Static Electricity

Static electricity can cause numerous problems within a system. The problems usually appear during the winter months when humidity is low or in extremely dry climates where the humidity is low year-round. In these cases, you might need to take special precautions to ensure that your PC is not damaged.

Static discharges outside a system-unit chassis are rarely a source of permanent problems within the system. Usually, the worst possible effect of a static discharge to the case, keyboard, or even a location near the computer is a parity check (memory) error or a system lockup. In some cases, I have been able to cause parity checks or system lockups by simply walking past a PC. Most static-sensitivity problems are caused by improper grounding of the system power. Be sure that you always use a three-prong, grounded power cord plugged in to a properly grounded outlet. If you are unsure about the outlet, you can buy an outlet tester such as those described earlier in this chapter at most electronics supply or hardware stores for only a few dollars.

Whenever you open a system unit or handle circuits removed from the system, you must be much more careful with static. You can permanently damage a component with a static discharge if the charge is not routed to a ground. I usually recommend handling boards and adapters first by a grounding point such as the bracket to minimize the potential for static damage.

An easy way to prevent static problems is with good power-line grounding, which is extremely important for computer equipment. A poorly designed power-line grounding system is one of the primary causes of poor computer design. The best way to prevent static damage is to prevent the static charge from getting into the computer in the first place. The chassis ground in a properly designed system serves as a static guard for the computer that redirects the static charge safely to the ground. For this ground to be complete, therefore, the system must be plugged in to a properly grounded three-wire outlet.

If the static problem is extreme, you can resort to other measures. One is to use a grounded static mat underneath the computer. Touch the mat first before you touch the computer to ensure that any static charges are routed to ground and away from the system unit's internal parts. If problems still persist, you might want to check out the building's electrical ground. I have seen installations that had three-wire outlets that were rendered useless by the building's ungrounded electrical service.

Power-Line Noise

To run properly, a computer system requires a steady supply of clean noise-free power. In some installations, however, the power line serving the computer serves heavy equipment also, and the voltage variations resulting from the on/off cycling of this equipment can cause problems for the computer. Certain types of equipment on the same power line also can cause voltage spikes—short transient signals of sometimes 1,000v or more—that can physically damage a computer. Although these spikes are rare, they can be crippling. Even a dedicated electrical circuit used only by a single computer can experience spikes and transients, depending on the quality of the power supplied to the building or circuit.

During the site-preparation phase of a system installation, you should be aware of these factors to ensure a steady supply of clean power:

- If possible, the computer system should be on its own circuit with its own circuit breaker. This setup does not guarantee freedom from interference, but it helps.
- The circuit should be checked for a good, low-resistance ground, proper line voltage, freedom from interference, and freedom from brownouts (voltage dips).

- A three-wire circuit is a must, but some people substitute grounding-plug adapters to adapt a grounded plug to a two-wire socket. This setup is not recommended; the ground is there for a reason.
- Power-line noise problems increase with the resistance of the circuit, which is a function of wire size and length. To decrease resistance, therefore, avoid extension cords unless absolutely necessary, and then use only heavy-duty extension cords.
- Inevitably, you will want to plug in other equipment later. Plan ahead to avoid the temptation to connect too many items to a single outlet. If possible, provide a separate power circuit for non-computer-related devices.

Air conditioners, coffee makers, copy machines, laser printers, space heaters, vacuum cleaners, and power tools are some of the worst corrupters of a PC system's power. Any of these items can draw an excessive amount of current and play havoc with a PC system on the same electrical circuit. I've seen offices in which all the computers begin to crash at about 9:05 a.m. daily, which is when all the coffee makers are turned on!

Also, try to ensure that copy machines and laser printers do not share a circuit with other computer equipment. These devices draw a large amount of power.

Another major problem in some companies is partitioned offices. Many of these partitions are prewired with their own electrical outlets and are plugged in to one another in a sort of power-line daisy chain, similar to chaining power strips together. I pity the person in the cubicle at the end of the electrical daisy chain, who is likely to have very erratic power!

As a real-world example of too many devices sharing a single circuit, I can describe several instances in which a personal computer had a repeating parity check problem. All efforts to repair the system had been unsuccessful. The reported error locations from the parity check message were inconsistent, which normally indicates a problem with power. The problem could have been the power supply in the system unit or the external power supplied from the wall outlet. This problem was solved one day as I stood watching the system. The parity check message was displayed at the same instant someone two cubicles away turned on a copy machine. Placing the computers on a separate line solved the problem.

By following the guidelines in this section, you can create the proper power environment for your systems and help to ensure trouble-free operation.

Radio-Frequency Interference

Radio-frequency interference (RFI) is easily overlooked as a problem factor. The interference is caused by any source of radio transmissions near a computer system. Living next door to a 50,000-watt commercial radio station is one sure way to get RFI problems, but less-powerful transmitters can cause problems, too. I know of many instances in which cordless telephones have caused sporadic random keystrokes to appear, as though an invisible entity were typing on the keyboard. I also have seen RFI cause a system to lock up. Solutions to RFI problems are more difficult to state because every case must be handled differently. Sometimes, simply moving the system eliminates the problem because radio signals can be directional in nature. At other times, you must invest in specially shielded cables for external devices such as the keyboard and the monitor.

One type of solution to an RFI noise problem with cables is to pass the cable through a toroidal iron core, a doughnut-shaped piece of iron placed around a cable to suppress both the reception and transmission of electromagnetic interference (EMI). Many monitors include a toroid on the cable that connects to the computer. If you can isolate an RFI noise problem in a particular cable, you often can solve the problem by passing the cable through a toroidal core. Because the cable must pass through the center hole of the core, it often is difficult, if not impossible, to add a toroid to a cable that already has end connectors installed.

Radio Shack sells a special snap-together toroid designed specifically to be added to cables already in use. This toroid looks like a thick-walled tube that has been sliced in half. You simply lay the cable in the center of one of the halves, and snap the other half over the first. This type of construction makes it easy to add the noise-suppression features of a toroid to virtually any existing cable.

The best, if not the easiest, way to eliminate an RFI problem is to correct it at the source. It is unlikely that you'll be able to convince the commercial radio station near your office to shut down, but if you are dealing with a small radio transmitter that is generating RFI, sometimes you can add a filter to the transmitter that suppresses spurious emissions. Unfortunately, problems sometimes persist until the transmitter is either switched off or moved some distance away from the affected computer.

Dust and Pollutants

Dirt, smoke, dust, and other pollutants are bad for your system. The power-supply fan carries airborne particles through your system, and they collect inside. If your system is used in an extremely harsh environment, you might want to investigate some of the industrial systems on the market designed for harsh conditions.

Many companies make special hardened versions of their systems for harsh environments. Industrial systems usually use a different cooling system from the one used in a regular PC. A large cooling fan is used to pressurize the case rather than depressurize it. The air pumped into the case passes through a filter unit that must be cleaned and changed periodically. The system is pressurized so that no contaminated air can flow into it; air flows only outward. The only way air can enter is through the fan and filter system.

These systems also might have special keyboards impervious to liquids and dirt. Some flat-membrane keyboards are difficult to type on, but are extremely rugged; others resemble the standard types of keyboards but have a thin, plastic membrane that covers all the keys. You can add this membrane to normal types of keyboards to seal them from the environment.

A new breed of humidifier can cause problems with computer equipment. This type of humidifier uses ultrasonics to generate a mist of water sprayed into the air. The extra humidity helps cure problems with static electricity resulting from a dry climate, but the airborne water contaminants can cause many problems. If you use one of these systems, you might notice a white ash-like deposit forming on components. The deposit is the result of abrasive and corrosive minerals suspended in the vaporized water. If these deposits collect on the system components, they can cause all kinds of problems. The only safe way to run one of these ultrasonic humidifiers is to use distilled water. If you use a humidifier, be sure it does not generate these deposits.

If you do your best to keep the environment for your computer equipment clean, your system will run better and last longer. Also, you will not have to open your unit as often for complete preventive maintenance cleaning.

Basic Troubleshooting Guidelines

This section lists basic and general system troubleshooting procedures and guidelines. For specific procedures for troubleshooting a component in the system, see the chapter or section dedicated to that part of the PC.

Before starting any system troubleshooting, a few basic steps should be performed to ensure a consistent starting point and to allow isolating the failed component:

1. Turn off the system and any peripheral devices. Disconnect all external peripherals from the system, except for the keyboard and the video display.
2. Make sure the system is plugged in to a properly grounded power outlet.
3. Make sure the keyboard and video displays are connected to the system. Turn on the video display, and turn up the brightness and contrast controls to at least two-thirds of the maximum. Some displays have onscreen controls that may not be intuitive. Consult the display documentation for more information on how to adjust these settings.
4. To allow the system to boot from a hard disk, make sure there is no floppy disk in the floppy drive. Or put a known good bootable floppy with DOS or diagnostics on it in the floppy drive for testing.
5. Turn on the system. Observe the power supply, chassis fans (if any), and the lights on either the system front panel or power supply. If the fans don't spin and the lights don't light, the power supply or motherboard might be defective.
6. Observe the power on self test (POST). If no errors are detected, the system beeps once and boots up. Errors that display on the screen (*nonfatal* errors) and that do not lock up the system display a text message that varies according to BIOS type and version. Record any errors that occur and refer to the CD accompanying this book for a list of BIOS error codes for more information on any specific codes you see. Errors that lock up the system (*fatal* errors) are indicated by a series of audible beeps. Refer to the CD for a list of beep error codes.
7. Confirm that the operating system loads successfully.

Note

The CD accompanying this book contains an exhaustive listing of BIOS error codes, error messages, and beep codes for BIOSes from Phoenix, AMI, Award, Microid Research, and IBM.

Problems During the POST

Problems that occur during the POST are usually caused by incorrect hardware configuration or installation. Actual hardware failure is a far less frequent cause. If you have a POST error, check the following:

1. Are all cables correctly connected and secured?
2. Are the configuration settings correct in Setup?

3. Are all drivers properly installed?
4. Are switches and jumpers on the baseboard correct, if changed from the default settings?
5. Are all resource settings on add-in boards and peripheral devices set so that there are no conflicts, for example, two add-in boards sharing the same interrupt?
6. Is the power supply set to the proper input voltage (110/220v)?
7. Are adapter boards and disk drives installed correctly?
8. Is there a keyboard attached?
9. Is a bootable hard disk (properly partitioned and formatted) installed?
10. Does the BIOS support the drive you have installed, and if so are the parameters entered correctly?
11. Is a bootable floppy disk installed in drive A:?
12. Are all memory SIMMs or DIMMs installed correctly? Try reseating them.
13. Is the operating system properly installed?

Hardware Problems After Booting

If problems occur after the system has been running, and without having made any hardware or software changes, it is possible a hardware fault has occurred. Here is a list of items to check in that case:

1. Try reinstalling the software that has crashed or refuses to run.
2. Try clearing CMOS RAM and running Setup.
3. Check for loose cables, a marginal power supply, or other random component failures.
4. A transient voltage spike, power outage, or brownout might have occurred. Symptoms of voltage spikes include a flickering video display, unexpected system reboots, and the system not responding to user commands. Reload the software and try again.
5. Try reseating the memory modules (SIMMs, DIMMs, or RIMMs).

Problems Running Software

Problems running application software (especially new software) are usually caused by or related to the software itself, or that the software is incompatible with the system.

1. Does the system meet the minimum hardware requirements for the software? Check the software documentation to be sure.
2. Check to see that the software is correctly installed. Reinstall if necessary.
3. Check to see that the latest drivers are installed.
4. Scan the system for viruses using the latest antivirus software.

Problems with Adapter Cards

Problems related to add-in boards are usually related to improper board installation or resource (interrupt, DMA or I/O address) conflicts. Chapter 4, “Motherboards and Buses,” has a detailed discussion of these system resources, what they are, how to configure them, and how to troubleshoot them. Also be sure to check drivers for the latest versions and be sure the card is compatible with your system and the operating system version you are using.

Sometimes adapter cards can be picky about which slot they are running in. Although technically a PCI or ISA adapter should be able to run in any of the slots, sometimes minor timing or signal variations occur from slot to slot. I have found on numerous occasions that simply moving a card from one slot to another can make a failing card begin to work properly. Sometimes moving a card works just by the inadvertent cleaning (wiping) of the contacts that takes place when removing and reinstalling the card, but in other cases I can duplicate the problem by putting the card back into its original slot. When all else fails, try moving the cards around!

Caution

Note that PCI cards become slot specific after their drivers are installed. By this I mean that if you move the card to another slot, the plug-and-play resource manager will see it as if you have removed one card and installed a new one. You will therefore have to install the drivers all over again for that card. Don't move a PCI card to a different slot unless you are prepared with all the drivers at hand to do the driver installation. ISA cards don't share this quirk since the system is not aware of which slot an ISA card is in.

One common problem I've seen cropping up lately is with people installing newer PCI video cards in older systems with PCI slots. The PCI bus has gone through several revisions; most older slots are “2.0” type and most newer cards need “2.1” or later PCI slots. The version of PCI your system has is dictated by the motherboard chipset. If you install a newer video or other PCI card that requires 2.1 slots in a system with 2.0 slots, often the system won't boot up or operate at all.

If you check the chipset reference information in Chapter 4, you might be able to determine which revision of PCI slots your motherboard has by knowing which chipset it has. If this is your problem, the only solution is to change either the card or motherboard so that they are both compatible.

CHAPTER 26

File Systems and Data Recovery

FAT Disk Structures

Physically it is the hard disks and other media that provide the basic technology for storing data. Logically, however, it is the file system that provides the hierarchical structure of volumes and directories in which you store individual files and the organizational model that makes it possible for the system to locate data anywhere on a given disk or drive. File systems are normally an integrated part of an operating system (OS), and many of the newer OSes provide support for several file systems from which you can choose.

The most commonly used file systems today are based on a file allocation table (FAT), which keeps track of the data stored in each cluster on a disk. There are several varieties of the FAT system called FAT12, FAT16, and FAT32, all of which are differentiated by the number of digits used in the allocation table numbers. In other words, FAT32 uses 32-bit numbers to keep track of data clusters; FAT16 uses 16-bit numbers, and so on. The different FAT systems are normally used as follows:

- *FAT12*. Used on all volumes smaller than 16MB (for example, floppies)
- *FAT16*. Used on volumes from 16MB through 2GB
- *FAT32*. Optionally used on volumes from 512MB through 2TB

FAT12 and FAT16 are the file systems originally used by DOS and Windows and are supported by virtually every other PC operating system in use today. Most PC drives or volumes today are formatted under one of the FAT file systems.

FAT32 is supported by Windows 95B and later versions, including 95C, 98, Me, and Windows 2000 (which also supports NTFS). Although all PC operating systems I am aware of support at least FAT12 and FAT16, some have support for non-FAT file systems as well. Windows NT introduced the NT File System (NTFS), which is unique to NT and Windows 2000 and not supported by Windows 9x/Me. OS/2 1.2 introduced the High Performance File System (HPFS), which is unique to OS/2, although NT versions 3.x also supported it.

This chapter examines these file systems in more detail. Because of the popularity of the FAT file systems, they are emphasized, although the additional capabilities provided by HPFS or NTFS are also discussed.

To manage files on a disk and enable all applications to see a consistent interface to the file system no matter what type of storage hardware is being used, the operating system (OS) creates several structures on the disk. These structures are the same for any OS that supports the FAT file system, including Windows 9x, NT, and Windows 2000. The following list shows all the structures and areas that FAT uses to manage a disk, in roughly the same order that they appear on the media:

- Master and extended partition boot records (sectors)
- Volume boot record
- Root directory
- File allocation tables (FATs)
- Clusters (allocation units in the data area)
- Diagnostic read-and-write cylinder

All these structures are detailed later in this section. A hard disk has all these disk-management structures, and a floppy disk has all but the master and extended partition boot records and diagnostic cylinder. The volume boot record through data area structures are repeated for each partition or volume on a drive. These structures are created on hard disk drives or other high-capacity media by the FDISK program included with all operating systems. You cannot use FDISK on a floppy disk because floppy disks cannot be partitioned. Figure 26.1 is a simple diagram showing the relative locations of these FAT disk-management structures on a 2111MB Western Digital hard disk.

Note

Some removable cartridge drives, such as the SuperDisk (LS-120) and Iomega Zip drive, function like high-capacity floppy disk drives. They lack a master boot record (MBR) and diagnostic cylinder and cannot be partitioned like hard disk drives. Other higher capacity removable drives, such as the Iomega Jaz, can be partitioned like a hard disk drive.

Figure 26.1 shows the placement and arrangement of the file management structures on a typical drive. This particular example uses a Western Digital Caviar AC12100, but all PC hard drives using the FAT file system would be similar except for the number of cylinders.

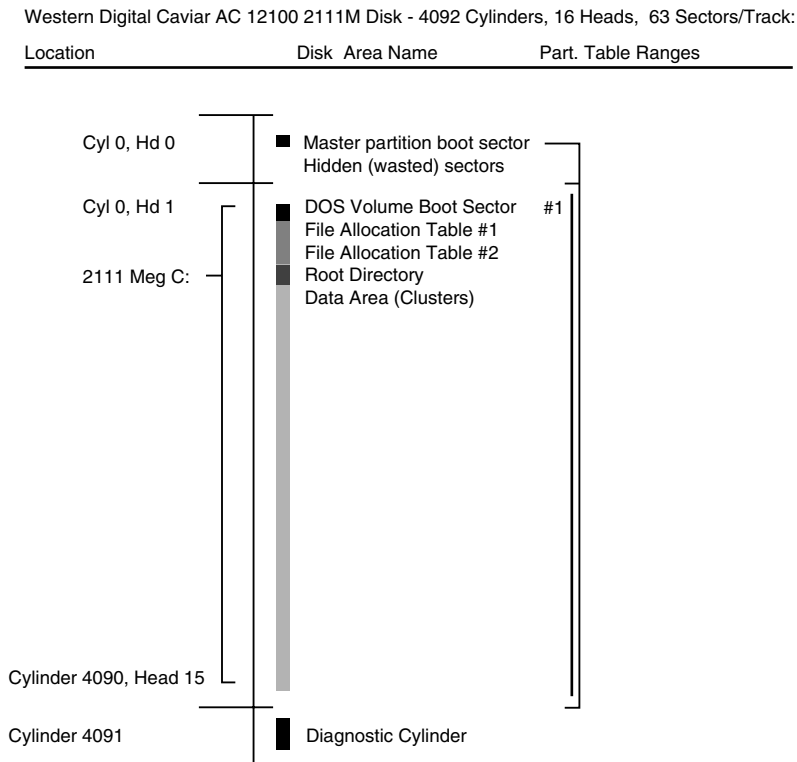

Figure 26.1 FAT file management structures on a typical drive.

Each disk area has a purpose and function. If one of these special areas is damaged, serious consequences can result. Damage to one of these sensitive structures usually causes a domino effect, limiting access to other areas of the disk or causing further problems in using the disk. For example, the OS cannot normally access a drive at all if the MBR is corrupted. Therefore, you should understand these data structures well enough to be able to repair them when necessary. Rebuilding these special tables and areas of the disk is essential to the art of data recovery.

Master Partition Boot Record

The first PC OS to support hard disks, DOS 2.0 released in 1983, was also the first to introduce the 16-bit FAT and the capability to partition a drive. *Partitioning* is basically dividing the drive into multiple volumes. One concept easily misunderstood is that all drives that *can* be partitioned *must* be partitioned; that is, you have to partition the drive even if you are only going to set it up with only one partition. Another name for a partition is a *logical volume*, because the partition shows up as an additional drive letter or volume to the OS.

Although the primary use for partitioning today is to divide a single drive into multiple volumes for use by the same OS, originally it was intended to allow multiple different OSes, each with different file systems, to co-exist on a single drive. This multi-OS capability still exists today, although often additional aftermarket utilities are required to manage and boot from multiple OSes on a single machine.

To use a hard disk with different operating systems, you can logically divide the disk by creating partitions. You can, for example, use FDISK to create one or more FAT partitions for use with DOS or Windows 9x, and leave the rest of the disk storage area for use by another OS's file system. Each of the FAT partitions will appear to the OS as a separate drive letter.

Note

For more information about creating and formatting partitions, see Chapter 14, "Physical Drive Installation and Configuration."

Information about each of the partitions on the disk is stored in a partition (or volume) boot record at the beginning of each partition. There is also a main table listing the partitions embedded in the master partition boot record.

The master partition boot record (or master boot sector) is always located in the first sector of the entire disk (cylinder 0, head 0, sector 1) and consists of the following structures:

- *Master partition table.* Contains a list of the partitions on the disk and the locations of their volume boot records. This table is very small and can contain only four entries at the most. Therefore, to accommodate more partitions, operating systems such as DOS can divide a single extended partition into multiple logical volumes.
- *Master boot code.* A small program that is executed by the system BIOS, the main function of which is to pass control of the system to the partition that has been designated as active (or bootable).

Primary and Extended FAT Partitions

Most OSes are designed to support up to 24 partitions on a single hard disk drive (represented by the drive letters C: through Z:), but the partition table in the master partition boot record can have a maximum of only four entries. To resolve this discrepancy, the FDISK program enables you to create two types of FAT partitions: a primary partition and an extended partition. The first FAT partition that you create on a disk should be the primary, which is listed in the master partition table and appears to the operating system as a single drive letter.

An extended partition is listed in the master partition table like the primary, but it differs in that you can use its disk space to create multiple logical partitions, or volumes. You can create only one extended partition on a single drive, meaning that there will never normally be more than two entries in the master partition table devoted to FAT volumes.

The logical volumes that you create in the extended partition appear as separate drive letters to the operating system, but they are not listed in the master partition table. Logical volumes cannot be active partitions, and are therefore not bootable. You can create up to 23 volumes out of a single extended partition (assuming that you have already created a primary FAT partition, which brings the total to 24).

Each of the logical partitions (or volumes) in an extended partition includes an extended partition table that contains information about that volume. The master partition table's entry for the extended partition contains a reference to the first volume's extended partition table. This table in turn contains a reference detailing the location of the second volume's table. This chain of references continues, linking all the volumes in the extended partition to the master partition table.

Of course, few people have any reason to create 24 FAT partitions on a single disk drive, but the extended partition makes it possible to exceed the four-entry limitation of the master partition table.

Because the master boot record contains the first program that the system executes when you boot a PC, it is frequently a target for creators of computer viruses. A virus that infects or destroys the master boot record can make it impossible for the BIOS to find the active partition, thus preventing the operating system from loading. Because the master boot record contains the first program executed by the system, a virus stored there loads before any antivirus code can detect it. To remove a master boot record virus, you must first boot the system from a clean, uninfected floppy disk and then run an antivirus program.

Each partition on a disk contains a volume boot record as its first sector, which is listed in the master partition table. With the FDISK utility, you can designate a single partition as active (or bootable). The master partition boot record causes the active partition's volume boot record to receive control whenever the system is started or reset. You can also create additional disk partitions for Novell NetWare, Windows NT's NTFS, OS/2's HPFS, AIX (UNIX), XENIX, or other file systems, using disk utilities provided with the operating systems that support them. These partitions are listed in the master partition table, even though they may use different structures within the partition.

However, you cannot access the data stored on these foreign operating system partitions with DOS. In some cases, you cannot access FAT partitions using other operating systems either, although OS/2 and Windows NT do support FAT in addition to their own file systems: HPFS and NTFS. You must create at least one partition on a hard disk for it to be accessible by an operating system. Creating a partition adds an entry to the master partition table.

Table 26.1 shows the format of the Master Boot Record (MBR) and its partition tables. The table lists the fields in each of the master partition table's four entries, the location on the disk where each field begins (the offset), and its length. Some of the fields are stored as *dwords*—four bytes read in reverse order—because of the internal structure of the Intel processors.

Table 26.1 Master Boot Record (Partition Tables)

Master Partition Table Entry #1		
Offset	Length	Description
1BEh 446	1 byte	Boot indicator byte (80h = active, else 00h)
1BFh 447	1 byte	Starting head (or side) of partition
1C0h 448	16 bits	Starting cylinder (10 bits) and sector (6 bits)
1C2h 450	1 byte	System indicator byte (see Table 26.2)
1C3h 451	1 byte	Ending head (or side) of partition
1C4h 452	16 bits	Ending cylinder (10 bits) and sector (6 bits)
1C6h 454	1 dword	Relative sector offset of partition
1CAh 458	1 dword	Total number of sectors in partition
Partition Table Entry #2		
Offset	Length	Description
1CEh 462	1 byte	Boot indicator byte (80h = active, else 00h)
1CFh 463	1 byte	Starting head (or side) of partition
1D0h 464	16 bits	Starting cylinder (10 bits) and sector (6 bits)
1D2h 466	1 byte	System indicator byte (see Table 26.2)
1D3h 467	1 byte	Ending head (or side) of partition
1D4h 468	16 bits	Ending (10 bits) and sector (6 bits)
1D6h 470	1 dword	Relative sector offset of partition
1DAh 474	1 dword	Total number of sectors in partition
Partition Table Entry #3		
Offset	Length	Description
1DEh 478	1 byte	Boot indicator byte (80h = active, else 00h)
1DFh 479	1 byte	Starting head (or side) of partition
1E0h 480	16 bits	Starting cylinder (10 bits) and sector (6 bits)
1E2h 482	1 byte	System indicator byte (see Table 26.2)
1E3h 483	1 byte	Ending head (or side) of partition
1E4h 484	16 bits	Ending cylinder (10 bits) and sector (6 bits)
1E6h 486	1 dword	Relative sector offset of partition
1EAh 490	1 dword	Total number of sectors in partition

Partition Table Entry #4

Offset	Length	Description
1EEh 494	1 byte	Boot indicator byte (80h = active, else 00h)
1EFh 495	1 byte	Starting head (or side) of partition
1F0h 496	16 bits	Starting cylinder (10 bits) and sector (6 bits)
1F2h 498	1 byte	System indicator byte (see Table 26.2)
1F3h 499	1 byte	Ending head (or side) of partition
1F4h 500	16 bits	Ending cylinder (10 bits) and sector (6 bits)
1F6h 502	1 dword	Relative sector offset of partition
1FAh 506	1 dword	Total number of sectors in partition

Signature Bytes

Offset	Length	Description
1FEh 510	2 bytes	Boot sector signature (55AAh)

A word equals 2 bytes read in reverse order, and a dword equals two words read in reverse order.

The data in the partition table entries tells the system where each partition starts and ends on the drive, how big it is, whether it is bootable, and what type of file system is contained in the partition. Each entry in the Master Partition Table contains a system indicator byte that identifies the file system type used in the partition referenced by that entry. Table 26.2 shows the standard values and meanings of the system indicator bytes.

Table 26.2 Standard System Indicator Byte Values

Value	Partition Type	Mode Translation	Partition Size
00h	None	—	—
01h	Primary FAT12	CHS	0–15MB
04h	Primary FAT16	CHS	16MB–32MB
05h	Extended	CHS	16MB–32MB
06h	Primary FAT16	CHS	32MB–2GB
07h	NTFS/HPFS	All	All
0Ah	OS/2 Bootmanager	All	All
0Bh	Primary FAT32	LBA	512MB–2TB
0Ch	Primary FAT32	LBA	512MB–2TB
0Eh	Primary FAT16	LBA	32MB–2GB
0Fh	Extended	LBA	32MB–2GB

CHS = Cylinder Head Sector

LBA = Logical Block Address

Table 26.3 Non-Standard System Indicator Byte Values

Value	Partition Type
02h	MS-XENIX Root
03h	MS-XENIX usr
08h	AIX File System Boot
09h	AIX Data
12h	Compaq diagnostics
50h	Ontrack Disk Manager read/only DOS
51h	Ontrack Disk Manager read/write DOS
54h	Ontrack Disk Manager non-DOS
55h	Micro House EZ-Drive non-DOS
56h	Golden Bow Vfeature Deluxe
61h	Storage Dimensions SpeedStor
63h	IBM 386/ix or UNIX System V/386
64h	Novell NetWare 286
65h	Novell NetWare 386
75h	IBM PC/IX
82h	Linux swap file
83h	Linux native file system
DBh	DR Concurrent DOS/CPM-86
E1h	SpeedStor 12-bit FAT extended
E4h	SpeedStor 16-bit FAT extended
F4h	SpeedStor primary
FFh	UNIX Bad Block Table Partition

These values can be useful for somebody trying to manually repair a partition table using a disk editor such as the Diskedit program included with Norton Utilities.

Undocumented FDISK

FDISK is a very powerful program. In DOS 5 and later versions, including Windows 9x/Me, Windows NT, and Windows 2000, it gained some additional capabilities. Unfortunately, these capabilities were never documented in any of the Microsoft documentation for Windows or DOS. The most important undocumented parameter in FDISK is the **/MBR** (Master Boot Record) parameter, which causes FDISK to rewrite the Master Boot Record code area, leaving the partition table area intact.

The **/MBR** parameter is tailor-made for eliminating boot-sector virus programs that infect the Master Partition Boot Record (cylinder 0, head 0, sector 1) of a hard disk. To use this feature, enter the following:

```
FDISK /MBR
```

FDISK then rewrites the boot record code, leaving the partition tables intact. This should not cause any problems on a normally functioning system, but just in case, I recommend backing up the partition table information to floppy disk before trying it. You can do this by using a third-party product such as Norton Utilities.

Be aware that using FDISK with the /MBR switch will overwrite the partition tables if the two signature bytes at the end of the sector (55AAh) are damaged. This situation is highly unlikely, however. In fact, if these signature bytes were damaged, you would know; the system would not boot and would act as though there were no partitions at all.

Volume Boot Records

The volume boot record is the first sector on any area of a drive addressed as a partition or volume (or logical DOS disk). On a floppy disk or removable cartridge (such as a Zip disk), for example, this sector is the first one on the disk because DOS recognizes the disk as a volume without the need for partitioning. On a hard disk, the volume boot record or sectors are located as the first sector within any disk area allocated as a nonextended partition, or any area recognizable as a logical volume. Refer to Figure 26.1 for an idea of the physical relationship between this volume boot record and the other data structures on a disk. The volume boot record resembles the master partition boot record in that it contains two elements, which are as follows:

- *Disk parameter block.* Sometimes called the media parameter block, the disk parameter block contains specific information about the volume, such as its size, the number of disk sectors it uses, the size of its clusters, and the volume label name.
- *Volume boot code.* The program that begins the process of loading the operating system. For DOS and Windows 9x/Me systems, this is the IO.SYS file.

The volume boot record of the active partition on a disk is loaded by the system ROM BIOS for floppy disks or by the master partition boot record on a hard disk. The program code in the volume boot record is given control of the system; it performs some tests and then attempts to load the first system file (in DOS/Windows, this is IO.SYS). The volume boot record, such as the master boot record, is transparent to the running system; it is outside the data area of the disk on which files are stored.

Note

Many of the systems today are capable of booting from drives other than standard floppy disk and hard disk drives. In these cases, the boot drive must be specifically supported by system BIOS. For example, some BIOS products enable you to select an ATAPI CD-ROM as a boot device, in addition to the floppy and hard disk drives.

Other types of removable media, such as Zip cartridges and LS-120 disks, can also be made bootable. When properly supported by the BIOS, an LS-120 drive can replace the existing floppy disk drive as drive A:.

On a FAT partition, you create a volume boot record with the **FORMAT** command (high-level format) included with DOS and Windows 9x. Hard disks on FAT systems have a volume boot record at the beginning of every DOS logical drive area allocated on the disk, in both the primary and extended partitions. Although all the logical drives contain the program area as well as a data table area, only the program code from the volume boot record in the active partition on a hard disk is executed. The others are read by the operating system files during bootup to obtain their data tables and determine the volume parameters.

The volume boot record contains program code and data. The single data table in this sector is called the media parameter block or disk parameter block. The operating system needs the information this table contains to verify the capacity of the disk volume as well as the location of important structures such as the FAT. The format of this data is very specific.

Table 26.4 shows the format and layout of the DOS boot record (DBR), including the location of each field within the record (the offset) in both hexadecimal and decimal notation and the length of each field.

Table 26.4 DOS Boot Record (DBR) Format Offset

Hex	Dec	Field Length	Description
00h	0	3 bytes	Jump instruction to boot program code
03h	3	8 bytes	OEM name and DOS version (IBM 5.0)
0Bh	11	1 word	Bytes/sector (usually 512)
0Dh	13	1 byte	Sectors/cluster (must be a power of 2)
0Eh	14	1 word	Reserved sectors (boot sectors, usually 1)
10h	16	1 byte	FAT copies (usually 2)
11h	17	1 word	Maximum root directory entries (usually 512)
13h	19	1 word	Total sectors (if partition <= 32MB, else 0)
15h	21	1 byte	Media descriptor byte (F8h for hard disks)
16h	22	1 word	Sectors/FAT
18h	24	1 word	Sectors/track
1Ah	26	1 word	Number of heads
1Ch	28	1 dword	Hidden sectors (if partition <= 32MB, 1 word only)

For DOS 4.0 or Higher Only, Else 00h

Hex	Dec	Field Length	Description
20h	32	1 dword	Total sectors (if partition > 32MB, else 0)
24h	36	1 byte	Physical drive no. (00h=floppy, 80h=hard disk)
25h	37	1 byte	Reserved (00h)
26h	38	1 byte	Extended boot record signature (29h)
27h	39	1 dword	Volume serial number (32-bit random number)
2Bh	43	11 bytes	Volume label (NO NAME stored if no label)
36h	54	8 bytes	File system ID (FAT12 or FAT16)

For All Versions of DOS

Hex	Dec	Field Length	Description
3Eh	62	448 bytes	Boot program code
1FEh	510	2 bytes	Signature bytes (55AAh)

A word is 2 bytes read in reverse order, and a dword is two words read in reverse order.

Root Directory

A *directory* is a simple database containing information about the files stored on a FAT partition. Each record in this database is 32 bytes long, with no delimiters or separating characters between the fields or records. A directory stores almost all the information that the operating system knows about a file, including the following:

- *Filename and extension.* The eight-character name and three-character extension of the file. The dot between the name and the extension is implied, but not included in the entry.

Note

To see how Windows 9x extends filenames to allow 255 characters within the 8.3 directory structure, see “VFAT and Long Filenames,” later in this chapter.

- *File attribute byte.* The byte containing the flags representing the standard DOS file attributes, using the format shown in Table 26.6.
- *Date/Time of last change.* The date and time that the file was created or last modified.
- *File size.* The size of the file, in bytes.
- *Link to start cluster.* The number of the cluster in the partition where the beginning of the file is stored. To learn more about clusters, see “Clusters (Allocation Units)” later in this chapter.

There is information that a directory does not contain about a file. This includes where the rest of its clusters in the partition are located and whether the file is contiguous or fragmented. This information is contained in the FAT.

There are two basic types of directories: the root directory and subdirectories. Any given volume can have only one root directory. The root directory is always stored on a disk in a fixed location immediately following the two copies of the FAT. Root directories vary in size because of the different types and capacities of disks, but the root directory of a given disk is fixed. After a root directory is created by the `FORMAT` command, it has a fixed length and cannot be extended to hold more entries. The root directory entry limits are shown in Table 26.5. Subdirectories are stored as files in the data area of the disk and can grow in size dynamically, therefore they have no fixed length limits.

Table 26.5 Root Directory Entry Limits

Drive Type	Maximum Root Directory Entries
Hard disk	512
1.44MB floppy disk	224
2.88MB floppy disk	448
Jaz and Zip	512
LS-120	512

Note

One advantage of the FAT32 file system is that the root directory can be located anywhere on the disk, and it can have an unlimited number of entries. FAT32 is discussed in more detail later in this chapter.

Every directory, whether it is the root directory or a subdirectory, is organized in the same way. Entries in the directory database store important information about individual files and how files are named on the disk. The directory information is linked to the FAT by the starting cluster entry. In fact, if no file on a disk were longer than one single cluster, the FAT would be unnecessary. The directory stores all the information needed by DOS to manage the file, with the exception of the list of clusters that the file occupies other than the first one. The FAT stores the remaining information about the other clusters that the file occupies.

To trace a file on a disk, use a disk editor such as the DISKEDIT program that comes with the Norton Utilities. Start by looking up the directory entry to get the information about the starting cluster of the file and its size. Then, using the appropriate editor commands, go to the FAT where you can follow the chain of clusters that the file occupies until you reach the end of the file. By using the directory and FAT in this manner, you can visit all the clusters on the disk that are occupied by the file. This type of technique can be useful when these entries are corrupted and when you are trying to find missing parts of a file.

FAT directory entries are 32 bytes long and are in the format shown in Table 26.6, which shows the location (or offset) of each field within the entry (in both hexadecimal and decimal form) and the length of each field.

Table 26.6 FAT Directory Format

Offset (Hex)	Offset (Dec)	Field Length	Description
00h	0	8 bytes	Filename
08h	8	3 bytes	File extension
0Bh	11	1 byte	File attributes
0Ch	12	10 bytes	Reserved (00h)
16h	22	1 word	Time of creation
18h	24	1 word	Date of creation
1Ah	26	1 word	Starting cluster
1Ch	28	1 dword	Size in bytes

Filenames and extensions are left-justified and padded with spaces, (which are represented as ASCII 32h bytes). In other words, if your filename is "AL", it is really stored as "AL-----", where the hyphens are spaces. The first byte of the filename indicates the file status for that directory entry, shown in Table 26.7.

Table 26.7 Directory Entry Status Byte (First Byte)

Hex	File Status
00h	Entry never used; entries past this point not searched.
05h	Indicates that the first character of the filename is actually E5h.
E5h	s (lowercase sigma). Indicates that the file has been erased.
2Eh	. (period). Indicates that this entry is a directory. If the second byte is also 2Eh, the cluster field contains the cluster number of the parent directory (0000h, if the parent is the root).

A word is 2 bytes read in reverse order, and a dword is two words read in reverse order.

Table 26.8 describes the FAT directory file attribute byte. Attributes are one-bit flags that control specific properties of a file, such as whether it is hidden or designated as read-only. Each flag is individually activated (1) or deactivated (0) by changing the bit value. The combination of the eight bit values can be expressed as a single hexadecimal byte value; for example, 07h translates to 00000111, and the 1 bits in positions 3, 2, and 1 indicate the file is System, Hidden, and Read-Only.

Table 26.8 FAT Directory File Attribute Byte

Bit Positions 7 6 5 4 3 2 1 0	Hex Value	Description
0 0 0 0 0 0 0 1	01h	Read-only file
0 0 0 0 0 0 1 0	02h	Hidden file
0 0 0 0 0 1 0 0	04h	System file
0 0 0 0 1 0 0 0	08h	Volume label
0 0 0 1 0 0 0 0	10h	Subdirectory
0 0 1 0 0 0 0 0	20h	Archive (updated since backup)
0 1 0 0 0 0 0 0	40h	Reserved
1 0 0 0 0 0 0 0	80h	Reserved
Examples		
0 0 0 0 0 1 1 1	07h	System, hidden, read-only
0 0 1 0 0 0 0 1	21h	Read-only, archive
0 0 1 1 0 0 1 0	32h	Hidden, subdirectory, archive
0 0 1 0 0 1 1 1	27h	Read-only, hidden, system, archive

File Allocation Tables (FATs)

The file allocation table (FAT) is a list of numerical entries describing how each cluster in the partition is allocated. The data area of the partition has a single entry in the table for each of its clusters. Sectors in the nondata area of the partition are outside the range of the disk controlled by the FAT. Thus, the sectors that comprise the boot records, FATs, and the root directory are outside the range of sectors controlled by the FAT.

▶▶ See “The Data Area,” p. 1450.

The FAT does not manage every data sector specifically, but rather allocates space in groups of sectors called *clusters* or *allocation units*. A cluster is a unit of storage consisting of one or more sectors. The size of a cluster is determined by the FDISK program during the creation of the partition, based on the partition's size. The smallest space that a file can occupy in a partition is one cluster; all files use space in integer (whole) cluster units. If a file is one byte larger than one cluster, two whole clusters are used.

You can think of the FAT as a type of spreadsheet that tracks the allocation of the disk's clusters. Each cell in the spreadsheet corresponds to a single cluster on the disk. The number stored in that cell is a code indicating whether the cluster is used by a file and, if so, where the next cluster of the file is located. Thus, to determine which clusters a particular file is using, you would start by looking at the first FAT reference in the file's directory entry. When you look up the referenced cluster in the FAT, the table contains a reference to the file's next cluster. Each FAT reference, therefore, points to the next cluster in what is called a FAT chain, until you reach the cluster containing the end of the file. Numbers stored in the FAT are hexadecimal numbers that are either 12 or 16 bits long. The 16-bit FAT numbers are easy to follow in a disk sector editor because they take an even two bytes of space. The 12-bit numbers are 1 1/2 bytes long, which presents a problem because most disk sector editors show data in byte units. To edit a 12-bit FAT, you must do some hex/binary math to convert the displayed byte units to FAT numbers. Fortunately (unless you are using the DOS DEBUG program), most of the available tools and utility programs have a FAT-editing mode that automatically converts the numbers for you. Most of them also show the FAT numbers in decimal form, which most people find easier to handle. Table 26.9 shows the relationship between the directory and FAT for a given file (assuming that the file is not fragmented).

Table 26.9 Directory and FAT Relationship (File Not Fragmented)

<i>Directory</i>		
Name	Starting Cluster	Size
USCONST.TXT	1000	4

<i>FAT16 File Allocation Table</i>		
FAT Cluster #	Value	Meaning
00002	0	First cluster available
...
00999	0	Cluster available
01000	1001	In use, points to next cluster
01001	1002	In use, points to next cluster
01002	1003	In use, points to next cluster
01003	FFFFh	End of File
01004	0	Cluster available
01005	0	Cluster available
...
65526	0	Last cluster available

In this example, the directory entry states that the file starts in cluster number 1000. In the FAT, that cluster has a non-zero value, which indicates that it is in use; the specific value indicates where the file that is using it would continue. In this case, the entry for cluster 1000 is 1001, which means the file continues in cluster 1001. The entry in 1001 points to 1002, and from 1002 the entry points to 1003. The entry for 1003 is FFFFh, which is an indication that the cluster is in use, but that the file ends here and uses no additional clusters.

The use of the FAT becomes more clear when you see that files can be fragmented. Let's say that before the USCONST.TXT file was written, another file already occupied clusters 1002 and 1003. If USCONST.TXT was written starting at 1000, it would not have been capable of being completely written before running into the other file. As such, the operating system would skip over the used clusters and continue the file in the next available cluster. The end result is shown in Table 26.10.

Table 26.10 Directory and FAT Relationship (Fragmented File)

<i>Directory</i>		
Name	Starting Cluster	Size
PLEDGE.TXT	1002	2
USCONST.TXT	1000	4

<i>FAT16 File Allocation Table</i>		
FAT Cluster #	Value	Meaning
00002	0	First cluster available
...
00999	0	Cluster available
01000	1001	In use, points to next cluster
01001	1004	In use, points to next cluster
01002	1003	In use, points to next cluster
01003	FFFFh	End of File
01004	1005	In use, points to next cluster
01005	FFFFh	End of File
...
65526	0	Last cluster available

In this example, USCONST.TXT was interrupted by the PLEDGE.TXT file that was previously written, so those clusters are skipped over, and the pointers in the FAT reflect that. Note that the defrag programs included with DOS and Windows will take an example like this and move the files so they are contiguous, one after the other.

The first two entries in the FAT are reserved and contain information about the table itself. All remaining entries correspond to specific clusters on the disk. Most FAT entries consist of a

reference to another cluster containing the next part of a particular file. However, some FAT entries contain hexadecimal values with special meanings, as follows:

- *0000h*. Indicates that the cluster is not in use by a file.
- *FFF7h*. Indicates that at least one sector in the cluster is damaged and that it should not be used to store data.
- *FFFF8h–FFFFh*. Indicates that the cluster contains the end of a file and that no reference to another cluster is needed.

The FDISK program determines whether a 12-bit or 16-bit FAT is placed on a disk, even though the FAT isn't written until you perform a high-level format (using the `FORMAT` utility). On today's systems, usually only floppy disks use 12-bit FATs, but FDISK also creates a 12-bit FAT if you create a hard disk volume that is smaller than 16MB (32,756 sectors). On hard disk volumes of more than 16MB, FDISK creates a 16-bit FAT. On drives larger than 512MB, the FDISK program included in Windows 95 OSR2 and Windows 98 enables you to create 32-bit FATs.

FDISK creates two copies of the FAT. Each one occupies contiguous sectors on the disk, and the second FAT copy immediately follows the first. Unfortunately, the operating system uses the second FAT copy only if sectors in the first FAT copy become unreadable. If the first FAT copy is corrupted, which is a much more common problem, the operating system does not use the second FAT copy. Even the `CHKDSK` command does not check or verify the second FAT copy. Moreover, whenever the OS updates the first FAT, it automatically copies large portions of the first FAT to the second FAT. If the first copy was corrupted and subsequently updated by the OS, a large portion of the first FAT would be copied over to the second FAT copy, damaging it in the process. After the update, the second copy is usually a mirror image of the first one, complete with any corruption. Two FATs rarely stay out of sync for very long. When they are out of sync and the OS writes to the disk, it updates the first FAT and also overwrites the second FAT with the first. This is why disk repair and recovery utilities warn you to stop working as soon as you detect a FAT problem. Programs such as Norton Disk Doctor use the second copy of the FAT as a reference to repair the first one, but if the OS has already updated the second FAT, repair may be impossible.

Clusters (Allocation Units)

The term *cluster* was changed to *allocation unit* in DOS 4.0 (although many people continue to use the old term). *Allocation unit* is appropriate because a single cluster is the smallest unit of the disk that the operating system can handle when it writes or reads a file. A cluster is equal to one or more 512-byte sectors, in a power of two. Although a cluster can be a single disk sector, it is usually more than one. Having more than one sector per cluster reduces the size and processing overhead of the FAT and enables the operating system to run faster because it has fewer individual units to manage. The trade-off is in wasted disk space. Because operating systems manage space only in full-cluster units, every file consumes space on the disk in increments of one cluster.

Table 26.11 shows the default cluster (or allocation unit) sizes for the various floppy disk formats used over the years.

Table 26.11 Default Floppy Disk Cluster (Allocation Unit) Sizes

Drive Type	Cluster (Allocation Unit) Size	Density
5 1/4-inch 360KB	2 sectors (1,024 bytes)	Low
5 1/4-inch 1.2MB	1 sector (512 bytes)	High
3 1/2-inch 720KB	2 sectors (1,024 bytes)	Low
3 1/2-inch 1.44MB	1 sector (512 bytes)	High
3 1/2-inch 2.88MB	2 sectors (1,024 bytes)	Extra

It seems strange that the high-density disks, which have many more individual sectors than low-density disks, sometimes have smaller cluster sizes. The larger the FAT, the more entries the operating system must manage, and the slower it seems to function. This sluggishness is due to the excessive overhead required to manage all the individual clusters; the more clusters to be managed, the slower things become. The trade-off is in the minimum cluster size. High-density floppy disk drives are faster than their low-density counterparts, so perhaps IBM and Microsoft determined that the decrease in cluster size balances the drive's faster operation and offsets the use of a larger FAT.

Because the operating system can allocate only whole clusters, there is inevitably a certain amount of wasted storage space. File sizes rarely fall on cluster boundaries, so the last cluster allocated to a particular file is rarely filled completely. The extra space left over between the actual end of the file and the end of the cluster is called *slack*. A partition with large clusters has more slack space, whereas smaller clusters generate less slack.

For hard disks, the cluster size varies greatly among different partition sizes. The field in the disk parameter block that specifies the cluster size is two bytes long, meaning that its maximum possible value is 65,535. Thus, the largest possible cluster is 32KB, because a 64KB cluster would require a value of 65,536 in this field. Table 26.12 shows the cluster sizes that FDISK selects for a particular volume size.

Table 26.12 Default Hard Disk Cluster (Allocation Unit) Sizes

Hard Disk Volume Size	Cluster (Allocation Unit) Size	FAT Type
0MB to less than 16MB	8 sectors or 4,096 bytes	12-bit
16MB through 128MB	4 sectors or 2,048 bytes	16-bit
More than 128–256MB	8 sectors or 4,096 bytes	16-bit
More than 256B–512MB	16 sectors or 8,192 bytes	16-bit
More than 512B–1,024MB	32 sectors or 16,384 bytes	16-bit
More than 1,024B–2,048MB	64 sectors or 32,768 bytes	16-bit

The effect of larger cluster sizes on disk utilization can be substantial. A 2GB partition containing about 5,000 files, with average slack of one-half of the last 32KB cluster used for each file, wastes over 78MB [5000×(.5×32)KB] of file space.

The cluster size, in combination with the structure of the FAT, also dictates the maximum possible FAT partition size. Because the FAT uses 16-byte entries to reference the clusters in the partition, there can be a maximum of only 65,536 (2¹⁶) clusters. At 32KB per cluster, this means that the largest possible FAT partition is 2,096,832KB or 2,047.6875MB in size.

Even if the 2-byte cluster size field could contain the value indicating 64KB clusters, the maximum partition size would still be constrained. The maximum partition size would be limited by the field in the disk parameter block that specifies the number of sectors per cluster. This field is only one byte long and its value must be a power of two. This makes its highest possible value 128 sectors, which equates to a maximum cluster size of 64KB. 65,536 clusters at 64K each equals a maximum partition size of 4GB.

Note

Windows NT does support the use of 64KB clusters on FAT16 partitions, enabling you to create partitions up to 4GB in size. However, the huge amount of slack that generally results from clusters this large makes this practice undesirable. Also note that no other operating systems with FAT16 support will be able to access a FAT16 partition larger than 2GB.

The Data Area

The data area of a partition is the place where the actual files are stored. It is located following the boot record, file allocation tables, and root directory. This is the area of the disk that is divided into clusters and managed by the FAT and root directory.

Diagnostic Read-and-Write Cylinder

The FDISK partitioning program always reserves the last cylinder of a hard disk for use as a special diagnostic read-and-write test cylinder. Because this cylinder is reserved is one reason FDISK always reports fewer total cylinders than the drive manufacturer states are available. Operating systems do not use this cylinder for any normal purpose because it lies outside the partitioned area of the disk.

◀◀ See "Disk Formatting," p. 621.

On systems with IDE or SCSI disk interfaces, the drive and controller might also allocate an additional area past the logical end of the drive for a bad-track table and spare sectors. This situation might account for additional discrepancies between the FDISK and the drive manufacturer's reported sizes.

The diagnostics area enables software such as a manufacturer-supplied diagnostics disk to perform read-and-write tests on a hard disk without corrupting any user data.

VFAT and Long Filenames

The original Windows 95 release uses what is essentially the same FAT file system as DOS, except for a few important enhancements. Like much of the rest of Windows 95, the operating system

support for the FAT file system was rewritten using 32-bit code and called *VFAT* (virtual file allocation table). VFAT works in combination with the 32-bit protected mode VCACHE (that replaces the 16-bit real mode SMARTDrive cache used in DOS and Windows 3.1) to provide better file system performance. However, the most obvious improvement in VFAT is its support for long filenames. DOS and Windows 3.1 had been encumbered by the standard 8.3 file naming convention for many years, and adding long filename support was a high priority in Windows 95, particularly in light of the fact that Macintosh and OS/2 users had long enjoyed this capability.

The problem for the Windows 95 designers, as is often the case in the PC industry, was backward compatibility. It is no great feat to make long filenames possible when you are designing a new file system from scratch, as Microsoft did years before with Windows NT's NTFS. However, the Windows 95 developers wanted to add long filenames to the existing FAT file system and still make it possible to store those names on existing DOS volumes and for previous versions of DOS and Windows to access the files.

VFAT provides the capability to assign file and directory names that are up to 255 characters in length (including the length of the path). The three-character extension is maintained because, like previous Windows versions, Windows 95 relies on the extensions to associate file types with specific applications. VFAT's long filenames can also include spaces, as well as the following characters, which standard DOS 8.3 names cannot: +,;=[].

The first problem when implementing the long filenames was how to make them usable to previous versions of DOS and 16-bit Windows applications that support only 8.3 names. The resolution to this problem is to give each file two names: a long filename and an alias that uses the traditional 8.3 naming convention. When you create a file with a long filename in Windows 9x, VFAT uses the following process to create an equivalent 8.3 alias name:

1. The first three characters after the last dot in the long filename become the extension of the alias.
2. The first six characters of the long filename (excluding spaces, which are ignored) are converted into uppercase and become the first six characters of the alias filename. If any of these six characters are illegal under the standard 8.3 naming rules (that is, +,;=[or]), VFAT converts those characters into underscores.
3. VFAT adds the two characters ~1 as the seventh and eighth characters of the alias filename, unless this will result in a name conflict, in which case it uses ~2, ~3, and so on, as needed.

Aliasing in Windows NT/2000

Note that Windows NT/2000 creates aliases differently than Windows 9x (as shown later):

NT/2000 begins by taking the first six legal characters in the LFN and follows them with a tilde and number. If the first six characters are unique, then a number 1 follows the tilde.

If the first six characters aren't unique, a number 2 is added. NT/2000 uses the first three legal characters following the last period in the LFN for a file extension.

At the fifth iteration of this process, NT/2000 takes only the first two legal characters, performs a hash on the filename to produce four hexadecimal characters, places the four hex characters after the first two legal characters and appends a ~5. The ~5 remains for all subsequent aliases; only the hex numbers change.

Tip

You can modify the behavior of the VFAT filename truncation mechanism to make it use the first eight characters of the long filename instead of the first six characters plus ~1. To do this, you must add a new binary value to the HKEY_LOCAL_MACHINE\System\CurrentControlSet\control\FileSystem Registry key called NameNumericTail, with a value of 0. Changing the value to 1 returns the truncation process to its original state.

VFAT stores this alias filename in the standard name field of the file's directory entry. Any version of DOS or 16-bit Windows can therefore access the file using the alias name. The big problem that still remains, however, is where to store the long filenames. Clearly, it is impossible to store a 255-character filename in a 32-byte directory entry (because each character requires one byte). However, modifying the structure of the directory entry would make the files unusable by previous DOS versions.

The developers of VFAT resolved this problem by using additional directory entries to store the long filenames. Each of the directory entries is still 32 bytes long, so up to eight may be required for each long name, depending on its length. To ensure that these additional directory entries are not misinterpreted by earlier DOS versions, VFAT flags them with a combination of attributes that is not possible for a normal file: read-only, hidden, system, and volume label. These attributes cause DOS to ignore the long filename entries, while preventing them from being mistakenly overwritten.

Caution

When using long filenames on a standard FAT partition, it is a good idea to avoid storing them in the root directory. Files with long names that take up multiple directory entries can more easily use up the limited number of entries allotted to the root directory than files with 8.3 names. On FAT32 drives, this is not a problem, because the root directory has an unlimited number of entries.

This solution for implementing backward compatible long filenames in Windows 9x is ingenious, but it is not without its problems. Most of these problems stem from the use of applications that can access only the 8.3 alias names assigned to files. In some cases, if you open a file with a long name using one of these programs and save it again, the connection to the additional directory entries containing the long name is severed and the long name is lost.

This is especially true for older versions of disk utilities, such as Norton Disk Doctor, that are not designed to support VFAT. Most older applications ignore the additional directory entries because of the combination of attributes assigned to them, but disk repair utilities are usually designed to detect and "correct" discrepancies of this type. The result is that running an old version of Norton Disk Doctor on a partition with long filenames will result in the loss of all the long names. In the same way, backup utilities not designed for use with VFAT can strip off the long filenames from a partition.

Note

When using VFAT's long filename capabilities, it is definitely preferable that you use disk and backup utilities that are intended to support VFAT. Windows 9x includes VFAT-compatible disk repair, defragmentation, and backup programs. If, however, you are for some reason inclined to use an older program that does not support VFAT, Windows 9x includes a clumsy, but effective, solution.

There is a program included on the Windows 9x CD-ROM called LFNBK.EXE. It doesn't install with the operating system, but you can use it to strip the long filenames from a VFAT volume and store them in a text file called LFNBK.DAT. You can then work with the files on the volume as though they were standard 8.3 FAT files. Afterward, you can use LFNBK.EXE to restore the long filenames to their original places (assuming the file and directory structure has not changed). This is not a convenient solution, nor is it recommended for use in anything but extraordinary circumstances, but the capability is there if needed.

Another problem with VFAT's long filenames involves the process by which the file system creates the 8.3 alias names. VFAT creates a new alias every time you create or copy a file into a new directory, meaning that it is possible for the alias to change. For example, you might have a file called Expenses-January98.doc stored in a directory with the alias EXPENS~1.DOC. If you use Windows 9x Explorer to copy this file to directory that already contains a file called Expenses-December97.doc, you are likely to find that this existing file is already using the alias EXPENS~1.DOC. In this case, VFAT will assign EXPENS~2.DOC as the alias of the newly copied file, with no warning to the user. This is not a problem for applications that support VFAT because the long filenames are unchanged, but a user running an older application may open the EXPENS~1.DOC file expecting to find the list of January 1998 expenses, and see the December 1997 expenses list instead.

FAT32

When the FAT file system was being developed, 2GB hard disk drives were a fantasy, and no one expected the partition size limitation imposed by the combination of 16-bit FAT entries and 32KB cluster sizes to be a problem. Today, however, even low-end PCs come equipped with hard drives holding at least 2GB, and 16 or 20GB drives are common. When you use the standard FAT file system with these larger drives, you have to create several partitions, each no larger than approximately 2GB. To many users, having multiple drive letters representing a single disk is confusing, making it difficult to organize and locate files.

To address this problem, Microsoft has released an enhanced version of the FAT file system, called FAT32. FAT32 works just like the standard FAT, the only difference is that it uses numbers with more digits, meaning it can manage more clusters on a disk. Unlike VFAT, which is a Windows 9x innovation that makes use of existing file system structures, FAT32 is an enhancement of the FAT file system itself. In other words, while VFAT is implemented as part of the Windows 9x Virtual Machine Manager (Vmm.vxd), FAT32 is implemented by the FDISK program before the Windows GUI is even loaded. FAT32 was first included in the Windows 95 OEM Service Release 2 (OSR2), and is also part of Windows 98/Me. Windows 2000 also provides support for FAT32.

Note

Because the FAT32 file system is implemented by the FDISK utility when you partition the drive, you cannot use FAT32 on a floppy disk or any removable cartridge that does not use a partition table. However, any medium that you can partition with FDISK, such as an Iomega Jaz cartridge, can use FAT32.

The most obvious improvement in FAT32 is that by using 32-bit values for FAT entries instead of 16-bit ones, the maximum number of clusters allowed in a single partition jumps from 65,536 (216) to 268,435,456. This value is equivalent to 2²⁸, not 2³², because four bits out of the 32 are

reserved for other uses. FAT32 also uses 32-bit values for the low-level operating system calls used to retrieve a specific disk sector.

These expanded values blow the top off of the 2GB limit on partition sizes; FAT32 partitions can theoretically be up to 2TB in size (1TB = 1,024GB). This figure is derived from a new maximum of 4,294,967,296 (2³²) possible 512-byte sectors. Individual files can be up to 4GB in size; they are limited by the size field in the directory entry, which is 4 bytes long. Because the clusters are numbered using 32-bit values instead of 16-bit ones, the format of the directory entries on a FAT32 partition must be changed slightly. The 2-byte Link to Start Cluster field is increased to 4 bytes, using 2 of the 10 bytes (bytes 12 to 21) in the directory entry that were reserved for future use.

Another important difference in FAT32 partitions is the nature of the root directory. In a FAT32 partition, the root directory does not occupy a fixed position on the disk as in a FAT16 partition. Instead, it can be located anywhere in the partition and expand to any size. This eliminates the preset limit on root directory entries and provides the infrastructure needed to make FAT32 partitions dynamically resizable. Microsoft has not yet implemented this feature in Windows 9x, but there are third-party products such as PowerQuest's PartitionMagic that take advantage of this capability.

The primary drawback of FAT32 is that it is not compatible with previous versions of DOS and Windows 95. You cannot boot to a previous version of DOS or (pre-OSR2) Windows 95 from a FAT32 drive, nor will a system started with an old DOS or Windows 95 boot disk be capable of seeing FAT32 partitions. Apart from Windows 95 OSR2, Windows 98/Me, and Windows 2000, the only operating system that natively supports FAT32 is Linux.

FAT32 Cluster Sizes

Because FAT32 partitions can have so many more clusters than FAT16 partitions, the clusters themselves can be smaller. Using smaller clusters reduces the wasted disk space caused by slack. For example, the same 2GB partition with 5,000 files on it mentioned earlier would use 4KB clusters with FAT32 instead of 32KB clusters with FAT16. Assuming the same amount of slack for each file, the smaller cluster size reduces the average amount of wasted space on that partition from over 78MB to under 10MB.

To compare FAT16 and FAT32, you can look at how a file would be stored on each. For FAT16, I'll use the same example as before. With FAT16 the cluster numbers are stored as 16-bit entries, from 0000h–FFFFh. The largest value possible is FFFFh, which corresponds to 65,535 in decimal, but several numbers at the beginning and end are reserved for special use. The actual cluster numbers allowed in a FAT16 system range from 0002h to FFF6h, which is 2–65,526 in decimal. All files have to be stored in cluster numbers within that range. That leaves only 65,524 valid clusters to use for storing files (cluster numbers below 2 and above 65,526 are reserved), meaning a partition has to be broken up into that many clusters or less. A typical file entry under FAT16 might look like Table 26.13.

Table 26.13 FAT16 File Entries

Directory		
Name	Starting Cluster	Size
USCONST.TXT	1000	4
FAT16 File Allocation Table		
FAT Cluster #	Value	Meaning
00002	0	First cluster available
...
00999	0	Cluster available
01000	1001	In use, points to next cluster
01001	1002	In use, points to next cluster
01002	1003	In use, points to next cluster
01003	FFFFh	End of File
01004	0	Cluster available
...
65526	0	Last cluster available

With FAT32, the cluster numbers range from 00000000h to FFFFFFFFh, which is from 0 to 4,294,967,295 in decimal. Again some values at the low and high end are reserved, and only values from between 00000002h and FFFFFFF6h are valid, which is to say from 2 through 4,294,967,286 are valid. This leaves 4,294,967,284 valid entries, which means the drive must be split into that many clusters or less. Since a drive can be split into so many more clusters, they can be smaller, which conserves on disk space. The same file as shown earlier might be stored on a FAT32 system as shown in Table 26.14.

Table 26.14 FAT32 File Entries

Directory		
Name	Starting Cluster	Size
USCONST.TXT	1000	8
FAT32 File Allocation Table		
FAT Cluster #	Value	Meaning
000000002	0	First cluster available
...
0000000999	0	Cluster available
0000001000	1001	In use, points to next cluster
0000001001	1002	In use, points to next cluster
0000001002	1003	In use, points to next cluster

(continues)

Table 26.14 Continued

FAT32 File Allocation Table		
FAT Cluster #	Value	Meaning
0000001003	1004	In use, points to next cluster
0000001004	1005	In use, points to next cluster
0000001005	1006	In use, points to next cluster
0000001006	1007	In use, points to next cluster
0000001007	FFFFFFFFh	End of File
0000001008	0	Cluster available
...
4,294,967,286	0	Last cluster available

Because the FAT32 system allows for many more clusters to be allocated, the cluster size is usually smaller. So, although files overall use more individual clusters, there is less wasted space because the last cluster is, on average, only half filled.

Note

PC Magazine has released a free DOS utility called CHKDRV that calculates the slack on a FAT16 or FAT32 partition. You can download this program from <ftp://ftp.zdnet.com/pcmag/1995/0627/chkdrv.zip>.

Table 26.15 lists the cluster sizes for various FAT32 partition sizes.

Table 26.15 FAT32 Cluster Sizes

Partition Size	Cluster Size
0MB to less than 260MB	512 bytes
260MB–8GB	4,096 bytes
6–16GB	8,192 bytes
16–32GB	16,384 bytes
32GB–2TB	32,768 bytes

Of course, using smaller clusters means there must be many more of them and more entries in the FAT as well. A 2GB partition using FAT32 requires 524,288 FAT entries, whereas the same drive needs only 65,536 entries using FAT16. Thus, the size of one copy of the FAT16 table is 128KB (65,536 entries \times 16 bits = 1,048,576 bits/8 = 131,072 bytes/1,024 = 128KB), whereas the FAT32 table is 2MB in size.

The size of the FAT has a definite impact on the performance of the file system. Windows 9x uses its VCACHE to try to keep the FAT in memory at all times to improve file system performance. The use of 4KB clusters for drives up to 8GB in size is, therefore, a reasonable compromise for the average PC's memory capacity. If the file system were to use clusters that are equal to one disk sector (1 sector = 512KB) in an attempt to minimize slack as much as possible, the FAT table for a 2GB drive would contain 4,194,304 entries and be 16MB in size.

This would monopolize a substantial portion of the memory in the average system, probably resulting in noticeably degraded performance. Although at first it might seem as though even a 2MB FAT is quite large when compared to 128KB, keep in mind that hard disk drives are a great deal faster now than they were when the FAT file system was originally designed. In practice, implementing FAT32 on a Windows 9x system typically results in a minor (less than five percent) improvement in file system performance. However, systems that perform a great many sequential disk writes may see an equally minor degradation in performance.

FAT Mirroring

FAT32 also takes greater advantage of the two copies of the FAT stored on a disk partition. On a FAT16 partition, the first copy of the FAT is always the primary copy and replicates its data to the secondary FAT, sometimes corrupting it in the process. On a FAT32 partition, when the system detects a problem with the primary copy of the FAT, it can switch to the other copy, which then becomes the primary. The system can also disable the FAT mirroring process to prevent the viable FAT from being corrupted by the other copy. This provides a greater degree of fault tolerance to FAT32 partitions, often making it possible to repair a damaged FAT without an immediate system interruption or a loss of table data.

Creating FAT32 Partitions

Despite the substantial changes provided by FAT32, the new file system does have a large effect on the procedures you use to create and manage partitions. You create new FAT32 partitions in Windows 9x using the FDISK utility from the command prompt, just like you would create FAT16 partitions. When you launch FDISK, the program examines your hard disk drives and, if they have a capacity greater than 512MB, presents the following message:

```
Your computer has a disk larger than 512 MB. This version of Windows
includes improved support for large disks, resulting in more efficient
use of disk space on large drives, and allowing disks over 2 GB to be
formatted as a single drive.
```

```
IMPORTANT: If you enable large disk support and create any new drives on this
disk, you will not be able to access the new drive(s) using other operating
systems, including some versions of Windows 95 and Windows NT, as well as
earlier versions of Windows and MS-DOS. In addition, disk utilities that
were not designed explicitly for the FAT32 file system will not be able
to work with this disk. If you need to access this disk with other operating
systems or older disk utilities, do not enable large drive support.
```

```
Do you wish to enable large disk support (Y/N).....? [N]
```

If you answer Yes to this question, any partitions you create that are larger than 512MB will be FAT32 partitions. If you want to create partitions larger than 2GB, you must use FAT32. Otherwise, you can choose which file system you prefer. All the screens following this one are the same as those in previous versions of FDISK.

Normally, the FDISK utility determines the cluster size that will be used when you format the partition, based on the partition's size and the file system used. However, you can override FDISK using an undocumented switch for the FORMAT utility. If you use the command

```
FORMAT /Z:n
```

where n multiplied by 512 equals the desired cluster size in bytes, you can create a partition that uses cluster sizes that are larger or smaller than the defaults for the file system.

Caution

The `/Z` switch does not override the 65,536 cluster limit on FAT16 partitions, so it is recommended that you use it only with FAT32. In addition, you should not use this switch on a production system without extensive testing first. Modifying the cluster size might increase or reduce the amount of slack on the partition, but it also might have a pronounced effect on the performance of the drive.

Converting FAT16 to FAT32

The Windows 95 OSR2 release can create FAT32 partitions only out of empty disk space. If you want to convert an existing FAT16 partition to FAT32, you have to back up the data, destroy the FAT16 partition, create a new FAT32 partition, and then restore the data. Windows 98/Me, on the other hand, includes a FAT32 Conversion Wizard that enables you to migrate existing partitions in place.

The wizard gathers the information needed to perform the conversion, informs you of the consequences of implementing FAT32, and attempts to prevent data loss and other problems. After you have selected the drive that you want to convert, the wizard performs a scan for applications (such as disk utilities) that might not function properly on the converted partition. The wizard gives you the opportunity to remove these and warns you to back up the data on the partition before proceeding with the conversion. Even if you don't use the Microsoft Backup utility that the wizard offers, backing up your data is a strongly recommended precaution.

After you answer all the wizard's prompts and confirm that you want to continue with the conversion, the system reboots to a DOS prompt. The actual conversion is a DOS process, making it possible to convert even the partition on which Windows 98/Me is installed. Because the conversion must deal with the existing partition data in addition to creating new volume boot record information, FATs, and clusters, the process can take far longer than partitioning and formatting an empty drive. Depending on the amount of data involved and the new cluster size, the conversion might take several hours to complete.

After you convert a FAT16 partition to FAT32, you cannot convert it back with Windows 98 or Me's tools, except by destroying the partition and using FDISK to create a new one. Therefore, be sure to carefully consider your actions before proceeding. It is also a good idea to take other precautions before beginning the conversion process, such as connecting the system to a UPS. A power failure during the conversion could result in a loss of data.

FAT32 and PartitionMagic

Windows 95 OSR2 and Windows 98/Me include only basic tools for creating FAT32 partitions, but there is a product called PartitionMagic, from PowerQuest, which provides many other partition manipulation features. PartitionMagic can convert FAT16 partitions to FAT32 in place, as the Windows 98/Me FAT32 Conversion Wizard can, but unlike Windows 98/Me, it can also convert FAT32 partitions back to FAT16.

Among many other things, this product can also resize FAT16 and FAT32 partitions without destroying the data they contain, shrink and expand FAT clusters, and tell you how much disk space you will save as the result of changing the cluster size. PartitionMagic takes advantage of the inherent capabilities of the FAT16 and FAT32 file systems to provide features that will probably be added to Windows 9x at some future time.

FAT File System Errors

File system errors can, of course, occur because of hardware problems, but you are more likely to see them result from software crashes and improper system handling. Turning off a system without shutting down Windows properly, for example, can result in errors that cause clusters to be incorrectly listed as in use when they are not. Some of the most common file system errors that occur on FAT partitions are described in the following sections.

Lost Clusters

Probably the most common file system error, lost clusters are clusters that the FAT designates as being in use when they actually are not. Most often caused by an interruption of a file system process due to an application crash or a system shutdown, for example, the FAT entry of a lost cluster may contain a reference to a subsequent cluster. However, the FAT chain stemming from the directory entry has been broken somewhere along the line.

Lost clusters would appear in the file structure as shown in Table 26.16.

Table 26.16 Lost Clusters in a File Structure

<i>Directory</i>		
Name	Starting Cluster	Size
(no entry)	0	0
<i>FAT16 File Allocation Table</i>		
FAT Cluster #	Value	Meaning
00002	0	First cluster available
...
00999	0	Cluster available
01000	1001	In use, points to next cluster
01001	1002	In use, points to next cluster
01002	1003	In use, points to next cluster
01003	FFFFh	End of File
01004	0	Cluster available
...
65526	0	Last cluster available

The operating system sees a valid chain of clusters in the FAT, but no corresponding directory entry to back it up. This is most often caused by programs that are terminated before they can close their open files. The operating system normally modifies the FAT chain as the file is written, and the final step when closing is to create a matching directory entry. If the system is interrupted before the file is closed, lost clusters are the result.

Disk repair programs check for lost clusters by tracing the FAT chain for each file and subdirectory in the partition and building a facsimile of the FAT in memory. After compiling a list of all the FAT entries that indicate properly allocated clusters, the program compares this facsimile with the actual FAT. Any entries denoting allocated clusters in the real FAT that do not appear in the facsimile are lost clusters because they are not part of a valid FAT chain.

The utility typically gives you the opportunity to save the data in the lost clusters as a file before it changes the FAT entries to show them as unallocated clusters. If your system crashed or lost power while you were working with a word processor data file, for example, you might be able to retrieve text from the lost clusters in this way. When left unrepaired, lost clusters are unavailable for use by the system, reducing the storage capacity of your drive.

The typical choices you have for correcting lost clusters are to assign them a made-up name or zero out the FAT entries. If you assign them a name, you can at least look at the entries as a valid file, and then delete the file if you find it useless. The CHKDSK program is designed to fix lost clusters by assigning them names starting with FILE0001.CHK. If there is more than one lost chain, sequential numbers following the first one will be used. The lost clusters shown earlier could be corrected by CHKDSK, as shown in Table 26.17.

Table 26.17 Finding Lost Clusters

<i>Directory</i>		
Name	Starting Cluster	Size
FILE0001.CHK	1000	4
<i>FAT16 File Allocation Table</i>		
FAT Cluster #	Value	Meaning
00002	0	First cluster available
...
00999	0	Cluster available
01000	1001	In use, points to next cluster
01001	1002	In use, points to next cluster
01002	1003	In use, points to next cluster
01003	FFFFh	End of File
01004	0	Cluster available
...
65526	0	Last cluster available

As you can see, a new entry was created to match the FAT entries. The name is made up because there is no way for the repair utility to know what the original name of the file might have been.

Cross-Linked Files

Cross-linked files occur when two directory entries improperly reference the same cluster in their Link to Start Cluster fields. The result is that each file uses the same FAT chain. Because the clusters can store data from only one file, working with one of the two files can inadvertently overwrite the other file's data.

Cross-linked files would appear in the file structure as shown in Table 26.18.

Table 26.18 Cross-Linked Files

<i>Directory</i>		
Name	Starting Cluster	Size
USCONST.TXT	1000	4
PLEDGE.TXT	1002	2

<i>FAT16 File Allocation Table</i>		
FAT Cluster #	Value	Meaning
00002	0	First cluster available
...
00999	0	Cluster available
01000	1001	In use, points to next cluster
01001	1002	In use, points to next cluster
01002	1003	In use, points to next cluster
01003	FFFFh	End of File
01004	0	Cluster available
...
65526	0	Last cluster available

In this case there are two files that claim ownership of clusters 1002 and 1003. These files are said to be cross-linked on 1002. When a situation like this arises, normally one of the files is valid and the other is corrupt, being that only one actual given set of data can occupy a given cluster. The normal repair is to copy both files involved to new names, which will duplicate their data separately in another area of the disk, and then delete *all* the files that are cross-linked. It is important to delete them all because by deleting one of them, the FAT chain will be zeroed, which will further damage the other entries. Then you can examine the files you copied to determine which one is good and which is corrupt.

Detecting cross-linked files is a relatively easy task for a disk repair utility because it has to examine only the partition's directory entries and not the file clusters themselves. However, by the time that the utility detects the error, the data from one of the two files is probably already lost, although you may be able to recover parts of it from lost clusters.

Invalid Files or Directories

Sometimes the information in a directory entry for a file or subdirectory can be corrupted to the point at which the entry is not just erroneous (as in cross-linked files) but invalid. The entry may have a cluster or date reference that is invalid or may violate the rules for the entry format in some other way. In most cases, disk repair software can correct these problems, permitting access to the file.

FAT Errors

As discussed earlier, corruption of the FAT can sometimes be repaired by accessing its duplicate copy. Disk repair utilities typically rely on this technique to restore a damaged FAT to its original state, as long as the copy has not been corrupted by the mirroring process. FAT32 tables are more likely to be repairable, because their more advanced mirroring capabilities make it less likely for the copy to be corrupted.

An example of a damaged FAT might appear to the operating system shown in Table 26.19.

Table 26.19 Damaged FAT

<i>Directory</i>		
Name	Starting Cluster	Size
USCONST.TXT	1000	4
<i>FAT16 File Allocation Table</i>		
FAT Cluster #	Value	Meaning
00002	0	First cluster available
...
00999	0	Cluster available
01000	1001	In use, points to next cluster
01001	0	Cluster available
01002	1003	In use, points to next cluster
01003	FFFFh	End of File
01004	0	Cluster available
...
65526	0	Last cluster available

This single error would cause multiple problems to appear. The file USCONST.TXT would now come up as having an *allocation error*—where the size in the directory no longer matches the number of clusters in the FAT chain. The file would end after cluster 1001 in this example, and the rest of the data would be missing if one loaded this file for viewing. Also there would be two lost clusters; that is 1002 and 1003 appear to have no directory entry that owns them. When multiple problems like this appear, it is often due to a single incident of damage. The repair in this case could involve copying the data from the backup FAT back to the primary FAT, but in most cases the backup will be similarly damaged. Normal utilities would truncate the file and

create an entry for a second file out of the lost clusters. You would have to figure out yourself that they really belong together. This is where having knowledge in data recovery can help over using automated utilities that cannot think for themselves.

FAT File System Utilities

The CHKDSK, RECOVER, and SCANDISK commands are the DOS damaged-disk recovery team. These commands are crude, and their actions sometimes are drastic, but at times they are all that is available or needed. RECOVER is best known for its function as a data recovery program. CHKDSK usually is used for inspection of the file structure. Many users are unaware that CHKDSK can implement repairs to a damaged file structure. DEBUG, a crude, manually controlled program, can help in the case of a disk disaster, if you know exactly what you are doing.

SCANDISK is a safer, more automated, more powerful replacement for CHKDSK and RECOVER. It should be used in their place if you are running DOS 6 or higher or Windows 9x.

The CHKDSK Command

The useful and powerful DOS CHKDSK command is frequently misunderstood. To casual users, the primary function of CHKDSK seems to be providing a disk space allocation report for a given volume as well as a memory allocation report. CHKDSK does those things, but its primary value is in discovering, defining, and repairing problems with the DOS directory and FAT system on a disk volume. In handling data recovery problems, CHKDSK is a valuable tool, although it is crude and simplistic compared to some of the aftermarket utilities that perform similar functions.

The output of the CHKDSK command when it runs on a typical hard disk is as follows:

```
Volume 4GB_SCSI   created 01-31-1998 5:05p
Volume Serial Number is 1882-18CF

2,146,631,680 bytes total disk space
  163,840 bytes in 3 hidden files
  16,220,160 bytes in 495 directories
  861,634,560 bytes in 10,355 user files
1,268,613,120 bytes available on disk

    32,768 bytes in each allocation unit
    65,510 total allocation units on disk
    38,715 available allocation units on disk

655,360 total bytes memory
632,736 bytes free
```

A little-known CHKDSK function is its capability to report on a specified file's (or group of files') level of fragmentation. CHKDSK can also produce a list of all files (including hidden and system files) on a particular volume, such as a super DIR command. By far, the most important CHKDSK capabilities are its detection and correction of problems in the FAT file system.

The name of the CHKDSK program is misleading: It seems to be a contraction of *check disk*. The program does not actually check a disk, or even the files on a disk, for integrity. CHKDSK cannot even truly show how many bad sectors are on a disk, much less locate and mark them. The real

function of CHKDSK is to inspect the directories and FATs to see whether they correspond with each other or contain discrepancies. CHKDSK does not detect (and does not report on) damage in a file; it checks only the FAT and directory areas of a disk.

CHKDSK also can test files for contiguity. Files loaded into contiguous tracks and sectors of a disk or floppy disk naturally are more efficient. Files spread over wide areas of the disk make access operations take longer. DOS always knows the location of all a file's fragments by using the cluster references in the FAT. Sometimes, for various reasons, these references might be lost or corrupted and leave DOS incapable of locating some portion of a file. Using CHKDSK can alert you to this condition and even enable you to reclaim the unused file space.

CHKDSK Command Syntax

The syntax of the CHKDSK command is as follows:

```
CHKDSK [d:\path\] [filename] [/F] [/V]
```

The `d:` switch specifies the disk volume to analyze. The `\path` and `filename` options specify files to check for fragmentation in addition to the volume analysis. Wildcards are permitted in the filename specification, to specify multiple files in a specified directory for fragmentation analysis. One limitation of the fragmentation analysis is that it does not check for fragmentation across directory boundaries, only within a specified directory.

The `/F` (Fix) switch enables CHKDSK to perform repairs if it finds problems with the directories and FATs. If `/F` is not specified, the program cannot write to the disk and no repairs are performed.

The `/V` (Verbose) switch causes the program to list all the entries in all the directories on a disk and give detailed information in cases where it encounters errors.

The drive, path, and file specifiers are optional. If you add no parameters for the command, CHKDSK processes the default volume or drive and does not check files for contiguity. If you specify `[path]` and `[filename]` parameters, CHKDSK checks all specified files to see whether they are stored contiguously on the disk. The program displays one of two messages as a result:

```
All specified file(s) are contiguous
```

or

```
[filename] Contains xxx non-contiguous blocks
```

CHKDSK displays the second message for each file on the disk that it finds to be fragmented and displays the number of fragments that compose the file. A fragmented file is one that is scattered around the disk in pieces rather than existing in one contiguous area of the disk. Fragmented files are slower to load than contiguous files, which reduces disk performance. Fragmented files are also much more difficult to recover if a problem with the FAT or directory on the disk occurs.

If you have only DOS, there are several ways to accomplish a full defragmentation. To defragment files on a floppy disk, you can format a new floppy disk and use `COPY` or `XCOPY` to copy all the files from the fragmented disk to the replacement. For a hard disk, you must completely back up, format, and then restore the disk. This procedure is time-consuming and dangerous, which is why there are so many third-party defragmenting utilities available.

CHKDSK Operation

CHKDSK reports problems found in a disk volume's FAT or directory system with one of several descriptive messages that vary to fit the specific error. Sometimes the messages are cryptic or misleading. CHKDSK does not specify how an error should be handled. It does not tell you whether CHKDSK can repair the problem, whether you must use some other utility, or what the consequences of the error and the repair will be. Neither does CHKDSK tell you what caused the problem nor how to avoid repeating the problem.

The primary function of CHKDSK is to compare the directory and FAT to determine whether they agree with each other—that is, whether all the data in the directory entries for the files (such as the starting cluster and size information) corresponds to what is in the FAT (such as chains of clusters with end-of-chain indicators). CHKDSK also checks subdirectory file entries, as well as the special “dot” (.) and “double dot” (..) entries that tie the subdirectory system together.

The second function of CHKDSK is to implement repairs to the disk structure. CHKDSK patches the disk so that the directory and FAT are in alignment and agreement. From a repair standpoint, understanding CHKDSK is relatively easy. CHKDSK almost always modifies the directories on a disk to correspond to what it finds in the FAT. There are only a few special cases in which CHKDSK modifies the FAT. When it does, the FAT modifications are always the same type of simple change.

Think of CHKDSK's repair capability as a directory patcher. Because CHKDSK cannot repair most types of FAT damage effectively, it simply modifies the disk directories to match whatever problems it finds in the FAT.

CHKDSK is not a very smart repair program and often can do more damage repairing the disk than if it had left the disk alone. In many cases, the information in the directories is correct and can be used (by some other utility) to help repair the FAT tables. If you have run CHKDSK with the /F parameter, however, the original directory information no longer exists, and a good FAT repair is impossible.

Caution

You should never run CHKDSK with the /F parameter without first running it in read-only mode (without the /F parameter) to determine whether and to what extent damage exists.

Only after carefully examining the disk damage and determining how CHKDSK would fix the problems should you run CHKDSK with the /F parameter. If you do not specify the /F parameter when you run CHKDSK, the program does not make corrections to the disk. Rather, it performs repairs in a mock fashion. This limitation is a safety feature because you do not want CHKDSK to take action until you have examined the problem. After deciding whether CHKDSK will make the correct assumptions about the damage, you might want to run it with the /F parameter.

Caution

Sometimes people place a `CHKDSK /F` command in their `AUTOEXEC.BAT` file; this is a very dangerous practice. If a system's disk directories and FAT system become damaged, attempting to load a program whose directory and FAT entries are damaged might lock the system. If, after you reboot, CHKDSK is fixing the problem because it is in

(continues)

(continued)

the AUTOEXEC.BAT, it can irreparably damage the file structure of the disk. In many cases, **CHKDSK** ends up causing more damage than originally existed, and no easy way exists to undo the **CHKDSK** repair. Because **CHKDSK** is a simple utility that often makes faulty assumptions in repairing a disk, you must run it with great care when you specify the `/F` parameter.

Problems reported by **CHKDSK** are usually problems with the software and not the hardware. You rarely see a case in which lost clusters, allocation errors, or cross-linked files reported by **CHKDSK** were caused directly by a hardware fault, although it is certainly possible. The cause is usually a defective program or a program that was stopped before it could close files or purge buffers. A hardware fault certainly can stop a program before it can close files, but many people think that these error messages signify fault with the disk hardware, which is almost never the case.

The **RECOVER** Command

The DOS **RECOVER** command is designed to mark clusters as bad in the FAT when the clusters cannot be read properly. When the system cannot read a file because of a problem with a sector on the disk going bad, the **RECOVER** command can mark the FAT so that those clusters are not used by another file. When used improperly, this program is highly dangerous. The **RECOVER** utility has not been included in DOS since version 5 and is not supplied in Windows 9x, as its functionality has been replaced by **SCANDISK**.

Caution

Be very careful when you use **RECOVER**. Used improperly, it can do severe damage to your files and the FAT. If you enter the **RECOVER** command without a filename for it to work on, the program assumes that you want every file on the disk recovered, and operates on every file and subdirectory on the disk. It converts all subdirectories to files, places all filenames in the root directory, and gives them new names (FILE0000.REC, FILE0001.REC, and so on). This process essentially wipes out the file system on the entire disk. Do not use **RECOVER** without providing a filename for it to work on. This program should be considered as dangerous as the **FORMAT** command.

SCANDISK

It's a good idea to check your FAT partitions regularly for the problems discussed in this chapter and any other difficulties that may arise. By far an easier and more effective solution for disk diagnosis and repair than **CHKDSK** and **RECOVER** is the **SCANDISK** utility, included with DOS 6 and higher versions as well as with Windows 9x. This program is more thorough and comprehensive than **CHKDSK** or **RECOVER**, and can perform the functions of both of them—and a great deal more. Windows 95 OSR2 and Windows 98 include **SCANDISK** versions that support FAT32 partitions.

SCANDISK is like a scaled-down version of third-party disk repair programs such as Norton Disk Doctor, and it can verify both file structure and disk sector integrity. If **SCANDISK** finds problems, it can repair directories and FATs. If the program finds bad sectors in the middle of a file, it marks the clusters (allocation units) containing the bad sectors as bad in the FAT, and attempts to read the file data by rerouting around the defect.

Windows 9x includes both DOS and Windows versions of SCANDISK, which are named SCANDISK.EXE and SCANDSKW.EXE, respectively. Windows 9x scans your drives at the beginning of the operating system installation process and automatically loads the DOS version of SCANDISK whenever you restart your system after turning it off without completing the proper shutdown procedure. You can also launch SCANDISK.EXE from a DOS prompt or from a batch file using the following syntax.

```
Scandisk x: [/a] [/n] [/p] [dblSPACE.nnn/drvSPACE.nnn]
x: - designator of the drive that you want to scan
/a - scans all local fixed hard disks
/n - noninteractive mode; requires no user input
/p - scans only, without correcting errors
/custom - runs Scandisk with the options configured in the
    ➤[CUSTOM] section of the Scandisk.ini file
dblSPACE.nnn or drvSPACE.nnn - scans a compressed volume file,
    ➤where nnn is replaced by the file extension (such as 001)
```

The SCANDISK.INI file, located in the C:\WINDOWS\COMMAND directory on a Windows 9x system by default, contains extensive and well-documented parameters that you can use to control the behavior of SCANDISK.EXE. Note that the options in the SCANDISK.INI file are applied only to the DOS version of the utility and have no effect on the Windows GUI version.

You can also run the GUI version of the utility by opening the Start menu and choosing Programs, Accessories, System Tools. Both versions scan and repair the FAT and the directory and file structures, repair problems with long filenames, and scan volumes that have been compressed with DriveSpace or DoubleSpace.

SCANDISK provides two basic testing options: Standard and Thorough. The difference between the two is that the Thorough option causes the program to scan the entire surface of the disk for errors in addition to the items just mentioned. You can also select whether to run the program interactively or let it automatically repair any errors that it finds.

The DOS and Windows 9x versions of SCANDISK also test the FAT in different ways. The DOS version scans and, if necessary, repairs the primary copy of the file allocation table. After this it copies the repaired version of the primary to the backup copy. The Windows version, however, scans both copies of the FAT. If the program finds discrepancies between the two copies, it uses the data from the copy that it judges to be correct and reassembles the primary FAT using the best data from both copies.

SCANDISK also has an Advanced Options dialog box that enables you to set the following parameters:

- Whether the program should display a summary of its findings
- Whether the program should log its findings
- How the program should repair cross-linked files (two directory entries pointing to the same cluster)
- How the program should repair lost file fragments
- Whether to check files for invalid names, dates, and times

Although SCANDISK is good, and is certainly a vast improvement over CHKDSK, I would recommend using one of the commercial packages, such as the Norton Utilities, for any major disk problems. These utilities go far beyond what is included in DOS or Windows 9x.

Disk Defragmentation

The entire premise of the FAT file systems is based on the storage of data in clusters that can be located anywhere on the disk. This enables the computer to store a file of nearly any size at any time. The process of following a FAT chain to locate all the clusters holding the data for a particular file can force the hard disk drive to access many different locations on the disk. Because of the physical work involved in moving the disk drive heads, reading a file that is heavily fragmented in this way is slower than reading one that is stored on consecutive clusters.

As you regularly add, move, and delete files on a disk over a period of time, the files become increasingly fragmented, which can slow down disk performance. You can relieve this problem by periodically running a disk defragmentation utility on your drives, such as the one included with Windows 9x. When you run Disk Defragmenter, the program reads each of the files in the disk, using the FAT table to access its clusters, wherever they might be located.

The program then writes the file to a series of contiguous clusters and deletes the original. By progressively reading, erasing, and writing files, the program eventually leaves the disk in a state where all its files exist on contiguous clusters. As a result, the drive is capable of reading any file on the disk with a minimum of head movement, thus providing what is often a noticeable performance increase.

The Windows 95 Disk Defragmentation utility provides this basic defragmenting function. It also enables you to select whether you want to arrange the files on the disk to consolidate the empty clusters into one contiguous free space (which takes longer). The Windows 98/Me version adds a feature that examines the files on the disk and arranges them with the most often used program files grouped together at the front of the disk, which can make programs load faster.

To show how defragmenting works, see the example of a fragmented file shown in Table 26.20.

Table 26.20 Fragmented File

<i>Directory</i>		
Name	Starting Cluster	Size
PLEDGE.TXT	1002	2
USCONST.TXT	1000	4
<i>FAT16 File Allocation Table</i>		
FAT Cluster #	Value	Meaning
00002	0	First cluster available
...
00999	0	Cluster available
01000	1001	In use, points to next cluster

FAT16 File Allocation Table

FAT Cluster #	Value	Meaning
01001	1004	In use, points to next cluster
01002	1003	In use, points to next cluster
01003	FFFFh	End of file
01004	1005	In use, points to next cluster
01005	FFFFh	End of file
...
65526	0	Last cluster available

In the preceding example, the file USCONST.TXT is fragmented in two pieces. If we ran a defragmenting program, the files would be read off the disk and rewritten in a contiguous fashion. One possible outcome is shown in Table 26.21.

Table 26.21 Defragmented File

<i>Directory</i>		
Name	Starting Cluster	Size
PLEDGE.TXT	1004	2
USCONST.TXT	1000	4

FAT16 File Allocation Table		
FAT Cluster #	Value	Meaning
00002	0	First cluster available
...
00999	0	Cluster available
01000	1001	In use, points to next cluster
01001	1002	In use, points to next cluster
01002	1003	In use, points to next cluster
01003	FFFFh	End of file
01004	1005	In use, points to next cluster
01005	FFFFh	End of file
...
65526	0	Last cluster available

Although it doesn't look like much was changed, you can see that now both files are in one piece, stored one right after the other. Because defragmenting involves reading and rewriting a possibly large number of files on your drive, it can take a long time, especially if you have a lot of fragmented files and not very much free working space on the drive.

Third-party defragmentation utilities, such as the Speed Disk program included in the Norton Utilities, provide additional features, such as the capability to select specific files that should be

moved to the front of the disk. Speed Disk can also defragment the Windows 9x swap file and files that are flagged with the system and hidden attributes, which Disk Defragmenter will not touch.

Caution

Although the disk-defragmentation utilities included with Windows 9x and third-party products are usually quite safe, you should always be aware that defragmenting a disk is an inherently dangerous procedure. The program reads, erases, and rewrites every file on the disk and has the potential to cause damage to your data when interrupted improperly. Although I have never seen a problem result from the process, an unforeseen event such as a power failure during a defragmentation procedure can conceivably be disastrous. I strongly recommend that you always run a disk-repair utility such as **SCANDISK** on your drives before defragmenting them, and have a current backup ready.

Third-Party Programs

When you get a `Sector not found` error reading drive C:, the best course of action is to use one of the third-party disk-repair utilities on the market, rather than DOS's **RECOVER** or even **SCANDISK**. The Norton Utilities by Symantec stands as perhaps the premier data recovery package on the market today. This package is comprehensive and automatically repairs most types of disk problems.

Programs such as Norton Disk Doctor can perform much more detailed repairs with a greater amount of safety. If the error is on a floppy disk, use Norton's DiskTool before you use Disk Doctor. DiskTool is specially designed to help you recover data from floppy disks. Disk Doctor and DiskTool preserve as much of the data in the file as possible and can mark the FAT so the bad sectors or clusters of the disk are not used again. These programs also save Undo information, making it possible for you to reverse any data recovery operation.

Disk Doctor and DiskTool are part of Symantec's Norton Utilities package, which includes a great many other useful tools. For example, Norton Utilities has an excellent sector editor that enables you to view and edit any part of a disk, including the master and volume boot records, FATs, and other areas that fall outside of the disk's normal data area. Currently, no other program is as comprehensive or as capable of editing disks at the sector level. The disk editor included with Norton Utilities can give the professional PC troubleshooter or repairperson the ability to work directly with any sector on the disk, but this does require extensive knowledge of sector formats and disk structures. The documentation with the package is excellent and can be very helpful if you are learning data recovery on your own.

Note

Data recovery is a lucrative service that the more advanced technician can provide. People are willing to pay much more to get their data back than to replace a hard drive.

For more automatic recovery that anybody can perform, Norton Utilities has several other useful modules. Disk Doctor and Calibrate are two of the modules included with the Norton Utilities

(both version 8.0 for DOS/Windows and the latest Norton 2000 for Windows). Together, these two utilities provide exhaustive testing of the data structures and sectors of a hard drive. Disk Doctor works with both hard disks and floppy disks. It tests the capability of the drive to work with the system in which it is installed, including the drive's boot record, FATs, file structure, and data areas. Calibrate, which is used for the most intensive testing of the data area of a drive, also tests the hard drive controller electronics.

You can also use Calibrate to perform deep-pattern testing of IDE and SCSI drives. This process writes millions of bytes of data to every sector of the drive to see whether it can properly retain data. It moves data if the sector where the data is stored is flawed. Bad sectors are then marked as bad in the FAT.

Because of the excellent disk editor, anybody serious about data recovery needs a copy of Norton Utilities. The many other modules that are included are excellent as well. The latest versions now include NDIAGS, which is a comprehensive PC hardware diagnostic.

The most important consideration when you purchase third-party disk utilities is to choose products that support your file system. Norton Utilities, for example, is available in a DOS version and a Windows version, and only the latter supports FAT32 partitions. Note that the Windows version still includes DOS-level utilities such as DISKEDIT.

NTFS

NTFS is Windows NT's native file system. Although NT supports FAT partitions, NTFS provides many advantages over FAT, including long filenames, support for larger files and partitions, extended attributes, and increased security. NTFS, like all of Windows NT, was newly designed from the ground up. Backward compatibility with previous Microsoft operating systems was not a concern, because the developers were intent on creating an entirely new 32-bit platform. As a result, no operating systems other than Windows NT can read NTFS partitions.

This is an important consideration. All the other Windows operating systems are fundamentally based on DOS and leave you the alternative of booting to a DOS prompt in special situations. Whether you have to run a special DOS utility to configure a piece of hardware or perform an emergency disk repair, the DOS option is always there.

Windows NT/2000 is not DOS-based. You can open a window that provides a DOS-like command prompt in Windows NT/2000, but this is actually a DOS emulation, not a true shell. You cannot boot the system to a command prompt, avoiding the GUI, as you can with Windows 9x. You can, of course, bypass NT/2000 entirely by starting the system with a DOS boot disk, but if you have NTFS partitions on your drives, you will not be able to access them from the DOS prompt.

NTFS supports filenames of up to 255 characters, using spaces, multiple periods, and any other standard characters except the following: `*?/\;<>|`. Because NTFS file offsets are 64 bits long, files and partitions can be truly enormous: up to 16EB (exabytes) in size (16EB = 2^{64} bytes = 17,179,869,184TB)! To give you an idea of just how much data this is, it is estimated that all the words ever spoken by humans throughout history would occupy 5EB of storage.

NTFS Architecture

Although NTFS partitions are very different from FAT partitions internally, they do comply with the extra-partitional disk structures described earlier in this chapter. NTFS partitions are listed in the master partition table of a disk drive's master boot record, just like FAT partitions, and they have a volume boot record as well, although it is formatted somewhat differently.

When a volume is formatted with NTFS, system files are created in the root directory of the NTFS volume. These system files can be stored at any physical location on the NTFS volume. This means that damage to any specific location on the disk will probably not render the entire partition inaccessible.

There are normally 10 NTFS system files created when you format an NTFS volume. Table 26.22 shows the name and descriptions for these files.

Table 26.22 NTFS System Files

Filename	Meaning	Description
\$mft	Master File Table (MFT)	Contains a record for every file on the NTFS volume in its Data attribute
\$mftmirr	Master File Table2 (MFT2)	Mirror of the MFT used for recoverability purposes
\$badclus	Bad Cluster File	Contains all the bad clusters on the volume
\$bitmap	Cluster Allocation Bitmap	Contains the bitmap for the entire volume, showing which clusters are used
\$boot	Boot File	Contains the volume's bootstrap if the volume is bootable
\$attrdef	Attribute Definitions Table	Contains the definition of all system and user-defined attributes on the volume
\$logfile	Log File	Logs file transactions, used for recoverability purposes
\$quota	Quota Table	Table used to indicate disk quota usage for each user on a volume, used in NTFS 5
\$upcase	Uppcase Table	Table used for converting uppercase and lowercase characters to the matching uppercase Unicode characters
\$volume	Volume	Contains volume information such as volume name and version

An NTFS partition is based on a structure called the Master File Table, or MFT. The MFT concept expands on that of the FAT. Instead of using a table of cluster references, the MFT contains much more detailed information about the files and directories in the partition. In some cases, it even contains the files and directories themselves.

The first record in the MFT is called the descriptor, which contains information about the MFT itself. The volume boot record for an NTFS partition contains a reference that points to the location of this descriptor record. The second record in the MFT is a mirror copy of the descriptor, which provides fault tolerance, should the first copy be damaged.

The third record is the log file record. All NTFS transactions are logged to a file that can be used to restore data in the event of a disk problem. The bulk of the MFT consists of records for the files and directories that are stored on the partition. NTFS files take the form of objects that have

both user- and system-defined attributes. Attributes on NTFS partitions are more comprehensive than the few simple flags used on FAT partitions. All the information on an NTFS file is stored as attributes of that file. In fact, even the file data itself is an attribute. Unlike FAT files, the attributes of NTFS files are part of the file itself; they are not listed separately in a directory entry. Directories exist as MFT records as well, but they consist mainly of indexes listing the files in the directory; they do not contain the size, date, time, and other information about the individual files.

Thus, an NTFS drive's MFT is much more than a cluster list, like a FAT; it is actually the primary data storage structure on the partition. If a file or directory is relatively small (less than approximately 1,500 bytes), the entire thing may even be stored in the MFT. For larger amounts of storage, the MFT record for a file or directory contains pointers to external clusters in the partition. These external clusters are called extents. All the records in the MFT, including the descriptors and the log file, are capable of using extents for storage of additional attributes. The attributes of a file that are part of the MFT record are called resident attributes. Those stored in extents are called nonresident attributes.

NTFS 5.0

Along with Windows 2000 came a new variation of NTFS called NTFS 5. This update of the NT File System includes several new features that are exploited and even required by Windows 2000. Because of this, when you install Windows 2000 any existing NTFS volumes are automatically upgraded to NTFS 5 (there is no way to override). If you also run Windows NT versions earlier than Windows NT 4 Service Pack 4 (SP4), NT 4 will no longer be able to access the NTFS 5 volumes. If you want to run both NT 4 and Windows 2000 on the same system (as in a dual-boot configuration), you will need to upgrade NT 4 by installing Service Pack 4 or later; there is an updated NTFS.SYS driver in Service Pack 4 that enables NT 4 to read from and write to NTFS 5 volumes.

New features of the NTFS 5 file system include

- *Disk quotas.* System administrators can limit the amount of disk space users can consume on a per-volume basis. The three quota levels are: Off, Tracking, and Enforced.
- *Encryption.* NTFS 5 can automatically encrypt and decrypt files as they are read from and written to the disk.
- *Reparse points.* Programs can trap open operations against objects in the file system and run their own code before returning file data. This can be used to extend file system features such as mount points, which you can use to redirect data read and written from a folder to another volume or physical disk.
- *Sparse files.* This feature allows programs to create very large files as placeholders, but to consume disk space by adding to the files only as needed.
- *USN (Update Sequence Number) Journal.* Provides a log of all changes made to files on the volume.

Because these features, especially the USN Journal, are required for Windows 2000 to run, a Win2000 domain controller must use an NTFS 5.0 partition as the system volume.

NTFS Compatibility

Although NTFS partitions are not directly accessible by DOS and other operating systems, Windows NT/2000 is designed for network use, and NTFS files are expected to be accessed by other operating systems. For this reason, NTFS continues to support the standard DOS file attributes and the 8.3 FAT naming convention.

One of the main reasons for using NTFS is the security that it provides for its files and directories. NTFS security attributes are called *permissions* and are designed to enable system administrators to control access to files and directories by granting specific rights to users and groups. This is a much more granular approach than the FAT file system attributes, which apply to all users.

However, you can still set the FAT-style attributes on NTFS files using the standard Windows NT/2000 file management tools, including Windows NT/2000 Explorer and even the DOS `ATTRIB` command. When you copy FAT files to an NTFS drive over the network, the FAT-style attributes remain in place until you explicitly remove them. This can be an important consideration, because the FAT-style attributes take precedence over the NTFS permissions. A file on an NTFS drive that is flagged with the FAT read-only attribute, for example, cannot be deleted by a Windows NT/2000 user, even if that user has NTFS permissions that grant him or her full access.

To enable DOS and 16-bit Windows systems to access files on NTFS partitions over a network, the file system maintains an 8.3 alias name for every file and directory on the partition. The algorithm for deriving the alias from the long filename is the same as that used by Windows 95's VFAT. Windows NT/2000 also provides its FAT partitions with the same type of long filename support used by VFAT, allocating additional directory entries to store the long filenames as needed.

Creating NTFS Drives

NTFS is for use on hard disk drives. You cannot create an NTFS floppy disk (although you can format removable media such as Iomega Zip and Jaz cartridges to use NTFS). Three basic ways to create an NTFS disk partition are as follows:

- Create a new NTFS volume out of unpartitioned disk space during the Windows NT installation process or after the installation with the Disk Administrator utility.
- Format an existing partition to NTFS (destroying its data in the process) using the Windows NT Format dialog box (accessible from Windows NT Explorer or Disk Administrator), or the `FORMAT` command (with the `/fs:ntfs` switch) from the command prompt.
- Convert an existing FAT partition to NTFS (preserving its data) during the Windows NT/2000 installation process or after the installation with the command-line `CONVERT` utility.

NTFS Tools

Because it uses a fundamentally different architecture, virtually none of the troubleshooting techniques outlined earlier in this chapter are applicable when dealing with NTFS partitions, nor can the disk utilities intended for use on FAT partitions address them. Windows NT/2000 has a rudimentary capability to check a disk for file system errors and bad sectors, but apart from that, the operating system contains no other disk repair or defragmentation utilities.

The NTFS file system, however, does have its own automatic disk repair capabilities. In addition to Windows NT/2000's fault-tolerance features, such as disk mirroring (maintaining the same data on two separate drives) and disk striping with parity (splitting data across several drives with parity information for data reconstruction), the OS also uses a disk error recover technique called *cluster remapping*.

With cluster remapping, when Windows NT/2000 detects a bad sector on an NTFS partition, it automatically remaps the data in that cluster to another cluster. If the drive is part of a fault-tolerant drive array, any lost data is reconstructed from the duplicate data on the other drives.

Despite these features, however, there is still a real need for disk repair and defragmentation utilities for Windows NT/2000. They have been a long time in coming, but there are now finally third-party utilities that can repair and defragment NTFS drives. One I recommend is Norton Utilities 2000 by Symantec, which works on all versions of Windows.

Common Drive Error Messages and Solutions

There are several common error messages that are associated with problems in the file system or drives. This section covers the common ones, listing their cause and possible solutions.

Some of the most common file system errors are shown in the following list:

- Missing Operating System
- NO ROM BASIC - SYSTEM HALTED
- Boot error Press F1 to retry
- Invalid drive specification
- Invalid Media Type
- Hard Disk Controller Failure

These normally occur when booting the system or when trying to log in to or access a drive. The following section describes each of these errors and offers possible solutions.

Missing Operating System

This error indicates problems in the master boot record (MBR) or partition table entries. The partition table entries might be pointing to a sector that is not the actual beginning of a partition. This can also be caused by invalid BIOS settings, caused in some cases by a dead or dying battery. In fact in my experience, corrupt or improper BIOS settings are the number-one cause of this problem. Another cause can be virus damage to the MBR. This error can also occur if there is no active partition defined in the partition table.

The normal solution is to correct the invalid BIOS settings. The BIOS settings for drive parameters must be set to the same values as when the drive was partitioned and formatted to read the drive correctly. If the MBR is damaged or virus infected, you can try FDISK/MBR to repair. Other types of damage will require more sophisticated use of a disk editor utility or repartitioning and reformatting the drive to start over.

NO ROM BASIC - SYSTEM HALTED

This error is generated by the AMI BIOS when the boot sector or master boot record of the boot drive is damaged or missing. This error can also occur if the boot device has been improperly configured or is not configured at all in the BIOS. In this case, data in the partition might be valid and undamaged, but there is no bootable partition.

IBM systems in this situation used to drop into a built-in BIOS version of BASIC, but most non-IBM BIOS manufacturers did not license this code from Microsoft. So instead of dropping into BASIC, they would display this cryptic message. Because the most common cause of this type of error is a failure to set at least one partition as active (bootable), the normal solution is to run FDISK and set the primary partition as active. If this is not the problem, the solution would be to repair the damaged MBR or to correct the improper BIOS settings.

Other possible problems include corrupted or missing drive parameters in the BIOS Setup.

Boot Error Press F1 to Retry

This error is generated by the Phoenix BIOS when the hard disk is missing a master boot record or boot sector or when there is a problem accessing the boot drive. This has the same meaning as NO ROM BASIC does on an AMI BIOS. The most common cause of this message is having no partitions defined as active (bootable). See the section on NO ROM BASIC earlier in the chapter for more information.

Invalid Drive Specification

This error occurs when you attempt to log in to a drive that has not been partitioned or for which the partition table entry has been damaged or is incorrect. Use FDISK to partition the drive or to check out the existing partitions. If they are damaged, you will normally want to use a data recovery utility such as the Norton Utilities to correct the problem. Such correction may require manual editing of the partition table with the DISKEDIT program included with the Norton Utilities. Another solution is to repartition the drive from scratch, but this will cause any existing data on the drive to be overwritten.

Invalid Media Type

This indicates the partition table is valid, but the volume boot sector, directory, or file allocation tables are corrupt, damaged, or not yet initialized. For example, this is the standard error you would receive if you tried to access a drive that had been partitioned but not yet formatted. The FORMAT command is what creates the volume boot record (VBR), file allocation tables (FATs), and directories on the disk.

The repair usually involves using a data recovery utility, such as the Norton Utilities Disk Doctor, or redoing the high-level format on the drive. Since high-level formatting does not actually destroy the data, one technique to recover is to high-level (OS Format) the volume, and then immediately unformat it using the unformat utility included with the Norton Utilities.

Hard Disk Controller Failure

This message indicates the hard disk controller has failed, the hard disk controller is not set up properly in the BIOS, or the controller cannot communicate with the attached drives, such as with cable problems.

The solution is to check out the drive installation and make sure the cables to the drive are properly installed, the drive is receiving power, it is spinning, and the BIOS Setup definitions are correct. If all these are correct, the drive, cable, or controller might be physically damaged. Replace them with known good spares one at a time until the problem is solved.

General File System Troubleshooting

Here are some general procedures to follow for troubleshooting drive access, file system, or boot problems:

1. Start the system using a Windows startup disk, or any bootable MS-DOS disk that contains FDISK.EXE, FORMAT.COM, SYS.COM, and SCANDISK.EXE (Windows 95B or later versions preferred).
2. If your system cannot boot from the floppy, you might have more serious problems with your hardware. Check the floppy drive and the motherboard for proper installation and configuration.
3. Run FDISK from the Windows startup disk. Select option 4 (Display partition information).
4. If the partitions are listed, make sure that the bootable partition (normally the primary partition) is defined as active (look for an uppercase *A* in the Status column.)
5. If no partitions are listed and you do not want to recover any of the data existing on the drive now, use FDISK to create new partitions, and then use FORMAT to format the partitions. This will overwrite any previously existing data on the drive.
6. If you want to recover the data on the drive and no partitions are being shown, you will need to use a data recovery program, such as the Norton Utilities by Symantec or Lost and Found by PowerQuest, to recover the data.
7. If all the partitions appear in FDISK.EXE, and one is defined as active, run the SYS command as follows to restore the system files to the hard disk:

```
SYS C:
```
8. For this to work properly, it is important that the disk you boot from be a startup disk from the same operating system (or version of Windows) you have on your hard disk.
9. You should receive the message `System Transferred` if the command works properly. Remove the disk from drive A: and restart the system. If you still have the same error as before after you restart your computer, your drive might be improperly configured or damaged.
10. Run SCANDISK from the Windows startup disk or an aftermarket data recovery utility such as the Norton Utilities to check for problems with the hard disk.
11. Using SCANDISK, perform a surface scan. If SCANDISK reports any physically damaged sectors on the hard disk, the drive may need to be replaced.

Glossary

This glossary contains computer and electronics terms that are applicable to the subject matter in this book. The glossary is meant to be as comprehensive as possible on the subject of upgrading or repairing PCs. Many terms correspond to the latest technology in disk interfaces, modems, video and display equipment, and standards that govern the PC industry. Although a glossary is a resource not designed to be read from beginning to end, you should find that scanning through this one is interesting, if not enlightening, with respect to some of the newer PC technology.

The computer industry is filled with abbreviations used as shorthand for a number of terms. This glossary defines many abbreviations, as well as the term on which the abbreviation is based. The definition of an abbreviation usually is included under the acronym. For example, *Video Graphics Array* is defined under the abbreviation *VGA* rather than under *Video Graphics Array*. This organization makes it easier to look up a term—*IDE*, for example—even if you do not know in advance what it stands for (*Integrated Drive Electronics*).

For additional reference, *Que's Computer Dictionary* (ISBN: 0-7897-1670-4) is a comprehensive dictionary of computer terminology.

These Web sites can also help you with terms that are not included in this glossary:

<http://www.webopedia.com>

.INF file A Windows driver and device information file used to install new drivers or services.

10Base2 IEEE standard for baseband Ethernet at 10Mbps over RG-58 coaxial cable to a maximum distance of 185 meters. Also known as Thin Ethernet (Thinnet) or IEEE 802.3.

10Base5 IEEE standard for baseband Ethernet at 10Mbps over thick coaxial cable to a maximum distance of 500 meters. Also known as Thick Ethernet or Thicknet.

10BaseT A 10Mbps CSMA/CD Ethernet LAN that works on Category 3 or better twisted-pair wiring that is very similar to standard telephone cabling. 10BaseT Ethernet LANs work on a “star” configuration in which the wire from each workstation routes directly to a 10BaseT hub. Hubs may be joined together.

56K The generic term for modems that can receive data at 56Kbps. See also *V.90*, *X2*, *Kflex*.

100BaseT A 100Mbps CSMA/CD Ethernet local area network (LAN) that works on Category 5 twisted-pair wiring. 100BaseT Ethernet LANs work on a “star” configuration in which the wire from each workstation routes directly to a central 100BaseT hub. This is the new standard for 100Mbps Ethernet.

100BaseVG The joint Hewlett-Packard-AT&T proposal for Fast Ethernet running at 100Mbps. It uses four pairs of Category 5 cable using the 10BaseT twisted-pair wiring scheme to transmit or receive. 100BaseVG splits the signal across the four wire pairs at 25MHz each. This standard has not found favor with corporations and has been almost totally replaced by 100BaseT.

286 See *80286*.

386 See *80386DX*.

486 See *80486DX*.

586 A generic term used to refer to fifth-generation processors similar to the Intel Pentium.

640KB barrier The limit imposed by the PC-compatible memory model using DOS mode. DOS programs can address only 1MB total memory, and PC-compatibility generally requires the top 384KB to be reserved for the system, leaving only the lower 640KB for DOS or other real-mode applications.

8086 An Intel microprocessor with 16-bit registers, a 16-bit data bus, and a 20-bit address bus. This processor can operate only in real mode.

8087 An Intel math coprocessor designed to perform floating-point math with much greater speed and precision than the main CPU. The 8087 can be installed in most 8086- and 8088-based systems, and adds more than 50 new instructions to those available in the primary CPU alone.

8088 An Intel microprocessor with 16-bit registers, an 8-bit data bus, and a 20-bit address bus. This processor can operate only in real mode and was designed as a low-cost version of the 8086.

8514/A An analog video display adapter from IBM for the PS/2 line of personal computers. Compared to previous display adapters such as EGA and VGA, it provides a high resolution of 1,024×768 pixels with as many as 256 colors or 64 shades of gray. It provides a video coprocessor that performs two-dimensional graphics functions internally, thus relieving the CPU of graphics tasks. It uses an interlaced monitor; it scans every other line every time the screen is refreshed.

80286 An Intel microprocessor with 16-bit registers, a 16-bit data bus, and a 24-bit address bus. It can operate in both real and protected virtual modes.

80287 An Intel math coprocessor designed to perform floating-point math with much greater speed and precision than the main CPU. The 80287 can be installed in most 286- and some 386DX-based systems, and adds more than 50 new instructions to what is available in the primary CPU alone.

80386 See *80386DX*.

80386DX An Intel microprocessor with 32-bit registers, a 32-bit data bus, and a 32-bit address bus. This processor can operate in real, protected virtual, and virtual real modes.

80386SX An Intel microprocessor with 32-bit registers, a 16-bit data bus, and a 24-bit address bus. This processor, designed as a low-cost version of the 386DX, can operate in real, protected virtual, and virtual real modes.

80387 An Intel math coprocessor designed to perform floating-point math with much greater speed and precision than the main CPU. The 80387 can be installed in most 386DX-based systems, and adds more than 50 new instructions to those available in the primary CPU alone.

80486 See *80486DX*.

80486DX An Intel microprocessor with 32-bit registers, a 32-bit data bus, and a 32-bit address

bus. The 486DX has a built-in cache controller with 8KB of cache memory as well as a built-in math coprocessor equivalent to a 387DX. The 486DX can operate in real, protected virtual, and virtual real modes.

80486DX2 A version of the 486DX with an internal clock doubling circuit that causes the chip to run at twice the motherboard clock speed. If the motherboard clock is 33MHz, the DX2 chip will run at 66MHz. The DX2 designation applies to chips sold through the OEM market, while a retail version of the DX2 is sold as an overdrive processor.

80486DX4 A version of the 486DX with an internal clock tripling circuit that causes the chip to run at three times the motherboard clock speed. If the motherboard clock is 33.33MHz, the DX4 chip will run at 100MHz.

80486SX An Intel microprocessor with 32-bit registers, a 32-bit data bus, and a 32-bit address bus. The 486SX is the same as the 486DX except that it lacks the built-in math coprocessor function and was designed as a low-cost version of the 486DX. The 486SX can operate in real, protected virtual, and virtual real modes.

abend Short for abnormal end. A condition occurring when the execution of a program or task is terminated unexpectedly because of a bug or crash.

absolute address An explicit identification of a memory location, device, or location within a device.

AC (alternating current) The frequency is measured in cycles per seconds (cps) or hertz (Hz). The standard value running through the wall outlet is 120 volts at 60Hz, through a fuse or circuit breaker that usually can handle about 15 or 20 amps.

accelerator board An add-in board replacing the computer's CPU with circuitry that enables the system to run faster. See *graphics accelerator*.

access light The LED on the front of a drive or other device (or on the front panel of the system) that indicates the computer is reading or writing data on the device.

access mechanism See *actuator*.

access time The time that elapses from the instant information is requested to the point that delivery is completed. Usually described in nanoseconds (ns) for memory chips, and in milliseconds (ms) for disk drives. Most manufacturers

rate average access time on a hard disk as the time required for a seek across one third of the total number of cylinders plus one half of the time for a single revolution of the disk platters (latency).

accumulator A register (temporary storage) in which the result of an operation is formed.

acoustic coupler A device used to connect a computer modem to a phone line by connecting to the handset of a standard AT&T-style phone. The audible sounds to and from the modem are transmitted to the handset through the coupler while the handset is resting in the coupler. Although often thought of as obsolete, an acoustic coupler can be used to ensure the availability of a modem connection when traveling and access to an RJ-11 jack is unavailable.

ACPI (Advanced Configuration and Power Interface) A standard developed by Intel, Microsoft, and Toshiba that is designed to implement power management functions in the operating system. ACPI is a replacement for APM. See also *APM*.

active high Designates a digital signal that has to go to a high value to be true. Synonymous with positive.

active low Designates a digital signal that has to go to a low value to be true. Synonymous with negative.

active matrix A type of LCD screen that contains at least one transistor for every pixel on the screen. Color active-matrix screens use three transistors for each pixel, one each for the red, green, and blue dots. The transistors are arranged on a grid of conductive material, with each connected to a horizontal and a vertical member. See also *TFT*.

actuator The device that moves a disk drive's read/write heads across the platter surfaces. Also known as an access mechanism.

adapter The device that serves as an interface between the system unit and the devices attached to it. Often synonymous with circuit board, circuit card, or card, but may also refer to a connector or cable adapter, which changes one type of connector to another.

adapter description files (ADF) Refers to the setup and configuration files and drivers necessary to install an adapter card such as a network adapter card. Primarily used with Micro Channel Architecture bus cards.

add-in board See *expansion card*.

address Refers to where a particular piece of data or other information is found in the computer. Also can refer to the location of a set of instructions.

address bus One or more electrical conductors used to carry the binary-coded address from the microprocessor throughout the rest of the system.

ADSL (Asymmetric Digital Subscriber Line) A high-speed transmission technology originally developed by Bellcore and now standardized by ANSI as T1.413. ADSL uses existing UTP copper wires to communicate digitally at high speed between the telephone company central office (CO) and the subscriber. ADSL sends information asymmetrically, meaning it is faster one way than the other. The original ADSL speed was T-1 (1.536Mbps) downstream from the carrier to the subscriber's premises and 16Kbps upstream. However, ADSL is available in a variety of configurations and speeds. See *DSL*.

AGP (Accelerated Graphics Port) Developed by Intel, a fast dedicated interface between the video adapter or chipset and the motherboard chipset North Bridge. AGP is 32 bits wide, runs at 66MHz base speed, and can transfer 1, 2, or 4 bits per cycle (1x, 2x, or 4x modes) for a throughput of up to 1,066 MB/sec.

aliasing Undesirable visual effects (sometimes called artifacts) in computer-generated images, caused by inadequate sampling techniques. The most common effect is jagged edges along diagonal or curved object boundaries. See also *antialiasing*.

allocation unit See *cluster*.

alphanumeric characters A character set that contains only letters (A–Z) and digits (0–9). Other characters, such as punctuation marks, may also be allowed.

ampere The basic unit for measuring electrical current. Also called *amp*.

analog The representation of numerical values by physical variables such as voltage, current, and so on; continuously variable quantities whose values correspond to the quantitative magnitude of the variables.

analog loopback A modem self-test in which data from the keyboard is sent to the modem's transmitter, modulated into analog form, looped back to the receiver, demodulated into digital form, and returned to the screen for verification.

analog signals Continuously variable signals. Analog circuits are more subject to distortion and noise than are digital circuits but are capable of handling complex signals with relatively simple circuitry. See also *digital signals*.

analog-to-digital converter An electronic device that converts analog signals to digital form.

AND A logic operator having the property that if P is a statement, Q is a statement, R is a statement..., then the AND of P, Q, R... is true if all statements are true and is false if any statement is false.

AND gate A logic gate in which the output is 1 only if all inputs are 1.

animation The process of displaying a sequential series of still images to achieve a motion effect.

ANSI (American National Standards Institute) A nongovernmental organization founded in 1918 to propose, modify, approve, and publish data processing standards for voluntary use in the United States. Also the U.S. representative to the International Standards Organization (ISO) in Paris and the International Electrotechnical Commission (IEC). For more information, see the Vendor List on the CD. Contact ANSI, 1430 Broadway, New York, NY 10018.

answer mode A state in which the modem transmits at the predefined high frequency of the communications channel and receives at the low frequency. The transmit/receive frequencies are the reverse of the calling modem, which is in originate mode. See also *originate mode*.

antialiasing Software adjustment to make diagonal or curved lines appear smooth and continuous in computer-generated images. See also *aliasing*.

anti-static mat A pad placed next to a computer upon which components are placed while servicing the system to prevent static damage. Also can refer to a larger sized mat below an entire computer desk and chair to discharge static from a user before he touches the computer.

antivirus Software that prevents files containing viruses from running on a computer or software that detects, repairs, cleans, or removes virus-infected files.

APA All points addressable. A mode in which all points of a displayable image can be controlled by the user or a program.

aperture grille A type of shadow mask used in CRTs. The most common is used in Sony's Trinitron monitors, which use vertical phosphor stripes and vertical slots in the mask, compared to the traditional shadow mask that uses phosphor dots and round holes in the mask. See also *shadow mask*.

API (Application Program Interface) A system call (routine) that gives programmers access to the services provided by the operating system. In IBM-compatible systems, the ROM BIOS and DOS together present an API that a programmer can use to control the system hardware.

APM (Advanced Power Management) A specification sponsored by Intel and Microsoft originally proposed to extend the life of batteries in battery-powered computers. It is now used in desktop computers, as well. APM allows application programs, the system BIOS, and the hardware to work together to reduce power consumption. An APM-compliant BIOS provides built-in power-management services to the operating system. The application software communicates power-saving data via predefined APM interfaces. Replaced in newer systems by ACPI. See also *ACPI*.

application End-user oriented software such as a word processor, spreadsheet, database, graphics editor, game, or Web browser.

arbitration A method by which multiple devices attached to a single bus can bid or arbitrate to get control of that bus.

archive bit The bit in a file's attribute byte that sets the archive attribute. Tells whether the file has been changed since it last was backed up.

archive medium A storage medium (floppy disk, tape cartridge, or removable cartridge) to hold files that need not be accessible instantly.

ARCnet (Attached Resource Computer Network) A baseband, token-passing LAN technology offering a flexible bus/star topology for connecting personal computers. Operating at 2.5Mbit/sec, it is one of the oldest LAN systems and was popular in low-cost networks. Originally developed by John Murphy of Datapoint Corporation, although ARCnet interface cards are available from a variety of vendors.

areal density A calculation of the bit density (bits per inch, or BPI) multiplied by the track density (tracks per inch, or TPI), which results in a figure indicating how many bits per square inch are present on the disk surface.

ARQ (Automatic repeat request) A general term for error-control protocols that feature error detection and automatic retransmission of defective blocks of data.

ASCII (American Standard Code for Information Interchange) A standard 7-bit code created in 1965 by Robert W. Bemer to achieve compatibility among various types of data processing equipment. The standard ASCII character set consists of 128 decimal numbers ranging from 0 through 127, which are assigned to letters, numbers, punctuation marks, and the most-common special characters. In 1981, IBM introduced the extended ASCII character set with the IBM PC, extending the code to 8 bits and adding characters from 128 through 255 to represent additional special mathematical, graphics, and foreign characters.

ASCII character A 1-byte character from the ASCII character set, including alphabetic and numeric characters, punctuation symbols, and various graphics characters.

ASME (American Society of Mechanical Engineers) (<http://www.asme.org/>) ASME International has nearly 600 codes and standards in print, and its many committees involve more than 3,000 individuals, mostly engineers but not necessarily members of the society. The standards are used in more than 90 countries throughout the world.

aspect ratio The measurement of a film or television viewing area in terms of relative height and width. The aspect ratio of most modern motion pictures varies from 3:5 to as large as 3:7, which creates a problem when a wide-format motion picture is transferred to the more square-shaped television screen, with its aspect ratio of 3:4.

assemble The act of translating a program expressed in an assembler language into a computer machine language.

assembler language A computer-oriented language whose instructions are usually in one-to-one correspondence with machine language instructions.

asymmetrical modulation A duplex transmission technique that splits the communications channel into one high-speed channel and one slower channel. During a call under asymmetrical modulation, the modem with the greater amount of data to transmit is allocated the high-speed channel. The modem with less data is allocated the slow, or back, channel. The modems dynamically reverse the channels during a call if the volume of data transfer changes.

asynchronous communication Data transmission in which the length of time between transmitted characters may vary. Timing depends on the actual time for the transfer to take place, as opposed to synchronous communication, which is timed rigidly by an external clock signal. Because the receiving modem must be signaled about when the data bits of a character begin and end, start and stop bits are added to each character. See also *synchronous communication*.

asynchronous memory Memory that runs using a different timing or clock rate (usually slower) than the motherboard speed.

AT clock Refers to the Motorola 146818 real-time clock (RTC) and CMOS RAM chip which first debuted in the IBM AT and whose function has been present in all PC-compatible systems since. Keeps track of the time of day and makes this data available to the operating system or other software.

ATA (AT Attachment interface) An IDE disk interface standard introduced in March 1989 that defines a compatible register set and a 40-pin connector and its associated signals. See also *IDE*.

ATA-2 The second generation AT Attachment interface specification. This version defines faster transfer modes and logical block addressing schemes to allow high-performance, large-capacity drives. Also called Fast ATA, Fast ATA-2, and enhanced IDE (EIDE).

ATAPI (AT Attachment Packet Interface) A specification that defines device-side characteristics for an IDE-connected peripheral, such as CD-ROM or tape drives. ATAPI is essentially an adaptation of the SCSI command set to the IDE interface.

ATM (Asynchronous Transfer Mode) A high-bandwidth, low-delay, packet-like switching and multiplexing technique. Usable capacity is segmented into fixed-size cells consisting of header and information fields, allocated to services on demand.

attribute byte A byte of information, held in the directory entry of any file, that describes various attributes of the file, such as whether it is read-only or has been backed up since it last was changed. Attributes can be set by the DOS ATTRIB command.

ATX A motherboard and power supply form factor standard designed by Intel and introduced in 1995 that is characterized by a double row of rear external I/O connectors on the motherboard; a single keyed power supply connector; memory and

processor locations that are designed not to interfere with the installation of adapter cards; and an improved cooling flow.

audio A signal that can be heard, such as through the speaker of the PC. Many PC diagnostics tests use both visual (onscreen) codes and audio signals.

audio frequencies Frequencies that can be heard by the human ear (approximately 20–20,000Hz).

auto-answer A setting in modems enabling them to answer incoming calls over the phone lines automatically.

auto-dial A feature in modems enabling them to dial phone numbers without human intervention.

auto-disconnect A modem feature that allows a modem to hang up the telephone line when the modem at the other end hangs up.

auto-redial A modem or software feature that automatically redials the last number dialed if the number is busy or does not answer.

AUTOEXEC.BAT A special batch file that DOS executes at startup. Contains any number of DOS commands that are executed automatically, including the capability to start programs at startup. See also *batch file*.

automatic head parking Disk drive head parking performed whenever the drive is powered off. Found in all modern hard disk drives with a voice-coil actuator.

available memory Memory currently not in use by the operating system, drivers, or applications that may be used to load additional software.

average access time The average time it takes a disk drive to begin reading any data placed anywhere on the drive. This includes the average seek time, which is when the heads are moved, as well as the latency, which is the average amount of time required for any given data sector to pass underneath the heads. Together, these factors make up the average access time. See also *average seek time* and *latency*.

average latency The average time required for any byte of data stored on a disk to rotate under the disk drive's read/write head. Equal to one half the time required for a single rotation of a platter.

average seek time The average amount of time it takes to move the heads from one random cylinder location to another, usually including any head

settling time. In many cases, the average seek time is defined as the seek time across one third of the total number of cylinders.

AVI (Audio Video Interleave) A storage technique developed by Microsoft for its Video for Windows product that combines audio and video into a single frame or track, saving valuable disk space and keeping audio in synchronization with the corresponding video.

B-channel The two bearer channels in ISDN that run at 64Kbps each and that carry the data.

backbone The portion of the Internet or wide area network (WAN) transmission wiring that connects the main Internet/WAN servers and routers and is responsible for carrying the bulk of the Internet/WAN data.

backplane A rarely used motherboard design in which the components normally found on a motherboard are located instead on an expansion adapter card plugged into a slot. In these systems, the board with the slots is the backplane.

backup The process of duplicating a file or library onto a separate piece of media. Good insurance against the loss of an original.

backup disk Contains information copied from another disk. Used to make sure that original information is not destroyed or altered.

backward compatibility The design of software and hardware to work with previous versions of the same software or hardware.

bad sector A disk sector that cannot hold data reliably because of a media flaw or damaged format markings.

bad track table A label affixed to the casing of a hard disk drive that tells which tracks are flawed and cannot hold data. The listing is entered into the low-level formatting program.

balanced signal Refers to signals consisting of equal currents moving in opposite directions. When balanced or nearly balanced signals pass through twisted-pair lines, the electromagnetic interference effects such as crosstalk caused by the two opposite currents largely cancel each other out. Differential signaling is a method that uses balanced signals.

balun Short for balanced/unbalanced. A type of transformer that enables balanced cables to be joined with unbalanced cables. Twisted-pair (balanced) cables, for example, can be joined with coaxial (unbalanced) cables if the proper balun transformer is used.

bandwidth 1) Generally, the measure of the range of frequencies within a radiation band required to transmit a particular signal. The difference between the lowest and highest signal frequencies. The bandwidth of a computer monitor is a measure of the rate that a monitor can handle information from the display adapter. The wider the bandwidth, the more information the monitor can carry, and the greater the resolution. 2) Used to describe the data-carrying capacity of a given communications circuit or pathway. The bandwidth of a circuit is a measure of the rate at which information can be passed.

bank The collection of memory chips or modules that make up a block of memory readable or writable by the processor in a single cycle. This block, therefore, must be as large as the data bus of the particular microprocessor. In PC systems, the processor data bus (and therefore the bank size) is usually 8, 16, 32, or 64 bits wide. Optionally, some systems also incorporate an additional parity or ECC bit for each 8 data bits, resulting in a total of 9, 18, 36, or 72 bits (respectively) for each bank. Memory in a PC must always be added or removed in full-bank increments.

bar code The code used on consumer products and inventory parts for identification purposes. Consists of bars of varying thickness that represent characters and numerals that are read with an optical reader. The most common version is called the Universal Product Code (UPC).

base address Starting location for consecutive string of memory or I/O addresses/ports.

base memory The amount of memory available to the operating system or application programs within the first megabyte, accessible in the processor's real mode.

base-2 Refers to the computer numbering system that consists of two numerals: 0 and 1. Also called binary.

baseband transmission The transmission of digital signals over a limited distance. ARCnet and Ethernet local area networks use baseband signaling. Contrasts with broadband transmission, which refers to the transmission of analog signals over a greater distance.

BASIC (Beginner's All-purpose Symbolic Instruction Code) A popular computer programming language. Originally developed by John Kemeny and Thomas Kurtz in the mid-1960s at Dartmouth College. Normally, an interpretive language, meaning that each statement is translated

and executed as it is encountered, but can be a compiled language, in which all the program statements are compiled before execution.

batch file A set of commands stored in a disk file for execution by the operating system. A special batch file called AUTOEXEC.BAT is executed by DOS each time the system is started. All DOS batch files have a BAT file extension.

baud A unit of signaling speed denoting the number of discrete signal elements that can be transmitted per second. The word baud is derived from the name of J.M.E. Baudot (1845–1903), a French pioneer in the field of printing telegraphy and the inventor of Baudot code. Although technically inaccurate, baud rate commonly is used to mean bit rate. Because each signal element or baud may translate into many individual bits, bits per second (bps) normally differs from baud rate. A rate of 2,400 baud means that 2,400 frequency or signal changes per second are being sent, but each frequency change may signal several bits of information. For example, 33.6Kbps modems actually transmit at only 2,400 baud.

Baudot code A 5-bit code used in many types of data communications, including teletype (TTY), radio teletype (RTTY), and telecommunications devices for the deaf (TDD). Baudot code has been revised and extended several times. See also *baud*.

bay An opening in a computer case or chassis that holds disk drives.

BBS (bulletin board system) A computer that operates with a program and a modem to enable other computers with modems to communicate with it, often on a round-the-clock basis. Thousands of PC IBM- and Apple-related BBSes offer a wealth of information and public-domain software that can be downloaded.

bezel A cosmetic panel that covers the face of a drive or some other device.

Bézier curve A mathematical method for describing a curve, often used in illustration and CAD programs to draw complex shapes.

bidirectional 1) Refers to lines over which data can move in two directions, such as a data bus or a telephone line. 2) Refers to the capability of a printer to print from right to left and from left to right alternately.

binary Refers to the computer numbering system that consists of two numerals: 0 and 1. Also called base-2.

BIOS (basic input/output system) The part of an operating system that handles the communications between the computer and its peripherals. Often burned into read-only memory (ROM) chips or rewritable flash (EEPROM) memory chips.

bipolar A category of semiconductor circuit design, which was used to create the first transistor and the first integrated circuit. Bipolar and CMOS are the two major transistor technologies. Most all personal computers use CMOS technology chips. CMOS uses far less energy than bipolar.

bisynchronous (binary synchronous control) An earlier protocol developed by IBM for software applications and communicating devices operating in synchronous environments. The protocol defines operations at the link level of communications—for example, the format of data frames exchanged between modems over a phone line.

bit binary digit Represented logically by 0 or 1 and electrically by 0 volts and (typically) 5 volts. Other methods are used to represent binary digits physically (tones, different voltages, lights, and so on), but the logic is always the same.

bit density Expressed as bits per inch (BPI). Defines how many bits can be written onto one linear inch of a track. Sometimes also called linear density.

bit depth The number of bits used to describe the color of each pixel on a computer display. For example, a bit depth of two means that the monitor can display only black and white pixels; a bit depth of four means the monitor can display 16 different colors; a bit depth of eight allows for 256 colors; and so on.

bitmap A method of storing graphics information in memory in which a bit devoted to each pixel (picture element) onscreen indicates whether that pixel is on or off. A bitmap contains a bit for each point or dot on a video display screen and allows for fine resolution because any point or pixel onscreen can be addressed. A greater number of bits can be used to describe each pixel's color, intensity, and other display characteristics.

blank or blanking interval A period in which no video signal is received by a monitor, while the videodisc or digital video player searches for the next video segment or frame to display.

block A string of records, words, or characters formed for technical or logic reasons and to be treated as an entity.

block diagram The logical structure or layout of a system in graphics form. Does not necessarily match the physical layout and does not specify all the components and their interconnections.

BMP A Windows graphics format that may be device dependent or independent. Device-independent BMP files (DIB) are coded for translation to a wide variety of displays and printers.

BNC (Bayonet-Neill-Concelman) Also known as British-Naval-Connector, Baby-N-Connector, or Bayonet-Nut-Coupler; nobody seems to be quite sure what the actual name is. This bayonet-locking connector is noted for its excellent shielding and impedance-matching characteristics, resulting in low noise and minimal signal loss at any frequency up to 4GHz. It is used in Ethernet 10Base2 networks (also known as IEEE 802.3, or Thinnet) to terminate coaxial cables. It is also used for some high-end video monitors.

bonding In ISDN, joining two 64Kbps B-channels to achieve 128Kbps speed.

Boolean operation Any operation in which each of the operands and the result take one of two values.

boot To load a program into the computer. The term comes from the phrase "pulling a boot on by the bootstrap."

boot record The first sector on a disk or partition that contains disk parameter information for the BIOS and operating system as well as bootstrap loader code that instructs the system how to load the operating system files into memory, thus beginning the initial boot sequence to boot the machine.

boot sector See *boot record*.

boot sector virus A virus designed to occupy the boot sector of a disk. Any attempt to start or boot a system from this disk will transfer the virus to the hard disk, after which it will subsequently be loaded every time the system is started. Most PC viruses are boot sector viruses.

bootstrap A technique or device designed to bring itself into a desired state by means of its own action. The term is used to describe the process by which a device such as a PC goes from its initial power-on condition to a running condition without human intervention. See also *boot*.

boule Purified, cylindrical silicon crystals from which semiconducting electronic chips including microprocessors, memory, and other chips in a PC are manufactured.

bps (bits per second) The number of binary digits, or bits, transmitted per second. Sometimes confused with baud.

branch prediction A feature of fifth-generation (Pentium and higher) processors that attempts to predict whether a program branch will be taken and then fetches the appropriate following instructions.

bridge In local area networks, an interconnection between two similar networks. Also the hardware equipment used to establish such an interconnection.

broadband transmission A term used to describe analog transmission. Requires modems for connecting terminals and computers to the network. Using frequency division multiplexing, many different signals or sets of data can be transmitted simultaneously. The alternative transmission scheme is baseband, or digital, transmission.

brownout An AC supply voltage drop in which the power does not shut off entirely but continues to be supplied at lower than normal levels.

bubble memory A special type of nonvolatile read/write memory introduced by Intel in which magnetic regions are suspended in crystal film and data is maintained when the power is off. A typical bubble memory chip contains about 512KB, or more than four million bubbles. Bubble memory failed to catch on because of slow access times measured in several milliseconds. It has, however, found a niche use as solid-state "disk" emulators in environments where conventional drives are unacceptable, such as in military or factory use.

buffer A block of memory used as a holding tank to store data temporarily. Often positioned between a slower peripheral device and the faster computer. All data moving between the peripheral and the computer passes through the buffer. A buffer enables the data to be read from or written to the peripheral in larger chunks, which improves performance. A buffer that is x bytes in size usually holds the last x bytes of data that moved between the peripheral and CPU. This method contrasts with that of a cache, which adds intelligence to the buffer so that the most often accessed data rather than the last accessed data remains in the buffer (cache). A cache can improve performance greatly over a plain buffer.

bug An error or defect in a program.

burn-in The operation of a circuit or equipment to establish that its components are stable and to screen out defective parts or assemblies.

burst mode A memory cycling technology that takes advantage of the fact that most memory accesses are consecutive in nature. After setting up the row and column addresses for a given access, using burst mode can then access the next three adjacent addresses with no additional latency.

Burst Static RAMs (BSRAMs) Short for Pipeline Burst SRAM, BSRAMs are a common type of static RAM chip used for memory caches where access to subsequent memory locations after the first byte is accessed takes fewer machine cycles.

bus A linear electrical signal pathway over which power, data, and other signals travel. It is capable of connecting to three or more attachments. A bus is generally considered to be distinct from radial or point-to-point signal connections. The term comes from the Latin *omnibus* meaning “for all.” When used to describe a topology, bus always implies a linear structure.

bus mouse An obsolete type of mouse used in the 1980s that plugs into a special mouse expansion board instead of a serial port or motherboard mouse port. The bus mouse connector looks like a motherboard mouse (sometimes called PS/2 mouse) connector, but the pin configurations are different and not compatible.

busmaster An intelligent device that when attached to the Micro Channel, EISA, VLB, or PCI bus can bid for and gain control of the bus to perform its specific task without processor intervention.

byte A collection of bits that makes up a character or other designation. Generally, a byte is 8 data bits. When referring to system RAM, an additional parity (error-checking) bit is also stored (see *parity*), making the total 9 bits.

C A high-level computer programming language. A frequently used programming language on mainframes, minis, and PC computer systems. C++ is a popular variant.

cache An intelligent buffer. By using an intelligent algorithm, a cache contains the data that is accessed most often between a slower peripheral device and the faster CPU. See also *L1 cache*, *L2 cache*, and *disk cache*.

CAM (Common Access Method) A committee formed in 1988 that consists of a number of computer peripheral suppliers and is dedicated to developing standards for a common software interface between SCSI peripherals and host adapters.

capacitor A device consisting of two plates separated by insulating material and designed to store an electrical charge.

card A printed circuit board containing electronic components that form an entire circuit, usually designed to plug into a connector or slot. Sometimes also called an adapter.

card edge connector See *edge connector*.

CardBus A PC card specification for a 32-bit interface that runs at 33MHz and provides 32-bit data paths to the computer's I/O and memory systems, as well as a new shielded connector that prevents CardBus devices from being inserted into slots that do not support the latest version of the PC card standard.

carpal tunnel syndrome A painful hand injury that gets its name from the narrow tunnel in the wrist that connects ligament and bone. When undue pressure is put on the tendons, they can swell and compress the median nerve, which carries impulses from the brain to the hand, causing numbness, weakness, tingling, and burning in the fingers and hands. Computer users get carpal tunnel syndrome primarily from improper keyboard ergonomics that result in undue strain on the wrist and hand.

carrier A continuous frequency signal capable of being either modulated or impressed with another information-carrying signal. The reference signal used for the transmission or reception of data. The most common use of this signal with computers involves modem communications over phone lines. The carrier is used as a signal on which the information is superimposed.

carrier detect signal A modem interface signal that indicates to the attached data terminal equipment (DTE) that it is receiving a signal from the distant modem. Defined in the RS-232 specification. Same as the received line-signal detector.

cathode ray tube (CRT) A device that contains electrodes surrounded by a glass sphere or cylinder and displays information by creating a beam of electrons that strike a phosphor coating inside the display unit. This device is most commonly used in computer monitors and terminals.

CAV (Constant Angular Velocity) An optical disk recording format where the data is recorded on the disk in concentric circles. CAV disks are rotated at a constant speed. This is similar to the recording technique used on floppy disk drives. CAV limits the total recorded capacity compared to CLV

(Constant Linear Velocity), which is also used in optical recording.

CCITT An acronym for the Comité Consultatif International de Télégraphique et Téléphonique (in English, the International Telegraph and Telephone Consultative Committee or the Consultative Committee for International Telegraph and Telephone). Renamed ITU (International Telecommunications Union). See *ITU*.

CCS (Common Command Set) A set of SCSI commands specified in the ANSI SCSI-1 Standard X3.131-1986 Addendum 4.B. All SCSI devices must be capable of using the CCS to be fully compatible with the ANSI SCSI-1 standard.

CD (compact disc or compact audio disc) A 4.75-inch (12cm) optical disc that contains information encoded digitally in the constant linear velocity (CLV) format. This popular format for high-fidelity music offers 90 decibels signal/noise ratio, 74 minutes of digital sound, and no degradation of quality from playback. The standards for this format (developed by NV Philips and Sony Corporation) are known as the Red Book. The official (and rarely used) designation for the audio-only format is CDDA (compact disc-digital audio). The simple audio format is also known as CD-A (compact disc-audio). A smaller (3-inch) version of the CD is known as CD-3.

CD Video A CD format introduced in 1987 that combined 20 minutes of digital audio and 6 minutes of analog video on a standard 4.75-inch CD. Upon introduction, many firms renamed 8-inch and 12-inch videodiscs as CDV, in an attempt to capitalize on the consumer popularity of the audio CD. The term fell out of use in 1990 and was replaced in some part by laserdisc and more recently, DVD.

CD+G Compact Disc-Graphics A CD format that includes extended graphics capabilities as written into the original CD-ROM specifications. Includes limited video graphics encoded into the CD subcode area. Developed and marketed by Warner New Media.

CD+MIDI (Compact Disc-Musical Instrument Digital Interface) A CD format that adds to the CD+G format digital audio, graphics information, and musical instrument digital interface (MIDI) specifications and capabilities. Developed and marketed by Warner New Media.

CD-I (Compact Disc-Interactive) A compact disc format released in October 1991 that provides

audio, digital data, still graphics, and motion video. The standards for this format (developed by NV Philips and Sony Corporation) are known as the Green Book. CD-I did not catch on with consumers and is now considered obsolete.

CD-R (Compact Disc-Recordable, sometimes also called CD-Writable) CD-R disks are compact discs that can be recorded and read as many times as desired. CD-R is part of the Orange Book Standard defined by ISO. CD-R technology is used for mass production of multimedia applications. CD-R discs can be compatible with CD-ROM, CD-ROM XA, and CD audio. Orange Book specifies multisession capabilities, which allow data recording on the disc at different times in several recording sessions. Kodak's Photo CD is an example of CD-R technology and fits up to 100 digital photographs on a single CD. Multisession capability allows several rolls of 35mm film to be added to a single disc on different occasions.

CD-ROM (Compact Disc-Read Only Memory) A 4.75-inch laser-encoded optical memory storage medium with the same constant linear velocity (CLV) spiral format as audio CDs and some videodiscs, CD-ROMs can hold about 650MB of data. CD-ROMs require more error-correction information than the standard prerecorded compact audio disc. The standards for this format (developed by NV Philips and Sony Corporation) are known as the Yellow Book. See also *CD-ROM XA*.

CD-ROM drive A device that retrieves data from a CD-ROM disc; differs from a standard audio CD player by the incorporation of additional error-correction circuitry. CD-ROM drives usually can also play music from audio CDs.

CD-ROM XA (Compact Disc-Read Only Memory eXtended Architecture) The XA standard was developed jointly by Sony, Philips, and Microsoft in 1988 and is now part of the Yellow Book standard. XA is a built-in feature of newer CD-ROM drives, and supports simultaneous sound playback with data transfer. Non-XA drives support either sound playback or data transfer, but not both simultaneously. XA also provides for data compression right on the disk, which can also increase data transfer rates.

CD-RW (Compact Disc-ReWritable) A type of rewritable CD-ROM technology defined in Part III of the Orange Book standard that uses a different type of disc that the drive can rewrite at least one thousand times. CD-RW drives can also be used to write CD-R discs, and they can read CD-ROMs.

CD-RWs have a lower reflectivity than standard CD-ROMs, and CD-ROM drives must be of the newer multiread variety to read them. CD-RW was initially known as CD-E (for CD-Erasable).

CD-WO (Compact Disc-Write Once) A variant on CD-ROM that can be written to once and read many times; developed by NV Philips and Sony Corporation. Also known as CD-WORM (CD-write once/read many), CD-Recordable, or CD-Writable. Standards for this format are known as the Orange Book.

CD-WORM See *CD-WO*.

Centronics connector Refers to one of two types of cable connectors used with either parallel or SCSI devices.

ceramic substrate A thin, flat, fired ceramic part used to hold an IC chip (usually made of beryllium oxide or aluminum oxide).

CERN (Conseil Européen pour la Recherche Nucléaire; The European Laboratory for Particle Physics) The site in Geneva where the World Wide Web was created in 1989.

CGA (Color Graphics Adapter) A type of PC video display adapter introduced by IBM on August 12, 1981, that supports text and graphics. Text is supported at a maximum resolution of 80×25 characters in 16 colors with a character box of 8×8 pixels. Graphics is supported at a maximum resolution of 320×200 pixels in 16 colors or 640×200 pixels in two colors. The CGA outputs a TTL (digital) signal with a horizontal scanning frequency of 15.75KHz, and supports TTL color or NTSC composite displays.

channel 1) Any path along which signals can be sent. 2) In ISDN, data bandwidth is divided into two B-channels that bear data and one D-channel that carries information about the call.

character A representation, coded in binary digits, of a letter, number, or other symbol.

character set All the letters, numbers, and characters that a computer can use to represent data. The ASCII standard has 256 characters, each represented by a binary number from 1 to 256. The ASCII set includes all the letters in the alphabet, numbers, most punctuation marks, some mathematical symbols, and other characters.

charge coupled device A light sensing and storage device used in scanners and digital cameras to capture the pixels.

check bit See *parity*.

checksum Short for summation check, a technique for determining whether a package of data is valid. The package, a string of binary digits, is added up and compared with the expected number.

chip Another name for an IC, or integrated circuit. Housed in a plastic or ceramic carrier device with pins for making electrical connections.

chip carrier A ceramic or plastic package that carries an integrated circuit.

chipset A single chip or pair of chips that integrates into it the clock generator, bus controller, system timer, interrupt controller, DMA controller, CMOS RAM/clock, and keyboard controller. See also *North Bridge* and *South Bridge*.

CHS (Cylinder Head Sector) The term used to describe the nontranslating scheme used by the BIOS to access IDE drives that are less than or equal to 528MB in capacity. See *LBA*.

CIF (Common Image Format) The standard sample structure that represents the picture information of a single frame in digital HDTV, independent of frame rate and sync/blank structure. The uncompressed bit rate for transmitting CIF at 29.97 frames/sec is 36.45Mbps.

circuit A complete electronic path.

circuit board The collection of circuits gathered on a sheet of plastic, usually with all contacts made through a strip of pins. The circuit board usually is made by chemically etching metal-coated plastic.

CISC (Complex Instruction Set Computer) Refers to traditional computers that operate with large sets of processor instructions. Most modern computers, including the Intel 80xxx processors, are in this category. CISC processors have expanded instruction sets that are complex in nature and require several to many execution cycles to complete. This structure contrasts with RISC (reduced instruction set computer) processors, which have far fewer instructions that execute quickly.

clean room 1) A dust-free room in which certain electronic components (such as chips or hard disk drives) must be manufactured and serviced to prevent contamination. Rooms are rated by Class numbers. A Class 100 clean room must have fewer than 100 particles larger than 0.5 microns per cubic foot of space. 2) A legal approach to copying software or hardware where one team analyzes the product and writes a detailed description, followed by a second team who reads the description

written by the first and who then develops a compatible version of the product. When done correctly, such a design methodology will survive a legal attack.

client/server A type of network in which every computer is either a server with a defined role of sharing resources with clients or a client that can access the resources on the server.

clock The source of a computer's timing signals. Synchronizes every operation of the CPU.

clock multiplier A processor feature where the internal core runs at a higher speed than the motherboard or processor bus. See also *overclocking*.

clock speed A measurement of the rate at which the clock signal for a device oscillates, usually expressed in millions of cycles per second (MHz).

clone Originally referred to an IBM-compatible computer system that physically as well as electrically emulates the design of one of IBM's personal computer systems. More currently, it refers to any PC system running an Intel or compatible processor in the 80x86 family.

cluster Also called allocation unit. A group of one or more sectors on a disk that forms a fundamental unit of storage to the operating system. Cluster or allocation unit size is determined by the operating system when the disk is formatted. Larger clusters generally offer faster system performance but waste disk space.

CLV (Constant Linear Velocity) An optical recording format where the spacing of data is consistent throughout the disk, and the rotational speed of the disk varies depending on what track is being read. Additionally, more sectors of data are placed on the outer tracks compared to the inner tracks of the disk, which is similar to zone recording on hard drives. CLV drives will adjust the rotational speed to maintain a constant track velocity as the diameter of the track changes. CLV drives rotate faster near the center of the disk and slower toward the edge. Rotational adjustment maximizes the amount of data that can be stored on a disk. CD audio and CD-ROM use CLV recording.

CMOS (complementary metal-oxide semiconductor) A type of chip design that requires little power to operate. In PCs, a battery-powered CMOS memory and clock chip is used to store and maintain the clock setting and system configuration information.

CMYK (Cyan Magenta Yellow Black) The standard four-color model used for printing.

coated media Hard disk platters coated with a reddish iron-oxide medium on which data is recorded.

coaxial cable Also called coax cable. A data-transmission medium noted for its wide bandwidth, immunity to interference, and high cost compared to other types of cable. Signals are transmitted inside a fully shielded environment, in which an inner conductor is surrounded by a solid insulating material and then an outer conductor or shield. Used in many local area network systems such as Ethernet and ARCnet.

COBOL (Common Business-Oriented Language) A high-level computer programming language primarily used by some larger companies. It has never achieved popularity on personal and small business computers.

code page A table used in DOS 3.3 and later that sets up the keyboard and display characters for various foreign languages.

code page switching A DOS feature in versions 3.3 and later that changes the characters displayed onscreen or printed on an output device. Primarily used to support foreign-language characters. Requires an EGA or better video system and an IBM-compatible graphics printer.

CODEC (COder-DECoder) A device that converts voice signals from their analog form to digital signals acceptable to more modern digital PBXs and digital transmission systems. It then converts those digital signals back to analog so that you may hear and understand what the other party is saying.

coercivity A measurement in units of oersteds of the amount of magnetic energy to switch or "coerce" the flux change in the magnetic recording media. High-coercivity disk media requires a stronger write current.

cold boot Starting or restarting a computer by resetting or turning on the power supply. See also *warm boot*.

collision In a LAN, if two computers transmit a packet of data at the same time on the network, the data may become garbled, which is known as a collision.

collision detection/avoidance A process used on a LAN to prevent data packets from interfering with each other and to determine whether data packets have encountered a collision and initiate a resend of the affected packets.

Color Graphics Adapter See *CGA*.

color palette The colors available to a graphics adapter for display.

COM port A serial port on a PC that conforms to the RS-232 standard. See also *RS-232*.

COMDEX The largest international computer trade show and conference in the world. COMDEX/Fall is held in Las Vegas during October, and COMDEX/Spring usually is held in Chicago or Atlanta during April.

command An instruction that tells the computer to start, stop, or continue an operation.

command interpreter The operating system program that controls a computer's shell or user interface. The command interpreter for MS-DOS is COMMAND.COM. The command interpreter for Windows is WIN.COM.

COMMAND.COM An operating system file that is loaded last when the computer is booted. The command interpreter or user interface and program-loader portion of DOS.

common The ground or return path for an electrical signal. If a wire, it usually is colored black.

common mode noise Noise or electrical disturbances that can be measured between a current- or signal-carrying line and its associated ground. Common mode noise is frequently introduced to signals between separate computer equipment components through the power distribution circuits. It can be a problem when single-ended signals are used to connect different equipment or components that are powered by different circuits.

CompactFlash An ATA flash memory card physical format that is approximately one third the size of a standard PC card. Often abbreviated CF, CompactFlash cards are identical in function to standard ATA Flash PC cards but use 50 pin connectors instead of 68. ATA flash cards contain built-in disk controller circuitry to enable the card to function as a solid-state disk drive. CF cards can plug into a CompactFlash socket or with an adapter into a standard Type I or II PC-card slot.

compatible 1) In the early days of the PC industry when IBM dominated the market, a term used to refer to computers from other manufacturers that had the same features as a given IBM model. 2) In general, software or hardware that conforms to industry standards or other de facto standards so that it can be used in conjunction with or in lieu of other versions of software or hardware from other vendors in a like manner.

compiler A program that translates a program written in a high-level language into its equivalent machine language. The output from a compiler is called an object program.

complete backup A backup of all information on a hard disk, including the directory tree structure.

composite video Television picture information and sync pulses combined. The complete wave form of the color video signal composed of chrominance and luminance picture information; blanking pedestal; field, line, and color sync pulses; and field equalizing pulses. Some video cards have an RCA jack that outputs a composite video signal. See also *RGB*.

compressed file A file that has been reduced in size via one or more compression techniques.

computer Device capable of accepting data, applying prescribed processes to this data, and displaying the results or information produced.

computer-based training (CBT) The use of a computer to deliver instruction or training; also known as Computer-Aided (or Assisted) Instruction (CAI), Computer-Aided Learning (CAL), Computer-Based Instruction (CBI), and Computer-Based Learning (CBL).

CONFIG.SYS A file that can be created to tell DOS how to configure itself when the machine starts up. Can load device drivers, set the number of DOS buffers, and so on.

configuration file A file kept by application software to record various aspects of the software's configuration, such as the printer it uses.

console The unit, such as a terminal or a keyboard, in your system with which you communicate with the computer.

contiguous Touching or joined at the edge or boundary, in one piece.

continuity In electronics, an unbroken pathway. Testing for continuity normally means testing to determine whether a wire or other conductor is complete and unbroken (by measuring 0 ohms). A broken wire shows infinite resistance (or infinite ohms).

control cable The wider of the two cables that connect an ST-506/412 or ESDI hard disk drive to a controller card. A 34-pin cable that carries commands and acknowledgments between the drive and controller.

controller The electronics that control a device such as a hard disk drive and intermediate the passage of data between the device and the computer.

controller card An adapter holding the control electronics for one or more devices such as hard disks. Ordinarily occupies one of the computer's slots.

conventional memory The first megabyte or first 640KB of system memory accessible by an Intel processor in real mode. Sometimes called base memory.

convergence Describes the capability of a color monitor to focus the three colored electron beams on a single point. Poor convergence causes the characters onscreen to appear fuzzy and can cause headaches and eyestrain.

coprocessor An additional computer processing unit designed to handle specific tasks in conjunction with the main or central processing unit.

copy protection A hardware or software scheme to prohibit making illegal copies of a program.

core An old-fashioned term for computer memory.

core speed The internal speed of a processor. With all modern processors, this speed is faster than the system bus speed and that speed relationship is regulated by the clock multiplier in the processor.

CP/M (Control Program for Microcomputers, originally Control Program/Monitor) An operating system created by Gary Kildall, the founder of Digital Research. Created for the old 8-bit microcomputers that used the 8080, 8085, and Z-80 microprocessors. Was the dominant operating system in the late 1970s and early 1980s for small computers used in a business environment.

cps (characters per second) A data transfer rate generally estimated from the bit rate and the character length. At 2,400bps, for example, 8-bit characters with start and stop bits (for a total of 10 bits per character) are transmitted at a rate of approximately 240cps. Some protocols, such as V.42 and MNP, employ advanced techniques such as longer transmission frames and data compression to increase characters per second.

CPU (Central Processing Unit) The computer's microprocessor chip; the brains of the outfit. Typically, an IC using VLSI (very-large-scale integration) technology to pack several different

functions into a tiny area. The most common electronic device in the CPU is the transistor, of which several thousand to several million or more are found.

crash A malfunction that brings work to a halt. A system crash usually is caused by a software malfunction, and ordinarily you can restart the system by rebooting the machine. A head crash, however, entails physical damage to a disk and probable data loss.

CRC (cyclic redundancy checking) An error-detection technique consisting of a cyclic algorithm performed on each block or frame of data by both sending and receiving modems. The sending modem inserts the results of its computation in each data block in the form of a CRC code. The receiving modem compares its results with the received CRC code and responds with either a positive or negative acknowledgment. In the ARQ protocol implemented in high-speed modems, the receiving modem accepts no more data until a defective block is received correctly.

crosstalk The electromagnetic coupling of a signal on one line with another nearby signal line. Crosstalk is caused by electromagnetic induction, where a signal traveling through a wire creates a magnetic field that induces a current in other nearby wires.

CRT (cathode-ray tube) A term used to describe a television or monitor screen tube.

current The flow of electrons, measured in amperes, or amps.

cursor The small flashing hyphen that appears onscreen to indicate the point at which any input from the keyboard will be placed.

cycle Time for a signal to transition from leading edge to the next leading edge.

cyclic redundancy checking See *CRC*.

cylinder The set of tracks on a disk that are on each side of all the disk platters in a stack and are the same distance from the center of the disk. The total number of tracks that can be read without moving the heads. A floppy drive with two heads usually has 160 tracks, which are accessible as 80 cylinders. A typical 4GB hard disk has 10 platters with 20 heads (19 for data and one servo head) and 4,000 cylinders, in which each cylinder is composed of 19 tracks.

D-channel In ISDN, a 16Kbps channel that is used to transmit control data about a connection.

D/A Converter (DAC) A device that converts digital signals to analog form.

daisy chain Stringing up components in such a manner that the signals move serially from one to the other. Most microcomputer multiple disk drive systems are daisy-chained. The SCSI bus system is a daisy-chain arrangement, in which the signals move from computer to disk drives to tape units, and so on.

daisywheel printer An impact printer that prints fully formed characters one at a time by rotating a circular print element composed of a series of individual spokes, each containing two characters that radiate from a center hub. Produces letter-quality output.

DAT (Digital Audio Tape) A small cassette containing 4mm-wide tape used for storing large amounts of digital information. DAT technology emerged in Europe and Japan in 1986 as a way to produce high-quality, digital audio recordings and was modified in 1988 to conform to the DDS (digital data storage) standard for storing computer data. Raw capacities for a single tape are 2GB for DDS, 4GB for DDS-2, and 12GB for DDS-3, with double that for compressed data.

data 1) Groups of facts processed into information. A graphic or textural representation of facts, concepts, numbers, letters, symbols, or instructions used for communication or processing. 2) An android from the twenty-fourth century with a processing speed of 60 trillion operations per second and a storage capacity of 800 quadrillion bits, and who serves on the USS Enterprise NCC-1701-D with the rank of lieutenant commander.

data bus The connection that transmits data between the processor and the rest of the system. The width of the data bus defines the number of data bits that can be moved into or out of the processor in one cycle.

data cable Generically, a cable that carries data. Specific to HD connections, the narrower (20 pin) of two cables that connects an ST-506/412 or ESDI hard disk drive to a controller card.

data communications A type of communication in which computers and terminals can exchange data over an electronic medium.

data compression A technique where mathematical algorithms are applied to the data in a file to eliminate redundancies and therefore reduce the size of the file. See also *lossy compression* and *lossless compression*.

data link layer In networking, the layer of the OSI reference model that controls how the electrical impulses enter or leave the network cable. Ethernet and Token Ring are the two most common examples of data link layer protocols.

data separator A device that separates data and clock signals from a single encoded signal pattern. Usually, the same device does both data separation and combination and is sometimes called an endec, or encoder/decoder.

data transfer rate The maximum rate at which data can be transferred from one device to another.

daughterboard Add-on board to increase functionality and/or memory. Attaches to existing board.

DB-9 9-pin D-shell connector, primarily used for PC serial ports.

DB-25 25-pin D-shell connector, primarily used for PC parallel ports.

DC Direct current, such as that provided by a power supply or batteries.

DC-600 (Data Cartridge 600) A data-storage medium invented by 3M in 1971 that uses a quarter-inch-wide tape 600 feet in length.

DCE (Data Communications Equipment) The hardware that performs the communication—usually a dial-up modem that establishes and controls the data link through the telephone network. See also *DTE*.

DDE (Dynamic Data Exchange) A form of inter-process communications used by Microsoft Windows to support the exchange of commands and data between two applications running simultaneously. This capability has been enhanced further with object linking and embedding (OLE).

de facto standard A software or hardware technology that is not officially made a standard by any recognized standards organization but that is used as a reference for consumers and vendors due to its dominance in the marketplace.

DEBUG The name of a utility program included with DOS used for specialized purposes such as altering memory locations, tracing program execution, patching programs and disk sectors, and performing other low-level tasks.

decibel (dB) A logarithmic measure of the ratio between two powers, voltages, currents, sound intensities, and so on. Signal-to-noise ratios are expressed in decibels.

dedicated line A user-installed telephone line that connects a specified number of computers or terminals within a limited area, such as a single building. The line is a cable rather than a public-access telephone line. The communications channel also may be referred to as nonswitched because calls do not go through telephone company switching equipment.

dedicated servo surface In voice-coil-actuated hard disk drives, one side of one platter given over to servo data that is used to guide and position the read/write heads.

default Any setting assumed at startup or reset by the computer's software and attached devices and operational until changed by the user. An assumption the computer makes when no other parameters are specified. When you type DIR without specifying the drive to search, for example, the computer assumes that you want it to search the default drive. The term is used in software to describe any action the computer or program takes on its own with embedded values.

defect map A list of unusable sectors and tracks coded onto a drive during the low-level format process.

defragmentation The process of rearranging disk sectors so files are stored on consecutive sectors in adjacent tracks.

degauss 1) To remove magnetic charges, or to erase magnetic images. Normal applications include monitors and disks or tapes. Most monitors incorporate a degaussing coil, which surrounds the CRT, and automatically energize this coil for a few seconds when powered up to remove color or image distorting magnetic fields from the metal mask inside the tube. Some monitors include a button or control that can be used for additional applications of this coil to remove more stubborn magnetic traces. 2) Also the act of erasing or demagnetizing a magnetic disk or tape using a special tool called a degaussing coil.

density The amount of data that can be packed into a certain area on a specific storage media.

desktop A personal computer that sits on a desk.

device driver A memory-resident program loaded by CONFIG.SYS that controls an unusual device, such as an expanded memory board.

Dhrystone A benchmark program used as a standard figure of merit indicating aspects of a computer system's performance in areas other than

floating-point math performance. Because the program does not use any floating-point operations, performs no I/O, and makes no operating system calls, it is most useful for measuring the processor performance of a system. The original Dhrystone program was developed in 1984 and was written in Ada, although the C and Pascal versions became more popular by 1989.

diagnostics Programs used to check the operation of a computer system. These programs enable the operator to check the entire system for any problems and to indicate in what area the problems lie.

dial-up adapter In Windows 9x, a software program that uses a modem to emulate a network interface card for networking. Most commonly used to connect to an Internet service provider or a dial-up server for remote access to a LAN.

die An individual chip (processor, RAM, or other integrated circuit) cut from a finished silicon chip wafer and built into the physical package that will connect it to the rest of the PC or a circuit board.

differential An electrical signaling method where a pair of lines are used for each signal in "push-pull" fashion. In most cases, differential signals are balanced so that the same current flows on each line in opposite directions. This is unlike single-ended signals, which use only one line per signal referenced to a single ground. Differential signals have a large tolerance for common-mode noise and little crosstalk when used with twisted-pair wires even in long cables. Differential signaling is expensive because two pins are required for each signal.

digital loopback A test that checks the modem's RS-232 interface and the cable that connects the terminal or computer and the modem. The modem receives data (in the form of digital signals) from the computer or terminal and immediately returns the data to the screen for verification.

digital signals Discrete, uniform signals. In this book, the term refers to the binary digits 0 and 1.

digitize To transform an analog wave to a digital signal that a computer can store. Conversion to digital data and back is performed by a D/A Converter (DAC), often a single-chip device. How closely a digitized sample represents an analog wave depends on the number of times the amplitude of a wave is measured and recorded (the rate of digitization) as well as the number of different

levels that can be specified at each instance. The number of possible signal levels is dictated by the resolution in bits.

DIMM (Dual Inline Memory Module) A 64-bit wide, 168-pin memory module used in Pentium and newer PCs. They are available in several versions, including 5v or 3v, buffered or unbuffered, with FPM/EDO or SDRAM memory, and in 64-bit (non-ECC/parity) or 72-bit (ECC/parity) form. Most Pentium and newer PCs require 3.3v unbuffered SDRAM DIMMs in either non-ECC or ECC versions (ECC recommended).

DIP (Dual Inline Package) A family of rectangular, integrated-circuit flat packages that have leads on the two longer sides. Package material is plastic or ceramic.

DIP switch A tiny switch (or group of switches) on a circuit board. Named for the form factor of the carrier device in which the switch is housed.

direct memory access (DMA) A process by which data moves between a disk drive (or other device) and system memory without direct control of the central processing unit, thus freeing it up for other tasks.

Direct Rambus DRAM See *RDRAM*.

directory An area of a disk that stores the titles given to the files saved on the disk and serves as a table of contents for those files. Contains data that identifies the name of a file, the size, the attributes (system, hidden, read-only, and so on), the date and time of creation, and a pointer to the location of the file. Each entry in a directory is 32 bytes long.

disc Flat, circular, rotating medium that can store various types of information, both analog and digital. Disc is often used in reference to optical storage media, whereas disk refers to magnetic storage media. Disc is often used as a short form for videodisc or compact audio disc (CD).

disk Alternative spelling for disc that generally refers to magnetic storage medium on which information can be accessed at random. Floppy disks and hard disks are examples.

disk access time See *access time*.

disk cache A portion of memory on the PC motherboard or on a drive interface card or controller used to store frequently accessed information from the drive (such as the file allocation table [FAT] or directory structure) to speed up disk access. With a larger disk cache, additional data

from the data portion of a drive can be cached as well. See also *cache*, *L1 cache*, and *L2 cache*.

disk partition See *partition*.

display adapter The interface between the computer and the monitor that transmits the signals that appear as images on the display. This can take the form of an expansion card or a chip built into the motherboard.

dithering The process of creating more colors and shades from a given color palette. In monochrome displays or printers, dithering will vary the black-and-white dot patterns to simulate shades of gray. Grayscale dithering is used to produce different shades of gray when the device can only produce limited levels of black or white outputs. Color screens or printers use dithering to create additional colors by mixing and varying the dot sizing and spacing. For example, when converting from 24-bit color to 8-bit color (an 8-bit palette has only 256 colors compared to the 24-bit palette's millions), dithering adds pixels of different colors to simulate the original color. Dithering is also known as error diffusion.

DLL (Dynamic Link Library) An executable driver program module for Microsoft Windows that can be loaded on demand and linked in at runtime and subsequently unloaded when the driver is no longer needed.

DMA See *direct memory access*.

DMI (Desktop Management Interface) DMI is an operating system- and protocol-independent standard developed by the Desktop Management Task Force (DMTF) for managing desktop systems and servers. DMI provides a bidirectional path to interrogate all the hardware and software components within a PC, allowing hardware and software configurations to be monitored from a central station in a network.

docking station Equipment that allows a laptop or notebook computer to use peripherals and accessories normally associated with desktop systems.

doping Adding chemical impurities to silicon (which is naturally a nonconductor), creating a material with semiconductor properties that is then used in the manufacturing of electronic chips.

DOS (Disk Operating System) A collection of programs stored on the DOS disk that contain routines enabling the system and user to manage information and the hardware resources of the computer.

DOS must be loaded into the computer before other programs can be started.

dot pitch A measurement of the width of the dots that make up a pixel. The smaller the dot pitch, the sharper the image.

dot-matrix printer An impact printer that prints characters composed of dots. Characters are printed one at a time by pressing the ends of selected wires against an inked ribbon and paper.

double density (DD) An indication of the storage capacity of a floppy drive or disk in which eight or nine sectors per track are recorded using MFM encoding. See also *MFM encoding*.

downtime Operating time lost because of a computer malfunction.

DPMI (DOS Protected Mode Interface) An industry-standard interface that allows DOS applications to execute program code in the protected mode of the 286 or later Intel processor. The DPMI specification is available from Intel.

DPMS (Display Power Management Signaling) A VESA standard for signaling a monitor or display to switch into energy conservation modes. DPMS provides for two low energy modes: standby and suspend.

DRAM (Dynamic Random Access Memory) The most common type of computer memory, DRAM can be made very inexpensively compared to other types of memory. DRAM chips are small and inexpensive because they normally require only one transistor and a capacitor to represent each bit. The capacitors must be energized every 15ms or so (hundreds of times per second) to maintain their charges. DRAM is volatile, meaning it will lose data with no power or without regular refresh cycles.

drive A mechanical device that manipulates data storage media.

driver A program designed to interface a particular piece of hardware to an operating system or other standard software.

drum The cylindrical photoreceptor in a laser printer that receives the document image from the laser and applies it to the page as it slowly rotates.

DSL (Digital Subscriber Line) A high-speed digital modem technology. DSL is either symmetric or asymmetric. Asymmetric provides faster downstream speeds, which is suited for Internet usage and video on demand. Symmetric provides the same rate coming and going. See also *ADSL*.

DSM (Digital Storage Media) A digital storage or transmission device or system.

DSP (Digital Signal Processor) Dedicated, limited function processor often found in modems, sound cards, cellular phones, and so on.

DTE (Data Terminal [or Terminating] Equipment) The device, usually a computer or terminal, that generates or is the final destination of data. See also *DCE*.

dual cavity pin grid array Chip packaging designed by Intel for use with the Pentium Pro processor that houses the processor die in one cavity of the package and the L2 cache memory in a second cavity within the same package.

Dual Independent Bus (DIB) Architecture

A processor technology with the existence of two independent buses on the processor—the L2 cache bus and the processor-to-main-memory system bus. The processor can use both buses simultaneously, thus getting as much as two times more data into and out of the processor than a single bus architecture processor. The Intel Pentium Pro, Pentium II, and newer processors have DIB architecture.

dual scan display A lower-quality but economical type of LCD color display that has an array of transistors running down the x and y axes of two sides of the screen. The number of transistors determines the screen's resolution.

duplex Indicates a communications channel capable of carrying signals in both directions.

DVD (Digital Versatile Disc) Originally called Digital Video Disc. A new type of high-capacity CD-ROM disc and drive format with up to 28 times the capacity of standard CD-ROM. The disc is the same diameter as a CD-ROM but can be recorded on both sides and on two layers for each side. Each side holds 4.7GB on a single layer disc, while dual-layer versions hold 8.5GB per side, for a maximum of 17GB total if both sides and both layers are used, which is the equivalent of 28 CD-ROMs. DVD drives can read standard audio CDs and CD-ROMs.

DVI (Digital Video Interactive) A standard that was originally developed at RCA Laboratories and sold to Intel in 1988. DVI integrates digital motion, still video, sound, graphics, and special effects in a compressed format. DVI is a highly sophisticated hardware compression technique used in interactive multimedia applications.

Dvorak keyboard A keyboard design by August Dvorak that was patented in 1936 and approved by

ANSI in 1982. Provides increased speed and comfort and reduces the rate of errors by placing the most frequently used letters in the center for use by the strongest fingers. Finger motions and awkward strokes are reduced by more than 90 percent in comparison with the familiar QWERTY keyboard. The Dvorak keyboard has the five vowel keys, AOEU, together under the left hand in the center row and the five most frequently used consonants, DHTNS, under the fingers of the right hand.

dynamic execution A processing technique that allows the processor to dynamically predict the order of instructions and execute them out of order internally if necessary for an improvement in speed. Makes use of the three techniques Multiple Branch Prediction, Data Flow Analysis, and Speculative Execution.

EBCDIC (Extended Binary Coded Decimal Interchange Code) An IBM-developed 8-bit code for the representation of characters. It allows 256 possible character combinations within a single byte. EBCDIC is the standard code on IBM minicomputers and mainframes, but not on the IBM microcomputers, where ASCII is used instead.

ECC (Error Correcting Code) A type of system memory or cache that is capable of detecting and correcting some types of memory errors without interrupting processing.

ECP (Enhanced Capabilities Port) A type of high-speed parallel port jointly developed by Microsoft and Hewlett-Packard that offers improved performance for the parallel port and requires special hardware logic.

edge connector The part of a circuit board containing a series of printed contacts that is inserted into an expansion slot or connector.

EDO (Extended Data Out) **RAM** A type of RAM chips that allow for a timing overlap between successive accesses, thus improving memory cycle time.

EEPROM (Electrically Erasable Programmable Read Only Memory) A type of nonvolatile memory chip used to store semipermanent information in a computer such as the BIOS. An EEPROM can be erased and reprogrammed directly in the host system without special equipment. This is used so manufacturers can upgrade the ROM code in a system by supplying a special program that erases and reprograms the EEPROM chip with the new code. Also called a flash ROM.

EGA (Enhanced Graphics Adapter) A type of PC video display adapter first introduced by IBM on September 10, 1984, that supports text and graphics. Text is supported at a maximum resolution of 80×25 characters in 16 colors with a character box of 8×14 pixels. Graphics is supported at a maximum resolution of 640×350 pixels in 16 (from a palette of 64) colors. The EGA outputs a TTL (digital) signal with a horizontal scanning frequency of 15.75, 18.432, or 21.85KHz, and supports TTL color or TTL monochrome displays.

EIA (Electronic Industries Association) An organization that defines electronic standards in the United States.

EIDE (Enhanced Integrated Drive Electronics) A specific Western Digital implementation of the ATA-2 specification. See also *ATA-2*.

EISA (Extended Industry Standard Architecture) An extension of the Industry Standard Architecture (ISA) bus developed by IBM for the AT. The EISA design was led by Compaq Corporation. Later, eight other manufacturers (AST, Epson, Hewlett-Packard, NEC, Olivetti, Tandy, Wyse, and Zenith) joined Compaq in a consortium founded September 13, 1988. This group became known as the “gang of nine.” The EISA design was patterned largely after IBM’s Micro Channel Architecture (MCA) in the PS/2 systems, but unlike MCA, EISA allows for backward compatibility with older plug-in adapters.

electronic mail (email) A method of transferring messages from one computer to another.

electrostatic discharge (ESD) The grounding of static electricity. A sudden flow of electricity between two objects at different electrical potentials. ESD is a primary cause of integrated circuit damage or failure.

embedded controller In disk drives, a controller built into the same physical unit that houses the drive rather than on a separate adapter card. IDE and SCSI drives both use embedded controllers.

embedded servo data Magnetic markings embedded between or inside tracks on disk drives that use voice-coil actuators. These markings enable the actuator to fine-tune the position of the read/write heads.

EMM (Expanded Memory Manager) A driver that provides a software interface to expanded memory. EMMs were originally created for expanded

memory boards, but can also use the memory management capabilities of the 386 or later processors to emulate an expanded memory board.

EMM386.EXE is an example of an EMM that comes with DOS.

EMS (Expanded Memory Specification)

Sometimes also called the LIM spec because it was developed by Lotus, Intel, and Microsoft. Provides a way for microcomputers running under DOS to access additional memory. EMS memory management provides access to a maximum of 32MB of expanded memory through a small (usually 64KB) window in conventional memory. EMS is a cumbersome access scheme designed primarily for pre-286 systems that could not access extended memory.

emulator A piece of test apparatus that emulates or imitates the function of a particular chip.

encoding The protocol by which data is carried or stored by a medium.

encryption The translation of data into unreadable codes to maintain security.

endec (encoder/decoder) A device that takes data and clock signals and combines or encodes them using a particular encoding scheme into a single signal for transmission or storage. The same device also later separates or decodes the data and clock signals during a receive or read operation. Sometimes called a data separator.

Energy Star A certification program started by the Environmental Protection Agency. Energy Star-certified computers and peripherals are designed to draw less than 30 watts of electrical energy from a standard 110-volt AC outlet during periods of inactivity. Also called Green PCs.

Enhanced Graphics Adapter See *EGA*.

Enhanced Small Device Interface See *ESDI*.

EPP (Enhanced Parallel Port) A type of parallel port developed by Intel, Xircom, and Zenith Data Systems that operates almost at ISA bus speed and offers a tenfold increase in the raw throughput capability over a conventional parallel port. EPP is especially designed for parallel port peripherals such as LAN adapters, disk drives, and tape backups.

EPROM (Erasable Programmable Read-Only Memory) A type of read-only memory (ROM) in which the data pattern can be erased to allow a new pattern. EPROM usually is erased by ultraviolet light and recorded by a higher-than-normal voltage programming signal.

equalization A compensation circuit designed into modems to counteract certain distortions introduced by the telephone channel. Two types are used: fixed (compromise) equalizers and those that adapt to channel conditions (adaptive). Good-quality modems use adaptive equalization.

error control Various techniques that check the reliability of characters (parity) or blocks of data. V.42, MNP, and HST error-control protocols use error detection (CRC) and retransmission of error frames (ARQ).

error message A word or combination of words to indicate to the user that an error has occurred somewhere in the program.

ESCD (Extended System Configuration Data) Area in CMOS or Flash/NVRAM where Plug-and-Play information is stored.

ESDI (Enhanced Small Device Interface) A hardware standard developed by Maxtor and standardized by a consortium of 22 disk drive manufacturers on January 26, 1983. A group of 27 manufacturers formed the ESDI steering committee on September 15, 1986, to enhance and improve the specification. A high-performance interface used primarily with hard disks, ESDI provides for a maximum data transfer rate to and from a hard disk of between 10 and 24Mbit/sec.

Ethernet A type of network protocol developed in the late 1970s by Bob Metcalfe at Xerox Corporation and endorsed by the IEEE. One of the oldest LAN communications protocols in the personal computing industry, Ethernet networks use a collision-detection protocol to manage contention.

expanded memory Otherwise known as EMS memory, memory that conforms to the EMS specification. Requires a special device driver and conforms to a standard developed by Lotus, Intel, and Microsoft.

expansion card An integrated circuit card that plugs into an expansion slot on a motherboard to provide access to additional peripherals or features not built into the motherboard. Also referred to as an add-in board.

expansion slot A slot on the motherboard that physically and electrically connects an expansion card to the motherboard and the system buses.

eXtended Graphics Array See *XGA*.

extended memory Direct processor-addressable memory that is addressed by an Intel (or compatible) 286, 386, or 486 processor in the region

beyond the first megabyte. Addressable only in the processor's protected mode of operation.

extended partition A nonbootable DOS partition containing DOS volumes. Starting with DOS v3.3, the DOS FDISK program can create two partitions that serve DOS: an ordinary, bootable partition (called the primary partition) and an extended partition, which may contain as many as 23 volumes from D: to Z:.

external device A peripheral that is installed outside of the system case.

extra-high density (ED) An indication of the storage capacity of a floppy drive or disk in which 36 sectors per track are recorded using a vertical recording technique with MFM encoding.

fast-ATA (fast AT attachment interface) Also called fast ATA-2, these are specific Seagate and Quantum implementations of the ATA-2 interface. See also *ATA-2*.

Fast Page Mode RAM A type of RAM that improves on standard DRAM speed by allowing for faster access to all the data within a given row of memory by keeping the row address the same and changing only the column.

FAT (file allocation table) A table held near the outer edge of a disk that tells which sectors are allocated to each file and in what order.

FAT32 A disk file allocation system from Microsoft that uses 32-bit values for FAT entries instead of 16-bit values used by the original FAT system, enabling partition sizes up to 2TB (terabytes). FAT32 first appeared in Windows 95B and is also found in Windows 98 and Windows NT 5.0.

fax/modem A peripheral that integrates the capabilities of a fax machine and a modem in one expansion card or external unit.

FCPGA (Flip-Chip Pin Grid Array) A type of chip packaging first used in the Socket PGA370 version of the Pentium III where the raw processor die has bumped contacts spaced on the face of the die and is mounted facedown to a Pin Grid Array carrier. The heat sink is then directly attached to the back of the raw silicon die surface.

FDISK The name of the disk-partitioning program under several operating systems to create the master boot record and allocate partitions for the operating system's use.

feature connector On a video adapter, a connector that allows an additional video feature card such as a separate 3D accelerator, video capture

card, or MPEG decoder to be connected to the main video adapter and display.

FIFO (first-in, first-out) A method of storing and retrieving items from a list, table, or stack so that the first element stored is the first one retrieved.

file A collection of information kept somewhere other than in random-access memory.

file attribute Information held in the attribute byte of a file's directory entry.

file compression See *compressed file*.

filename The name given to the disk file. For DOS, it must be one to eight characters long and may be followed by a filename extension, which can be one to three characters long. Windows 95 eases these constraints by allowing filenames of up to 255 characters.

FireWire Also called IEEE 1394. A serial I/O interface standard that is extremely fast, with data transfer rates up to 400MB/sec, 800MB/sec, or 3.2GB/sec, depending on the version of standard used.

firmware Software contained in a read-only memory (ROM) device. A cross between hardware and software.

fixed disk Also called a hard disk, a disk that cannot be removed from its controlling hardware or housing. Made of rigid material with a magnetic coating and used for the mass storage and retrieval of data.

flash ROM A type of EEPROM developed by Intel that can be erased and reprogrammed in the host system. See also *EEPROM*.

flicker A monitor condition caused by refresh rates that are too low in which the display flashes visibly. This can cause eyestrain or more severe physical problems.

floating-point unit (FPU) Sometimes called the math coprocessor; handles the more complex calculations of the processing cycle.

floppy disk A removable disk using flexible magnetic media enclosed in a semirigid or rigid plastic case.

floppy disk controller The logic and interface that connects a floppy disk drive to the system.

floppy tape A tape standard that uses drives connecting to an ordinary floppy disk controller.

optical drive A special type of high-capacity removable disk drive that uses an optical mechanism to properly position the drive read/write

heads over the data tracks on the disk, allowing for more precise control of the read/write positioning and therefore narrower track spacing and more data packed into a smaller area than traditional floppy disks.

flow control A mechanism that compensates for differences in the flow of data input to and output from a modem or other device.

FM encoding Frequency modulation encoding. An outdated method of encoding data on the disk surface that uses up half the disk space with timing signals.

FM synthesis An audio technology that uses one sine wave operator to modify another and create an artificial sound that mimics an instrument.

folder In a graphical user interface, a simulated file folder that holds documents (text, data, or graphics), applications, and other folders. A folder is like a DOS subdirectory.

form factor The physical dimensions of a device. Two devices with the same form factor are physically interchangeable. The IBM PC, XT, and XT Model 286, for example, all use power supplies that are internally different but have exactly the same form factor.

FORMAT The DOS format program that performs both low- and high-level formatting on floppy disks but only high-level formatting on hard disks.

formatted capacity The total number of bytes of data that can fit on a formatted disk. The unformatted capacity is higher because space is lost defining the boundaries between sectors.

formatting Preparing a disk so that the computer can read or write to it. Checks the disk for defects and constructs an organizational system to manage information on the disk.

FORTRAN (Formula translator) A high-level programming language developed in 1954 by John Backus at IBM, primarily for programs dealing with mathematical formulas and expressions similar to algebra and used primarily in scientific and technical applications.

fragmentation The state of having a file scattered around a disk in pieces rather than existing in one contiguous area of the disk. Fragmented files are slower to read than files stored in contiguous areas and can be more difficult to recover if the FAT or a directory becomes damaged.

frame 1) A data communications term for a block of data with header and trailer information attached. The added information usually includes a frame number, block size data, error-check codes, and start/end indicators. 2) Also a single, complete picture in a video or film recording. A video frame consists of two interlaced fields of either 525 lines (NTSC) or 625 lines (PAL/SECAM), running at 30 frames per second (NTSC) or 25 frames per second (PAL/SECAM).

frame buffer A memory device that stores, pixel by pixel, the contents of an image. Frame buffers are used to refresh a raster image. Sometimes they incorporate local processing capability. The "depth" of the frame buffer is the number of bits per pixel, which determines the number of colors or intensities that can be displayed.

frame rate The speed at which video frames are scanned or displayed, 30 frames per second for NTSC, 25 frames a second for PAL/SECAM.

FTP (File Transfer Protocol) A method of transferring files over the Internet. FTP can be used to transfer files between two machines on which the user has accounts. Anonymous FTP can be used by a user to retrieve a file from a server without having an account on that server.

full duplex Signal flow in both directions at the same time. In microcomputer communications, also may refer to the suppression of the online local echo.

full-height drive A drive unit that is 3 1/4 inches high, 5 3/4 inches wide, and 8 inches deep.

full-motion video A video sequence displayed at full television standard resolutions and frame rates. In the U.S., this would equate to NTSC video at 30 frames per second.

function keys Special-purpose keys that can be programmed to perform various operations. Serve many different functions depending on the program being used.

gas-plasma display Commonly used in portable systems, a type of display that operates by exciting a gas, usually neon or an argon-neon mixture, through the application of a voltage. When sufficient voltage is applied at the intersection of two electrodes, the gas glows an orange-red. Because gas-plasma displays generate light, they require no backlighting.

gateway Officially, an application-to-application conversion program or system. For example, an email gateway would convert between SMTP (Internet) email format to MHS (Novell) email format. The term gateway is also used as a slang term for router. See also *router*.

gender When describing connectors for PCs, connectors are described as male if they have pins or female if they have receptacles designed to accept the pins of a male connector.

genlocking The process of aligning the data rate of a video image with that of a digital device to digitize the image and enter it into computer memory. The machine that performs this function is known as a genlock.

GIF (Graphics Interchange Format) A popular raster graphics file format developed by CompuServe that handles 8-bit color (256 colors) and uses the LZW method to achieve compression ratios of approximately 1.5:1 to 2:1.

giga A multiplier indicating one billion (1,000,000,000) of some unit. Abbreviated as g or G. When used to indicate a number of bytes of memory storage, the multiplier definition changes to 1,073,741,824. One gigabit, for example, equals 1,000,000,000 bits, and one gigabyte equals 1,073,741,824 bytes.

gigabyte (GB) A unit of information storage equal to 1,073,741,824 bytes.

graphics accelerator A video processor or chipset specially designed to speed display and rendering of graphical objects onscreen.

graphics adapter See *video adapter*.

Green Book The standard for Compact Disc-Interactive (CD-I). Philips developed CD-I technology for the consumer market, to be connected to a television instead of a computer monitor. CD-I is not a computer system but a consumer device that made a small splash in the market and disappeared. CD-I disks require special code and are not compatible with standard CD-ROMs. A CD-ROM cannot be played on the CD-I machine, but Red Book audio can be played on CD-I devices.

GUI (Graphical User Interface) A type of program interface that allows users to choose commands and functions by pointing to a graphical icon using either a keyboard or pointing device such as a mouse. Windows and OS/2 are the most popular GUIs available for PC systems.

half duplex Signal flow in both directions but only one way at a time. In microcomputer communications, half duplex may refer to activation of the online local echo, which causes the modem to send a copy of the transmitted data to the screen of the sending computer.

half-height drive A drive unit that is 1.625 inches high, and either 5.75 or 4 inches wide and 4 or 8 inches deep.

halftoning A process that uses dithering to simulate a continuous tone image such as a photograph or shaded drawing using various sizes of dots. Newspapers, magazines, and many books use halftoning. The human eye will merge the dots to give the impression of gray shades.

hard disk A high-capacity disk storage unit characterized by a normally nonremovable rigid substrate medium. The platters in a hard disk normally are constructed of aluminum or glass/ceramic. Also sometimes called a fixed disk.

hard error An error in reading or writing data that is caused by damaged hardware.

hardware Physical components that make up a microcomputer, monitor, printer, and so on.

HDLC (High-Level Data Link Control) A standard protocol developed by the ISO for software applications and communicating devices operating in synchronous environments. Defines operations at the link level of communications—for example, the format of data frames exchanged between modems over a phone line.

head A small electromagnetic device inside a drive that reads, records, and erases data on the media.

head actuator The device that moves read/write heads across a disk drive's platters. Most drives use a stepper-motor or a voice-coil actuator.

head crash A (usually) rare occurrence in which a read/write head strikes a platter surface with sufficient force to damage the magnetic medium.

head parking A procedure in which a disk drive's read/write heads are moved to an unused track so that they will not damage data in the event of a head crash or other failure.

head seek The movement of a drive's read/write heads to a particular track.

heat sink A mass of metal attached to a chip carrier or socket for the purpose of dissipating heat.

helical scan A type of recording technology that has vastly increased the capacity of tape drives. Invented for use in broadcast systems and now used in VCRs. Conventional longitudinal recording records a track of data straight across the width of a single-track tape. Helical scan recording packs more data on the tape by positioning the tape at an angle to the recording heads. The heads spin to record diagonal stripes of information on the tape.

hexadecimal number A number encoded in base-16, such that digits include the letters A-F as well as the numerals 0-9 (for example, 8BF3, which equals 35,827 in base-10).

hidden file A file that is not displayed in DOS directory listings because the file's attribute byte holds a special setting.

high density (HD) An indication of the storage capacity of a floppy drive or disk in which 15 or 18 sectors per track are recorded using MFM encoding.

high sierra format A standard format for placing files and directories on CD-ROMs, proposed by an ad hoc committee of computer vendors, software developers, and CD-ROM system integrators. (Work on the format proposal began at the High Sierra Hotel at Lake Tahoe, Nevada.) A revised version of the format was adopted by the ISO as ISO 9660.

high-definition television (HDTV) Video formats offering greater visual accuracy (or resolution) than current NTSC, PAL, or SECAM broadcast standards. HDTV formats generally range in resolution from 655 to 2,125 scanning lines, having an aspect ratio of 5:3 (or 1.67:1) and a video bandwidth of 30-50MHz (5+ times greater than NTSC standard). Digital HDTV has a bandwidth of 300MHz. HDTV is subjectively comparable to 35mm film.

high-level formatting Formatting performed by the DOS FORMAT program. Among other things, it creates the root directory and FATs.

history file A file created by utility software to keep track of earlier use of the software. Many backup programs, for example, keep history files describing earlier backup sessions.

hit ratio In describing the efficiency of a disk or memory cache, the ratio of the number of times the data is found in the cache to the total number of data requests is the hit ratio. 1:1 would be a perfect hit ratio, meaning that every data request was found in the cache. The closer to 1:1 the ratio is, the more efficient the cache.

HMA (High Memory Area) The first 64KB of extended memory, which is controlled typically by the HIMEM.SYS device driver. Real-mode programs can be loaded into the HMA to conserve conventional memory. Normally, DOS 5.0 and later use the HMA exclusively to reduce the DOS conventional memory footprint.

horizontal scan rate In monitors, the speed at which the electron beam moves laterally across the screen. Normally expressed as a frequency; typical monitors range from 31.5KHz to 90KHz, with the higher frequencies being more desirable.

HPT (High-Pressure Tin) A PLCC socket that promotes high forces between socket contacts and PLCC contacts for a good connection.

HST (High-Speed Technology) The USRobotics proprietary high-speed modem-signaling scheme, developed as an interim protocol until the V.32 protocol could be implemented in a cost-effective manner.

HTML (Hypertext Markup Language) A language used to describe and format plain-text files on the Web. HTML is based on pairs of tags that allow you to mix graphics with text, change the appearance of text, and create hypertext documents with links to other documents.

HTTP (Hypertext Transfer Protocol) The protocol that describes the rules that a browser and server use to communicate over the World Wide Web. HTTP allows a Web browser to request HTML documents from a Web server. See also *hypertext*.

Huffman coding A technique that minimizes the average number of bytes required to represent the characters in a text. Huffman coding works for a given character distribution by assigning short codes to frequently occurring characters and longer codes to infrequently occurring characters.

hypertext A technology that allows for quick and easy navigation between and within large documents. Hypertext links are pointers to other sections within the same document, other documents, or other resources such as FTP sites, images, or sounds.

Hz An abbreviation for hertz, a frequency measurement unit used internationally to indicate one cycle per second.

I/O (input/output) A circuit path that enables independent communications between the processor and external devices.

I/O port (input/output port) Used to communicate to and from devices, such as a printer or disk.

IBMBIO.COM One of the DOS system files required to boot the machine. The first file loaded from disk during the boot. Contains extensions to the ROM BIOS.

IBMDOS.COM One of the DOS system files required to boot the machine. Contains the primary DOS routines. Loaded by IBMBIO.COM, it in turn loads COMMAND.COM.

IC (integrated circuit) A complete electronic circuit contained on a single chip. May consist of only a few or thousands of transistors, capacitors, diodes, or resistors, and generally is classified according to the complexity of the circuitry and the approximate number of circuits on the chip. SSI (small-scale integration) equals 2 to 10 circuits. MSI (medium-scale integration) equals 10 to 100 circuits. LSI (large-scale integration) equals 100 to 1,000 circuits. VLSI (very-large-scale integration) equals 1,000 to 10,000 circuits. ULSI (ultra-large-scale integration) equals more than 10,000 circuits.

IDE (Integrated Drive Electronics) Describes a hard disk with the disk controller circuitry integrated within it. The first IDE drives commonly were called hard cards. Also refers to the ATA interface standard, the standard for attaching hard disk drives to ISA bus IBM-compatible computers. IDE drives typically operate as though they were standard ST-506/412 drives. See also *ATA*.

IEEE 802.3 See *10Base2*.

IEEE 1394 See *FireWire*.

incremental backup A backup of all files that have changed since the last backup.

inductive A property where energy can be transferred from one device to another via the magnetic field generated by the device even though no direct electrical connection is established between the two.

initiator A device attached to the SCSI bus that sends a command to another device (the target) on the SCSI bus. The SCSI host adapter plugged into the system bus is an example of a SCSI initiator.

inkjet printer A type of printer that sprays one or more colors of ink on the paper. Can produce output with quality approaching that of a laser printer at a lower cost.

input Data sent to the computer from the keyboard, telephone, video camera, another computer, paddles, joysticks, and so on.

instruction Program step that tells the computer what to do for a single operation.

integrated circuit See *IC*.

interface A communications device or protocol that enables one device to communicate with another. Matches the output of one device to the input of the other device.

interlacing A method of scanning alternate lines of pixels on a display screen. The odd lines are scanned first from top to bottom and left to right. The electron gun goes back to the top and makes a second pass, scanning the even lines. Interlacing requires two scan passes to construct a single image. Because of this additional scanning, interlaced screens often seem to flicker unless a long persistence phosphor is used in the display.

interleave ratio The number of sectors that pass beneath the read/write heads before the "next" numbered sector arrives. When the interleave ratio is 3:1, for example, a sector is read, two pass by, and then the next is read. A proper interleave ratio, laid down during low-level formatting, enables the disk to transfer information without excessive revolutions due to missed sectors.

interleaved memory The process of alternating access between two banks of memory to overlap accesses, thus speeding up data retrieval.

internal command In DOS, a command contained in COMMAND.COM so that no other file must be loaded to perform the command. DIR and COPY are two examples of internal commands.

internal device A peripheral device that is installed inside the main system case either in an expansion slot or in a drive bay.

internal drive A disk or tape drive mounted inside one of a computer's disk drive bays (or a hard disk card, which is installed in one of the computer's slots).

Internet A computer network that joins many government, university, and private computers together over phone lines. The Internet traces its origins to a network set up in 1969 by the Department of Defense. You can connect to the Internet through many online services such as CompuServe and America Online, or you can connect through local Internet service providers (ISPs). Internet computers use the TCP/IP communications protocol. There are several million hosts on the Internet. A host is a mainframe, mini, or workstation that directly supports the Internet protocol (the IP in TCP/IP).

interpreter A program for a high-level language that translates and executes the program at the

same time. The program statements that are interpreted remain in their original source language, the way the programmer wrote them—that is, the program does not need to be compiled before execution. Interpreted programs run slower than compiled programs and always must be run with the interpreter loaded in memory.

interrupt A suspension of a process, such as the execution of a computer program, caused by an event external to that process and performed in such a way that the process can be resumed. An interrupt can be caused by internal or external conditions such as a signal indicating that a device or program has completed a transfer of data.

interrupt vector A pointer in a table that gives the location of a set of instructions that the computer should execute when a particular interrupt occurs.

IO.SYS One of the DOS system files required to boot the machine. The first file loaded from disk during the boot. Contains extensions to the ROM BIOS.

IPX (internet packet exchange) Novell NetWare's native LAN communications protocol used to move data between server and/or workstation programs running on different network nodes. IPX packets are encapsulated and carried by the packets used in Ethernet and the similar frames used in Token-Ring networks.

IRQ (interrupt request) Physical connections between external hardware devices and the interrupt controllers. When a device such as a floppy controller or a printer needs the attention of the CPU, an IRQ line is used to get the attention of the system to perform a task. On PC and XT IBM-compatible systems, eight IRQ lines are included, numbered IRQ0 through IRQ7. On the AT and PS/2 systems, 16 IRQ lines are numbered IRQ0 through IRQ15. IRQ lines must be used only by a single adapter in the ISA bus systems, but Micro Channel Architecture (MCA) adapters can share interrupts.

ISA (Industry Standard Architecture) The bus architecture that was introduced as an 8-bit bus with the original IBM PC in 1981 and later expanded to 16 bits with the IBM PC/AT in 1984. ISA slots are still found in PC systems today.

ISA bus clock Clock that operates the ISA bus at normally 8.33MHz.

ISDN (Integrated Services Digital Network) An international telecommunications standard that enables a communications channel to carry digital

data simultaneously with voice and video information.

ISO (International Standards Organization) The ISO, based in Paris, develops standards for international and national data communications. The U.S. representative to the ISO is the American National Standards Institute (ANSI). See also *high sierra format*.

ISO 9660 An international standard that defines file systems for CD-ROM discs, independent of the operating system. ISO (International Standards Organization) 9660 has two levels. Level one provides for DOS file system compatibility, while Level two allows filenames of up to 32 characters. See also *high sierra format*.

ITU (International Telecommunications Union) Formerly called CCITT. An international committee organized by the United Nations to set international communications recommendations, which frequently are adopted as standards, and to develop interface, modem, and data network recommendations. The Bell 212A standard for 1,200bps communication in North America, for example, is observed internationally as CCITT V.22. For 2,400bps communication, most U.S. manufacturers observe V.22bis, while V.32, V.32bis, V.34, and V.34+ are standards for 9,600, 14,400, 28,800, and 33,600bps, respectively. The V.90 standard recently was defined for 56Kbps modems.

J-lead J-shaped leads on chip carriers, which can be surface-mounted on a PC board or plugged into a socket that then is mounted on a PC board, usually on .050-inch centers.

Java An object-oriented programming language and environment similar to C or C++. Java was developed by Sun Microsystems and is used to create network-based applications.

Jaz drive A proprietary type of removable media drive with a magnetic hard disk platter in a rigid plastic case. Developed by Iomega and currently available in 1GB and 2GB sizes.

JEDEC (Joint Electronic Devices Engineering Council) A group that establishes standards for the electronics industry.

joystick An input device generally used for game software usually consisting of a central upright stick that controls horizontal and vertical motion and one or more buttons to control discrete events such as firing guns. More complex models may resemble flight yokes and steering wheels or may incorporate tactile feedback.

JPEG (Joint Photographic Experts Group) The international consortium of hardware, software, and publishing interests who, under the auspices of the ISO, has defined a universal standard for digital compression and decompression of still images for use in computer systems. JPEG compresses at about a 20:1 ratio before visible image degradation occurs. A lossy data compression standard that was originally designed for still images but can also compress real-time video (30 frames per second) and animation. Lossy compression permanently discards unnecessary data, resulting in some loss of precision.

jukebox A type of CD-ROM drive that allows several CD-ROM discs to be in the drive at the same time. The drive itself determines which disc is needed by the system and loads the discs into the reading mechanism as needed.

jumper A small, plastic-covered metal clip that slips over two pins protruding from a circuit board. Sometimes also called a shunt. When in place, the jumper connects the pins electrically and closes the circuit. By doing so, it connects the two terminals of a switch, turning it "on."

Kermit A protocol designed for transferring files between microcomputers and mainframes. Developed by Frank DaCruz and Bill Catchings at Columbia University (and named after the talking frog on *The Muppet Show*), Kermit is widely accepted in the academic world.

kernel Operating system core component.

key disk In software copy protection, a distribution floppy disk that must be present in a floppy disk drive for an application program to run.

keyboard The primary input device for most computers consisting of keys with letters of the alphabet, digits, punctuation, and function control keys.

keyboard macro A series of keystrokes automatically input when a single key is pressed.

keylock Physical locking mechanism to prevent internal access to the system unit or peripherals.

KFlex A proprietary standard for 56Kbps modem transmissions developed by Rockwell and implemented in modems from a variety of vendors. Superseded by the official V.90 standard for 56Kbps modems. See also *X2* and *V.90*.

kilo A multiplier indicating one thousand (1,000) of some unit. Abbreviated as k or K. When

used to indicate a number of bytes of memory storage, the multiplier definition changes to 1,024. One kilobit, for example, equals 1,000 bits, and one kilobyte equals 1,024 bytes.

kilobyte (KB) A unit of information storage equal to 1,024 bytes.

L1 cache (level one) A memory cache that is built into the CPU core of 486 and later generation processors. See *cache* and *disk cache*.

L2 cache (level two) A second-level memory cache that is external to the processor core, usually larger and slower than L1. Normally found on the motherboard of 386, 486, and Pentium systems and inside the processor package or module in Pentium Pro and Pentium II systems. Moving the L2 cache onto the processor in the Pentium Pro and Pentium II allows it to run at speeds up to full processor speed rather than motherboard speed. See *SEC*, *cache*, and *disk cache*.

landing zone An unused track on a disk surface on which the read/write heads can land when power is shut off. The place that a parking program or a drive with an autopark mechanism parks the heads.

LAPM (link-access procedure for modems) An error-control protocol incorporated in CCITT Recommendation V.42. Like the MNP and HST protocols, uses cyclic redundancy checking (CRC) and retransmission of corrupted data (ARQ) to ensure data reliability.

laptop computer A computer system smaller than a briefcase but larger than a notebook that usually has a clamshell design in which the keyboard and display are on separate halves of the system, which are hinged together. These systems normally run on battery power.

large mode Another name for the LBA translation scheme used by IDE drives to translate the cylinder, head, and sector specifications of the drive to those usable by an enhanced BIOS.

large scale integration See *IC*.

laser printer A type of printer that is a combination of an electrostatic copying machine and a computer printer. The output data from the computer is converted by an interface into a raster feed, similar to the impulses that a TV picture tube receives. The impulses cause the laser beam to scan a small drum that carries a positive electrical charge. Where the laser hits, the drum is discharged. A toner, which also carries a positive

charge, is then applied to the drum. This toner, a fine black powder, sticks only to the areas of the drum that have been discharged electrically. As it rotates, the drum deposits the toner on a negatively charged sheet of paper. Another roller then heats and bonds the toner to the page.

latency 1) The amount of time required for a disk drive to rotate half of a revolution. Represents the average amount of time to locate a specific sector after the heads have arrived at a specific track. Latency is part of the average access time for a drive. 2) The initial setup time required for a memory transfer in DRAM to select the row and column addresses for the memory to be read/written.

LBA (Logical Block Addressing) A method used with SCSI and IDE drives to translate the cylinder, head, and sector specifications of the drive to those usable by an enhanced BIOS. LBA is used with drives that are larger than 528MB and causes the BIOS to translate the drive's logical parameters to those usable by the system BIOS.

LCC (Leadless Chip Carrier) A type of integrated circuit package that has input and output pads rather than leads on its perimeter.

LCD (Liquid Crystal Display) A display that uses liquid crystal sealed between two pieces of polarized glass. The polarity of the liquid crystal is changed by an electric current to vary the amount of light that can pass through. Because LCD displays do not generate light, they depend on either the reflection of ambient light or backlighting the screen. The best type of LCD, the active-matrix or thin-film transistor (TFT) LCD, offers fast screen updates and true color capability.

LED (Light-Emitting Diode) A semiconductor diode that emits light when a current is passed through it.

LIF (Low Insertion Force) A type of socket that requires only a minimum of force to insert a chip carrier.

light pen A handheld input device with a light-sensitive probe or stylus connected to the computer's graphics adapter board by a cable. Used for writing or sketching onscreen or as a pointing device for making selections. Unlike mice, not widely supported by software applications.

line voltage The AC voltage available at a standard wall outlet, nominally 110–120v.

Lithium Ion A portable system battery type that is longer-lived than either NiCad or NiMH

technologies, cannot be overcharged, and holds a charge well when not in use. Lithium Ion batteries are also lighter weight than the either NiCad or NiMH technologies. Because of these superior features, Li-ion batteries have come to be used in all but the very low end of the portable system market.

local area network (LAN) The connection of two or more computers, usually via a network adapter card or NIC.

local bus A generic term used to describe a bus that is directly attached to a processor and which operates at the processor's speed and data transfer width.

local echo A modem feature that enables the modem to send copies of keyboard commands and transmitted data to the screen. When the modem is in command mode (not online to another system), the local echo normally is invoked through an ATE1 command, which causes the modem to display your typed commands. When the modem is online to another system, the local echo is invoked by an ATFO command, which causes the modem to display the data it transmits to the remote system.

logical drive A drive as named by a DOS drive specifier, such as C: or D:. Under DOS 3.3 or later, a single physical drive can act as several logical drives, each with its own specifier.

logical unit number See *LUN*.

lossless compression A compression technique that preserves all the original information in an image or other data structures.

lossy compression A compression technique that achieves optimal data reduction by discarding redundant and unnecessary information in an image.

lost clusters Clusters that have been marked accidentally as "unavailable" in the FAT even though they don't belong to any file listed in a directory. See also *cluster*.

low-level formatting Formatting that divides tracks into sectors on the platter surfaces. Places sector-identifying information before and after each sector and fills each sector with null data (usually hex F6). Specifies the sector interleave and marks defective tracks by placing invalid checksum figures in each sector on a defective track.

LPT port Line Printer port, a common system abbreviation for a parallel printer port.

LPX A semi-proprietary motherboard design used in many Low Profile or Slimline case systems. Because there is no formal standard, these are typically not interchangeable between vendors and are often difficult to find replacement parts for repair or upgrade.

luminance Measure of brightness usually used in specifying monitor brightness.

LUN (Logical Unit Number) A number given to a device (a logical unit) attached to a SCSI physical unit and not directly to the SCSI bus. Although as many as eight logical units can be attached to a single physical unit, normally a single logical unit is a built-in part of a single physical unit. A SCSI hard disk, for example, has a built-in SCSI bus adapter that is assigned a physical unit number or SCSI ID, and the controller and drive portions of the hard disk are assigned a LUN (usually 0). See also *PUN*.

LZH (Lempel Zev Welch) A compression scheme used in the GIF graphic format.

machine address A hexadecimal (hex) location in memory.

machine language Hexadecimal program code that a computer can understand and execute. It can be output from assembler or compiler.

magnetic domain A tiny segment of a track just large enough to hold one of the magnetic flux reversals that encode data on a disk surface.

magneto-optical recording An erasable optical disk recording technique that uses a laser beam to heat pits on the disk surface to the point at which a magnet can make flux changes.

magneto-resistive A technology originally developed by IBM and commonly used for the read element of a read/write head on a high-density magnetic disk. Based on the principle that the resistance to electricity changes in a material when brought in contact with a magnetic field, in this case, the read element material and the magnetic bit. Such drives use a magnetoresistive read sensor for reading and a standard inductive element for writing. A magnetoresistive read head is more sensitive to magnetic fields than inductive read heads.

mask A photographic map of the circuits for a particular layer of a semiconductor chip used in manufacturing the chip.

master partition boot sector On hard disks, a one-sector record that gives essential information about the disk and tells the starting locations of

the various partitions. Always the first physical sector of the disk.

math coprocessor A processing chip designed to quickly handle complex arithmetic computations involving floating-point arithmetic, offloading these from the main processor. Originally contained in a separate coprocessor chip, starting with the 486 family of processors, Intel has incorporated the math coprocessor into the main processors in what is called the floating-point unit.

MCA (Micro Channel Architecture) Developed by IBM for the PS/2 line of computers and introduced on April 2, 1987. Features include a 16- or 32-bit bus width and multiple master control. By allowing several processors to arbitrate for resources on a single bus, the MCA is optimized for multitasking, multiprocessor systems. Offers switchless configuration of adapters, which eliminates one of the biggest headaches of installing older adapters.

MCGA (MultiColor Graphics Array) A type of PC video display circuit introduced by IBM on April 2, 1987, that supports text and graphics. Text is supported at a maximum resolution of 80×25 characters in 16 colors with a character box of 8×16 pixels. Graphics is supported at a maximum resolution of 320×200 pixels in 256 (from a palette of 262,144) colors or 640×480 pixels in two colors. The MCGA outputs an analog signal with a horizontal scanning frequency of 31.5KHz, and supports analog color or analog monochrome displays.

MCI (Media Control Interface) A device-independent specification for controlling multimedia devices and files. MCI is a part of the multimedia extensions and offers a standard interface set of device control commands. MCI commands are used for audio recording and playback and animation playback. Device types include CD audio, digital audio tape players, scanners, MIDI sequencers, videotape players or recorders, and audio devices that play digitized waveform files.

MDA (Monochrome Display Adapter; also, MGA—Mono Graphics Adapter) A type of PC video display adapter introduced by IBM on August 12, 1981, that supports text only. Text is supported at a maximum resolution of 80×25 characters in four colors with a character box of 9×14 pixels. Colors, in this case, indicate black, white, bright white, and underlined. Graphics modes are not supported. The MDA outputs a digital signal with a horizontal scanning frequency of 18.432KHz, and supports TTL monochrome displays. The IBM MDA also included a parallel printer port.

mean time between failure See *MTBF*.

mean time to repair See *MTTR*.

medium The magnetic coating or plating that covers a disk or tape.

mega A multiplier indicating one million (1,000,000) of some unit. Abbreviated as m or M. When used to indicate a number of bytes of memory storage, the multiplier definition changes to 1,048,576. One megabit, for example, equals 1,000,000 bits, and one megabyte equals 1,048,576 bytes.

megabyte (MB) A unit of information storage equal to 1,048,576 bytes.

memory Any component in a computer system that stores information for future use.

memory caching A service provided by extremely fast memory chips that keeps copies of the most recent memory accesses. When the CPU makes a subsequent access, the value is supplied by the fast memory rather than by relatively slow system memory.

memory-resident program A program that remains in memory after it has been loaded, consuming memory that otherwise might be used by application software.

menu software Utility software that makes a computer easier to use by replacing DOS commands with a series of menu selections.

MFM encoding (Modified Frequency Modulation encoding) A method of encoding data on the surface of a disk. The coding of a bit of data varies by the coding of the preceding bit to preserve clocking information.

MHz An abbreviation for megahertz, a unit of measurement indicating the frequency of one million cycles per second. One hertz (Hz) is equal to one cycle per second. Named after Heinrich R. Hertz, a German physicist who first detected electromagnetic waves in 1883.

MI/MIC (Mode Indicate/Mode Indicate Common) Also called forced or manual originate. Provided for installations in which equipment other than the modem does the dialing. In such installations, the modem operates in dumb mode (no auto-dial capability), yet must go off-hook in originate mode to connect with answering modems.

micro (μ) A prefix indicating one millionth (1/1,000,000 or .000001) of some unit.

micron A unit of measurement equaling one millionth of a meter. Often used in measuring the

size of circuits in chip manufacturing processes. Current state-of-the-art chip fabrication builds chips with 0.25-micron circuits.

microprocessor A solid-state central processing unit much like a computer on a chip. An integrated circuit that accepts coded instructions for execution.

microsecond (μ s) A unit of time equal to one millionth (1/1,000,000 or .000001) of a second.

MIDI (Musical Instrument Digital Interface) An interface and file format standard for connecting a musical instrument to a microcomputer and storing musical instrument data. Multiple musical instruments can be daisy-chained and played simultaneously with the help of the computer and related software. The various operations of the instruments can be captured, saved, edited, and played back. A MIDI file contains note information, timing (how long a note is held), volume, and instrument type for as many as 16 channels. Sequencer programs are used to control MIDI functions such as recording, playback, and editing. MIDI files store only note instructions and not actual sound data.

milli (m) A prefix indicating one thousandth (1/1,000 or .001) of some unit.

millisecond (ms) A unit of time equal to one thousandth (1/1,000 or .001) of a second.

minitower A type of PC system case that is shorter than a full- or mid-sized tower.

MIPS (million instructions per second) Refers to the average number of machine-language instructions a computer can perform or execute in one second. Because different processors can perform different functions in a single instruction, MIPS should be used only as a general measure of performance among different types of computers.

MMX An Intel processor enhancement that adds 57 new instructions designed to improve multimedia performance. MMX also implies a doubling of the internal L1 processor cache.

mnemonic An abbreviated name for something that is used in a manner similar to an acronym. Computer processor instructions are often abbreviated with a mnemonic such as JMP (Jump), CLR (Clear), STO (Store), INIT (Initialize). A mnemonic name for an instruction or an operation makes it easy to remember and convenient to use.

MNP (Microcom Networking Protocol) Asynchronous error-control and data-compression

protocols developed by Microcom, Inc., and now in the public domain. Ensures error-free transmission through error detection (CRC) and retransmission of erred frames. MNP Levels 1–4 cover error control and have been incorporated into CCITT Recommendation V.42. MNP Level 5 includes data compression but is eclipsed in superiority by V.42bis, an international standard that is more efficient. Most high-speed modems will connect with MNP Level 5 if V.42bis is unavailable.

MO (Magneto-Optical) MO drives use both magnetic and optical storage properties. MO technology is erasable and recordable, as opposed to CD-ROM (Read-Only) and WORM (Write-Once) drives. MO uses laser and magnetic field technology to record and erase data.

Mobile module (MMO) A type of processor packing from Intel for mobile computers consisting of a Pentium or Pentium II processor in its TCP form, mounted on a small daughterboard along with the power supply for the processor's unique voltage requirements, the system's L2 cache memory, and the "North Bridge" part of the motherboard chipset.

modem (modulator/demodulator) A device that converts electrical signals from a computer into an audio form transmittable over telephone lines, or vice versa. Modulates, or transforms, digital signals from a computer into the analog form that can be carried successfully on a phone line; also demodulates signals received from the phone line back to digital signals before passing them to the receiving computer.

module An assembly that contains a complete circuit or subcircuit.

Monochrome Display Adapter See *MDA*.

MOS (metal-oxide semiconductor) Refers to the three layers used in forming the gate structure of a field-effect transistor (FET). MOS circuits offer low-power dissipation and enable transistors to be jammed close together before a critical heat problem arises. PMOS, the oldest type of MOS circuit, is a silicon-gate P-channel MOS process that uses currents made up of positive charges. NMOS is a silicon-gate N-channel MOS process that uses currents made up of negative charges and is at least twice as fast as PMOS. CMOS, Complementary MOS, is nearly immune to noise, runs off almost any power supply, and is an extremely low-power circuit technique.

motherboard The main circuit board in the computer. Also called planar, system board, or backplane.

mouse An input device invented by Douglas Engelbart of Stanford Research Center in 1963 and popularized by Xerox in the 1970s. A mouse consists of a roller ball and a tracking mechanism on the underside that relays the mouse's horizontal and vertical position to the computer, allowing precise control of the pointer location on the screen. The top side features two or three buttons and possibly a small wheel used to select or click items on screen.

MPC A trademarked abbreviation for Multimedia Personal Computer. The original MPC specification was developed by Tandy Corporation and Microsoft as the minimum platform capable of running multimedia software. In the summer of 1995, the MPC Marketing Council introduced an upgraded MPC 3 standard. The MPC 1 Specification defines the following minimum standard requirements: a 386SX or 486 CPU; 2MB RAM; 30MB hard disk; VGA video display; 8-bit digital audio subsystem; CD-ROM drive; and systems software compatible with the applications programming interfaces (APIs) of Microsoft Windows version 3.1 or later. The MPC 2 specification defines the following minimum standard requirements: 25MHz 486SX with 4MB RAM; 160MB hard disk; 16-bit sound card; 65,536 color video display; double-speed CD-ROM drive; and systems software compatible with the applications programming interfaces (APIs) of Microsoft Windows version 3.1 or later. The MPC 3 Specification defines the following minimum standard requirements: 75MHz Pentium with 8MB RAM; 540MB hard disk; 16-bit sound card; 65,536 color video display; quad speed CD-ROM drive; OM-1-compliant MPEG-1 video, and systems software compatible with the applications programming interfaces (APIs) of Microsoft Windows version 3.1 and DOS 6.0 or later.

MPEG (Motion Picture Experts Group) A working ISO committee that has defined standards for lossy digital compression and decompression of motion video/audio for use in computer systems. See also *lossy compression*. The MPEG-1 standard delivers decompression data at 1.2 to 1.5MB/sec, allowing CD players to play full-motion color movies at 30 frames per second. MPEG-1 compresses at about a 50:1 ratio before image degradation occurs, but compression ratios as high as 200:1 are attainable.

MPEG-2 extends to the higher data rates (2–15Mbps) needed for signals delivered from remote sources (such as broadcast, cable, or satellite). MPEG-2 is designed to support a range of picture aspect ratios, including 4:3 and 16:9. MPEG compression produces about a 50 percent volume reduction in file size.

MPR The Swedish government standard for maximum video terminal radiation. The current version is called MPR II.

MSDOS.SYS One of the DOS system files required to boot the machine. Contains the primary DOS routines. Loaded by IO.SYS, it in turn loads COMMAND.COM.

MTBF (Mean Time Between Failure) A statistically derived measure of the probable time a device will continue to operate before a hardware failure occurs, usually given in hours. Because no standard technique exists for measuring MTBF, a device from one manufacturer can be significantly more or significantly less reliable than a device with the same MTBF rating from another manufacturer.

MTTR (Mean Time To Repair) A measure of the probable time it will take a technician to service or repair a specific device, usually given in hours.

Multicolor Graphics Array See *MCGA*.

multimedia The integration of sound, graphic images, animation, motion video, and text in one environment on a computer. It is a set of hardware and software technologies that are rapidly changing and enhancing the computing environment.

multisession A term used in CD-ROM recording to describe a recording event. Multisession capabilities allow data recording on the disk at different times in several recording sessions. Kodak's Photo CD is an example of CD-R technology. See also *session* (single or multisession).

multitask To run several programs simultaneously.

multithread To concurrently process more than one message by an application program. OS/2, Windows 95, and Windows NT are examples of multithreaded operating systems. Each program can start two or more threads, which carry out various interrelated tasks with less overhead than two separate programs would require.

multiuser system A system in which several computer terminals share the same central processing unit (CPU).

nano (n) A prefix indicating one billionth (1/1,000,000,000 or .000000001) of some unit.

nanosecond (ns) A unit of time equal to one billionth (1/1,000,000,000 or .000000001) of a second.

NetBEUI (NetBIOS Extended User Interface) A network protocol used primarily by Windows NT and most suitable for small peer-to-peer networks.

NetBIOS (Network Basic Input/Output System) A commonly used network protocol originally developed by IBM and Sytek for PC local area networks. NetBIOS provides session and transport services (Layers 4 and 5 of the OSI model).

network A system in which a number of independent computers are linked to share data and peripherals, such as hard disks and printers.

Network Interface Card (NIC) An adapter that connects a PC to a network.

network layer In the OSI reference model, the layer that switches and routes the packets as necessary to get them to their destinations. This layer is responsible for addressing and delivering message packets.

NiCad The oldest of the three battery technologies used in portable systems, nickel cadmium batteries are rarely used in portable systems today because of their shorter life and their sensitivity to improper charging and discharging. See also *NiMH* and *Lithium Ion*.

NiMH A battery technology used in portable systems. Nickel Metal-Hydride batteries have approximately a 30 percent longer life than NiCads, are less sensitive to the memory effect caused by improper charging and discharging, and do not use the environmentally dangerous substances found in NiCads. Newer Lithium Ion (Li-ion) batteries are far superior.

NLX A new low-profile motherboard form factor standard that is basically an improved version of the semiproprietary LPX design. Designed to accommodate larger processor and memory form factors and incorporate newer bus technologies such as AGP and USB. Besides design improvements, it is fully standardized, which means you should be able to replace one NLX board with another from a different manufacturer, something that was not normally possible with LPX.

noninterlaced monitor A desirable monitor design where the electron beam sweeps the screen in lines from top to bottom, one line after the other, completing the entire screen in one pass.

nonvolatile memory (NVRAM) Random-access memory whose data is retained when power is turned off. Sometimes NVRAM is retained without any power whatsoever, as in EEPROM or flash memory devices. In other cases, the memory is maintained by a small battery. NVRAM that is battery maintained is sometimes also called CMOS memory. CMOS NVRAM is used in IBM-compatible systems to store configuration information. True NVRAM often is used in intelligent modems to store a user-defined default configuration loaded into normal modem RAM at power-up.

nonvolatile RAM disk A RAM disk powered by a battery supply so that it continues to hold its data during a power outage.

North Bridge The Intel term for the main portion of the motherboard chipset that incorporates the interface between the processor and the rest of the motherboard. The North Bridge contains the cache, main memory, and AGP controllers as well as the interface between the high-speed (normally 66MHz or 100MHz) processor bus and the 33MHz PCI (Peripheral Component Interconnect) or 66MHz AGP (Accelerated Graphics Port) buses. See also *chipset* and *South Bridge*.

notebook computer A very small personal computer approximately the size of a notebook.

NTSC The National Television Standards Committee, which governs the standard for television and video playback and recording in the United States. The NTSC was originally organized in 1941 when TV broadcasting first began on a wide scale in black and white, and the format was revised in 1953 for color. The NTSC format has 525 scan lines, a field frequency of 60Hz, a broadcast bandwidth of 4MHz, line frequency of 15.75KHz, frame frequency of 1/30 of a second, and a color subcarrier frequency of 3.58MHz. It is an interlaced signal, which means that it scans every other line each time the screen is refreshed. The signal is generated as a composite of red, green, and blue signals for color and includes an FM frequency for audio and a signal for stereo. See also *PAL* and *SECAM*, which are incompatible systems used in Europe. NTSC is also called composite video.

null modem A serial cable wired so that two data terminal equipment (DTE) devices, such as personal computers, or two data communication equipment (DCE) devices, such as modems or mice, can be connected. Also sometimes called a modem-eliminator or a LapLink cable. To make a null-modem cable with DB-25 connectors, you wire

these pins together: 1-1, 2-3, 3-2, 4-5, 5-4, 6-8-20, 20-8-6, and 7-7.

numeric coprocessor See *math coprocessor*.

NVRAM (Nonvolatile Random Access Memory) Memory that retains data without power. Flash memory and battery-backed CMOS RAM are examples of NVRAM.

object hierarchy Occurs in a graphical program when two or more objects are linked and one object's movement is dependent on the other object. This is known as a parent-child hierarchy. In an example using a human figure, the fingers would be child objects to the hand, which is a child object to the arm, which is a child to the shoulder, and so on. Object hierarchy provides much control for an animator in moving complex figures.

OCR (Optical Character Recognition) An information-processing technology that converts human-readable text into computer data. Usually a scanner is used to read the text on a page, and OCR software converts the images to characters.

ODI (Open Data-link Interface) A device driver standard from Novell that allows you to run multiple protocols on the same network adapter card. ODI adds functionality to Novell's NetWare and network computing environments by supporting multiple protocols and drivers.

OEM (original equipment manufacturer) Any manufacturer that sells its product to a reseller. Usually refers to the original manufacturer of a particular device or component. Most Compaq hard disks, for example, are made by Conner Peripherals, who is considered the OEM.

OLE (object linking and embedding) An enhancement to the original Dynamic Data Exchange (DDE) protocol that allows you to embed or link data created in one application in a document created in another application and subsequently edit that data directly from the final document.

online fallback A feature that enables high-speed error-control modems to monitor line quality and fall back to the next lower speed if line quality degrades. Some modems fall forward as line quality improves.

open architecture A system design in which the specifications are made public to encourage third-party vendors to develop add-on products. The PC is a true open architecture system, but the Macintosh is proprietary.

operating system (OS) A collection of programs for operating the computer. Operating systems perform housekeeping tasks such as input and output between the computer and peripherals and accepting and interpreting information from the keyboard. DOS and OS/2 are examples of popular OSes.

optical disk A disk that encodes data as a series of reflective pits that are read (and sometimes written) by a laser beam.

Orange Book The standard for recordable compact discs (like CD-ROM, but recordable instead of read-only). Recordable compact discs are called CD-R and are becoming popular with the widespread use of multimedia. Part of the Orange Book standard defines rewritable Magneto-Optical disks and another section defines optical write-once, read-many (WORM) disks.

originate mode A state in which the modem transmits at the predefined low frequency of the communications channel and receives at the high frequency. The transmit/receive frequencies are the reverse of the called modem, which is in answer mode. See also *answer mode*.

OS/2 An operating system originally developed through a joint effort by IBM and Microsoft Corporation and later by IBM alone. Originally released in 1987, OS/2 is a 32-bit operating system designed to run on computers using the Intel 386 or later microprocessors. The OS/2 Workplace Shell, an integral part of the system, is a graphical interface similar to Microsoft Windows and the Apple Macintosh system.

OSI (Open Systems Interconnection) Reference Model Developed by the International Organization for Standardization (abbreviated as the ISO) in the 1980s, the OSI model splits a computer's networking stack into seven discrete layers. Each layer provides specific services to the layers above and below it.

output Information processed by the computer, or the act of sending that information to a mass storage device such as a video display, a printer, or a modem.

overclocking The process of running a processor at a speed faster than the officially marked speed by using a higher clock multiplier or faster bus speed. Not recommended or endorsed by processor manufacturers. See also *clock multiplier*.

OverDrive An Intel trademark name for its line of upgrade processors.

overlay Part of a program that is loaded into memory only when it is required.

overrun A situation in which data moves from one device faster than a second device can accept it.

overscanning A technique used in consumer display products that extends the deflection of a CRT's electron beam beyond the physical boundaries of the screen to ensure that images will always fill the display area.

overwrite To write data on top of existing data, thus erasing the existing data.

package A device that includes a chip mounted on a carrier and sealed.

pairing Combining processor instructions for optimal execution on superscalar processors.

PAL 1) Phase Alternating Line system. Invented in 1961, a system of TV broadcasting used in England and other European countries (except France). PAL's image format is 4:3, 625 lines, 50Hz, and 4MHz video bandwidth with a total 8MHz of video channel width. With its 625-line picture delivered at 25 frames per second, PAL provides a better image and an improved color transmission over the NTSC system used in North America. 2) Programmable Array Logic, a type of chip that has logic gates specified by a device programmer.

palmtop computer A computer system smaller than a notebook that is designed so that it can be held in one hand while being operated by the other. Many are now called PDAs or personal digital assistants.

parallel A method of transferring data characters in which the bits travel down parallel electrical paths simultaneously—for example, eight paths for 8-bit characters. Data is stored in computers in parallel form but may be converted to serial form for certain operations.

parity A method of error checking in which an extra bit is sent to the receiving device to indicate whether an even or odd number of binary 1 bits were transmitted. The receiving unit compares the received information with this bit and can obtain a reasonable judgment about the validity of the character. The same type of parity (even or odd) must be used by two communicating computers, or both may omit parity. When parity is used, a parity bit is added to each transmitted character. The bit's value is 0 or 1, to make the total number of 1s in the character even or odd, depending on which type of parity is used.

park program A program that executes a seek to the highest cylinder or just past the highest cylinder of a drive so that the potential of data loss is minimized if the drive is moved.

partition A section of a hard disk devoted to a particular operating system. Most hard disks have only one partition, devoted to DOS. A hard disk can have as many as four partitions, each occupied by a different operating system. DOS v3.3 or later can occupy two of these four partitions.

Pascal A high-level programming language named for the French mathematician Blaise Pascal (1623–1662). Developed in the early 1970s by Niklaus Wirth for teaching programming and designed to support the concepts of structured programming.

passive matrix Another name for dual scan display type LCDs.

PC card (PCMCIA) Personal Computer Memory Card International Association A credit card-sized expansion adapter for notebook and laptop PCs. PC card is the official PCMCIA trademark; however, both PC card and PCMCIA card are used to refer to these standards. PCMCIA cards are removable modules that can hold numerous types of devices including memory, modems, fax/modems, radio transceivers, network adapters, solid state disks, and hard disks.

PCI (Peripheral Component Interconnect) A standard bus specification initially developed by Intel that bypasses the standard ISA I/O bus and uses the system bus to increase the bus clock speed and take full advantage of the CPU's data path.

PCL (Printer Control Language) Developed by Hewlett-Packard in 1984 as a language for the HP LaserJet printer. PCL is now the de facto industry standard for PC printing. PCL defines a standard set of commands, enabling applications to communicate with HP or HP-compatible printers, and is supported by virtually all printer manufacturers.

peer-to-peer A type of network in which any computer can act as both a server (by providing access to its resources to other computers) and a client (by accessing shared resources from other computers).

pel See *pixel*.

Pentium An Intel microprocessor with 32-bit registers, a 64-bit data bus, and a 32-bit address bus. The Pentium has a built-in L1 cache that is segmented into a separate 8KB cache for code and another 8KB cache for data. The Pentium includes

an FPU or math coprocessor. The Pentium is backward compatible with the 486 and can operate in real, protected virtual, and virtual real modes.

Pentium II An Intel sixth-generation processor similar to the Pentium Pro, but with MMX capabilities and SEC cartridge packaging technology.

Pentium Pro An Intel sixth-generation processor with 32-bit registers, a 64-bit data bus, and a 36-bit address bus. The Pentium Pro has the same segmented Level 1 cache as the Pentium but also includes a 256KB, 512KB, or 1MB of L2 cache on separate die inside the processor package. The Pentium Pro includes a FPU or math coprocessor. The Pentium Pro is backward compatible with the Pentium and can operate in real, protected, and virtual real modes.

peripheral Any piece of equipment used in computer systems that is an attachment to the computer. Disk drives, terminals, and printers are all examples of peripherals.

persistence In a monitor, the quality of the phosphor chemical that indicates how long the glow caused by the electrons striking the phosphor will remain onscreen.

PGA 1) Pin Grid Array. A chip package that has a large number of pins on the bottom designed for socket mounting. 2) Professional Graphics Adapter. A limited-production, high-resolution graphics card for XT and AT systems from IBM.

Photo CD A technology developed by Eastman Kodak and Philips that stores photographic images on a CD-R recordable compact disc. Images stored on the Photo CD may have resolutions as high as 2,048×3,072 pixels. Up to 100 true-color images (24-bit color) can be stored on one disc. Photo CD images are created by scanning film and digitally recording the images on compact discs (CDs). The digitized images are indexed (given a 4-digit code), and thumbnails of each image on the disc are shown on the front of the case along with its index number. Multisession capability allows several rolls of film to be added to a single disc on different occasions.

photolithography The photographic process used in electronic chip manufacturing that creates transistors and circuit and signal pathways in semiconductors by depositing different layers of various materials on the chip.

photoresist A chemical used to coat a silicon wafer in the semiconductor manufacturing process that makes the silicon sensitive to light for photolithography.

physical drive A single disk drive. DOS defines logical drives, which are given a specifier, such as C: or D:. A single physical drive may be divided into multiple logical drives. Conversely, special software can span a single logical drive across two physical drives.

physical unit number See *PUN*.

PIF (Program Information File) A file that contains information about a non-Windows application specifying optimum settings for running the program under Windows 3.x. These are called property sheets in Windows 95.

pin 1) The lead on a connector, chip, module or device. 2) Personal Identification Number. A personal password used for identification purposes.

pin compatible Chips having the same pinout functions.

pinout A listing of which pins have what functions on a chip, socket, slot, or other connector.

PIO mode (programmed input/output mode) The standard data transfer modes used by IDE drives that use the processor's registers for data transfer. This is in contrast with DMA modes, which transfer data directly between main memory and the device. The slowest PIO mode is 0 and the fastest current mode is mode 4.

pipeline A path for instructions or data to follow.

pixel A mnemonic term meaning picture element. Any of the tiny elements that form a picture on a video display screen. Also called a pel.

planar board A term equivalent to motherboard, used by IBM in some of its literature.

plated media Hard disk platters plated with a form of thin metal film medium on which data is recorded.

platter A disk contained in a hard disk drive. Most drives have two or more platters, each with data recorded on both sides.

PLCC (Plastic Leaded-Chip Carrier) A popular chip-carrier package with J-leads around the perimeter of the package.

Plug and Play (PnP) A hardware and software specification developed by Intel that allows a PnP system and PnP adapter cards to automatically configure themselves. PnP cards are free from switches and jumpers and are configured via the PnP BIOS in the host system, or via supplied programs for non-PnP systems.

polling A communications technique that determines when a device is ready to send data. The system continually interrogates polled devices in a round-robin sequence. If a device has data to send, it sends back an acknowledgment and the transmission begins. Contrasts with interrupt-driven communications, in which the device generates a signal to interrupt the system when it has data to send.

port Plug or socket that enables an external device such as a printer to be attached to the adapter card in the computer. Also a logical address used by a microprocessor for communications between it and various devices.

port address One of a system of addresses used by the computer to access devices such as disk drives or printer ports. You may need to specify an unused port address when installing any adapter boards in a system unit.

port replicator For mobile computers, a device that plugs into the laptop and provides all of the ports for connecting external devices. The advantage of using a port replicator is that the external devices can be left connected to the replicator and the mobile computer connected to them all at once by connecting to the replicator, rather than connecting to each individual device. A port replicator differs from a docking station in that the latter can provide additional drive bays and expansion slots not found in port replicators.

portable computer A computer system smaller than a transportable system but larger than a laptop system. Most portable systems conform to the lunchbox style popularized by Compaq or the briefcase style popularized by IBM, each with a fold-down (removable) keyboard and built-in display. These systems characteristically run on AC power and not on batteries, include several expansion slots, and can be as powerful as full desktop systems.

POS (Programmable Option Select) The Micro Channel Architecture's POS eliminates switches and jumpers from the system board and adapters by replacing them with programmable registers. Automatic configuration routines store the POS data in a battery-powered CMOS memory for system configuration and operations. The configuration utilities rely on adapter description files (ADF) that contain the setup data for each card.

POST (power on self test) A series of tests run by the computer at power-on. Most computers scan and test many of their circuits and sound a beep

from the internal speaker if this initial test indicates proper system performance.

PostScript A page-description language developed primarily by John Warnock of Adobe Systems for converting and moving data to the laser-printed page. Instead of using the standard method of transmitting graphics or character information to a printer, telling it where to place dots one-by-one on a page, PostScript provides a way for the laser printer to interpret mathematically a full page of shapes and curves.

POTS (Plain Old Telephone Service) Standard analog telephone service.

power management Systems used initially in mobile computers (and now also used in desktop systems) to decrease power consumption by turning off or slowing down devices during periods of inactivity. See also *APM*.

power supply An electrical/electronic circuit that supplies all operating voltage and current to the computer system.

PPGA (Plastic Pin Grid Array) A chip-packaging form factor used by Intel as an alternative to traditional ceramic packaging.

PPP (Point-to-Point Protocol) A protocol that allows a computer to use the Internet with a standard telephone line and a high-speed modem. PPP is a new standard that replaces SLIP. PPP is less common than SLIP; however, it is increasing in popularity.

precompensation A data write modification required by some older drives on the inner cylinders to compensate for the higher density of data on the (smaller) inner cylinders.

primary partition An ordinary, single-volume bootable partition. See also *extended partition*.

processor See *microprocessor*.

processor speed The clock rate at which a microprocessor processes data. A typical Pentium PC, for example, operates at 200MHz (200 million cycles per second).

program A set of instructions or steps telling the computer how to handle a problem or task.

PROM (Programmable Read-Only Memory) A type of memory chip that can be programmed to store information permanently—information that cannot be erased.

proprietary Anything invented by one company and that uses components only available from that one company. Especially applies to cases

in which the inventing company goes to lengths to hide the specifications of the new invention or to prevent other manufacturers from making similar or compatible items. The opposite of standard or open architecture. Computers with nonstandard components that are available only from the original manufacturer, such as Apple Macintosh systems, are known as proprietary.

protected mode A mode available in all Intel and compatible processors except the first-generation 8086 and 8088. In this mode, memory addressing is extended beyond the 1MB limits of the 8088 and real mode, and restricted protection levels can be set to trap software crashes and control the system.

protocol A system of rules and procedures governing communications between two or more devices. Protocols vary, but communicating devices must follow the same protocol to exchange data. The data format, readiness to receive or send, error detection, and error correction are some of the operations that may be defined in protocols.

PS/2 mouse A mouse designed to plug into a dedicated mouse port (a round, 6-pin DIN connector) on the motherboard, rather than plug into a serial port. The name comes from the fact that this port was first introduced on the IBM PS/2 systems.

PUN (Physical Unit Number) A term used to describe a device attached directly to the SCSI bus. Also known as a SCSI ID. As many as eight SCSI devices can be attached to a single SCSI bus, and each must have a unique PUN or ID assigned from 7 to 0. Normally, the SCSI host adapter is assigned the highest-priority ID, which is 7. A bootable hard disk is assigned an ID of 0, and other nonbootable drives are assigned higher priorities.

QAM (Quadrature Amplitude Modulation) A modulation technique used by high-speed modems that combines both phase and amplitude modulation. This technique enables multiple bits to be encoded in a single time interval.

QIC (Quarter-Inch Committee) An industry association that sets hardware and software standards for tape-backup units that use quarter-inch-wide tapes.

QWERTY keyboard The standard typewriter or computer keyboard, with the characters Q, W, E, R, T, and Y on the top row of alpha keys. Because of the haphazard placement of characters, this keyboard can hinder fast typing.

rails Plastic strips attached to the sides of disk drives mounted in IBM ATs and compatibles so that the drives can slide into place. These rails fit into channels in the side of each disk drive bay position.

RAM (random-access memory) All memory accessible at any instant (randomly) by a micro-processor.

RAM disk A “phantom disk drive” in which a section of system memory (RAM) is set aside to hold data, just as though it were a number of disk sectors. To DOS, a RAM disk looks like and functions like any other drive.

RAMBUS Dynamic RAM See *RDRAM*.

random-access file A file in which all data elements (or records) are of equal length and written in the file end to end, without delimiting characters between. Any element (or record) in the file can be found directly by calculating the record’s offset in the file.

random-access memory See *RAM*.

raster A pattern of horizontal scanning lines normally on a computer monitor. An electromagnetic field causes the beam of the monitor’s tube to illuminate the correct dots to produce the required characters.

raster graphics A technique for representing a picture image as a matrix of dots. It is the digital counterpart of the analog method used in TV. There are several raster graphics standards.

RCA jack Also called a phono connector. A plug and socket for a two-wire coaxial cable used to connect audio and video components. The plug is a 1/8-inch thick prong that sticks out 5/16-inch from the middle of a cylinder.

RDRAM (Rambus DRAM) A high-speed dynamic RAM technology developed by Rambus, Inc., which will be supported by Intel’s 1999 and later motherboard chipsets. RDRAM transfers data at 1GB/sec or faster, which is significantly faster than SDRAM and other technologies and which will be capable of keeping up with future-generation high-speed processors. Memory modules with RDRAM chips are called RIMMs (Rambus Inline Memory Modules). Rambus licenses its technology to other semiconductor companies, who manufacture the chips and RIMMs.

read/write head A tiny magnet that reads and writes data on a disk track.

read-only file A file whose attribute setting in the file’s directory entry tells DOS not to allow software to write into or over the file.

read-only memory See *ROM*.

real mode A mode available in all Intel 8086-compatible processors that enables compatibility with the original 8086. In this mode, memory addressing is limited to 1MB.

real time The actual time in which a program or event takes place. In computing, real time refers to an operating mode under which data is received and processed and the results returned so quickly that the process appears instantaneous to the user. The term is also used to describe the process of simultaneous digitization and compression of audio and video information.

reboot The process of restarting a computer and reloading the operating system.

Red Book More commonly known as Compact Disc-Digital Audio (CD-DA), one of four compact disc standards. Red Book got its name from the color of the manual used to describe the CD Audio specifications. The Red Book audio standard requires that digital audio be sampled at a 44.1KHz sample rate using 16 bits for each sample. This is the standard used by audio CDs and many CD-ROMs.

refresh cycle A cycle in which the computer accesses all memory locations stored by DRAM chips so that the information remains intact. DRAM chips must be accessed several times a second, or else the information fades.

refresh rate Another term for the vertical scan frequency of monitors.

register Storage area in memory having a specified storage capacity, such as a bit, a byte, or a computer word, and intended for a special purpose.

Registry The system configuration files used by Windows 9x and Windows NT to store settings about installed hardware and drivers, user preferences, installed software, and other settings required to keep Windows running correctly. Replaces the WIN.INI and SYSTEM.INI files from Windows 3.x.

remote digital loopback A test that checks the phone link and a remote modem’s transmitter and receiver. Data entered from the keyboard is transmitted from the initiating modem, received by the remote modem’s receiver, looped through its transmitter, and returned to the local screen for verification.

remote echo A copy of the data received by the remote system, returned to the sending system, and displayed onscreen. A function of the remote system.

resolution 1) A reference to the size of the pixels used in graphics. In medium-resolution graphics, pixels are large. In high-resolution graphics, pixels are small. 2) A measure of the number of horizontal and vertical pixels that can be displayed by a video adapter and monitor.

RFI (Radio Frequency Interference) A high-frequency signal radiated by improperly shielded conductors, particularly when signal path lengths are comparable to or longer than the signal wavelengths. The FCC now regulates RFI in computer equipment sold in the U.S. under FCC Regulations Part 15, Subpart J.

RGB (Red-Green-Blue) A type of computer color display output signal comprised of separately controllable red, green, and blue signals; as opposed to composite video, in which signals are combined prior to output. RGB monitors typically offer higher resolution than composite monitors.

ribbon cable Flat cable with wires running in parallel, such as those used for internal IDE or SCSI.

RIMM (Rambus Inline Memory Module) A type of memory module made using RDRAM chips. See also *RDRAM*.

RISC (Reduced Instruction Set Computer) Differentiated from CISC, Complex Instruction Set Computer. RISC processors have simple instruction sets requiring only one or a few execution cycles. These simple instructions can be used more effectively than CISC systems with appropriately designed software, resulting in faster operations. See also *CISC*.

RJ-11 The standard 2-wire connector type used for single-line telephone connections.

RJ-14 The standard 4-wire connector type used for two-line telephone connections.

RJ-45 A standard connector type used in networking with twisted-pair cabling. Resembles an RJ-11/14 telephone jack, but RJ-45 is larger with more wires.

RLL (Run-Length Limited) A type of encoding that derives its name from the fact that the techniques used limit the distance (run length) between magnetic flux reversals on the disk platter. Several types of RLL encoding techniques exist, although only two are commonly used. (1,7) RLL

encoding increases storage capacity by about 30 percent over MFM encoding and is most popular in the very highest capacity drives due to a better window margin, while (2,7) RLL encoding increases storage capacity by 50 percent over MFM encoding and is used in the majority of RLL implementations. Most IDE, ESDI, and SCSI hard disks use one of these forms of RLL encoding.

RMA number (Return-Merchandise Authorization number) A number given to you by a vendor when you arrange to return an item for repairs. Used to track the item and the repair.

ROM (read-only memory) A type of memory that has values permanently or semipermanently burned in. These locations are used to hold important programs or data that must be available to the computer when the power initially is turned on.

ROM BIOS (read-only memory basic input/output system) A BIOS encoded in a form of read-only memory for protection. Often applied to important startup programs that must be present in a system for it to operate.

root directory The main directory of any hard or floppy disk. Has a fixed size and location for a particular disk volume and cannot be resized dynamically the way subdirectories can.

router Hardware that routes messages from one local area network to another. It is used to interconnect similar and dissimilar networks and can select the most expedient route based on traffic load, line speeds, costs, and network failures.

routine Set of frequently used instructions. May be considered as a subdivision of a program with two or more instructions that are related functionally.

RS-232 An interface introduced in August 1969 by the Electronic Industries Association. The RS-232 interface standard provides an electrical description for connecting peripheral devices to computers.

S-Video (Y/C) Type of video signal used in the Hi8 and S-VHS videotape formats in which the luminance and chrominance (Y/C) components are kept separate, providing greater control and quality of each image. S-video transmits luminance and color portions separately, thus avoiding the NTSC encoding process and its inevitable loss of picture quality.

scan codes The hexadecimal codes actually sent by the keyboard to the motherboard when a key is pressed.

scan lines The parallel lines across a video screen, along which the scanning spot travels in painting the video information that makes up a monitor picture. NTSC systems use 525 scan lines to a screen; PAL systems use 625.

scanning frequency A monitor measurement that specifies how often the image is refreshed. See also *vertical scan frequency*.

scratch disk A disk that contains no useful information and can be used as a test disk. IBM has a routine on the Advanced Diagnostics disks that creates a specially formatted scratch disk to be used for testing floppy drives.

SCSI (Small Computer System Interface) A standard originally developed by Shugart Associates (then called SASI for Shugart Associates System Interface) and later approved by ANSI in 1986. SCSI-2 was approved in 1994, and SCSI-3 is currently in the development process. Normally uses a 50-pin connector and permits multiple devices (up to eight including the host) to be connected in daisy-chain fashion.

SDLC (Synchronous Data Link Control) A protocol developed by IBM for software applications and communicating devices operation in IBM's Systems Network Architecture (SNA). Defines operations at the link level of communications—for example, the format of data frames exchanged between modems over a phone line.

SDRAM (Synchronous DRAM) RAM that runs at the same speed as the main system bus.

SEC (Single Edge Contact) An Intel processor packaging design in which the processor along with optional L2 cache chips are mounted on a small circuit board (much like an oversized memory SIMM), which may be sealed in a metal and plastic cartridge. The cartridge is then plugged into the motherboard through an edge connector called Slot 1 or Slot 2, which looks very much like an adapter card slot. There are several variations to the SEC Cartridge form factor: The Single Edge Contact Cartridge (SECC) has a cover and a thermal plate; the Single Edge Contact Cartridge 2 (SECC2) has a cover, but no thermal plate; and the Single Edge Processor Package (SEPP) has no cover or thermal plate. In implementations with no thermal plate, the heat sink is directly attached to the processor package or die.

SECAM Sequential Couleur A Mémoire (sequential color with memory), the French color TV system also adopted in Russia. The basis of operation is the sequential recording of primary colors in

alternate lines. The image format is 4:3, 625 lines, 50Hz, and 6MHz video bandwidth with a total 8MHz of video channel width.

SECC (Single Edge Contact Cartridge) See *SEC*.

SECC2 (Single Edge Contact Cartridge 2) See *SEC*.

sector A section of one track defined with identification markings and an identification number. Most sectors hold 512 bytes of data.

security software Utility software that uses a system of passwords and other devices to restrict an individual's access to subdirectories and files.

seek time The amount of time required for a disk drive to move the heads across one third of the total number of cylinders. Represents the average time it takes to move the heads from one cylinder to another randomly selected cylinder. Seek time is a part of the average access time for a drive.

semiconductor A substance, such as germanium or silicon, whose conductivity is poor at low temperatures but is improved by minute additions of certain substances or by the application of heat, light, or voltage. Depending on the temperature and pressure, a semiconductor can control a flow of electricity. Semiconductors are the basis of modern electronic-circuit technology.

SEPP (Single Edge Processor Package) See *SEC*.

sequencer A software program that controls MIDI file messages and keeps track of music timing. Because MIDI files store note instructions instead of actual sounds, a sequencer is needed to play, record, and edit MIDI sounds. Sequencer programs allow for recording and playback of MIDI files by storing the instrument, note pitch (frequency), duration (in real time) that each note is held, and loudness (amplitude) of each musical or sound-effect note.

sequential file A file in which varying-length data elements are recorded end to end, with delimiting characters placed between each element. To find a particular element, you must read the whole file up to that element.

serial The transfer of data characters one bit at a time, sequentially, using a single electrical path.

serial mouse A mouse designed to connect to a computer's serial port.

serial port An I/O connector used to connect to serial devices.

servo The mechanism in a drive that enables the head positioner to adjust continuously so that it is precisely placed above a given cylinder in the drive.

servo data Magnetic markings written on disk platters to guide the read/write heads in drives that use voice-coil actuators.

session (single or multisession) A term used in CD-ROM recording to describe a recording event. In a single session, data is recorded on a CD-ROM and an index is created. If additional space is left on the disc, another session can be used to record additional files along with another index. Some older CD-ROM drives do not expect additional recording sessions and therefore will be unable to read the additional session data on the disc. The advent of Kodak's Photo CD propelled the desire for multisession CD-ROM XA (extended architecture) drives.

settling time The time required for read/write heads to stop vibrating after they have been moved to a new track.

shadow mask A thin screen full of holes that adheres to the inside of a color CRT. The electron beam is aimed through the holes in the mask onto the phosphor dots. See also *aperture grille*.

shadow ROM A copy of a system's slower access ROM BIOS placed in faster access RAM, usually during the startup or boot procedure. This setup enables the system to access BIOS code without the penalty of additional wait states required by the slower ROM chips. Also called shadow RAM.

shell The generic name of any user interface software. COMMAND.COM is the standard shell for DOS. OS/2 comes with three shells: a DOS command shell, an OS/2 command shell, and the OS/2 Presentation Manager, a graphical shell.

shielded twisted-pair (STP) Unshielded twisted-pair (UTP) network cabling with a metal sheath or braid around it to reduce interference, usually used in Token-Ring networks.

shock rating A rating (usually expressed in G force units) of how much shock a disk drive can sustain without damage. Usually two different specifications exist for a drive powered on or off.

signal-to-noise (S/N) ratio The strength of a video or audio signal in relation to interference (noise). The higher the S/N ratio, the better the quality of the signal.

SIMD (Single Instruction Multiple Data)
The term used to describe the MMX and SSE

instructions added to the Intel processors. These instructions can process matrixes consisting of multiple data elements with only a single instruction, allowing for more efficient processing of graphics and sound data.

SIMM (Single Inline Memory Module) An array of memory chips on a small PC board with a single row of I/O contacts.

single-ended An electrical signaling method where a single line is referenced by a ground path common to other signals. In a single-ended bus intended for moderately long distances, there is commonly one ground line between groups of signal lines to provide some resistance to signal crosstalk. Single-ended signals require only one driver or receiver pin per signal, plus one ground pin per group of signals. Single-ended signals are vulnerable to common mode noise and crosstalk but are much less expensive than differential signaling methods.

SIP (Single Inline Package) A DIP-like package with only one row of leads.

skinny dip Twenty-four- and twenty-eight-position DIP devices with .300-inch row-to-row centerlines.

sleep See *suspend*.

SLIP (Serial Line Internet Protocol) An Internet protocol that is used to run the Internet Protocol (IP) over serial lines such as telephone circuits. IP allows a packet to traverse multiple networks on the way to its final destination.

slot A physical connector on a motherboard to hold an expansion card, SIMMs and DIMMs, or a processor card in place and make contact with the electrical connections.

Slot 1 The motherboard connector designed by Intel to accept its SEC cartridge processor design used by the Pentium II.

Slot 2 A motherboard connector for Pentium II Xeon processors intended mainly for fileserver applications. Slot 2 systems support up to four-way symmetric multiprocessing.

SMBIOS A BIOS that incorporates system management functions and reporting compatible with the Desktop Management Interface (DMI).

SMPTE time code An 80-bit standardized edit time code adopted by SMPTE, the Society of Motion Picture and Television Engineers. The SMPTE time code is a standard used to identify individual video frames in the video-editing

process. SMPTE time code controls such functions as play, record, rewind, and forward of video tapes. SMPTE time code displays video in terms of hours, minutes, seconds, and frames for accurate video editing.

snow A flurry of bright dots that can appear anywhere onscreen on a monitor.

socket A receptacle, usually on a motherboard although sometimes also found on expansion cards, that processors or chips can be plugged into.

Socket 1–8 The Intel specifications for eight different sockets to accept various Intel processors in the 486, Pentium, and Pentium Pro families.

SODIMM (Small Outline Dual Inline Memory Module) An industry-standard 144-pin memory module designed for use primarily in laptop and portable computers.

soft error An error in reading or writing data that occurs sporadically, usually because of a transient problem such as a power fluctuation.

software A series of instructions loaded in the computer's memory that instructs the computer in how to accomplish a problem or task.

SO-J (Small Outline J-lead) A small DIP package with J-shaped leads for surface mounting or socketing.

South Bridge The Intel term for the lower-speed component in the chipset that has always been a single individual chip. Also called the PIIX (PCI, ISA, IDE eXcelerator), the South Bridge connects to the 33MHz PCI bus and contains the IDE interface ports and the interface to the 8MHz ISA bus. It also normally contains the USB interface and even the CMOS RAM and real-time clock functions. The South Bridge contains all of the components that make up the ISA bus, including the interrupt and DMA controllers. See also *chipset* and *North Bridge*.

spindle The central post on which a disk drive's platters are mounted.

spindle count In notebook and laptop computers with interchangeable drives, spindle count refers to how many drives can be installed and used at the same time.

SRAM (Static Random Access Memory) A form of high-speed memory. SRAM chips do not require a refresh cycle like DRAM chips and can be made to operate at very high-access speeds. SRAM chips are very expensive because they normally require six transistors per bit. This also makes the chip larger

than conventional DRAM chips. SRAM is volatile, meaning it will lose data with no power.

SSE (Streaming SIMD Extensions) The name given by Intel for the 70 new MMX-type instructions added to the Pentium III processor when it was introduced. See *SIMD* and *MMX*.

ST-506/412 A hard disk interface invented by Seagate Technology and introduced in 1980 with the ST-506 5MB hard drive.

stair-stepping Jagged raster representation of diagonals or curves; corrected by antialiasing.

standby Defines an optional operating state of minimal power reduction with the shortest recovery time.

standby power supply A backup power supply that quickly switches into operation during a power outage.

Standoff In a motherboard and case design, small nonconductive spacers (usually plastic or nylon) used to keep the underside of the motherboard from contacting the metallic case, therefore preventing short circuits of the motherboard.

start/stop bits The signaling bits attached to a character before and after the character is transmitted during asynchronous transmission.

starting cluster The number of the first cluster occupied by a file. Listed in the directory entry of every file.

stepper motor actuator An assembly that moves disk drive read/write heads across platters by a sequence of small partial turns of a stepper motor.

stepping The code used to identify the revision of a processor. New masks are introduced to build each successive stepping, incorporating any changes needed to fix known bugs in prior stepings.

storage Device or medium on or in which data can be entered or held and retrieved at a later time. Synonymous with memory.

streaming In tape backup, a condition in which data is transferred from the hard disk as quickly as the tape drive can record the data so that the drive does not start and stop or waste tape.

string A sequence of characters.

subdirectory A directory listed in another directory. Subdirectories themselves exist as files.

subroutine A segment of a program that can be executed by a single call. Also called program module.

superscalar execution The capability of a processor to execute more than one instruction at a time.

surface mount Chip carriers and sockets designed to mount to the surface of a PC board.

surge protector A device in the power line that feeds the computer and provides protection against voltage spikes and other transients.

suspend Refers to a level of power management in which substantial power reduction is achieved by the display or other components. The components can have a longer recovery time from this state than from the standby state.

SVGA (Super VGA) Refers to a video adapter or monitor capable of 800×600 resolution.

SWEDAC (Swedish Board for Technical Accreditation) Regulatory agency establishing standards such as MPR1 and MPR2, which specify maximum values for both alternating electric fields and magnetic fields and provide monitor manufacturers with guidelines in creating low-emission monitors.

SXGA (Super XGA) Refers to a video adapter or monitor capable of 1280×1024 or greater resolution.

synchronous communication A form of communication in which blocks of data are sent at strictly timed intervals. Because the timing is uniform, no start or stop bits are required. Compare with asynchronous communication. Some mainframes support only synchronous communications unless a synchronous adapter and appropriate software have been installed. See also *asynchronous communication*.

system crash A situation in which the computer freezes up and refuses to proceed without rebooting. Usually caused by faulty software. Unlike a hard disk crash, no permanent physical damage occurs.

system files Files with the system attribute. Normally, the hidden files that are used to boot the operating system. The MS-DOS and Windows 9x system files include IO.SYS and MSDOS.SYS; the IBM DOS system files are IBMBIO.COM and IBMDOS.COM.

System Management Mode (SMM) Circuitry integrated into Intel processors that operates independently to control the processor's power use based on its activity level. It allows the user to specify time intervals after which the CPU will be powered down partially or fully and also supports

the suspend/resume feature that allows for instant power on and power off.

target A device attached to a SCSI bus that receives and processes commands sent from another device (the initiator) on the SCSI bus. A SCSI hard disk is an example of a target.

TCM (Trellis-coded modulation) An error-detection and correction technique employed by high-speed modems to enable higher-speed transmissions that are more resistant to line impairments.

TCO 1) Refers to the Swedish Confederation of Professional Employees, which has set stringent standards for devices that emit radiation. See also *MPR*. 2) Total Cost of Ownership. The cost of using a computer. It includes the cost of the hardware, software, and upgrades as well as the cost of the in-house staff and consultants that provide training and technical support.

TCP (Tape Carrier Package) A method of packaging processors for use in portable systems that reduces the size, the power consumed, and the heat generated by the chip. A processor in the TCP form factor is essentially a raw die encased in an oversized piece of polyamide film. The film is laminated with copper foil that is etched to form the leads that will connect the processor to the motherboard.

TCP/IP (Transmission Control Protocol/Internet Protocol) A set of protocols developed by the U.S. Department of Defense (DoD) to link dissimilar computers across many kinds of networks. This is the primary protocol used by the Internet.

temporary backup A second copy of a work file, usually having the extension BAK. Created by application software so that you easily can return to a previous version of your work.

temporary file A file temporarily (and usually invisibly) created by a program for its own use.

tera A multiplier indicating one trillion (1,000,000,000,000) of some unit. Abbreviated as t or T. When used to indicate a number of bytes of memory storage, the multiplier definition changes to 1,099,511,627,776. One terabit, for example, equals 1,000,000,000,000 bits, and one terabyte equals 1,099,511,627,776 bytes.

terabyte (TB) A unit of information storage equal to 1,099,511,627,776 bytes.

terminal A device whose keyboard and display are used for sending and receiving data over a communications link. Differs from a microcomputer in

that it has no internal processing capabilities. Used to enter data into or retrieve processed data from a system or network.

terminal mode An operational mode required for microcomputers to transmit data. In terminal mode, the computer acts as though it were a standard terminal such as a teletypewriter rather than a data processor. Keyboard entries go directly to the modem, whether the entry is a modem command or data to be transmitted over the phone lines. Received data is output directly to the screen. The more popular communications software products control terminal mode and enable more complex operations, including file transmission and saving received files.

terminator Hardware or circuits that must be attached to or enabled at both ends of an electrical bus. Functions to prevent the reflection or echoing of signals that reach the ends of the bus and to ensure that the correct impedance load is placed on the driver circuits on the bus. Most commonly used with the SCSI bus.

TFT (Thin Film Transistor) The highest quality and brightest LCD color display type. A method for packaging one to four transistors per pixel within a flexible material that is the same size and shape as the LCD display, so that the transistors for each pixel lie directly behind the liquid crystal cells that they control.

thin Ethernet See *10Base2*.

thin-film media Hard disk platters that have a thin film (usually three-millionths of an inch) of medium deposited on the aluminum substrate through a sputtering or plating process.

Thinnest See *10Base2*.

through-hole Chip carriers and sockets equipped with leads that extend through holes in a PC board.

throughput The amount of user data transmitted per second without the overhead of protocol information such as start and stop bits or frame headers and trailers.

TIFF (Tagged Image File Format) A way of storing and exchanging digital image data. Developed by Aldus Corporation, Microsoft Corporation, and major scanner vendors to help link scanned images with the popular desktop publishing applications. Supports three main types of image data: black-and-white data, halftones or dithered data, and grayscale data.

time code A frame-by-frame address code time reference recorded on the spare track of a videotape or inserted in the vertical blanking interval. The time code is an eight-digit number encoding time in hours, minutes, seconds, and video frames.

Token-Ring A type of local area network in which the workstations relay a packet of data called a token in a logical ring configuration. When a station wants to transmit, it takes possession of the token, attaches its data, and then frees the token after the data has made a complete circuit of the electrical ring. Transmits at speeds of 16Mbps. Because of the token-passing scheme, access to the network is controlled, unlike the slower 10BaseX Ethernet system in which collisions of data can occur, which wastes time. The Token-Ring network uses shielded twisted-pair wiring, which is cheaper than the coaxial cable used by 10Base2 and 10Base5 Ethernet and ARCnet.

toner The ultrafine colored plastic powder used in laser printers and photocopiers to produce the image on paper.

tower A personal computer that normally sits on the floor and that is mounted vertically rather than horizontally.

TPI (tracks per inch) Used as a measurement of magnetic track density. Standard 5 1/4-inch 360KB floppy disks have a density of 48 TPI, and the 1.2MB disks have a 96 TPI density. All 3 1/2-inch disks have a 135.4667 TPI density, and hard disks can have densities greater than 3,000 TPI.

track One of the many concentric circles that holds data on a disk surface. Consists of a single line of magnetic flux changes and is divided into some number of 512-byte sectors.

track density Expressed as tracks per inch (TPI); defines how many tracks are recorded in one inch of space measured radially from the center of the disk. Sometimes also called radial density.

track-to-track seek time The time required for read/write heads to move between adjacent tracks.

transport layer In the OSI reference model, when more than one packet is in process at any time, such as when a large file must be split into multiple packets for transmission, this is the layer that controls the sequencing of the message components and regulates inbound traffic flow.

transportable computer A computer system larger than a portable system and similar in size and shape to a portable sewing machine. Most

transportables conform to a design similar to the original Compaq portable, with a built-in CRT display. These systems are characteristically very heavy and run only on AC power. Because of advances primarily in LCD and plasma-display technology, these systems are largely obsolete and have been replaced by portable systems.

troubleshooting The task of determining the cause of a problem.

true-color images Also called 24-bit color images because each pixel is represented by 24 bits of data, allowing for 16.7 million colors. The number of colors possible is based on the number of bits used to represent the color. If 8 bits are used, there are 256 possible color values (2^8). To obtain 16.7 million colors, each of the primary colors (red, green, and blue) is represented by 8 bits per pixel, which allows for 256 possible shades for each of the primary red, green, and blue colors or $256 \times 256 \times 256 = 16.7$ million total colors.

TSR (Terminate-and-Stay-Resident) A program that remains in memory after being loaded. Because they remain in memory, TSR programs can be reactivated by a predefined keystroke sequence or other operation while another program is active. Usually called resident programs.

TTL (Transistor-to-Transistor Logic) Digital signals often are called TTL signals. A TTL display is a monitor that accepts digital input at standardized signal voltage levels.

twisted pair A type of wire in which two small, insulated copper wires are wrapped or twisted around each other to minimize interference from other wires in the cable. Two types of twisted-pair cables are available: unshielded and shielded. Unshielded twisted-pair (UTP) wiring commonly is used in telephone cables and provides little protection against interference. Shielded twisted-pair (STP) wiring is used in some networks or any application in which immunity from electrical interference is more important. Twisted-pair wire is much easier to work with than coaxial cable and is cheaper as well.

typematic The keyboard repeatedly sending the keypress code to the motherboard for a key that is held down. The delay before the code begins to repeat and the speed at which it repeats are user adjustable.

UART (Universal Asynchronous Receiver Transmitter) A chip device that controls the RS-232 serial port in a PC-compatible system.

Originally developed by National Semiconductor, several UART versions are in PC-compatible systems: The 8250B is used in PC- or XT-class systems, and the 16450 and 16550A are used in AT-class systems.

UltraDMA A protocol for transferring data to an ATA interface hard drive. The Ultra DMA/33 protocol transfers data in burst mode at a rate of 33 Mbytes/sec, while the even faster Ultra DMA/66 protocol transfers at 66 Mbytes/sec. Ultra DMA/66 also requires the use of a special 80-conductor cable for signal integrity. This cable is also recommended for Ultra DMA/33 and is backward compatible with standard ATA/IDE cables.

unformatted capacity The total number of bytes of data that can fit on a disk. The formatted capacity is lower because space is lost defining the boundaries between sectors.

uninterruptible power supply (UPS) A device that supplies power to the computer from batteries so that power will not stop, even momentarily, during a power outage. The batteries are recharged constantly from a wall socket.

Universal Asynchronous Receiver Transmitter See *UART*.

UPC (Universal Product Code) A 10-digit computer-readable bar code used in labeling retail products. The code in the form of vertical bars includes a five-digit manufacturer identification number and a five-digit product code number.

update To modify information already contained in a file or program with current information.

Upper Memory Area (UMA) The 384KB of memory between 640KB and 1MB.

URL (uniform resource locator) The primary naming scheme used to identify a particular site or file on the World Wide Web. URLs combine information about the protocol being used, the address of the site where the resource is located, the subdirectory location at the site, and the name of the particular file (or page) in question.

USB (Universal Serial Bus) A 12Mbit/sec (1.5MB/sec) interface over a simple four-wire connection. The bus supports up to 127 devices and uses a tiered star topology built on expansion hubs that can reside in the PC, any USB peripheral, or even standalone hub boxes.

utility Programs that carry out routine procedures to make computer use easier.

UTP (Unshielded Twisted Pair) A type of wire often used indoors to connect telephones or computer devices. Comes with two or four wires twisted inside a flexible plastic sheath or conduit and uses modular plugs and phone jacks.

V.21 An ITU standard for modem communications at 300bps. Modems made in the U.S. or Canada follow the Bell 103 standard but can be set to answer V.21 calls from overseas. The actual transmission rate is 300 baud and employs FSK (frequency shift keying) modulation, which encodes a single bit per baud.

V.22 An ITU standard for modem communications at 1,200bps, with an optional fallback to 600bps. V.22 is partially compatible with the Bell 212A standard observed in the U.S. and Canada. The actual transmission rate is 600 baud, using DPSK (differential-phase shift keying) to encode as much as two bits per baud.

V.22bis An ITU standard for modem communications at 2,400bps. Includes an automatic link-negotiation fallback to 1,200bps and compatibility with Bell 212A/V.22 modems. The actual transmission rate is 600 baud, using QAM (quadrature amplitude modulation) to encode as much as four bits per baud.

V.23 An ITU standard for modem communications at 1,200 or 600bps with a 75bps back channel. Used in the United Kingdom for some videotext systems.

V.25 An ITU standard for modem communications that specifies an answer tone different from the Bell answer tone used in the U.S. and Canada. Most intelligent modems can be set with an ATB0 command so that they use the V.25 2,100Hz tone when answering overseas calls.

V.32 An ITU standard for modem communications at 9,600bps and 4,800bps. V.32 modems fall back to 4,800bps when line quality is impaired and fall forward again to 9,600bps when line quality improves. The actual transmission rate is 2,400 baud using QAM (quadrature amplitude modulation) and optional TCM (trellis-coded modulation) to encode as much as four data bits per baud.

V.32bis An ITU standard that extends the standard V.32 connection range and supports 4,800; 7,200; 9,600; 12,000; and 14,400bps transmission rates. V.32bis modems fall back to the next lower speed when line quality is impaired, fall back further as necessary, and fall forward to the next higher speed when line quality improves. The

actual transmission rate is 2,400 baud using QAM (quadrature amplitude modulation) and TCM (trellis-coded modulation) to encode as much as six data bits per baud.

V.32terbo A proprietary standard proposed by several modem manufacturers that will be cheaper to implement than the standard V.32 fast protocol but that will only support transmission speeds of up to 18,800bps. Because it is not an industry standard, it is not likely to have widespread industry support.

V.34 An ITU standard that extends the standard V.32bis connection range, supporting 28,800bps transmission rates as well as all the functions and rates of V.32bis. This was called V.32fast or V.fast while under development.

V.34+ An ITU standard that extends the standard V.34 connection range, supporting 33,600bps transmission rates as well as all the functions and rates of V.34.

V.42 An ITU standard for modem communications that defines a two-stage process of detection and negotiation for LAPM error control. Also supports MNP error-control protocol, Levels 1–4.

V.42bis An extension of CCITT V.42 that defines a specific data-compression scheme for use with V.42 and MNP error control.

V.90 ITU-T designation for a defining the standard for 56Kbps communication. Supersedes the proprietary X2 schemes from U.S. Robotics (3Com) and K56Flex from Rockwell.

vaccine A type of program used to locate and eradicate virus code from infected programs or systems.

VCPI (Virtual Control Program Interface) A 386 and later processor memory management standard created by Phar Lap software in conjunction with other software developers. VCPI provides an interface between applications using DOS extenders and 386 memory managers.

Vertical Blanking Interval (VBI) The top and bottom lines in the video field, in which frame numbers, picture stops, chapter stops, white flags, closed captions, and more may be encoded. These lines do not appear on the display screen but maintain image stability and enhance image access.

vertical scan frequency The rate at which the electron gun in a monitor scans or refreshes the entire screen each second.

Very Large Scale Integration See *IC*.

VESA (Video Electronics Standards Association) Founded in the late 1980s by NEC Home Electronics and eight other leading video board manufacturers, with the main goal to standardize the electrical, timing, and programming issues surrounding 800×600 resolution video displays, commonly known as Super VGA. VESA has also developed the Video Local Bus (VL-Bus) standard for connecting high-speed adapters directly to the local processor bus.

VFAT (virtual file allocation table) A file system used in Windows for Workgroups and Windows 95/98. VFAT provides 32-bit protected mode access for file manipulation and supports long filenames (LFNs)—up to 255 characters in Windows 95 and later. VFAT compatible with the standard DOS 16-bit FAT. VFAT was called 32-bit file access in Windows for Workgroups. VFAT is not the same as FAT32.

VGA (video graphics array) A type of PC video display circuit (and adapter) first introduced by IBM on April 2, 1987, that supports text and graphics. Text is supported at a maximum resolution of 80×25 characters in 16 colors with a character box of 9×16 pixels. Graphics is supported at a maximum resolution of 320×200 pixels in 256 (from a palette of 262,144) colors or 640×480 pixels in 16 colors. The VGA outputs an analog signal with a horizontal scanning frequency of 31.5KHz and supports analog color or analog monochrome displays. Also refers generically to any adapter or display capable of 640×480 resolution.

VHS (Video Home System) A popular consumer videotape format developed by Matsushita and JVC.

video A system of recording and transmitting primarily visual information by translating moving or still images into electrical signals. The term video properly refers only to the picture, but as a generic term, video usually embraces audio and other signals that are part of a complete program. Video now includes not only broadcast television but many nonbroadcast applications such as corporate communications, marketing, home entertainment, games, teletext, security, and even the visual display units of computer-based technology.

Video 8 or 8mm Video Video format based on the 8mm videotapes popularized by Sony for camcorders.

video adapter An expansion card or chipset built into a motherboard that provides the capability to display text and graphics onscreen. If the

adapter is part of an expansion card, it also includes the physical connector for the monitor cable. If the chipset is on the motherboard, the video connector will be on the motherboard as well.

video graphics array See *VGA*.

video-on-CD or video CD A full-motion digital video format using MPEG video compression and incorporating a variety of VCR-like control capabilities. See also *White Book*.

virtual disk A RAM disk or “phantom disk drive” in which a section of system memory (usually RAM) is set aside to hold data, just as though it were a number of disk sectors. To DOS, a virtual disk looks like and functions like any other “real” drive.

virtual memory A technique by which operating systems (including OS/2) load more programs and data into memory than they can hold. Parts of the programs and data are kept on disk and constantly swapped back and forth into system memory. The applications’ software programs are unaware of this setup and act as though a large amount of memory is available.

virtual real mode A mode available in all Intel 80386-compatible processors. In this mode, memory addressing is limited to 4,096MB, restricted protection levels can be set to trap software crashes and control the system, and individual real-mode compatible sessions can be set up and maintained separately from one another.

virus A type of resident program designed to replicate itself. Usually at some later time when the virus is running, it causes an undesirable action to take place.

VL-Bus (VESA Local Bus) A standard 32-bit expansion slot bus specification used in 486 PCs. Now replaced by PCI bus.

VMM (Virtual Memory Manager) A facility in Windows enhanced mode that manages the task of swapping data in and out of 386 and later processor virtual real-mode memory space for multiple non-Windows applications running in virtual real mode.

voice-coil actuator A device that moves read/write heads across hard disk platters by magnetic interaction between coils of wire and a magnet. Functions somewhat like an audio speaker, from which the name originated.

voltage reduction technology An Intel processor technology that allows a processor to

draw the standard voltage from the motherboard but run the internal processor core at a lower voltage.

voltage regulator A device that smoothes out voltage irregularities in the power fed to the computer.

volume A portion of a disk signified by a single drive specifier. Under DOS v3.3 and later, a single hard disk can be partitioned into several volumes, each with its own logical drive specifier (C:, D:, E:, and so on).

volume label An identifier or name of up to 11 characters that names a disk.

VPN (virtual private network) A private network that is operated within a public network. In order to maintain privacy, VPNs use access control and encryption.

VRAM (video random-access memory) VRAM chips are modified DRAMs on video boards that enable simultaneous access by the host system's processor and the processor on the video board. A large amount of information thus can be transferred quickly between the video board and the system processor. Sometimes also called dual-ported RAM.

VxD (virtual device driver) A special type of Windows driver. VxDs run at the most privileged CPU mode (ring 0) and allow low-level interaction with the hardware and internal Windows functions.

wafer A thin circular piece of silicon from which processors, memory, and other semiconductor electronics are manufactured.

wait states Pause cycles during system operation that require the processor to wait one or more clock cycles until memory can respond to the processor's request. Enables the microprocessor to synchronize with lower-cost, slower memory. A system that runs with "zero wait states" requires none of these cycles because of the use of faster memory or a memory cache system.

warm boot Rebooting a system by means of a software command rather than turning the power off and back on. See also *cold boot*.

wave table synthesis A method of creating synthetic sound on a sound card that uses actual musical instrument sounds sampled and stored on ROM (or RAM) on the sound card. The sound card then modifies this sample to create any note needed for that instrument. Produces much better sound quality than FM synthesis.

Whetstone A benchmark program developed in 1976 and designed to simulate arithmetic-intensive programs used in scientific computing. Remains completely CPU-bound and performs no I/O or system calls. Originally written in ALGOL, although the C and Pascal versions became more popular by the late 1980s. The speed at which a system performs floating-point operations often is measured in units of Whetstones.

White Book A standard specification developed by Philips and JVC in 1993 for storing MPEG standard video on CDs. An extension of the Red Book standard for digital audio, Yellow Book standard for CD-ROM, Green Book standard for CD-I, and Orange Book standard for CD write-once.

Whitney technology A term referring to a magnetic disk design that usually has oxide or thin film media, thin film read/write heads, low floating-height sliders, and low-mass actuator arms that together allow higher-bit densities than the older Winchester technology. Whitney technology was first introduced with the IBM 3370 disk drive, circa 1979.

wide area network (WAN) A LAN that extends beyond the boundaries of a single building.

Winchester drive Any ordinary, nonremovable (or fixed) hard disk drive. The name originates from a particular IBM drive in the 1960s that had 30MB of fixed and 30 of removable storage. This 30-30 drive matched the caliber figure for a popular series of rifles made by Winchester, so the slang term Winchester was applied to any fixed-platter hard disk.

Winchester technology The term Winchester is loosely applied to mean any disk with a fixed or nonremovable recording medium. More precisely, the term applies to a ferrite read/write head and slider design with oxide media that was first employed in the IBM 3340 disk drive, circa 1973. Most drives today actually use Whitney technology.

Wintel The common name given to computers running Microsoft Windows using Intel processors. A slang term for the PC standard.

wire frames The most common technique used to construct a three-dimensional object for animation. A wire frame is given coordinates of length, height, and width. Wire frames are then filled with textures, colors, and movement. Transforming a wire frame into a textured object is called rendering.

word length The number of bits in a data character without parity, start, or stop bits.

World Wide Web (WWW) Also called the Web. A graphical information system based on hypertext that enables a user to easily access documents located on the Internet.

WORM (write-once, read-many or multiple) An optical mass-storage device capable of storing many megabytes of information but that can be written to only once on any given area of the disk. A WORM disk typically holds more than 200MB of data. Because a WORM drive cannot write over an old version of a file, new copies of files are made and stored on other parts of the disk whenever a file is revised. WORM disks are used to store information when a history of older versions must be maintained. Recording on a WORM disk is performed by a laser writer that burns pits in a thin metallic film (usually tellurium) embedded in the disk. This burning process is called ablation. WORM drives are frequently used for archiving data.

write precompensation A modification applied to write data by a controller to alleviate partially the problem of bit shift, which causes adjacent 1s written on magnetic media to read as though they were farther apart. When adjacent 1s are sensed by the controller, precompensation is used to write them closer together on the disk, thus enabling them to be read in the proper bit cell window. Drives with built-in controllers normally handle precompensation automatically. Precompensation normally is required for the inner cylinders of oxide media drives.

write protect Preventing a removable disk from being overwritten by means of covering a notch or repositioning a sliding switch, depending on the type of media.

X2 A proprietary modem standard developed by U.S. Robotics (since acquired by 3Com) that allows modems to receive data at up to 56Kbps. This has been superseded by the V.90 standard. See also *V.90*.

x86 A generic term referring to Intel and Intel-compatible PC microprocessors. Although the Pentium, Pentium Pro, and Pentium II do not have a numeric designation due to trademark law, they are later generations of this family.

XGA (eXtended Graphics Array) A type of PC video display circuit (and adapter) first introduced by IBM on October 30, 1990, that supports text

and graphics. Text is supported at a maximum resolution of 132×60 characters in 16 colors with a character box of 8×6 pixels. Graphics is supported at a maximum resolution of 1024×768 pixels in 256 (from a palette of 262,144) colors or 640×480 pixels in 65,536 colors. The XGA outputs an analog signal with a horizontal scanning frequency of 31.5 or 35.52KHz and supports analog color or analog monochrome displays. Also used to refer generically to any adapter or display capable of 1024×768 resolution.

XMM (eXtended Memory Manager) A driver that controls access to extended memory on 286 and later processor systems. HIMEM.SYS is an example of an XMM that comes with DOS.

Xmodem A file-transfer protocol—with error checking—developed by Ward Christensen in the mid-1970s and placed in the public domain. Designed to transfer files between machines running the CP/M operating system and using 300 or 1,200 bps modems. Until the late 1980s, because of its simplicity and public-domain status, Xmodem remained the most widely used microcomputer file-transfer protocol. In standard Xmodem, the transmitted blocks are 128 bytes. 1KB-Xmodem is an extension to Xmodem that increases the block size to 1,024 bytes. Many newer file-transfer protocols that are much faster and more accurate than Xmodem have been developed, such as Ymodem and Zmodem.

XMS (eXtended Memory Specification) A Microsoft-developed standard that provides a way for real-mode applications to access extended memory in a controlled fashion. The XMS standard is available from Microsoft.

XON/XOFF Standard ASCII control characters used to tell an intelligent device to stop or resume transmitting data. In most systems, typing Ctrl+S sends the XOFF character. Most devices understand Ctrl+Q as XON; others interpret the pressing of any key after Ctrl+S as XON.

Y-connector A Y-shaped splitter cable that divides a source input into two output signals.

Yellow Book The standard used by Compact Disc-Read Only Memory (CD-ROM). Multimedia applications most commonly use the Yellow Book standard, which specifies how digital information is to be stored on the CD-ROM and read by a computer. Extended Architecture (XA) is currently an extension of the Yellow Book that allows for the combination of different data types (audio and

video, for example) onto one track in a CD-ROM. Without XA, a CD-ROM can access only one data type at a time. Many CD-ROM drives are now XA capable.

Yellow Book standards See *CD-ROM*.

Ymodem A file-transfer protocol first released as part of Chuck Forsberg's YAM (yet another modem) program. An extension to Xmodem designed to overcome some of the limitations of the original. Enables information about the transmitted file, such as the filename and length, to be sent along with the file data and increases the size of a block from 128 to 1,024 bytes. Ymodem-batch adds the capability to transmit "batches" or groups of files without operator interruption. YmodemG is a variation that sends the entire file before waiting for an acknowledgment. If the receiving side detects an error in midstream, the transfer is aborted. YmodemG is designed for use with modems that have built-in error-correcting capabilities.

ZIF (Zero Insertion Force) Sockets that require no force for the insertion of a chip carrier. Usually accomplished through movable contacts and uses primarily 486, Pentium, and Pentium Pro processor systems.

ZIP (Zigzag Inline Package) A DIP package that has all leads on one edge in a zigzag pattern and mounts in a vertical plane.

Zip drive An external drive manufactured by Iomega that supports 100MB magnetic media on a 3 1/2-inch removable drive.

Zmodem A file-transfer protocol commissioned by Telenet and placed in the public domain. Like Ymodem, it was designed by Chuck Forsberg and developed as an extension to Xmodem to overcome the inherent latency when using Send/Ack-based protocols such as XModem and YModem. It is a streaming, sliding-window protocol.

zoned recording In hard drives, a way to increase the capacity of a hard drive is to format more sectors on the outer cylinders than on the inner ones. Zoned recording splits the cylinders into groups called zones, with each successive zone having more and more sectors per track as you move out from the inner radius of the disk. All the cylinders in a particular zone have the same number of sectors per track.

zoomed video A direct video bus connection between the PC card adapter and a mobile system's VGA controller, allowing high-speed video displays for videoconferencing applications and MPEG decoders.

List of Acronyms

Symbols

305 RAMAC (Random Access Method of Accounting)
82C836 SCAT (Single Chip AT)

A

AAD (Analog Alignment Diskette)
AGP (Accelerated Graphics Port)
ACPI (Advanced Configuration and Power Interface)
ADC (analog-to-digital converter)
ADPCM (Adaptive Differential Pulse Code Modulation)
ADSL (Asymmetrical DSL)
AGC (Automatic Gain Control)
AGP (Accelerated Graphics Port)
AMD (Advanced Micro Devices)
ANSI (American National Standards Institute)
API (Application Program Interface)
APIC (Advanced Programmable Interrupt Controller)
APM (Advanced Power Management)
ARLL (Advanced Run Length Limited)
ASPI (Advanced SCSI Programming Interface)
ATAPI (AT Attachment Packet Interface)

B

BASIC (Beginners All-Purpose Symbolic Instruction)
BBS (bulletin board system)
BEDO (Burst Extended-Data-Out)
BF (bus frequency)
BGA (Ball Grid Array)
BiCMOS (bipolar complementary metal oxide semiconductor)

BIOS (Basic Input Output System)
bps (bits per second)
BRI (Basic Rate Interface)
BSRAM (Burst Static RAM)
BTB (Branch Target Buffer)

C

CAD (Computer Aided Drafting)
CAM (Common Access Method)
CAM ATA (Common Access Method AT Attachment)
CAV (Constant Angular Velocity)
CBT (Computer-Based Training)
CCITT (Consultative Committee on International Telegraph)
CD-R (CD-Recordable)
CD-ROM (compact disc read-only memory)
CD-RW (CD-Rewritable)
CDSL (Consumer DSL)
CFC (chlorofluorocarbon)
CHS (Cylinder Head Sector)
CISC (Complex Instruction Set Computer)
CLKMUL (Clock Multiplier)
CLV (Constant Linear Velocity)
CMOS (Complementary Metal-Oxide Semiconductor)
CP/M (Control Program for Microprocessors)
CPU (Central Processing Unit)
CRC (cyclical redundancy checking)
CRT (cathode ray tube)
CSA (Canadian Standards Agency)
CSEL (Cable Select)
CSN (Card Select Number)
CSP (CompuCom Speed Protocol)
CSTN (color super-twist nematic)

D

DAC (Digital to Analog Converter)
 DASP (Drive Active/Slave Present)
 db (decibel)
 DBB (dynamic bass boost)
 DBR (DOS Boot Record)
 DDD (Digital Diagnostic Diskette)
 DDM (Digital Multi-Meter)
 DDR (Double Data Rate)
 DDR SDRAM (Double-Data-Rate SDRAM)
 DDWG (Digital Display Work Group)
 DIB (device-independent bitmap)
 DIB (Dual Independent Bus)
 DIME (Direct Memory Execute)
 DIMM (Dual Inline Memory Module)
 DIN (Deutsche Industrie Norm)
 DIP (Dual Inline Package)
 DIS (dynamic impedance stabilization)
 DLT (digital linear tape)
 DMA (Direct Memory Access)
 DMI (Desktop Management Interface)
 DMM (Digital Multi-Meter)
 DOS (Disk Operating System)
 dpi (dots per inch)
 DPMI (DOS protected mode interface)
 DPMS (Display Power-Management Signaling)
 DRAM (Dynamic RAM)
 DRDRAM (Direct RAMBUS DRAM)
 DSL (Digital Subscriber Line)
 DSP (digital signal processor)
 DSTN (double-layer super-twist nematic)
 DTV (Desktop Video)
 DV (digital video)
 DVD (Digital Versatile Disc)
 DVOM (Digital Volt-Ohm Meters)

E

ECC (Error Correcting Code)
 ECHS (Extended Cylinder Head Sector)
 ECM (Electronic Control Module)
 ECP (Enhanced Capabilities Port)
 EDC (Error Detection Code)
 EDO (Extended Data Out)
 EDO RAM (Extended Data Out RAM)
 EEPROM (Electrically Erasable Programmable Read Only Memory)
 EISA (Extended Industry Standard Architecture)
 ELF (extremely low frequency)
 EMI (electromagnetic interference)
 EMS (expanded memory support)
 EPIC (Explicitly Parallel Instruction Computing)
 EPP (Enhanced Parallel Port)
 EPROM (Erasable Programmable Read Only Memory)
 ESD (electrostatic discharge)
 ESDI (Enhanced Small Device Interface)
 ESP (Enhanced Serial Ports)

F

FAP (Fair Access Policy)
 FAT (file allocation table)
 FCC (Federal Communications Commission)
 FDIV (Floating Point Divide)
 FIFO (First In First Out)
 FIT (Failures in Time)
 FM (Frequency Modulation)
 FPM (Fast Page Mode) memory
 FPU (floating point unit)
 FSK (frequency-shift keying)
 FWH (Firmware Hub)

G

GMCH (Graphics Memory Controller Hub)
 GMR (Giant Magneto-Resistive)
 GUI (graphical user interface)

H

HAL (Hardware Abstraction Layer)
 HDA (Head Disk Assembly)
 HEL (Hardware Emulation Layer)
 HERS (hard error rates)
 HFC (hybrid fiber/coax)
 HFC (hydrofluorocarbon)
 HLF (High-Level Formatting)
 HMA (High Memory Area)
 HP-GL/2 (Hewlett Packard Graphics Language)
 HPA (high performance addressing)
 HPFS (High Performance File System)
 HRD (High-Resolution Diagnostic Diskette)
 HST (high-speed protocol)
 HUD (Heads Up Display)
 HVD (High Voltage Differential) signaling
 Hz (Hertz)

I

iCOMP (Intel Comparative Microprocessor Performance)
 ICH (Integrated Controller Hub)
 IC (integrated circuit)
 IDE (Integrated Drive Electronics)
 IDE/ATAPI (Integrated Drive Electronics/ATA Attachment Packet Interface)
 IDT (Integrated Device Technology)
 IEEE (Institute of Electrical and Electronic Engineers)
 IML (Initial Microcode Load)
 IPL (Initial Program Load)
 IPX (Internetwork Packet Exchange)
 IrDA (Infrared Data)
 IRQ (Interrupt Request)
 ISA (Industry Standard Architecture)
 ISDN (Integrated Services Digital Network)
 ISO (International Organization for Standardization)
 ITU (International Telecommunications Union)

J-K-L

JEDEC (Joint Electronic Devices Engineering Council)
 JPEG (Joint Photographic Experts Group)

LAPM (Link Access Procedure for Modems)
 LBA (Logical Block Addressing)
 LCDs (liquid crystal displays)
 Li-ion (lithium-ion)
 LIF (Low Insertion Force)
 LIM (Lotus Intel Microsoft)
 LLF (Low-Level Formatting)
 LVD (Low Voltage Differential)

M

MBR (master boot record)
 MCA (Micro Channel Architecture)
 MCM (Multi-Chip Module)
 MDRAM (Multibank DRAM)
 MFM (Modified Frequency Modulation)
 MFT (Master File Table)
 MIC (Memory Interface Controller)
 MIDI (Musical Instrument Digital Interface)
 MIG (Metal-In-Gap)
 MMO (mobile module)
 MMU (memory management unit)
 MMX (Multi-Media eXtensions)
 MNP (Microcom Networking Protocol)
 MOV (metal-oxide varistor)
 MPC (Multimedia PC)
 MPEG (Motion Pictures Expert Group)
 MPS (Multi-Processor Specification)
 MR (Magneto-Resistive)
 MSCDEX (Microsoft CD-ROM Extensions)
 MSD (Microsoft Diagnostics)
 MTBF (Mean Time Between Failures)
 MTTF (Mean Time To Failure)

N

NCITS (National Committee on Information Technology Standards)
 NC (Network Computer)
 NDP (numeric data processor)
 NEAT (New Enhanced AT)
 NetBEUI (NetBIOS Extended User Interface)
 NFAS (Non-Facility Associated Signaling)
 NiCad (nickel cadmium)
 NiMH (nickel metal-hydride)
 NMI (non-maskable interrupt)
 Non-Volatile RAM (NVRAM)
 NTSC (National Television System Committee)
 NVRAM (Non-Volatile RAM)

O

OEM (original equipment manufacturers)
 OLE (object linking and Embedding)
 OLGA (Organic Land Grid Array)
 OTP (one time programmable) chips

P

PAC (Pin Array Cartridge)
 PARD (Periodic and Random Deviation)
 PCI (Peripheral Component Interconnect)
 PCL (Printer Control Language)
 PCMCIA (Personal Memory Card International Association)
 PDL (Page Description Language)
 PFA (Predictive Failure Analysis)
 PGA (Pin Grid Array)
 PIIX (PCI ISA IDE Xcelerator) chips
 PIO (Programmed I/O)
 PJJ (Printer Job Language)
 PLGA (Plastic Land Grid Array)
 PnP (Plug and Play)
 POST (power on self test)
 PPA (Printing Performance Architecture)
 PPD (PostScript Printer Description)
 PPGA (Plastic Pin Grid Array)
 PPI (Programmable Peripheral Interface)
 PQFP (Plastic Quad Flat Pack)
 PRI (Primary Rate Interface)
 PRML (Partial-Response, Maximum-Likelihood)
 PSK (phase-shift keying)
 PSTN (Public Switched Telephone Network)
 PSU (power supply unit)

Q-R

QAM (quadrature-amplitude modulation)
 QFP (Quad Flat Pack)
 QIC (Quarter Inch Committee)

RAM (Random Access Memory)
 RAMDAC (Digital-to-Analog Converter)
 RDRAM (Rambus Dynamic RAM)
 RET (Resolution Enhancement Technology)
 RFI (radio-frequency interference)
 RIMM (Rambus Inline Memory Module)
 RIP (Raster Image Processing)
 RISC (Reduced Instruction Set Computer)
 RLL (Run Length Limited)
 RNG (Random Number Generator)
 ROM (Read Only Memory)
 ROS (raster output scanner)
 RTC (Real Time Clock)
 RTC/NVRAM (Real-Time Clock/Non-Volatile Memory)

S

S.M.A.R.T. (Self-Monitoring Analysis and Reporting Technology)
 S/T (Subscriber/Termination) Interface
 SAM (SCSI Architectural Model)
 SASI (Shugart Associates System Interface)
 SBIC (SCSI Bus Adapter Chip)
 SCSI (Small Computer System Interface)
 SDL (Shielded Data Link)
 SDRAM (Synchronous Dynamic RAM)
 SEC (Single Edge Cartridge)
 SEC (Single Edge Contact)
 SEC-DED (Single-Bit Error Correction-Double-bit Error Detection)
 SECC2 (Single Edge Contact Cartridge 2)
 SEP (Single Edge Processor)
 SERS (soft error rates)
 SEU (single event upset)
 SGRAM (Synchronous Graphics RAM)
 SIMD (Single Instruction, Multiple Data)
 SIMM (Single Inline Memory Module)
 SIPP (single inline pinned package)
 SIR (Serial Infra Red)
 SMI (System Management Interrupt)
 SMM (System Management Mode)
 SO-DIMM (Small Outline DIMM)
 SO-RIMM (Small Outline RIMM)
 SPD (Serial Presence Detect)
 SPGA (Staggered Pin Grid Array)
 SPP (Standard Parallel Port)
 SPS (Standby Power Supplies)
 SPSYNC (Spindle Synchronization)
 SRAM (Static RAM)
 SSE (Streaming SIMD Extensions)
 S/T (Subscriber/Termination) Interface, 1023
 STP (shielded twisted pair)
 SVGA (Super VGA)

T

TAB (tape automated bonding)
 TCP (tape carrier package)
 TF (Thin Film), 595
 TFT (thin film transistor)
 THD (Total Harmonic Distortion)
 TIP (Trouble in Paradise)
 TLB (Translation Lookaside Buffer)
 TSOP (Thin Small Outline Package)

U

UART (Universal Asynchronous Receiver Transmitter)
 UL (Underwriters Laboratories, Inc.)
 Ultra VGA (UVGA)
 UMA (Upper Memory Area)
 UMB (Upper Memory Block)
 UPI (Universal Peripheral Interface)
 UPS (Uninterruptible Power Supplies)
 USB (Universal Serial Bus)
 UTP (unshielded twisted pair)
 UVGA (Ultra VGA)

V

VESA (Video Electronics Standards Association)
 VESA VIP (VESA Video Interface Port)
 VFAT (virtual file allocation table)
 VGA (Video Graphics Array)
 VID (Voltage Identification)
 VL (Vesa Local) bus
 VLF (very low frequency)
 VLSI (very large scale integration)
 VRAM (Video RAM)
 VRM (Voltage Regulator Module)
 VRT (Voltage Reduction Technology)
 VTOC (Volume Table of Contents)
 VxD (virtual device driver)

W

WORM (write-once, read many)
 WRAM (Window RAM)
 WYSIWYG (what you see is what you get)

X-Y-Z

XGA (eXtended Graphics Array)
 XMS (extended memory specification)
 ZIF (Zero Insertion Force)
 ZV (Zoomed Video)

UPGRADING AND REPAIRING PCs 12TH EDITION

Tired of trying to keep pace with an ever-changing hardware market? Wish you knew more about that new processor or chipset that was just released? Want to know what the world's most renowned PC hardware authority has to say about a new technology?

If you answered "yes" to any of these questions, then point your browser to:

www.upgradingandrepairingpcs.com

Scott and Que have assembled this Web site to help you stay on top of an aggressive hardware market that can be confusing to the newbie and the hardware expert alike. Here, you'll find:

- In-depth analysis of new technologies
- Reviews of key technologies, hardware and industry trends
- Frequently asked questions from readers just like you
- How-to videos with Scott Mueller
- Send your hardware questions directly to Scott

Upgrading and Repairing PCs, 12th Edition

Scott Mueller

Thank you for making *Upgrading and Repairing PCs* by Scott Mueller the best-selling PC hardware repair book ever. Please help us tailor the content of the next edition to best fit your needs by taking a few minutes to answer these questions and returning this self-addressed form.

1. Does your job involve upgrading, repairing, building, or troubleshooting PCs on a regular basis?
 Yes No
2. Why did you buy this book?
 Professional use Personal use
3. Where did you buy this book?
 Bookstore Internet site Warehouse club
 Office club Computer store Consumer Electronics store
 Other _____
4. Which of the following certifications have you earned or do you plan to earn in the next six months?
A+: Have Plan to have
MCSE: Have Plan to have
Network+: Have Plan to have
Cisco (any) Have Plan to have
Other _____ Have Plan to have
5. What types of processors are in the computers that you currently use, upgrade, repair, build, or troubleshoot?
 Pentium 4 Pentium Pro AMD Duron
 Pentium III Pentium/Pentium MMX AMD K6 II
 Pentium II Mobile Pentium AMD K6
 Celeron 486 AMD K5
 Xeon 386 Cyrix 6x86/6x86MX
 Mobile Pentium II AMD Athlon Other _____
6. Which of the following processor architectures do you prefer or recommend in your systems?:
 Slot 1/Slot 2 Socket 370 Socket A
 Super Socket 7 Slot A No Preference
7. What type of bus slots are in use in the systems that you currently use, upgrade, repair, build, or troubleshoot?
 AGP PCI 8-bit ISA
 EISA MCA VL-Bus
 16-bit ISA
8. What types of removable magnetic media drives are currently in use in the systems that you use, upgrade, repair, build, or troubleshoot?
 360KB 5 1/4" floppy 2.88MB floppy Jaz
 1.2MB 5 1/4" floppy 21MB floptical Syquest or other optical
 720KB 3 1/2" floppy LS-120 (120M) Sparq
 1.44MB 3 1/2" floppy Zip Other _____
9. What types of hard drive interfaces are currently in use in the systems that you use, upgrade, repair, build, or troubleshoot?
 ST-506/412 IDE (ATA/33) SCSI
 ESDI IDE (ATA/66)
10. What operating systems are currently in use in the systems that you use, upgrade, repair, build, or troubleshoot?
 MS DOS 5 or earlier Windows Millennium Windows 2000 Server
DOS versions Edition (Me) Linux
 MS DOS 6.x Windows NT 3.5x Mac OS
 Windows 95 Windows NT 4 Other _____
 Windows 98 Windows 2000 Professional

11. What troubleshooting, diagnostic, or configuration software do you use to upgrade, repair, build, or troubleshoot PCs?

- PartitionMagic
- DriveImage
- Disk Manager
- Windows 98 System Information
- Norton Utilities
- Checkit
- MicroScope
- Other _____
- Tools provided with operating system (MSD, Control Panel, System Information)

12. What hardware or tools do you use to upgrade, repair, build, or troubleshoot PCs?

- POST card
- Memory tester
- Logic probe
- Digital multi-meter
- Loopback connectors (wrap plugs)
- Other _____

13. Please list the chapter numbers of the three chapters in this book that you find *most* useful:

Most useful _____ Second most useful _____ Third most useful _____

14. Please list the chapter numbers of the three chapters in this book that you find *least* useful:

Least useful _____ Second least useful _____ Third least useful _____

15. Please list any other upgrading, repairing, troubleshooting, or hardware configuration topics that are not covered in this book that you would like to see covered or that are covered that you would like to see covered in more detail:

16. What other books in the Scott Mueller Library do you plan on purchasing in the next six months?

- Upgrading and Repairing PCs, Linux Edition*
- Upgrading and Repairing Networks, Second Edition*
- Upgrading and Repairing PCs: Technician's Portable Reference*
- Upgrading and Repairing PCs: A+ Certification Study Guide*

License Agreement

By opening this package, you are agreeing to be bound by the following agreement:

You may not copy or redistribute the entire CD-ROM as a whole. Copying and redistribution of individual software programs on the CD-ROM is governed by terms set by individual copyright holders.

The installer and code from the author(s) are copyrighted by the publisher and the author(s). Individual programs and other items on the CD-ROM are copyrighted or are under GNU license by their various authors or other copyright holders.

This software is sold as is without warranty of any kind, either expressed or implied, including but not limited to the implied warranties of merchantability and fitness for a particular purpose. Neither the publisher nor its dealers or distributors assumes any liability for any alleged or actual damages arising from the use of this program. (Some states do not allow for the exclusion of implied warranties, so the exclusion may not apply to you.)

CD Installation Instructions

Installation Instructions for Windows 95, 98, Millennium Edition, NT 4, and 2000

1. Insert the CD-ROM into your CD-ROM drive.
2. From the Windows desktop, double-click the “My Computer” icon.
3. Double-click the icon representing your CD-ROM drive.
4. Double-click the icon titled START.EXE to run the Que Interface application.

Note

If Windows is installed on your computer, and you have the AutoPlay feature enabled, the SETUP.EXE program starts automatically whenever you insert the disc into your CD-ROM drive. Also, if the interface will not run on your machine, you should read the README.TXT in the root directory of the CD to navigate the disc via Explorer.

Note

This CD-ROM uses long and mixed-case filenames requiring the use of a protected-mode CD-ROM driver.

Installation Instructions for Windows 3.1 and Windows NT 3.5.1

1. Insert the CD-ROM into your CD-ROM drive.
2. From the File Manager, choose the drive letter assigned to your CD-ROM drive.
3. Open the README.TXT file to view the contents of the CD-ROM.

MS-DOS and Other OSes

Look in the individual directories for software and associated documentation. A README file in standard text format is available in the root directory of the CD-ROM for program descriptions.
