31.

$y = \ln x$ is reflected across the y -axis.

32.

The y -values of $y = \ln x$ are multiplied by $\frac{1}{2}$,

since $\ln \sqrt{x} = \frac{1}{2} \ln x$.

Since $f(-1) = 2, f^{-1}(2) = -1.$

6. $f(x)$ is one-to-one, so it has an inverse. Since

$f\left(\frac{1}{2}\right) = 2, f^{-1}(2) = \frac{1}{2}.$

7. $f'(x) = -5x^4 - 3x^2 = -(5x^4 + 3x^2) < 0$ for all $x \neq 0$. $f(x)$ is strictly decreasing at $x = 0$ because $f(x) > 0$ for $x < 0$ and $f(x) < 0$ for $x > 0$. Therefore $f(x)$ is strictly decreasing for x and so it has an inverse.

8. $f'(x) = 7x^6 + 15x^2 > 0$ for all $x \neq 0$. $f(x)$ is strictly increasing at $x = 0$ because $f(x) > 0$ for $x > 0$ and $f(x) < 0$ for $x < 0$. Therefore $f(x)$ is strictly increasing for all x and so it has an inverse.

9. $f'(\theta) = -\sin \theta < 0$ for $0 < \theta < \pi$. $f(\theta)$ is decreasing at $\theta = 0$ because $f(0) = 1$ and $f(\theta) < 1$ for $0 < \theta < \pi$. $f(\theta)$ is decreasing at $\theta = \pi$ because $f(\pi) = -1$ and $f(\theta) > -1$ for $0 < \theta < \pi$. Therefore $f(\theta)$ is strictly decreasing on $0 \leq \theta \leq \pi$ and so it has an inverse.

10. $f'(x) = -\csc^2 x < 0$ for $0 < x < \frac{\pi}{2}$. $f(x)$ is decreasing on $0 < x < \frac{\pi}{2}$ and so it has an inverse.

11. $f'(z) = 2(z-1) > 0$ for $z > 1$. $f(z)$ is increasing at $z = 1$ because $f(1) = 0$ and $f(z) > 0$ for $z > 1$. Therefore, $f(z)$ is strictly increasing on $z \geq 1$ and so it has an inverse.

12. $f'(x) = 2x + 1 > 0$ for $x \geq 2$. $f(x)$ is strictly increasing on $x \geq 2$ and so it has an inverse.

13. $f'(x) = \sqrt{x^4 + x^2 + 10} > 0$ for all real x . $f(x)$ is strictly increasing and so it has an inverse.

14. $f(r) = \int_r^1 \cos^4 t dt = -\int_1^r \cos^4 t dt$
 $f'(r) = -\cos^4 r < 0$ for all $r \neq k\pi + \frac{\pi}{2}$, k any integer.
 $f(r)$ is decreasing at $r = k\pi + \frac{\pi}{2}$ since $f'(r) < 0$ on the deleted neighborhood $\left(k\pi + \frac{\pi}{2} - \varepsilon, k\pi + \frac{\pi}{2} + \varepsilon\right)$. Therefore, $f(r)$ is strictly decreasing for all r and so it has an inverse.

43. f has an inverse because it is monotonic (increasing):

$$f'(x) = \sqrt{1+\cos^2 x} > 0$$

$$a. (f^{-1})(A) = \frac{f\left(\frac{2}{\pi}\right)}{1} = \frac{\sqrt{1+\cos^2\left(\frac{2}{\pi}\right)}}{1} = 1$$

$$b. (f^{-1})(B) = \frac{f\left(\frac{6}{5\pi}\right)}{1} = \frac{\sqrt{1+\cos^2\left(\frac{6}{5\pi}\right)}}{1} = \frac{\sqrt{2}}{1}$$

$$= \frac{\sqrt{2}}{2}$$

$$c. (f^{-1})(0) = \frac{f(0)}{1} = \frac{\sqrt{1+\cos^2(0)}}{1} = \frac{\sqrt{2}}{1}$$

$$44. a. y = \frac{ax+d}{cx+d}$$

$$cxy + dy = ax + b$$

$$cy - a)x = b - dy$$

$$x = \frac{b-dy}{cy-a} = -\frac{dy-b}{cy-a}$$

$$f^{-1}(y) = -\frac{dy-b}{cy-a}$$

$$f^{-1}(x) = -\frac{dx-b}{cx-a}$$

b. If $bc - ad = 0$, then $f(x)$ is either a constant function or undefined.

c. If $f = f^{-1}$, then for all x in the domain we have:

$$\frac{ax+b}{cx+d} + \frac{dx-b}{cx-a} = 0$$

$$(ax+b)(cx-a) + (dx-b)(cx+d) = 0$$

$$acx^2 + (bc - a^2)x - ab + dcx^2$$

$$+(d^2 - bc)x - bd = 0$$

$$(ac + dc)x^2 + (d^2 - a^2)x + (-ab - bd) = 0$$

Setting the coefficients equal to 0 gives three requirements:

(1) $a = -d$ or $c = 0$

(2) $a = \pm d$

(3) $a = -d$ or $b = 0$

If $a = d$, then $f = f^{-1}$ requires $b = 0$ and

$c = 0$, so $f(x) = \frac{ax}{d} = x$. If $a = -d$, there are

no requirements on b and c (other than

$bc - ad \neq 0$). Therefore, $f = f^{-1}$ if $a = -d$ or if f is the identity function.

45.

$$\int_0^1 f^{-1}(y) dy = (\text{Area of region B})$$

$$= 1 - (\text{Area of region A})$$

$$= 1 - \int_0^1 f(x) dx = 1 - \frac{2}{5} = \frac{3}{5}$$

46. $\int_0^a f(x) dx$ = the area bounded by $y = f(x)$, $y = 0$, and $x = a$ [the area under the curve].

$\int_0^b f^{-1}(y) dy$ = the area bounded by $x = f^{-1}(y)$, $x = 0$, and $y = b$.

ab = the area of the rectangle bounded by $x = 0$, $x = a$, $y = 0$, and $y = b$.

Case 1: $b > f(a)$

The area above the curve is greater than the area of the part of the rectangle above the curve, so the total area represented by the sum of the two integrals is greater than the area ab of the rectangle.

Case 2: $b = f(a)$

The area represented by the sum of the two integrals = the area ab of the rectangle.

Case 3: $b < f(a)$

The area below the curve is greater than the area of the part of the rectangle which is below the curve, so the total area represented by the sum of the two integrals is greater than the area ab of the rectangle.

$ab \leq \int_0^a f(x) dx + \int_0^b f^{-1}(y) dy$ with equality holding when $b = f(a)$.

47. Given $p > 1$, $q > 1$, $\frac{1}{p} + \frac{1}{q} = 1$, and $f(x) = x^{p-1}$,

solving $\frac{1}{p} + \frac{1}{q} = 1$ for p gives $p = \frac{q}{q-1}$, so

$$\frac{1}{p-1} = \frac{1}{\frac{q}{q-1} - 1} = \frac{1}{\left[\frac{q-(q-1)}{q-1}\right]} = \frac{q-1}{1} = q-1.$$

Thus, if $y = x^{p-1}$ then $x = y^{\frac{1}{p-1}} = y^{q-1}$, so $f^{-1}(y) = y^{q-1}$.

By Problem 44, since $f(x) = x^{p-1}$ is strictly

increasing for $p > 1$, $ab \leq \int_0^a x^{p-1} dx + \int_0^b y^{q-1} dy$

$$ab \leq \left[\frac{x^p}{p} \right]_0^a + \left[\frac{y^q}{q} \right]_0^b$$

$$ab \leq \frac{a^p}{p} + \frac{b^q}{q}$$

23. Let $u = x^2$ so $du = 2x dx$.

$$\int x \cdot 2^{x^2} dx = \frac{1}{2} \int 2^u du = \frac{1}{2} \cdot \frac{2^u}{\ln 2} + C$$

$$= \frac{2^{x^2}}{2 \ln 2} + C = \frac{2^{x^2-1}}{\ln 2} + C$$

24. Let $u = 5x - 1$, so $du = 5 dx$.

$$= \frac{10^{5x-1}}{5 \ln 10} + C$$

25. Let $u = \sqrt{x}$, so $du = \frac{1}{2\sqrt{x}} dx$.

$$\int_1^4 \frac{5\sqrt{x}}{\sqrt{x}} dx = 2 \left[\frac{5\sqrt{x}}{\ln 5} \right]_1^4 = 2 \left(\frac{25}{\ln 5} - \frac{5}{\ln 5} \right)$$

26. $\int_0^1 (10^{3x} + 10^{-3x}) dx = \int_0^1 10^{3x} dx + \int_0^1 10^{-3x} dx$

Let $u = 3x$, so $du = 3 dx$.

$$\int 10^{3x} dx = \frac{1}{3} \int 10^u du = \frac{1}{3} \cdot \frac{10^u}{\ln 10} + C$$

$$= \frac{10^{3x}}{3 \ln 10} + C$$

Now let $u = -3x$, so $du = -3 dx$.

$$\int 10^{-3x} dx = -\frac{1}{3} \int 10^u du = -\frac{1}{3} \cdot \frac{10^u}{\ln 10} + C$$

$$= -\frac{10^{-3x}}{3 \ln 10} + C$$

Thus, $\int_0^1 (10^{3x} + 10^{-3x}) dx = \left[\frac{10^{3x} - 10^{-3x}}{3 \ln 10} \right]_0^1$

 Evaluating this expression for $M = 7$ and $M = 8$ gives $E \approx 5.017 \times 10^8$ kW-h and $E \approx 1.560 \times 10^{10}$ kW-h, respectively.

 Frequency of $\bar{C} = 440(2^{1/12})^3 = 440\sqrt[4]{2} \approx 523.25$

40. Assume $\log_2 3 = \frac{p}{q}$ where p and q are integers, $q \neq 0$. Then $2^{p/q} = 3$ or $2^p = 3^q$. But $2^p = 2 \cdot 2 \dots 2$ (p times) and has only powers of 2 as factors and $3^q = 3 \cdot 3 \dots 3$ (q times) and has only powers of 3 as factors. $2^p = 3^q$ only for $p = q = 0$ which contradicts our assumption, so $\log_2 3$ cannot be rational.

41. If $y = A \cdot b^x$, then $\ln y = \ln A + x \ln b$, so the $\ln y$ vs. x plot will be linear. If $y = C \cdot x^d$, then $\ln y = \ln C + d \ln x$, so the $\ln y$ vs. $\ln x$ plot will be linear.

 RIGHT:

 $y' = e^{g(x) \ln f(x)} \frac{d}{dx} [g(x) \ln f(x)]$
 $= f(x)^{g(x)} \left[g'(x) \ln f(x) + g(x) \frac{1}{f(x)} f'(x) \right]$

 Note that RIGHT = WRONG 2 + WRONG 1.

43. $f(x) = (x^x)^x = x^{(x^2)} \neq x^{(x^x)} = g(x)$
 $f(x) = x^{(x^2)} = e^{x^2 \ln x}$
 $f'(x) = e^{x^2 \ln x} \frac{d}{dx} (x^2 \ln x) = e^{x^2 \ln x} \left(2x \ln x + x^2 \cdot \frac{1}{x} \right)$
 $= x^{(x^2)} (2x \ln x + x)$
 $g(x) = x^{(x^x)} = e^{x^x \ln x}$
 Using the result from Example 5
 $\left(\frac{d}{dx} x^x = x^x (1 + \ln x) \right)$:
 $g'(x) = e^{x^x \ln x} \frac{d}{dx} (x^x \ln x)$

&= x^{x^x + x} \left[\ln x + (\ln x)^2 + \frac{1}{x} \right]
\end{aligned}$$

44. $f(x) = \frac{a^x - 1}{a^x + 1}$

$$f'(x) = \frac{(a^x + 1)a^x \ln a - (a^x - 1)a^x \ln a}{(a^x + 1)^2} = \frac{2a^x \ln a}{(a^x + 1)^2}$$

Since a is positive, a^x is always positive. $(a^x + 1)^2$ is also always positive, thus $f'(x) > 0$ if $\ln a > 0$ and $f'(x) < 0$ if $\ln a < 0$. $f(x)$ is either always increasing or always decreasing, depending on a , so $f(x)$ has an inverse.

$$y = \frac{a^x - 1}{a^x + 1}$$

$$y(a^x + 1) = a^x - 1$$

$$a^x(y - 1) = -1 - y$$

$$a^x = \frac{1 + y}{1 - y}$$

$$x \ln a = \ln \frac{1 + y}{1 - y}$$

$$x = \frac{\ln \frac{1 + y}{1 - y}}{\ln a} = \log_a \frac{1 + y}{1 - y}$$

$$f^{-1}(y) = \log_a \frac{1 + y}{1 - y}$$

$$f^{-1}(x) = \log_a \frac{1 + x}{1 - x}$$

45. a. Let $g(x) = \ln f(x) = \ln \left(\frac{x^a}{a^x} \right) = a \ln x - x \ln a$.

$$g'(x) = \left(\frac{a}{x} \right) - \ln a$$

$$g'(x) < 0 \text{ when } x > \frac{a}{\ln a}, \text{ so as } x \rightarrow \infty \text{ } g(x)$$

is decreasing. $g''(x) = -\frac{a}{x^2}$, so $g(x)$ is

concave down. Thus, $\lim_{x \rightarrow \infty} g(x) = -\infty$, so

$$\lim_{x \rightarrow \infty} f(x) = \lim_{x \rightarrow \infty} e^{g(x)} = 0.$$

b. Again let $g(x) = \ln f(x) = a \ln x - x \ln a$. Since $y = \ln x$ is an increasing function, $f(x)$ is maximized when $g(x)$ is maximized.

$$g'(x) = \left(\frac{a}{x} \right) - \ln a, \text{ so } g'(x) > 0 \text{ on } \left(0, \frac{a}{\ln a} \right)$$

$$\text{and } g'(x) < 0 \text{ on } \left(\frac{a}{\ln a}, \infty \right).$$

Therefore, $g(x)$ (and hence $f(x)$) is

maximized at $x_0 = \frac{a}{\ln a}$.

c. Note that $x^a = a^x$ is equivalent to $g(x) = 0$.

By part b., $g(x)$ is maximized at $x_0 = \frac{a}{\ln a}$.

If $a = e$, then

$$g(x_0) = g\left(\frac{e}{\ln e}\right) = g(e) = e \ln e - e \ln e = 0.$$

Since $g(x) < g(x_0) = 0$ for all $x \neq x_0$, the equation $g(x) = 0$ (and hence $x^a = a^x$) has just one positive solution. If $a \neq e$, then

$$\begin{aligned}
g(x_0) &= g\left(\frac{a}{\ln a}\right) = a \ln\left(\frac{a}{\ln a}\right) - \frac{a}{\ln a} (\ln a) \\
&= a \left[\ln\left(\frac{a}{\ln a}\right) - 1 \right].
\end{aligned}$$

Now $\frac{a}{\ln a} > e$ (justified below), so

$$g(x_0) = a \left[\ln \frac{a}{\ln a} - 1 \right] > a(\ln e - 1) = 0. \text{ Since}$$

$g'(x) > 0$ on $(0, x_0)$, $g(x_0) > 0$, and

$\lim_{x \rightarrow 0} g(x) = -\infty$, $g(x) = 0$ has exactly one

solution on $(0, x_0)$.

Since $g'(x) < 0$ on (x_0, ∞) ,

$g(x_0) > 0$, and $\lim_{x \rightarrow \infty} g(x) = -\infty$, $g(x) = 0$ has

exactly one solution on (x_0, ∞) . Therefore,

the equation $g(x) = 0$ (and hence $x^a = a^x$) has exactly two positive solutions.

To show that $\frac{a}{\ln a} > e$ when $a \neq e$:

Consider the function $h(x) = \frac{x}{\ln x}$, for $x > 1$.

$$h'(x) = \frac{\ln(x)(1) - x\left(\frac{1}{x}\right)}{(\ln x)^2} = \frac{\ln x - 1}{(\ln x)^2}$$

Note that $h'(x) < 0$ on $(1, e)$ and $h'(x) > 0$ on (e, ∞) , so $h(x)$ has its minimum at (e, e) .

Therefore $\frac{x}{\ln x} > e$ for all $x \neq e, x > 1$.

- d. For the case $a = e$, part c. shows that $g(x) = e \ln x - x \ln e < 0$ for $x \neq e$. Therefore, when $x \neq e$, $\ln x^e < \ln e^x$, which implies $x^e < e^x$. In particular, $\pi^e < e^\pi$.

46. a. $f_u(x) = x^u e^{-x}$
 $f'_u(x) = ux^{u-1}e^{-x} - x^u e^{-x} = (u-x)x^{u-1}e^{-x}$
 Since $f'_u(x) > 0$ on $(0, u)$ and $f'_u(x) < 0$ on (u, ∞) , $f_u(x)$ attains its maximum at $x_0 = u$.

b. $f_u(u) > f_u(u+1)$ means
 $u^u e^{-u} > (u+1)^u e^{-(u+1)}$.

Multiplying by $\frac{e^{u+1}}{u^u}$ gives $e > \left(\frac{u+1}{u}\right)^u$.

$f_{u+1}(u+1) > f_{u+1}(u)$ means
 $(u+1)^{u+1} e^{-(u+1)} > u^{u+1} e^{-u}$.

Multiplying by $\frac{e^{u+1}}{u^{u+1}}$ gives $\left(\frac{u+1}{u}\right)^{u+1} > e$.

Combining the two inequalities,

$$\left(\frac{u+1}{u}\right)^u < e < \left(\frac{u+1}{u}\right)^{u+1}.$$

c. From part b., $e < \left(\frac{u+1}{u}\right)^{u+1}$.

Multiplying by $\frac{u}{u+1}$ gives $\frac{u}{u+1} e < \left(\frac{u+1}{u}\right)^u$.

We showed $\left(\frac{u+1}{u}\right)^u < e$ in part b., so

$$\frac{u}{u+1} e < \left(\frac{u+1}{u}\right)^u < e.$$

Since $\lim_{u \rightarrow \infty} \frac{u}{u+1} e = e$, this implies that

$$\lim_{u \rightarrow \infty} \left(\frac{u+1}{u}\right)^u = e, \text{ i.e., } \lim_{u \rightarrow \infty} \left(1 + \frac{1}{u}\right)^u = e.$$

Let $g(x) = x \ln x$.

Using L'Hôpital's Rule,

$$\begin{aligned} \lim_{x \rightarrow 0^+} g(x) &= \lim_{x \rightarrow 0^+} \frac{\ln x}{\frac{1}{x}} \\ &= \lim_{x \rightarrow 0^+} \frac{\frac{1}{x}}{-\frac{1}{x^2}} = \lim_{x \rightarrow 0^+} (-x) = 0 \end{aligned}$$

Therefore, $\lim_{x \rightarrow 0^+} x^x = e^0 = 1$.

$g'(x) = \ln x - 1$

Since $g'(x) < 0$ on $(0, e)$ and $g'(x) > 0$ on (e, ∞) , $g(x)$ has its minimum at (e, e) . Therefore, $f(x)$ has its minimum at (e, e^e) .

$$x(t) = 50e^{-t/50} \text{ satisfies } t = 0, x = 50.$$

$$\frac{dy}{dt} = 2\left(\frac{50e^{-t/50}}{100}\right) - 2\left(\frac{y}{200}\right)$$

$$y' + \left(\frac{1}{100}\right)y = e^{-t/50}$$

Integrating factor is $e^{t/100}$.

$$D[ye^{t/100}] = e^{-t/100}$$

$$y(t) = e^{-t/100}(C - 100e^{-t/100})$$

$$y(t) = e^{-t/100}(250 - 100e^{-t/100}) \text{ satisfies } t = 0, y = 150.$$

23. Let y be the number of gallons of pure alcohol in the tank at time t .

a. $y' = \frac{dy}{dt} = 5(0.25) - \left(\frac{5}{100}\right)y = 1.25 - 0.05y$

Integrating factor is $e^{0.05t}$.

$$y(t) = 25 + Ce^{-0.05t}; y = 100, t = 0, C = 75$$

$$y(t) = 25 + 75e^{-0.05t}; y = 50, t = T,$$

$$T = 20(\ln 3) \approx 21.97 \text{ min}$$

b. Let A be the number of gallons of pure alcohol drained away.

$$(100 - A) + 0.25A = 50 \Rightarrow A = \frac{200}{3}$$

It took $\frac{200}{5}$ minutes for the draining and the

same amount of time to refill, so

$$T = \frac{2\left(\frac{200}{3}\right)}{5} = \frac{80}{3} \approx 26.67 \text{ min.}$$

c. c would need to satisfy

$$\frac{200}{3} + \frac{200}{c} < 20(\ln 3).$$

$$c > \frac{10}{(3 \ln 3 - 2)} \approx 7.7170$$

d. $y' = 4(0.25) - 0.05y = 1 - 0.05y$

Solving for y , as in part a, yields

$y = 20 + 80e^{-0.05t}$. The drain is closed when $t = 0.8T$. We require that

$$(20 + 80e^{-0.05 \cdot 0.8T}) + 4 \cdot 0.25 \cdot 0.25 \cdot 0.8T = 50,$$

$$\text{or } 400e^{-0.04T} + T = 150.$$

24. a. $v' + av = -g$

Integrating factor: e^{at}

$$e^{at}(v' + av) = -ge^{at}; \frac{d}{dt}(ve^{at}) = -ge^{at}$$

$$ve^{at} = \int -ge^{at} dt = \frac{-g}{a}e^{at} + C; v = \frac{-g}{a} + Ce^{-at}$$

$$v = v_0, t = 0$$

$$v_0 = \frac{-g}{a} + C \Rightarrow C = v_0 + \frac{g}{a}$$

Therefore, $v = \frac{-g}{a} + \left(v_0 + \frac{g}{a}\right)e^{-at}$, so

$$v(t) = v_\infty + (v_0 - v_\infty)e^{-at}.$$

b. $\frac{dy}{dt} = v_\infty + (v_0 - v_\infty)e^{-at}$, so

$$y = v_\infty t - \frac{(v_0 - v_\infty)e^{-at}}{a} + C.$$

$$y = y_0, t = 0 \Rightarrow y_0 = \frac{-(v_0 - v_\infty)}{a} + C$$

$$\Rightarrow C = y_0 + \frac{v_0 - v_\infty}{a}$$

$$y = v_\infty t - \frac{(v_0 - v_\infty)e^{-at}}{a} + \left(y_0 + \frac{v_0 - v_\infty}{a}\right)$$

$$= y_0 + v_\infty t + \frac{v_0 - v_\infty}{a}(1 - e^{-at})$$

25. a. $v_\infty = -\frac{32}{0.05} = -640$

$$v(t) = [120 - (-640)]e^{-0.05t} + (-640) = 0 \text{ if}$$

$$t = 20 \ln\left(\frac{19}{16}\right).$$

$$y(t) = 0 + (-640)t$$

$$+ \left(\frac{1}{0.05}\right)[120 - (-640)](1 - e^{-0.05t})$$

$$= -640t + 15,200(1 - e^{-0.05t})$$

Therefore, the maximum altitude is

$$y\left(20 \ln\left(\frac{19}{16}\right)\right) = -12,800 \ln\left(\frac{19}{16}\right) + \frac{45,600}{19}$$

$$\approx 200.32$$

$$\begin{aligned} \text{b. } -640T + 15,200(1 - e^{-0.05T}) &= 0; \\ 95 - 4T - 95e^{-0.05T} &= 0 \end{aligned}$$

26. For t in $[0, 15]$,

$$v_{\infty} = \frac{-32}{0.10} = -320.$$

$$v(t) = (0 + 320)e^{-0.1t} - 320 = 320(e^{-0.1t} - 1);$$

$$v(15) = 320(e^{-1.5} - 1) \approx -248.6$$

$$y(t) = 8000 - 320t + 10(320)(1 - e^{-0.1t});$$

$$y(15) = 3200(2 - e^{-1.5}) \approx 5686$$

Let t be the number of seconds after the parachute opens that it takes Megan to reach the ground.

$$\text{For } t \text{ in } [15, 15+T], v_{\infty} = -\frac{32}{1.6} = -20.$$

$$0 = y(T + 15)$$

$$= [3200(2 - e^{-1.5})]$$

$$-20T + (0.625)[320(e^{-1.5} - 1) + 20](1 - e^{-1.6T})$$

$$\approx 5543 - 20T - 142.9e^{-1.6T} \approx 5543 - 20T \quad [\text{since}$$

$$T > 50, \text{ so } e^{-1.6T} < 10^{-35} \text{ (very small)}]$$

Therefore, $T \approx 277$, so it takes Megan about 292 s (4 min, 52 s) to reach the ground.

$$27. \text{ a. } e^{-\ln x + C} \left(\frac{dy}{dx} - \frac{y}{x} \right) = x^2 e^{-\ln x + C}$$

$$\frac{d}{dx} \left(e^C \frac{1}{x} y \right) = x e^C$$

$$\text{b. } e^C \frac{y}{x} = e^C \int x dx$$

$$\frac{y}{x} = \frac{x^2}{2} + C_1$$

$$y = e^{-\int P(x) dx} \int Q(x) e^{\int P(x) dx} dx$$

Let θ represent $\angle DAB$, then $\angle CAB$ is $\frac{\theta}{2}$. Since

$\triangle ABC$ is isosceles, $|AE| = \frac{b}{2}$, $\cos \frac{\theta}{2} = \frac{\frac{b}{2}}{a} = \frac{b}{2a}$ and

$\theta = 2 \cos^{-1} \frac{b}{2a}$. Thus sector ADB has area

$\frac{1}{2} \left(2 \cos^{-1} \frac{b}{2a} \right) b^2 = b^2 \cos^{-1} \frac{b}{2a}$. Let ϕ represent

$\angle DCB$, then $\angle ACB$ is $\frac{\phi}{2}$ and $\angle ECA$ is $\frac{\phi}{4}$, so

$\sin \frac{\phi}{4} = \frac{\frac{b}{2}}{a} = \frac{b}{2a}$ and $\phi = 4 \sin^{-1} \frac{b}{2a}$. Thus sector

DCB has area $\frac{1}{2} \left(4 \sin^{-1} \frac{b}{2a} \right) a^2 = 2a^2 \sin^{-1} \frac{b}{2a}$.

These sectors overlap on the triangles $\triangle DAC$ and $\triangle CAB$, each of which has area

$$\frac{1}{2} |AB| h = \frac{1}{2} b \sqrt{a^2 - \left(\frac{b}{2}\right)^2} = \frac{1}{2} b \frac{\sqrt{4a^2 - b^2}}{2}$$

The large circle has area πb^2 , hence the shaded region has area

$$\pi b^2 - b^2 \cos^{-1} \frac{b}{2a} - 2a^2 \sin^{-1} \frac{b}{2a} + \frac{1}{2} b \sqrt{4a^2 - b^2}$$

They have the same graph.

Conjecture: $\arcsin x = \arctan \frac{x}{\sqrt{1-x^2}}$ for

$-1 < x < 1$

Proof: Let $\theta = \arcsin x$, so $x = \sin \theta$.

Then $\frac{x}{\sqrt{1-x^2}} = \frac{\sin \theta}{\sqrt{1-\sin^2 \theta}} = \frac{\sin \theta}{\cos \theta} = \tan \theta$

so $\theta = \arctan \frac{x}{\sqrt{1-x^2}}$.

65.

It is the same graph as $y = \arccos x$.

Conjecture: $\frac{\pi}{2} - \arcsin x = \arccos x$

Proof: Let $\theta = \frac{\pi}{2} - \arcsin x$

Then $x = \sin \left(\frac{\pi}{2} - \theta \right) = \cos \theta$

so $\theta = \arccos x$.

66.

$y = \sin(\arcsin x)$ is the line $y = x$, but only defined for $-1 \leq x \leq 1$.

$y = \arcsin(\sin x)$ is defined for all x , but only the portion for $-\frac{\pi}{2} \leq x \leq \frac{\pi}{2}$ is the line $y = x$.

$$\begin{aligned}

Since $\frac{d\theta}{db} > 0$ for b in $[0, 2\sqrt{6})$

and $\frac{d\theta}{db} < 0$ for b in $(2\sqrt{6}, \infty)$, the angle is

maximized for $b = 2\sqrt{6} \approx 4.899$.

75. Let $h(t)$ represent the height of the elevator (the number of feet above the spectator's line of sight) t seconds after the line of sight passes horizontal, and let $\theta(t)$ denote the angle of elevation.

$$\text{Then } h(t) = 15t, \text{ so } \theta(t) = \tan^{-1} \left(\frac{15t}{60} \right) = \tan^{-1} \left(\frac{t}{4} \right).$$

$$\frac{d\theta}{dt} = \frac{1}{1 + \left(\frac{t}{4} \right)^2} \left(\frac{1}{4} \right) = \frac{4}{16 + t^2}$$

At $t = 6$, $\frac{d\theta}{dt} = \frac{4}{16 + 6^2} = \frac{1}{13}$ radians per second or about 4.41° per second.

76. Let $x(t)$ be the horizontal distance from the observer to the plane, in miles, t minutes before the plane is overhead. Let $t = 0$ when the distance to the plane is 3 miles. Then

$x(0) = \sqrt{3^2 - 2^2} = \sqrt{5}$. The speed of the plane is 10 miles per minute, so $x(t) = \sqrt{5} - 10t$. The angle of

elevation is $\theta(t) = \tan^{-1} \left(\frac{2}{x(t)} \right) = \tan^{-1} \left(\frac{2}{\sqrt{5} - 10t} \right)$,

$$\begin{aligned} \text{so } \frac{d\theta}{dt} &= \frac{1}{1 + \left(\frac{2}{\sqrt{5} - 10t} \right)^2} \left(\frac{-2}{(\sqrt{5} - 10t)^2} \right) (-10) \\ &= \frac{20}{(\sqrt{5} - 10t)^2 + 4}. \end{aligned}$$

When $t = 0$, $\frac{d\theta}{dt} = \frac{20}{9} \approx 2.22$ radians per minute.

77. Let x represent the position on the shoreline and let θ represent the angle of the beam ($x = 0$ and $\theta = 0$ when the light is pointed at P). Then

$$\theta = \tan^{-1} \left(\frac{x}{2} \right), \text{ so } \frac{d\theta}{dt} = \frac{1}{1 + \left(\frac{x}{2} \right)^2} \frac{1}{2} \frac{dx}{dt} = \frac{2}{4 + x^2} \frac{dx}{dt}$$

When $x = 1$,

$\frac{dx}{dt} = 5\pi$, so $\frac{d\theta}{dt} = \frac{2}{4 + 1^2} (5\pi) = 2\pi$. The beacon revolves at a rate of 2π radians per minute or 1 revolution per minute.

78. Let x represent the length of the rope and let θ represent the angle of depression of the rope.

Then $\theta = \sin^{-1} \left(\frac{8}{x} \right)$, so

$$\frac{d\theta}{dt} = \frac{1}{\sqrt{1 - \left(\frac{8}{x} \right)^2}} \left(-\frac{8}{x^2} \right) \frac{dx}{dt} = -\frac{8}{x\sqrt{x^2 - 64}} \frac{dx}{dt}.$$

When $x = 17$ and $\frac{dx}{dt} = -5$, we obtain

$$\frac{d\theta}{dt} = -\frac{8}{17\sqrt{17^2 - 64}} (-5) = \frac{8}{51}.$$

The angle of depression is increasing at a rate of $8/51 \approx 0.16$ radians per second.

79. Let x represent the distance to the center of the earth and let θ represent the angle subtended by the

earth. Then $\theta = 2 \sin^{-1} \left(\frac{6376}{x} \right)$, so

$$\begin{aligned} \frac{d\theta}{dt} &= 2 \frac{1}{\sqrt{1 - \left(\frac{6376}{x} \right)^2}} \left(-\frac{6376}{x^2} \right) \frac{dx}{dt} \\ &= -\frac{12,752}{x\sqrt{x^2 - 6376^2}} \frac{dx}{dt} \end{aligned}$$

When she is 3000 km from the surface

$x = 3000 + 6376 = 9376$ and $\frac{dx}{dt} = -2$. Substituting

these values, we obtain $\frac{d\theta}{dt} \approx 3.96 \times 10^{-4}$ radians per second.

54. a. The graph of $y = b - a \cosh\left(\frac{x}{a}\right)$ is symmetric about the y -axis, so if its width along the

x -axis is $2a$, its x -intercepts are $(\pm a, 0)$. Therefore, $y(a) = b - a \cosh\left(\frac{a}{a}\right) = 0$, so $b = a \cosh 1 \approx 1.54308a$.

b. The height is $y(0) \approx 1.54308a - a \cosh 0 = 0.54308a$.

c. If $2a = 48$, the height is about $0.54308a = (0.54308)(24) \approx 13$.

Volume is about $(422)(100) = 42,200 \text{ ft}^3$.

c. Length of the curve is

$$\int_{-24}^{24} \sqrt{1 + \left(\frac{dy}{dx}\right)^2} dx = \int_{-24}^{24} \sqrt{1 + \sinh^2\left(\frac{x}{24}\right)} dx = \int_{-24}^{24} \cosh\left(\frac{x}{24}\right) dx = \left[24 \sinh\left(\frac{x}{24}\right)\right]_{-24}^{24} = 48 \sinh 1 \approx 56.4$$

$$\begin{aligned} 58. \text{ a. } gd(-t) &= \tan^{-1}[\sinh(-t)] \\ &= \tan^{-1}(-\sinh t) = -\tan^{-1}(\sinh t) = -gd(t) \end{aligned}$$

so gd is odd.

$$D_t[gd(t)] = \frac{1}{1 + \sinh^2 t} \cdot \cosh t = \frac{\cosh t}{\cosh^2 t} = \text{sech } t > 0 \text{ for all } t, \text{ so } gd \text{ is increasing.}$$

$$D_t^2[gd(t)] = D_t(\text{sech } t) = -\text{sech } t \tanh t$$

$$D_t^2[gd(t)] = 0 \text{ when } \tanh t = 0, \text{ since } \text{sech } t > 0 \text{ for all } t. \tanh t = 0 \text{ at } t = 0 \text{ and } \tanh t < 0 \text{ for } t < 0, \text{ thus } D_t^2[gd(t)] > 0 \text{ for } t < 0 \text{ and } D_t^2[gd(t)] < 0 \text{ for } t > 0. \text{ Hence}$$

$gd(t)$ has an inflection point at $(0, gd(0)) = (0, \tan^{-1} 0) = (0, 0)$.

b. If $y = \tan^{-1}(\sinh t)$ then $\tan y = \sinh t$ so

$$\begin{aligned} \sin y &= \frac{\tan y}{\sqrt{\tan^2 y + 1}} = \frac{\sinh t}{\sqrt{\sinh^2 t + 1}} \\ &= \frac{\sinh t}{\cosh t} = \tanh t \text{ so } y = \sin^{-1}(\tanh t) \end{aligned}$$

$$\begin{aligned} \text{Also, } D_t y &= \frac{1}{1 + \sinh^2 t} \cdot \cosh t \\ &= \frac{\cosh t}{\cosh^2 t} = \frac{1}{\cosh t} = \text{sech } t, \end{aligned}$$

so $y = \int_0^x \operatorname{sech} u \, du$ by the Fundamental Theorem of Calculus.

59. Area = $\int_0^x \cosh t \, dt = [\sinh t]_0^x = \sinh x$
 Arc length = $\int_0^x \sqrt{1 + [D_t \cosh t]^2} \, dt = \int_0^x \sqrt{1 + \sinh^2 t} \, dt$
 $= \int_0^x \cosh t \, dt = [\sinh t]_0^x = \sinh x$

60. From Problem 54, the equation of an inverted catenary is $y = b - a \cosh \frac{x}{a}$. Given the information about the Gateway Arch, the curve passes through the points $(\pm 315, 0)$ and $(0, 630)$. Thus, $b = a \cosh \frac{315}{a}$ and $630 = b - a$, so $b = a + 630$.
 $a + 630 = a \cosh \frac{315}{a} \Rightarrow a \approx 128$, so $b \approx 758$.
 The equation is $y = 758 - 128 \cosh \frac{x}{128}$.

4. a. Let $q = 1 + 0.05 \cdot \left(\frac{30}{365}\right)$.

The amount of money after 30 days is $A_1 = A_0q - 144$.

The amount of money after 60 days is $A_2 = A_1q - 144 = A_0q^2 - 144q - 144$.

The amount of money after 90 days is $A_3 = A_2q - 144 = A_0q^3 - 144q^2 - 144q - 144$. Thus, the amount of money after $30n$ days is $A_n = A_0q^n - 144 \sum_{k=0}^{n-1} q^k = A_0q^n - 144 \left(\frac{q^n - 1}{q - 1} \right)$. If the amount of money after 3600 = 30 · 120 days is 0, we have $0 = A_0q^{120} - 144 \left(\frac{q^{120} - 1}{q - 1} \right)$.

$$A_0q^{120} = 144 \left(\frac{q^{120} - 1}{q - 1} \right)$$

$$A_0 = 144 \left(\frac{1 - q^{-120}}{q - 1} \right) = 144 \left[\frac{1 - \left(1 + 0.05 \cdot \left(\frac{30}{365} \right) \right)^{-120}}{0.05 \cdot \left(\frac{30}{365} \right)} \right]$$

Note that $-10 \cdot \left(\frac{365}{30} \right) \approx -120$.

$$\text{Thus, } A_0 = 144 \left[\frac{1 - \left(1 + 0.05 \cdot \left(\frac{30}{365} \right) \right)^{-10 \cdot (365/30)}}{0.05 \cdot \left(\frac{30}{365} \right)} \right]$$

$$A_n = A_0q^n - 144 \left(\frac{q^n - 1}{q - 1} \right), \text{ and if the amount of money after 3600 days is 0,}$$

$$A_0 = 144 \left(\frac{1 - q^{-120}}{q - 1} \right) = 144 \left[\frac{1 - e^{-0.05(3600/365)}}{e^{-0.05(30/365)} - 1} \right]$$

$$\text{Or, by using 10 years, } A_0 = 144 \left[\frac{1 - e^{-0.05 \cdot 10}}{e^{-0.05(30/365)} - 1} \right]$$

5. a. If you deposit A_0 into an account earning an interest rate of $100r$ percent, compounded continuously, then the amount you have at time t is $A(t) = A_0e^{rt}$. The money has doubled when $A(t) = 2A_0$ or $A_0e^{rt} = 2A_0$, so T satisfies the equation $A_0e^{rT} = 2A_0$.

$$A_0e^{r(70/100r)} = A_0e^{0.7} \approx 2A_0$$

- b. Solving $A_0e^{rT} = 2A_0$ for T to get $T = \frac{1}{r} \ln 2 \approx \frac{1}{r} (0.7) = \frac{70}{100r}$

6. If $f(t) = e^{kt}$, then $\frac{f'(t)}{f(t)} = \frac{ke^{kt}}{e^{kt}} = k$.

7. $f(x) = a_n x^n + a_{n-1} x^{n-1} + \dots + a_1 x + a_0$

$$\lim_{x \rightarrow \infty} \frac{f'(x)}{f(x)} = \lim_{x \rightarrow \infty} \frac{na_n x^{n-1} + (n-1)a_{n-1} x^{n-2} + \dots + a_1}{a_n x^n + a_{n-1} x + \dots + a_1 x + a_0} = \lim_{x \rightarrow \infty} \frac{\frac{na_n}{x} + \frac{(n-1)a_{n-1}}{x^2} + \dots + \frac{a_1}{x^n}}{a_n + \frac{a_{n-1}}{x} + \dots + \frac{a_1}{x^{n-1}} + \frac{a_0}{x^n}} = 0$$

8. $\frac{f'(x)}{f(x)} = k > 0$ can be written as

$$\frac{1}{y} \frac{dy}{dx} = k \text{ where } y = f(x).$$

$$\frac{dy}{y} = k dx \text{ has the solution } y = Ce^{kx}.$$

Thus, the equation $f(x) = Ce^{kx}$ represents exponential growth since $k > 0$.

9. $\frac{f'(x)}{f(x)} = k < 0$ can be written as $\frac{1}{y} \frac{dy}{dx} = k$ where $y = f(x)$. $\frac{dy}{y} = k dx$ has the solution $y = Ce^{kx}$.

Thus, $f(x) = Ce^{kx}$ which represents exponential decay since $k < 0$.

10. a. The error in $f(x)$ due to a relative error in the input of size Δx is $f(x + \Delta x) - f(x)$, thus the relative error in $f(x)$ due to this relative error in input is

$$\frac{f(x + \Delta x) - f(x)}{f(x)} = \frac{f(x + \Delta x) - f(x)}{f(x)} \cdot \frac{\Delta x}{\Delta x} \cdot \frac{x}{x} = \frac{f(x + \Delta x) - f(x)}{\Delta x \cdot f(x)} \cdot \frac{\Delta x}{x} = \frac{f(x + \Delta x) - f(x)}{\Delta x \cdot f(x)} \cdot \frac{(x + \Delta x) - x}{x} \cdot x$$

b. $\rho_x = \lim_{\Delta x \rightarrow 0} \frac{(x + \Delta x) - x}{x}$, while $\frac{d \ln(f(x))}{dx} = \frac{f'(x)}{f(x)}$, so $\lim_{\Delta x \rightarrow 0} \frac{f(x + \Delta x) - f(x)}{f(x)}$

$$= \lim_{\Delta x \rightarrow 0} \left[\frac{f(x + \Delta x) - f(x)}{\Delta x \cdot f(x)} \cdot \frac{(x + \Delta x) - x}{x} \cdot x \right] = \left[\lim_{\Delta x \rightarrow 0} \frac{f(x + \Delta x) - f(x)}{\Delta x} \cdot \frac{1}{f(x)} \right] \cdot \left[\lim_{\Delta x \rightarrow 0} \frac{(x + \Delta x) - x}{x} \right] \cdot x$$

$$= f'(x) \cdot \frac{1}{f(x)} \cdot \rho_x \cdot x = x \cdot \frac{d \ln(f(x))}{dx} \cdot \rho_x$$

c. $x \cdot \frac{d}{dx} [\ln(e^x)] = x \cdot \frac{d}{dx} (x) = x \cdot 1 = x$

11. a. In order of increasing slope, the graphs represent the curves $y = 2^x$, $y = 3^x$, and $y = 4^x$.

b. $\ln y$ is linear with respect to x , and at $x = 0$, $y = 1$ since $C = 1$.

c. The graph passes through the points (0.2, 4) and (0.6, 8). Thus, $4 = Cb^{0.2}$ and $8 = Cb^{0.6}$.
Dividing the second equation by the first, gets $2 = b^{0.4}$ so $b = 2^{5/2}$.
Therefore $C = 2^{3/2}$.

12. The graph of the equation whose log-log plot has negative slope contains the points (2, 7) and (7, 2).

$$\text{Thus, } 7 = C2^r \text{ and } 2 = C7^r, \text{ so } \frac{7}{2} = \left(\frac{2}{7}\right)^r. \ln \frac{7}{2} = r \ln \frac{2}{7} \Rightarrow r = \frac{\ln 7 - \ln 2}{\ln 2 - \ln 7} = -1 \text{ and } C = 14.$$

Hence, one equation is $y = 14x^{-1}$.

The graph of one equation contains the points

(7, 30) and (10, 70). Thus, $30 = C7^r$ and $70 = C10^r$, so $\frac{3}{7} = \left(\frac{7}{10}\right)^r$

$$\ln \frac{3}{7} = r \ln \frac{7}{10} \Rightarrow r = \frac{\ln 3 - \ln 7}{\ln 7 - \ln 10} \approx 2.38 \text{ and } C \approx 30 \cdot 7^{-2.38} \approx 0.29. \text{ Hence, another equation is } y = 0.29x^{2.38}.$$

The graph of another equation contains the points (1, 2) and (7, 5). Thus, $2 = C1^r$ and $5 = C7^r$, so $C = 2$ and

$\ln 5 - \ln 2 = r \ln 7 \Rightarrow r = \frac{\ln 5 - \ln 2}{\ln 7} \approx 0.47$. Hence, the last equation is $y = x^{0.47}$. Other answers are possible depending on selection of points.

13. a. $\eta = 3 \operatorname{sech}^2 \frac{x}{2}$

$$\eta' = -3 \operatorname{sech}^2 \frac{x}{2} \tanh \frac{x}{2}$$

$$3\eta^2 = 3 \cdot 9 \operatorname{sech}^4 \frac{x}{2} = 27 \operatorname{sech}^4 \frac{x}{2}$$

$$\eta^3 + 3(\eta')^2 = 27 \operatorname{sech}^6 \frac{x}{2} + 3 \left(9 \operatorname{sech}^4 \frac{x}{2} \tanh^2 \frac{x}{2} \right)$$

$$= 27 \operatorname{sech}^4 \frac{x}{2} \left(\operatorname{sech}^2 \frac{x}{2} + \tanh^2 \frac{x}{2} \right)$$

$$= 27 \operatorname{sech}^4 \frac{x}{2} = 3\eta^2$$

Thus, $\eta = 3 \operatorname{sech}^2 \frac{x}{2}$ satisfies the equation.
